## Motivation

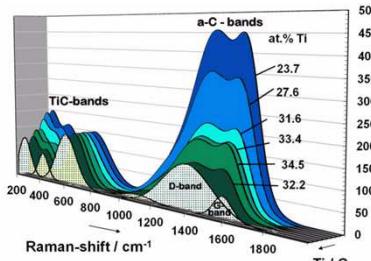

Carbon-based nanostructured composite coatings are attracting steadily increasing attention due to their promising properties. These materials often consist of nanocrystalline phases, clusters or particles homogeneously dispersed in an amorphous carbon matrix or covered by an amorphous carbon grain boundary phase. Advanced nanocomposite films providing simultaneously wear protection and low friction are required in engineering applications. We report on the synthesis and correlation between constitution, microstructure and properties of non-reactively magnetron sputtered TiC/a-C nanocomposite coatings.

## Deposition

If magnetron sputtering from a segmented TiC / Graphite target in an Ar atmosphere (0.6 Pa)  
 1 power supply, Power density 11.3 W/cm<sup>2</sup>  
 target-substrate distance 60 mm  
 Substrates: cemented carbide (Pos. 1 - Pos. 6).  
 If substrate bias voltage: 0, -150 V or -300 V  
 substrate temperature < 250°C

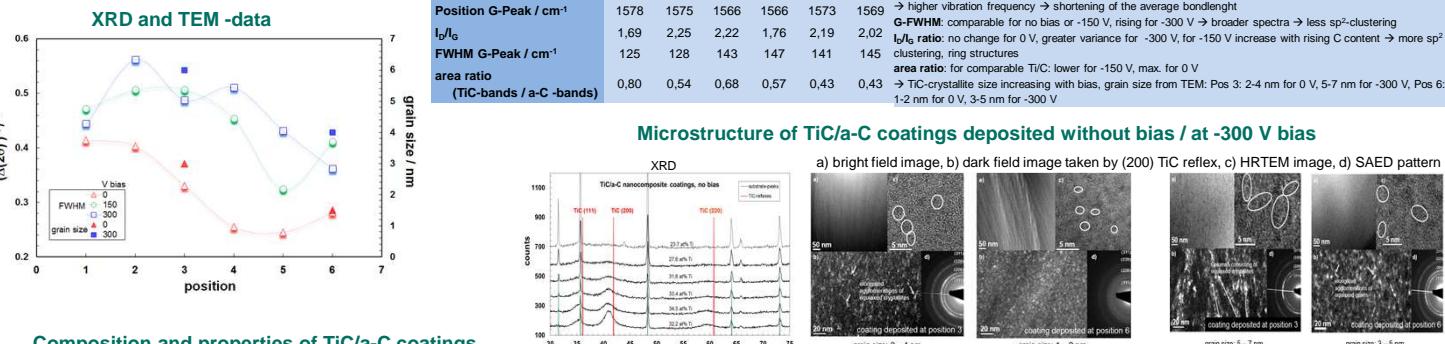

## Raman spectroscopy of TiC/a-C coatings

	Pos. 1	Pos. 2	Pos. 3	Pos. 4	Pos. 5	Pos. 6	a-C	
Position G-Peak / cm <sup>-1</sup>	1569	1565	1565	1568	1565	1567	1567	
I <sub>0</sub> /I <sub>0</sub>	2,16	2,22	2,00	2,09	2,12	1,99	1,31	
FWHM G-Peak / cm <sup>-1</sup>	115	116	132	122	129	126	172	
area ratio (TiC-bands / a-C-bands)	0,99	0,73	0,78	0,76	0,53	0,44		
- 150 V substrate bias	Pos. 1	Pos. 2	Pos. 3	Pos. 4	Pos. 5	Pos. 6		changes with increasing carbon content of the TiC/a-C-coatings
Position G-Peak / cm <sup>-1</sup>	1580	1574	1570	1571	1572	568		G-peak position unchanged → vibration frequency is related to the average C-C bond length → no change in a-C structure
I <sub>0</sub> /I <sub>0</sub>	1,66	1,71	1,88	1,80	1,94	2,05		G-FWHM increases → FWHM is uniquely related to the sp <sup>3</sup> clustering → decrease in crystallinity
FWHM G-Peak / cm <sup>-1</sup>	110	118	117	121	121	125		I <sub>0</sub> /I <sub>0</sub> ratio → decreasing with progressive disordering of the sp <sup>2</sup> -bonded rings and increase of sp <sup>3</sup> sites → bias influence
area ratio (TiC-bands / a-C-bands)	0,47	0,48	0,47	0,44	0,35	0,28		area ratio (TiC-bands / a-C-bands) → directly related to Ti/C ratio → linear decrease with rising C content → decreasing TiC grain size
- 300 V substrate bias	Pos. 1	Pos. 2	Pos. 3	Pos. 4	Pos. 5	Pos. 6		bias influence
Position G-Peak / cm <sup>-1</sup>	1578	1575	1566	1566	1573	1569		G-peak position: rising for -150 V, greater variance for -300 V → higher vibration frequency → shortening of the average bondlength
I <sub>0</sub> /I <sub>0</sub>	1,69	2,25	2,22	1,76	2,19	2,02		G-FWHM: comparable for no bias or -150 V, rising for -300 V → broader spectra → less sp <sup>2</sup> -clustering
FWHM G-Peak / cm <sup>-1</sup>	125	128	143	147	141	145		I <sub>0</sub> /I <sub>0</sub> ratio: no change for 0 V, greater variance for -300 V, for -150 V increase with rising C content → more sp <sup>2</sup> clustering, ring structures
area ratio (TiC-bands / a-C-bands)	0,80	0,54	0,68	0,57	0,43	0,43		area ratio: comparable Ti/C: lower for -150 V, max. for 0 V → TiC-crystallite size increasing with bias, grain size from TEM: Pos. 3: 2-4 nm for 0 V, 5-7 nm for -300 V, Pos. 6: 1-2 nm for 0 V, 3-5 nm for -300 V

## Summary

From the results of the combination of Raman spectroscopy, XRD, TEM, AFM and nano-indentation it is concluded that at least 3 effects play together in the formation of nanocomposite TiC/a-C films:

- formation of both the crystalline TiC and amorphous carbon phase
- densification of the amorphous carbon network by the ion bombardment
- preferential resputtering of the C atoms.

The most interesting growth effects are observed at -150 V bias voltage at the center positions 3 and 4. In this case the structure-property correlation is influenced by the interplay of all three effects, whereas in the outer sample positions and for the other bias voltages, always one of the three effects is dominating the formation of the TiC/a-C nanocomposite structure.
