Observation of Medium-Induced Modifications of Jet Fragmentation in Pb-Pb Collisions at \( \sqrt{s_{\text{NN}}} = 5.02 \) TeV Using Isolated Photon-Tagged Jets

A. M. Sirunyan et al.*
(CMS Collaboration)

Measurements of fragmentation functions for jets associated with an isolated photon are presented for the first time in \( pp \) and Pb-Pb collisions. The analysis uses data collected with the CMS detector at the CERN LHC at a nucleon-nucleon center-of-mass energy of 5.02 TeV. Fragmentation functions are obtained for jets with \( p_T^{\text{jet}} > 30 \) GeV/c in events containing an isolated photon with \( p_T > 60 \) GeV/c, using charged tracks with transverse momentum \( p_T^{\text{trk}} > 1 \) GeV/c in a cone around the jet axis. The association with an isolated photon constrains the initial \( p_T \) and azimuthal angle of the parton whose shower produced the jet. For central Pb-Pb collisions, modifications of the jet fragmentation functions are observed when compared to those measured in \( pp \) collisions, while no significant differences are found in the 50% most peripheral collisions. Jets in central Pb-Pb events show an excess (depletion) of low (high) \( p_T \) particles, with a transition around 3 GeV/c. This measurement shows for the first time the in-medium shower modifications of partons (quark dominated) with well-defined initial kinematics. It constitutes a new well-controlled reference for testing theoretical models of the parton passage through the quark-gluon plasma.

DOI: 10.1103/PhysRevLett.121.242301

A deconfined state of quarks and gluons, called the quark-gluon plasma (QGP) [1], is believed to be produced on a short timescale in high energy nucleus-nucleus collisions [2]. Occasionally, a pair of partons (quarks or gluons) in the colliding nuclei undergoes a high transverse momentum (\( p_T \)) scattering, a process that occurs over a shorter timescale. As they pass through and interact with the QGP, the scattered partons lose some of their energy [3–8]. The relative importance of the various mechanisms by which these partons lose energy to the medium has been a continuous focus of the field of relativistic heavy ion collisions [9–14].

The outgoing hard-scattered partons eventually fragment, and each forms a jet of collimated particles. The CERN LHC collaborations have conducted various (dijet studies: modifications of the jet yield in the medium (jet quenching) [15–17], jet fragmentation functions (the probability for a parton to fragment into particles carrying a given fraction of the jet momentum) [18,19], missing \( p_T \) in dijet systems [20–22], jet-track correlations [23], and the radial \( p_T \) profile of tracks within jets [24]. However, in these analyses, the energy lost by the partons diminishes the information about their initial properties. One way to overcome this challenge is to study processes in which the initial hard scattering produces a parton and an electroweak boson: the bosons do not experience quantum chromodynamic interactions and are largely unaffected by the QGP. At leading order, bosons are produced back to back with an associated parton having close to the same \( p_T \), modulo secondary effects such as multiple scatterings of the initial partons or initial state radiation. As a result, the jets associated with the boson should have parent partons whose \( p_T \) before any energy loss occurs is well defined. In addition, at LHC energies, the electroweak-boson + jet production is dominated by quark jets for \( p_T^{\text{jet}} > 30 \) GeV/c [25–27], therefore providing information specifically on quark energy loss.

The CMS Collaboration measured the azimuthal correlation and momentum imbalance of isolated-photon+jet pairs in \( pp \) and Pb-Pb collisions at nucleon-nucleon center-of-mass energies of \( \sqrt{s_{\text{NN}}} = 2.76 \) and 5.02 TeV [28,29] and of \( Z + \) jet pairs at \( \sqrt{s_{\text{NN}}} = 5.02 \) TeV [30]. In related studies, experiments at RHIC extracted jet fragmentation functions associated with photons without fully reconstructing the jets, but rather by studying direct-photon +hadron correlations [31,32]. This Letter presents the first measurement of the fragmentation function of jets that are fully reconstructed and associated with an isolated photon (i.e., one with no significant energy deposited around its location in the detector). This definition suppresses dijet events in which a high-\( p_T \) photon originates from one of the jets, either via collinear fragmentation of a parton (“fragmentation photons”) or via decays of neutral mesons **Full author list given at the end of the Letter.**
Photon-tagged fragmentation functions are presented as distributions of \( \xi_{\text{jet}} = \ln \left[ \frac{|p_{T,jet}^2|}{(p_{T,k} \cdot p_{T,jet})} \right] \), where \( p_{T,jet} \) and \( p_{T,k} \) are the 3-momenta of the jet and charged particle, respectively, and \( \xi_{\gamma} = \ln \left[ -\frac{|p_{T,\gamma}^2|}{(p_{T,k} \cdot p_{T,\gamma})} \right] \), where \( p_{T,\gamma} \) and \( p_{T,k} \) are the \( p_T \) with respect to the beam direction of the photon and charged particle, respectively. The \( \xi_{\text{jet}} \) variable gives the fragmentation pattern with respect to \( p_T \) of the reconstructed jet [33,34], and can be compared directly with results obtained using a dijet sample [18]. The \( \xi_{\gamma} \) variable is used to characterize the fragmentation pattern with respect to the \( p_T \) of the initial parton before any energy loss occurred. The \( p_{T,\gamma} \) is used instead of \( p_T \) because the photon and parton from a hard scattering have the same \( |p_T| \) at leading order, but not necessarily the same magnitude of longitudinal momentum.

The central feature of the CMS detector is a superconducting solenoid, providing a magnetic field of 3.8 T. Within the solenoid volume are a pixel and strip tracker, an electromagnetic calorimeter (ECAL), and a hadron calorimeter (HCAL). Hadron forward (HF) calorimeters extend the pseudorapidity coverage up to \( \eta = 5.2 \). In the case of Pb-Pb events, the HF signals are used to determine the degree of overlap (“centrality”) of the two colliding Pb nuclei [21] and the event-by-event azimuthal angle of maximum particle density (“event plane”) [35]. A more detailed description of the CMS detector can be found in Ref. [36].

The event samples are selected online with a dedicated photon trigger requiring one photon with \( p_{T,\gamma} > 40 \text{ GeV/c} \) [29], and are subjected to offline requirements to remove noncollision events [29,37]. For jets and photons, the reconstruction algorithms, analysis selections, and corrections for the energy scale and resolution are the same as in Ref. [29]. For the analysis of Pb-Pb collisions, the event centrality is defined as the fraction of the total inelastic hadronic cross section, starting at 0% for the most central collisions, and is evaluated as percentiles of the distribution of the energy deposited in the HF calorimeters [21]. Results are presented in four centrality intervals, ranging from a central 0%–10% (i.e., the 10% of the events having the largest overlap area of the two nuclei [38]), to a peripheral 50%–100% (the one closest to a \( pp \)-like environment) intervals.

The photon candidates are restricted to the barrel region of the ECAL, \( |p_T| < 1.44 \), and are required to have \( p_{T,\gamma} > 60 \text{ GeV/c} \). Electron contamination and anomalous signals caused by the interaction of heavily ionizing particles with the silicon avalanche photodiodes used for the ECAL readout are removed [39]. Background from ECAL showers induced by hadrons are rejected using the ratio of HCAL over ECAL energy inside a cone of radius \( \Delta R = \sqrt{(\Delta \eta)^2 + (\Delta \phi)^2} = 0.15 \) around the photon candidate [39,40]. Background contributions from fragmentation and decay photons are rejected by imposing isolation requirements [29,39]. The dominant remaining background is ECAL showers initiated by isolated neutral mesons decaying into pairs of photons that are reconstructed as a single photon. Because the pattern of energy deposited in the ECAL (i.e., the “shower shape”) is wider in \( \eta \) for these decay photons, their contribution can be reduced by a factor of \( \sim 2 \) using an upper limit on the width of the \( \eta \) distribution [39].

The energy of the reconstructed photons is corrected to account for the effects of the material in front of the ECAL and for incomplete containment of the shower energy in the ECAL crystals [41]. An additional correction is applied in Pb-Pb collisions to account for the contribution of the underlying event (UE). The corrections are obtained from photon events simulated using the CUETP8M1 tune [42] of the PYTHIA 8.212 [43] Monte Carlo (MC) event generator. The effect of the Pb-Pb UE is modeled by embedding the PYTHIA output in events generated using HYDJET 1.9 [44]. The background simulation is tuned to reproduce the observed charged-particle multiplicity and \( p_T \) spectrum in Pb-Pb data. The size of the resulting energy correction for isolated photons varies from 0% to 10%, depending on \( p_{T,\gamma} \) and the centrality of the collision.

The particle-flow algorithm [45] is used for the jet reconstruction with the anti-\( k_T \) algorithm provided in the FASTJET framework [46,47] with a distance parameter \( R = 0.3 \). In order to subtract the UE background in Pb-Pb collisions, an iterative algorithm [48] is employed [21,28,49]. In \( pp \) collisions, where the UE level is negligible, jets are reconstructed without UE subtraction (for a jet with \( p_T = 30 \text{ GeV/c} \), the UE contribution is at most 1%). The jet energy corrections are derived from simulation, separately for \( pp \) and Pb-Pb, and are confirmed via energy-balance methods in \( pp \) data [50]. Jets with \( |\eta| < 1.6 \) and corrected \( p_{T,\gamma} > 30 \text{ GeV/c} \) are selected. In order to compare the Pb-Pb and \( pp \) results, the jet energy and \( \phi_{\text{jet}} \) in \( pp \) events are smeared to match the corresponding resolutions in each of the Pb-Pb centrality intervals. The parametrization of the energy smearing function is given in Ref. [29]. To match the 0%–10% Pb-Pb data, the energy resolution of \( pp \) jets with \( p_{T,\gamma} = 30(90) \text{ GeV/c} \) changes from 18% (12%) to 35% (17%). The change in angular resolution is negligible (<2.2%).

In each event, photon + jet pairs are formed by associating the highest-\( p_{T,\gamma} \) isolated photon candidate with all jets that pass the jet selection criteria. An azimuthal separation of \( \Delta \phi_{\gamma,jet} = |\phi_{\gamma} - \phi_{\text{jet}}| > 7\pi/8 \) is applied to the photon + jet pairs to suppress contributions from background jets (not from the same hard scattering as the photon) and photon + multijet events (from an early splitting of the original parton). The tracks used in the measurement of the
systematic uncertainties are an average over all quadrature of the individual uncertainties. The quoted uncertainty related to the isolated photons, the same procedures as in Ref. [37].

The selected charged-particle tracks \((N^{\text{trk}})\) are used in conjunction with the selected photon + jet pairs to determine the fragmentation functions, \((1/N^{\text{jet}})(dN^{\text{trk}}/d^2p_T)\) and \((1/N^{\text{trk}})(dN^{\text{trk}}/d^2p_T)\), where \(N^{\text{jet}}\) represents the total number of photon + jet pairs. To isolate the contribution of photons, jets, and charged particles that are produced in the same hard scattering in Pb-Pb collisions, several combinatorial backgrounds are subtracted: tracks from the UE that fall within the cone around the selected jet, misidentified jets resulting from UE fluctuations, and jets not produced in the same hard parton-parton scatterings as the photon. The shape and magnitude of these contributions are estimated from data with an event mixing procedure, in which either the isolated photon or the jet is combined with jets and tracks found in events chosen randomly from a minimum-bias (MB) Pb-Pb data set with similar event characteristics (centrality, interaction vertex position, and event plane angle). The background contribution from UE tracks is estimated by correlating each selected jet with tracks from MB events. The backgrounds from jets produced by UE fluctuations or a different parton-parton scattering are estimated by correlating each selected photon with jets from randomly selected MB events as in Refs. [28,29]. The normalizations of these combinatorial background fragmentation functions are given by the number of MB events used. Simulations predict that the average UE particle density is slightly different between a MB event and an event containing a hard scattering, even when the two have the same collision centrality. Therefore, the normalized background distributions are further scaled with a residual factor to account for this effect. The final correction accounts for the photon purity, defined to be the fraction of nondecay photons within the collection of isolated photon candidates that pass the shower shape requirement. This fraction is extracted from the data using a template fit to the shower shape distribution, and is \(\sim\), 65\% (85\%) in 0\%–10\% (0\%–50\%) PbPb collisions [28,29]. The shape of the fragmentation functions from decay photons is estimated by repeating the analysis selecting photons with wider shower shapes.

Several sources of systematic uncertainty are considered: photon purity, energy scale, isolation, electron contamination, jet energy scale and resolution, tracking efficiency, and UE background. The total uncertainty is the sum in quadrature of the individual uncertainties. The quoted systematic uncertainties are an average over all \(\xi^{\text{jet}}\) and \(\xi_T\) bins and, in the case of the Pb-Pb results, are quoted only for events with 0\%–10\% centrality. To evaluate the systematic uncertainties related to the isolated photons, the same procedures as in Ref. [29] are applied. The uncertainty in the photon purity estimation is evaluated by varying the components of the shower shape template [28]. The maximum variations with respect to the nominal case are propagated as systematic uncertainties, amounting to 2.8 (5.4)\% for the Pb-Pb events, and 0.4 (0.4)\% for the \(pp\) results, for \(\xi^{\text{jet}}(\xi_T)\).

In the following, the uncertainties will continue to be quoted for central Pb-Pb first, then for \(pp\). The total systematic uncertainties resulting from the experimental criteria for an isolated photon are 1.7 (1.1)\% and 0.9 (0.7)\% for \(\xi^{\text{jet}}(\xi_T)\). The residual data-to-simulation photon energy scale difference after applying the photon energy corrections is also quoted as a systematic uncertainty of 1.2 (1.2)\% and < 0.1\% for \(\xi^{\text{jet}}(\xi_T)\). An uncertainty for the level of electron contamination is evaluated by repeating the analysis without applying the electron rejection criteria, and scaling down the difference in the \(\xi\) observables to the remaining electron level of contamination after applying the electron rejection, giving 0.6 (0.5)\% and < 0.1 (0.1)\% for \(\xi^{\text{jet}}(\xi_T)\). The efficiency for selecting photons has been extracted from MC calculations as a function of photon \(p_T\). An uncertainty is assigned by comparing the results to the ones obtained with a correction derived after loosening the selection criteria, giving 0.1 (0.5)\% and < 0.1 (< 0.1)\% for \(\xi^{\text{jet}}(\xi_T)\). The uncertainty related to the jet energy scale [29] amounts to 7.3 (6.5)\% and 2.4 (0.6)\% for \(\xi^{\text{jet}}(\xi_T)\), while the energy resolution [29] gives uncertainties of 2.8 (1.7)\% and 0.7 (0.5)\%. A systematic uncertainty is assigned to account for long-range \(\eta\) correlations [23] that contribute to the UE. It is estimated by constructing the observables using tracks lying within the same azimuthal angle as the jet, but separated by a large pseudorapidity interval, 1.5 < \(\Delta\eta\) < 2.4. The uncertainty is found to be 4.1 (3.3)\% and 1.7 (1.5)\% for \(\xi^{\text{jet}}(\xi_T)\). The uncertainty related to the tracking inefficiency is estimated as the difference in the track reconstruction efficiency between data and simulation [37]. It is 5 (4)\% for Pb-Pb \((pp)\) data, for both \(\xi^{\text{jet}}\) and \(\xi_T\), and is constant as a function of the track \(p_T\) and event centrality.

For the Pb-Pb results only, two additional sources of systematic uncertainties are considered. One accounts for possible inaccuracies in the background subtraction by combining two independent components. First, the effect of the background subtraction method is estimated using an alternative procedure (the so-called \(\eta\)-reflection method [18]), which has different sensitivities to various background sources. Second, results are compared to the ones where background distributions are not scaled for the UE particle density difference seen when comparing simulated MB events with those containing a hard scattering. The combined difference of 3.6 (3.5)\% for \(\xi^{\text{jet}}(\xi_T)\) is assigned as the uncertainty. The second uncertainty accounts for differences in the jet energy response due to \(\xi^{\text{jet}}\) and \(\xi_T\) variances in the jet fragmentation pattern, as studied in simulation [29]. The observed differences of 11\% for \(\xi^{\text{jet}} < 1\) and 4.3 (7.0)\% for \(\xi^{\text{jet}}(\xi_T) > 2.5\) are propagated.
as uncertainties in the corresponding $\xi^\text{jet}$ and $\xi^\gamma$T regions for the Pb-Pb results, while there are no significant differences in other $\xi^\text{jet}$ and $\xi^\gamma$T bins.

Figure 1 shows the photon-tagged fragmentation functions as a function of $\xi^\text{jet}$ for both Pb-Pb and pp collisions, together with their ratio of the Pb-Pb to pp results. The $\xi^\text{jet}$ distributions in Pb-Pb collisions represent the fragmentation pattern of jets that may have lost energy through interactions with the medium, while those for pp stand for unquenched jets. Because of this possibility of quenching, the collections of reconstructed jets in Pb-Pb and pp collisions do not necessarily have the same $p_T^\text{jet}$ spectrum, even though the samples are selected based on photon energy. The $\xi^\text{jet}$ distributions for 50%–100% centrality Pb-Pb collisions are consistent with those in pp collisions. In more central collisions, an enhancement of the fragmentation function in Pb-Pb collisions with respect to the reference pp data is observed for $\xi^\text{jet} > 2.5$ (corresponding to $p_T^\text{trk} < 2.5 \text{ GeV}/c$ for $p_T^\text{jet} = 30 \text{ GeV}/c$ and $\Delta R = 0$ between the track and the jet), indicating that there is a small excess of soft particles near the jet. Additionally, a slight suppression of the fragmentation function in the region $0.5 < \xi^\text{jet} < 2.5$ (corresponding to $18 < p_T^\text{trk} < 2.5 \text{ GeV}/c$ for $p_T^\text{jet} = 30 \text{ GeV}/c$ and $\Delta R = 0$) is also observed in the most central Pb-Pb collisions.

Figure 2 shows the photon-tagged fragmentation functions as a function of $\xi^\gamma$T for Pb-Pb and pp collisions, as well as their ratio. As for $\xi^\text{jet}$, the $\xi^\gamma$T distributions for Pb-Pb collisions are consistent with those in pp collisions.
peripheral Pb-Pb events are consistent with those in \( pp \) data. In more central collisions, an enhancement is observed in the Pb-Pb data relative to \( pp \) data in the \( \xi_T^\gamma > 3 \) region (corresponding to \( p_T^{\rm jet} \lesssim 3 \) GeV/c for \( p_T^\gamma = 60 \) GeV/c and \( \Delta \phi = \pi \) between the track and the photon). The magnitude of this enhancement increases as the Pb-Pb collisions become more central, and is more significant than the enhancement observed in the \( \xi_T^\gamma \) distributions. The differences between the \( pp \) and Pb-Pb distributions are quantified by comparing the two distributions using a \( \chi^2 \) test. The \( p \) values from the test are 10^{-3} and 10^{-20} for the \( \xi_T^\gamma \) and \( \xi_T^\ell \) distributions, respectively. Similarly, the \( \xi_T^\gamma \) distribution was compared to that for \( \xi_T^\gamma \) within the same system. The \( p \) values from the test are 10^{-3} and 10^{-10} for the Pb-Pb and \( pp \) results, respectively. A suppression of the \( \xi_T^\gamma \) distribution for the most central Pb-Pb collisions is also observed for \( 0.5 < \xi_T^\gamma < 3 \) (corresponding to \( p_T^{\rm jet} \gtrsim 3 \) GeV/c for \( p_T^\gamma = 60 \) GeV/c and \( \Delta \phi = \pi \)). This pattern of suppression and enhancement is direct evidence for energy loss by high-\( p_T \) partons as they traverse the high-density medium created in heavy ion collisions [51,52].

The enhancement at large \( \xi_T^\gamma \) and \( \xi_T^\ell \), together with the suppression at lower values, indicates that the showers of partons that emerge from the medium contain more lower-energy particles in Pb-Pb collisions. These particles can originate directly from high-energy partons that lose energy, as well as from the medium response, the recoil of the medium as the parton traverses through [34,53,54]. The enhancements and suppressions of the fragmentation patterns measured using a photon to estimate the initial parton energy (\( \xi_T^\gamma \)) are observed to be more pronounced than the ones measured using detector level jet energy (\( \xi_{\rm jet} \)). Qualitatively, this is not surprising. Because of effects such as out-of-cone radiation not being captured in the anti-\( k_T \) \( R = 0.3 \) jet area, a shift of the distributions to lower values for \( \xi_T^\gamma \) compared to \( \xi_T^\ell \) is observed even in the \( pp \) results. In Pb-Pb collisions, an additional shift happens when the jet is quenched: the jet momentum becomes lower than that of the parton, resulting in a shift to lower \( \xi_T^\gamma \). As a result, the modifications in the ratio Pb-Pb/\( pp \) are weakened by quenching in the \( \xi_T^\gamma \) case. This analysis, using events selected with a photon trigger which ensures that the initial parton \( p_T \) spectra are the same for \( pp \) and Pb-Pb, will allow testing the theoretical modeling of both the parton shower modification in the medium and the medium response to the passage of that parton.

In summary, the fragmentation functions of jets associated with isolated photons are measured for the first time in \( pp \) and Pb-Pb data collected at \( \sqrt{s_{\rm NN}} = 5.02 \) TeV by CMS. Fragmentation patterns as functions of \( \xi_T^\gamma = \ln \left[ (\vec{p}_T^{\gamma})^2 / (\vec{p}_T^{\rm jet})^2 \right] \) and \( \xi_T^\ell = \ln \left[ (\vec{p}_T^{\ell})^2 / (\vec{p}_T^{\rm jet} \cdot \vec{p}_T^\gamma) \right] \) are constructed using charged particles with \( p_T^{\rm jet} > 1 \) GeV/c, for jets with \( p_T^{\rm jet} > 30 \) GeV/c tagged by an isolated photon with \( p_T^\gamma > 60 \) GeV/c. When compared to the \( pp \) results, the \( \xi_T^\gamma \) and \( \xi_T^\ell \) distributions in central Pb-Pb collisions show an excess of low-\( p_T \) particles and a depletion of high-\( p_T \) particles inside the jet. This observation is more apparent in the \( \xi_T^\gamma \) distributions, where the photon-based selection allows for tagging the properties of the initial parton before quenching occurs. This measurement shows for the first time the in-medium parton shower modifications for events with well-defined initial parton kinematics, and constitutes a new well-controlled reference for testing theoretical models of the parton’s passage through the QGP.

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMWFW and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RPF (Cyprus); SENESCYT (Ecuador); MoER, ERC IUT, and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); OTKA and NIH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); LAS (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MBIE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, Federal Agency of Atomic Energy of the Russian FederationRosAtom, RAS, RFBR and RAEP (Russia); MESTD (Serbia); SEIDI, CPAN, PCTI and FEDER (Spain); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR, and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU and SFFR (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

The University of Alabama, Tuscaloosa, Alabama, USA
Boston University, Boston, Massachusetts, USA
Brown University, Providence, Rhode Island, USA
University of California, Davis, Davis, California, USA
University of California, Los Angeles, California, USA
University of California, Riverside, Riverside, California, USA
University of California, San Diego, La Jolla, California, USA
University of California, Santa Barbara—Department of Physics, Santa Barbara, California, USA
California Institute of Technology, Pasadena, California, USA
Carnegie Mellon University, Pittsburgh, Pennsylvania, USA
University of Colorado Boulder, Boulder, Colorado, USA
Cornell University, Ithaca, New York, USA
Fermi National Accelerator Laboratory, Batavia, Illinois, USA
University of Florida, Gainesville, Florida, USA
Florida International University, Miami, Florida, USA
Florida State University, Tallahassee, Florida, USA
Florida Institute of Technology, Melbourne, Florida, USA
University of Illinois at Chicago (UIC), Chicago, Illinois, USA
The University of Iowa, Iowa City, Iowa, USA
Johns Hopkins University, Baltimore, Maryland, USA
The University of Kansas, Lawrence, Kansas, USA
Kansas State University, Manhattan, Kansas, USA
Lawrence Livermore National Laboratory, Livermore, California, USA
University of Maryland, College Park, Maryland, USA
Massachusetts Institute of Technology, Cambridge, Massachusetts, USA
University of Minnesota, Minneapolis, Minnesota, USA
University of Mississippi, Oxford, Mississippi, USA
University of Nebraska-Lincoln, Lincoln, Nebraska, USA
State University of New York at Buffalo, Buffalo, New York, USA
Northeastern University, Boston, Massachusetts, USA
Northwestern University, Evanston, Illinois, USA
University of Notre Dame, Notre Dame, Indiana, USA
The Ohio State University, Columbus, Ohio, USA
Princeton University, Princeton, New Jersey, USA
University of Puerto Rico, Mayaguez, Puerto Rico
Purdue University, West Lafayette, Indiana, USA
Purdue University Northwest, Hammond, Indiana, USA
Rice University, Houston, Indiana, USA
University of Rochester, Rochester, New York, USA
The Rockefeller University, New York, USA
Rutgers, The State University of New Jersey, Piscataway, New Jersey, USA
University of Tennessee, Knoxville, Tennessee, USA
Texas A&M University, College Station, Texas, USA
Texas Tech University, Lubbock, Texas, USA
Vanderbilt University, Nashville, Tennessee, USA
University of Virginia, Charlottesville, Virginia, USA
Wayne State University, Detroit, Michigan, USA
University of Wisconsin—Madison, Madison, Wisconsin, USA

aDeceased.
bAlso at Vienna University of Technology, Vienna, Austria.
cAlso at IRFU, CEA, Université Paris-Saclay, Gif-sur-Yvette, France.
dAlso at Universidade Estadual de Campinas, Campinas, Brazil.
eAlso at Federal University of Rio Grande do Sul, Porto Alegre, Brazil.
fAlso at Université Libre de Bruxelles, Bruxelles, Belgium.
gAlso at Institute for Theoretical and Experimental Physics, Moscow, Russia.
hAlso at Joint Institute for Nuclear Research, Dubna, Russia.
Also at Ain Shams University, Cairo, Egypt.
Also at Cairo University, Cairo, Egypt.
Also at British University in Egypt, Cairo, Egypt.
Also at Fayoum University, El-Fayoum, Egypt.
Also at Department of Physics, King Abdulaziz University, Jeddah, Saudi Arabia.
Also at Université de Haute Alsace, Mulhouse, France.
Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia.
Also at Tbilisi State University, Tbilisi, Georgia.
Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland.
Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany.
Also at University of Hamburg, Hamburg, Germany.
Also at Brandenburg University of Technology, Cottbus, Germany.
Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary.
Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary.
Also at Institute of Physics, University of Debrecen, Debrecen, Hungary.
Also at IIT Bhubaneswar, Bhubaneswar, India.
Also at Shoolini University, Solan, India.
Also at University of Visva-Bharati, Santiniketan, India.
Also at University of Ruhuna, Matara, Sri Lanka.
Also at Isfahan University of Technology, Isfahan, Iran.
Also at Yazd University, Yazd, Iran.
Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran.
Also at Università degli Studi di Siena, Siena, Italy.
Also at INFN Sezione di Milano-Bicocca, Università di Milano-Bicocca, Milano, Italy.
Also at International Islamic University of Malaysia, Kuala Lumpur, Malaysia.
Also at Malaysian Nuclear Agency, MOSTI, Kajang, Malaysia.
Also at Consejo Nacional de Ciencia y Tecnología, Mexico city, Mexico.
Also at Warsaw University of Technology, Institute of Electronic Systems, Warsaw, Poland.
Also at National Research Nuclear University ‘Moscow Engineering Physics Institute’ (MEPhI), Moscow, Russia.
Also at Institute for Nuclear Research, Moscow, Russia.
Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia.
Also at University of Florida, Gainesville, Florida, USA.
Also at P.N. Lebedev Physical Institute, Moscow, Russia.
Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia.
Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia.
Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia.
Also at Scuola Normale e Sezione dell’INFN, Pisa, Italy.
Also at National and Kapodistrian University of Athens, Athens, Greece.
Also at Riga Technical University, Riga, Latvia.
Also at Universität Zürich, Zurich, Switzerland.
Also at Stefan Meyer Institute for Subatomic Physics.
Also at Gaziosmanpasa University, Tokat, Turkey.
Also at Istanbul Aydin University, Istanbul, Turkey.
Also at Mersin University, Mersin, Turkey.
Also at Piri Reis University, Istanbul, Turkey.
Also at Adiyaman University, Adiyaman, Turkey.
Also at Izmir Institute of Technology, Izmir, Turkey.
Also at Necmettin Erbakan University, Konya, Turkey.
Also at Marmara University, Istanbul, Turkey.
Also at Kafkas University, Kars, Turkey.
Also at Istanbul Bilgi University, Istanbul, Turkey.
Also at Rutherford Appleton Laboratory, Didcot, United Kingdom.
Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom.
Also at Monash University, Faculty of Science, Clayton, Australia.
Also at Instituto de Astrofísica de Canarias, La Laguna, Spain.
Also at Utah Valley University, Orem, Utah, USA.
Also at Purdue University, West Lafayette, Indiana, USA.
Also at Beykent University.
Also at Bingol University, Bingol, Turkey.
Also at Erzincan University, Erzincan, Turkey.
Also at Sinop University, Sinop, Turkey.
Also at Mimar Sinan University, Istanbul, Istanbul, Turkey.
Also at Texas A\&M University at Qatar, Doha, Qatar.
Also at Kyungpook National University, Daegu, Korea.
