Steffen Grohmann

Gravitational Wave
Advanced Detector Workshop
17-21 May 2021
Last-stage suspension scheme:

Heat sink at $T_{\text{HeatSink}}$

$T_{\text{Fiber}}(x)$

TM at 10 ... 20 K

$\dot{Q}_{\text{total}} = 200 \text{ mW}$

$T_{\text{HeatSink}} \rightarrow 2 \text{ K offers } T_{\text{Mirror}} \leq 10 \text{ K potential}$

Analytical calculations

4x High-purity fibers ($\Phi = 3 \text{ mm}$)

$T_{\text{Fiber}}(x) / K$

- Silicon (TPRC 1970)
- Sapphire (TPRC 1971)

$0 \leq x / \text{ m} \leq 2.5$
He-II: payload heat extraction

Two liquid phases of $^4$He:

- **He-I** (classical liquid helium)
  - Behaviour: ~ideal gas
  - $T_\lambda$ (1 atm) ≈ 2.17 K
  - $T > T_\lambda$
  - $T < T_\lambda$

- **He-II** ("two fluid model" [1][2])
  - Normal component
  - Superfluid component
    - Bose-Einstein condensate

---

**He-II: enhanced heat transfer properties**

TM cryostat cooling: temperature levels

Three temperature stages:

<table>
<thead>
<tr>
<th>Part(s)</th>
<th>Temp. level</th>
<th>Estimated cooling power</th>
</tr>
</thead>
<tbody>
<tr>
<td>Outer thermal shield</td>
<td>50…80 K</td>
<td>$x \ldots 10^3$ W</td>
</tr>
<tr>
<td>Inner thermal shield</td>
<td>5 K</td>
<td>$x \ldots 10^2$ W</td>
</tr>
<tr>
<td>Payload heat sink</td>
<td>2 K</td>
<td>$x \ldots 1$ W</td>
</tr>
</tbody>
</table>

$T_{\text{Inner Shield}} < T_{\text{Mirror}} (\sim 10 \text{ K})$ possible
Helium-based cooling power provision

Basis: He-refrigerator + subcooler

He-supplies:
- 50…80 K (HP)
- 5 K (LP)
- 2 K (VLP)

Example: Linde L-Series

Single refrigerator: large cooling power at three temperature levels

Basic layout: complete cryostat cooling

1. Outer shield cooldown
2. Inner shield cooldown
3. Payload preliminary cooldown
4. Payload link $\to \sim 5$ K
5. Payload link $\to \sim 3$ K
6. He-II formation
7. Steady-state (no flow)
Payload thermal link: He-II capillaries

Key boundary conditions:

- Operating pressure: 0.1 MPa
- Capillary length: 30 m
- Capillary cold end temp. (He-II): 1.80 K
- Capillary warm end temp. (He-II): 1.90 K

Dimensioning example (approx.):
10 capillaries with $d_i = 1.8 \text{ mm}$ can extract 200 mW from a payload at 1.9 K over 30 m distance with a $\Delta T$ of only 0.1 K.
1.8 K unit positioning possibilities

Corner cavern scheme:

1.8 K Unit main components:
- Vacuum vessel
- Low-pressure heat exchanger
- Vacuum pumps

Long capillaries offer low-noise cooling potential and flexible positioning of the 1.8 K units.

Vibration propagation via He-II hollow heat links
KAGRA experience on vibration transmission into payload

Heat links (6N Al)

Optic (OP)

He-II hollow capillaries as heatlinks of ET-LF payload

Payload thermal link operation 1.7…1.9 K

Lower thermal dissipations
- Cryogenic temperatures
- Dissipation-free superfluid component in He-II
Integration of He-II filled capillary into payload

- He-II filled capillary ($\varnothing \leq 3\, mm$)

- Hollow capillary as suspension fiber
  - Marionette
  - Mirror (?)

- Hollow capillary as external heat links

Source: [1] Payload design from P. Rapagnani: ET LF-Main Features and Constrains (26.04.21)
Theoretical description of thermal dissipation in He-II capillaries

Vibrational Noise into payload
- He-II capillaries → suspension fibers and/or heat links
- Cooling system noise

Experimental Proof of Concept
- Ultra-low noise He-cooling system
