NUTECH-2020

Warsaw, 4-7 October 2020

International Conference on Development and Applications of Nuclear Technologies

Mirco Grosse

Thermal limits of potential ATF cladding materials

Promising ATF concepts

Various coating systems:

- Metals
- Oxides or silicates
- MAX phases

Cr coated Zry is the most promising system

Cr in FeCrAL is boon and bane at once:

- irradiation induced embrittlement due to the formation of Cr rich α' precipitates
- Increase of the corrosion and HT oxidation resistance

less developed system best HT properties issues: - water corrosion

- joining

International Conference on Development and Applications of Nuclear Technologies

The QUENCH facility for bundle tests

- Bundle with 21 32 fuel rod simulators of ~2.5 m length
- Electrically heated: ~2 m;
- Fuel simulator: ZrO₂ pellets
- Quenching from bottom
- Off-gas analysis by mass spectrometer (H₂, steam ...)
- Extensive instrumentation for T, p, flow rates, water level, etc. (140 measurement channels)
- corner rods, can be removed during test

Results Issues of FeCrAl I) kinetic limitations

Oxidation behaviour of FeCrAl-based alloys during the transient tests from 500 to 1450°C with subsequent holding 1 h at 1450°C in steam. ■ and ★: alloy specimens showed catastrophic oxidation with non-protective Fe-based oxide scale

- and ★: alloy specimens formed protective alumina scale
- ▲ : alloy specimens with Y addition formed protective alumina scale

Summary and Conclusions

The maximumal temparatures for applications are often less than a-priori expected.

Cr-coated Zry-4: eutectic interaction between Cr and Zr results in a higher oxidation rate at temperatures above 1330°C. Catastrophic oxidation if the coating fails.

FeCrAl:

- Eutectic interaction between molten FeO and UO₂ at 1335°C can results in much earlier core melting.
- Material performance depends on heating rate. Time is needed to form a protective Al₂O₃ layer. Catastrophic oxidation occurs above 1330°C if no protective Al₂O₃ layer is formed.
- SiC: faster oxidation above the melting temperature of SiO₂ at 1720°C. Catastrophic oxidation occur if the monolithic outer layer fails (even at 1200°C).
- A lot of work has to be done to achieve accident tolerance. However, it is worth to do this work because the improvement of safety would be great.
