Stakeholder Collaboration –
From Conversation to Contribution

ABSTRACT
Establishing efficient and intensive stakeholder collaboration is a key factor in Web application development projects. Therefore, the form of collaboration needs to be shifted from simple conversation to valuable contribution, i.e. empowering stakeholders to directly contribute to the development effort. To achieve this, we introduce an approach combining Domain-specific Languages and an underlying technical platform.

Categories and Subject Descriptors
D.2.13 [Software Engineering]: Reusable Software - Domain Engineering; D.2.2 [Software Engineering]: Design Tools and Techniques - Evolutionary prototyping.

General Terms
Human Factors, Languages, Design

Keywords
Web Engineering, DSL, Workflow, Conceptual Modeling

1. INTRODUCTION
In Web application development projects, intensive stakeholder collaboration is decisive for a project’s success, especially when specifying requirements and aspects of the envisioned solution [4]. This requires a shift from stakeholders acting solely as information providers to stakeholders contributing actively and sometimes even autonomously to the development effort by understanding, validating and specifying parts of the solution being built. In order to allow for such an intensive form of stakeholder involvement, a set of common languages being used as a means of specification and communication between the developers and the stakeholders is required.

In our experience, stakeholders are mostly non-programmers with completely diverse educational backgrounds and work areas. Furthermore, most of them are not skilled in Web application development methodologies or modeling techniques. In our projects, we found existing approaches [3] towards a formal and systematic specification of Web applications to be a good means of specification and communication within the developer team, especially as they were designed to capture their associated problem domain as extensively as possible. However, for stakeholders they were too complex and required too much time to learn.

In this regard, Domain-Specific Languages (DSLs) are a promising alternative. DSLs are small, simple and highly-focused specification languages tailored to a clear problem domain, i.e. a specific aspect of a Web application. Incorporating well-known abstractions and notations derived from the problem domain, they are easy to learn, understand and use – both for developers and stakeholders. Employing DSLs in Web application development enables leveraging stakeholder collaboration from conversation to contribution.

2. DSL BUILDING BLOCKS
Figure 1 gives an overview of a DSL’s components, assigned to different layers according to their level of abstraction.

Figure 1: Overview of the components of a DSL
The conceptual layer comprises two models that constitute the core of a Domain-Specific Language: The Domain-Specific Model (DSM) and the Domain Interaction Model (DIM). The DSM, usually an XML Schema, embodies the core of a DSL specification and provides a formalized model for describing solutions within the DSL’s problem domain. In addition, a DSL includes one or more Domain Interaction Models which are based on the DSM and specify dedicated (graphical) notations for...
particular stakeholder groups. By providing audience-tailored DIM notations and complementary editing tools, the simplicity and usability of a DSL can be notably improved. The Domain Abstract Representation (DAR), located on the logical layer, represents a “DSL program”. Thus, it is based on the DSM, edited by using the DIM notations and stored in an XML document. The physical layer of a DSL consists of so-called Solution Building Blocks (SBBs) which are implemented as components of the WebComposition Service Linking System [1]. In conclusion, Web applications can be built in an evolutionary manner by composing SBBs and configuring them with DARs.

3. WEB-BASED PROCESS GUIDANCE

Problem Domain: Composing software products by assembling existing components is one of the challenging factors within EAI projects. While service composition for describing Web service choreography or orchestration plays a major role, the aspect of user guidance in Web applications is often neglected. We propose a DSL for describing such user guidance through various components of a Web application.

Domain Specific Model: Although the discussions about standardization of business process modeling (BPM) lasts over ten years, the absence of a commonly accepted interchange format still forms the main burden to business process management. Based on our experience during the process analysis in a university-wide integration project, we found a common denominator in using finite state machines (FSM). Our Process Guidance DSM utilizes common XLink attributes to formulate the behavior, traversal rules and its semantics. The ability to define all links in an external linkbase promises to cope with even more advanced concepts like personalization or even business process federations.

In the following, selected parts of the DSM are outlined in more detail. A workflow is described by a set of workstepTypes (1) that represent the states of the FSM and are instances of available Solution Building Blocks. They are realized as locator which form the connection to our technical platform [1] by specifying the linkbase and the xlink:href attributes.

<xs:complexType name="workstepType">
  <xs:attribute ref="xlink:type" fixed="locator"/>
  <xs:attribute ref="xlink:title"/>
  <xs:attribute ref="xlink:role"/>
  <xs:attribute ref="xlink:from" type="xs:string"/>
  <xs:attribute ref="xlink:href"/>
  <xs:attribute ref="xlink:actuate"/>
</xs:complexType>

The transitionType (2) expressed as xlink:type="arc" connects two states specified by xlink:from and xlink:to and activated by a token. In addition to behavioral aspects regarding the activation, xlink:actuate="onLoad" can be used to indicate spontaneous transitions to perform a continuous chain of worksteps without requesting a user for activation. In contrast, transitions that require a user input, are expressed with an xlink:actuate="onRequest".

<xs:complexType name="transitionType">
  <xs:attribute name="token" type="xs:NMTOKEN"/>
  <xs:attribute ref="xlink:from" fixed="arc"/>
  <xs:attribute ref="xlink:to"/>
  <xs:attribute ref="xlink:arcrole"/>
</xs:complexType>
