#### ABSTRACT

Chemical solution deposition is widely used in the preparation of rare-earth-based cuprate superconducting thin films, namely *RE*xBa2Cu3O7-*y* (*RE* rare earth element). The crystallographic orientation of the films is strongly dependent on the degree of supersaturation during crystallization. In this paper, we systematically studied the crucial factors affecting supersaturation, such as the type and stoichiometry of the rare earth element and the sintering temperature. Furthermore, the relationship between *c*-axis orientation and supersaturation was established. The results demonstrate that a small *RE* ionic radius (e.g., *RE* Yb) and reduced *rE*-stoichiometry, studied on the example of yttrium, are beneficial for the growth of *c*-axis-oriented films at lower temperatures. In addition, a Y-O/Ba-Cu-O stacked-layer structure was proposed to regulate the diffusion distance to the reaction site. Compared with a Y-Ba-Cu-O single-layer, a *c*-axis orientation percentage of more than 40 % is achieved in the Y-O/Ba-Cu-O stacked-layer at even lower sintering temperatures. The results suggest that a low supersaturation is favorable to promote the growth of *c*-axis-oriented nuclei and therefore suppresses the growth of random orientations. This paper provides a new strategy to realize orientation modulation of rare-earth-based cuprate superconducting thin films by controlled chemical solution method.

# **1. Introduction**

Chemical solution deposition (CSD) has been extensively studied in the field of functional thin films for many years [\[1](#page-7-0)–4]. A common feature of the CSD process is that the deposited film transforms from an amorphous intermediate/precursor to the desired crystalline state. It is well understood that the driving force of the transformation process depends on the supersaturation, which is closely related to the complex physical and chemical changes that occur during nucleation and film growth [5–[7\]](#page-7-0). Therefore, fine-modulation of the supersaturation allows a better understanding of the amorphous-crystalline transformation in the CSD process.

With better mechanical  $[8,9]$  and magnetic  $[10-12]$  properties, rareearth-based cuprate  $RE_xBa_2Cu_3O_{7-y}$  (,  $RE =$  rare earth) superconducting tapes have been widely used [13–[17\].](#page-7-0) Control of supersaturation has been successfully realized in the CSD route for the preparation of *RE*BCO superconducting films [18–[20\].](#page-7-0) As previous studies demonstrated, the

reaction path of the YBCO transformation varies with the solution chemistry. For example, in the trifluoroacetate-based metal–organic decomposition route (TFA-MOD), where the precursor solution and intermediary species in the film contain fluorine, the supersaturation is influenced by several key factors, such as the partial pressure of HF and  $H_2O$ ,  $p_{HF}$  and  $p_{H2O}$ , the temperature, additives, etc.  $[21-28]$  $[21-28]$ . In the preparation of YBCO films by CSD, lower supersaturation was found to be favorable for *c*-axis nucleation [\[23,24\]](#page-7-0), while the opposite was found for liquid phase epitaxy [29–[31\].](#page-7-0)

Due to increased environmental awareness, the use of fluorine has been questioned to some extent. Moreover, the slow growth rate (less than 10 nm/s) [\[32\]](#page-7-0) of the TFA-MOD process is a pressing issue. An alternative, fluorine-free (FF) MOD process is attracting more and more attention in the field [\[33](#page-7-0)–36]. Compared to the conventional TFA-MOD method, the FF-MOD approach could be considered a "green" process, which even allows much higher growth rates up to 100 nm/s [\[37\].](#page-7-0)

So far, the mechanisms of nucleation and growth of *RE*BCO

superconducting films by FF-MOD is not fully understood, though. A liquid phase of Ba-Cu-O is believed to form initially, followed by  $Y_2O_3$ dissolving into the liquid phase [\[35,37\]](#page-7-0). Eventually, the *RE*BCO phase crystallizes with a preferred orientation on the substrate. Due to the completely different chemical reaction path, it is still unclear how to control supersaturation in the FF-MOD route. Therefore, a systematic study on the effect of supersaturation on nucleation and growth of *RE*BCO is very important, also for further understanding and optimization of the whole process.

In our previous studies, we synthesized stable, fluorine-free precursor solutions with different rare earth elements (*RE* = Yb, Y, Dy, Gd, Eu, and Sm) and good superconducting performance of the resulting *RE*BCO films [\[38\]](#page-7-0). In this paper, the first motivation is to understand how the degree of supersaturation affects the orientation of *RE*BCO deposited on CeO2-buffered substrates. Moreover, we propose a multi-layer architecture of Ba-Cu-O and Y-O as a new strategy to regulate the distance of yttrium diffusion to the growth front. The *a*- and *c*-axis nuclei in the films were characterized by X-ray diffraction (XRD), Raman spectroscopy, and transmission electron microscopy (TEM). The diffusion behavior of yttrium in the liquid phase was investigated by TEM and time-of-flight secondary ion mass spectrometry (TOF-SIMS).

# **2. Experimental**

# *2.1. Precursor synthesis*

The precursor solutions of *RE*BCO, Ba-Cu-O and Y-O were synthesized using a fluorine-free propionate-based route, the details of which were reported in Refs [\[39,40\].](#page-7-0) For the Ba-Cu-O precursor, Ba- and Cuacetates were dissolved in propionic acid in the ratio Ba: $Cu = 2:3$  with a total cation concentration of 0.2 mol/L, and for the Y-O precursor, Yacetate is dissolved also in propionic acid with a cation concentration of 0.1 mol/L.

#### *2.2. Film preparation*

The films were deposited using a typical CSD process consisting of three main steps, namely dip coating, low-temperature pyrolysis, and high-temperature crystallization [\[38\].](#page-7-0) Flexible textured templates with an architecture of CeO<sub>2</sub>/LaMnO<sub>3</sub>/IBAD-MgO/Y<sub>2</sub>O<sub>3</sub>/Al<sub>2</sub>O<sub>3</sub>/C276 (provided by Shanghai Superconductor Technology) were used as substrate [\[41\]](#page-7-0). The respective precursor solutions were deposited on the substrate by dip-coating at a withdrawal speed of 1000 μm/s. Whereas the *RE*BCO precursor layer was deposited in the typical coating and pyrolysis procedure [\[38,42\],](#page-7-0) for the composite film with the Y-O/Ba-Cu-O stackedlayer, dip-coating and pyrolysis were repeated several times to obtain the desired multilayer structure: First, Ba-Cu-O precursor solution was deposited, followed by a pyrolysis process at 500 ◦C, which was repeated five times to increase the Ba-Cu-O layer thickness. Then, the Y-O precursor solution was deposited on the pyrolyzed Ba-Cu-O layer followed by a similar coating and pyrolysis procedure. Eventually, the architecture of the composite film consists of  $2 \times (Y-O)/5 \times (Ba-Cu-O)$ . For comparison, both the Y-Ba-Cu-O single layer and the Y-O/Ba-Cu-O stacked layer were sintered at high temperatures in the range 740–860 °C with an oxygen partial pressure  $pO<sub>2</sub>$  of 50 ppm at 1 bar total pressure.

#### *2.3. Structural characterization*

Phase composition and crystallographic orientation of the films were characterized by a four-circle X-ray diffractometer equipped with a twodimensional detector (Bruker D8 Advance, Cu-K $\alpha$  radiation,  $\lambda = 1.5406$ Å). The texture was also characterized by Raman spectroscopy (Renishaw inVia Qontor, Nd-YAG laser,  $\lambda = 532$  nm). The TEM crosssectional sample was prepared by conventional mechanical polishing and grinding, followed by ion milling. The TEM imaging and energy

#### **Table 1**

The *RE* ionic radii and peritectic temperatures of *RE*BCO for BaO:CuO of 3:5 [\[43\].](#page-7-0)

RE element	Yb		Dv	Gd	Εu	Sm
ionic radius (Å) peritectic temperature $(^{\circ}C)$	0.985 900	1.019 1000	1.027 1010	1.053 1030	1.066 1050	1.079 1060

dispersive X-ray spectroscopy (EDXS) were performed using an aberration-corrected scanning transmission electron microscope (STEM, FEI Talos F200 X) with a double-tilt holder and a cold field emission source operated at 200 kV. A time-of-flight secondary ion mass spectrometer (TOF-SIMS, GAIA3) was operated under a 5 kV focused ion beam (FIB), and a 50 pA detector was used to measure the distribution of Y and Ba along the thickness of the film. Depth distribution information is obtained by combining TOF-SIMS measurements with FIB (milling/ sputtering) to characterize a thin film structure. TOF-SIMS Explorer was used for the acquisition and analysis of the secondary ion signals. The data were acquired from  $10 \times 10 \mu m^2$  scan areas in the positive ion detection mode. In order to avoid crater edge artifacts, the data analysis regions of interest were limited to the central  $5 \times 5 \mu m^2$  areas.

#### **3. Results and discussion**

#### *3.1. Rare-earth species, supersaturation and orientation*

In contrast to the conventional TFA-MOD method, a transient Ba-Cu-O liquid phase is supposed to be present during the FF-MOD route. It plays an essential role for the YBCO phase evolution: it accelerates the crystallization and therefore enables an enhanced growth rate of the films. Our previous studies found that  $Y_2O_3$  nano-particles form in the intermediate state after decomposition  $[35]$ . Y<sub>2</sub>O<sub>3</sub> is very stable and has a high melting point. During high-temperature crystallization,  $Y_2O_3$ tends to migrate toward the surface layer of the film. As the reaction proceeds, however, yttrium re-diffuses into the Ba-Cu-O liquid phase, according to reaction scheme 1, and consequently YBCO is formed by epitaxial nucleation and growth at the interface.

$$
Y_2O_3(s) + liquid (Ba Cu O) \rightarrow YBa_2Cu_3O_{7-\delta}(s) + O_2(g) \uparrow
$$
 (1)

In this diffusion-controlled process, reaction parameters such as the diffusion distance to the reaction site, *D*, and the concentration, *C*, of yttrium in the Ba-Cu-O liquid phase determine the supersaturation, *δ*, at the nucleation site, which is most likely close to the film-substrate interface.  $\delta$  is the main driving force for the formation of YBCO. However, due to the fast growth rate and limited diffusion time, a certain enrichment of yttrium is still present in the upper layers of the YBCO film even after the reaction is complete [\[35\]](#page-7-0). Since yttrium segregation and re-dissolution are the forward and reverse directions of an equilibrium reaction, they occur simultaneously; their respective reaction rates, though, depend on the reaction conditions. For *RE*BCO films with different rare earth elements, the chemical reaction paths governed by this segregation/re-diffusion process are very similar in principle. However, type and stoichiometry of *RE* and the sintering temperature affect *δ* during the *RE*BCO phase formation and ultimately have a strong influence on the crystalline orientation.

For *RE*BCO bulk materials, the peritectic temperature of *RE*BCO was found to increase with the ionic radius of *RE*, as shown in Table 1 for a ratio BaO:CuO of 3:5  $[43]$ . For thin films, the growth mode may be different, but the results on bulk samples may serve as guideline to understand the relationship between the *RE* element and supersaturation. For this study, we selected six rare earth elements (Yb, Y, Dy, Gd, Eu, and Sm), with small to large ionic radii of *RE*.

To shed light on the effect of rare earth type and stoichiometry on *δ*, a series of *RE*BCO films were was prepared by the FF-MOD method. We analyzed the degree of *c*-axis orientation in fully reacted *RE*BCO films

**Fig. 1.** Contour plot of the influence of *RE* ionic size and sintering temperature on *fX* (Eq. (3)).

based on 2D XRD frames. According to our previous research, there are three texture components {006}, {103} and {200} in YBCO films, which we took into consideration for the evaluation, cf. [Fig. 3.](#page-3-0) Moreover, the *c*-axis orientation represents the biaxial texture component [\[35,44\].](#page-7-0) According to literature reports  $[20]$ , the epitaxy fraction is calculated by integrating the results of (005) *RE*BCO reflection at  $\chi$  =  $0^\circ$  (*I*<sup>exp</sup><sub>*epi*</sub>) and *χ* ≠  $0^\circ$  (*I*<sub>*ring*</sub>) in two-dimensional (2D) XRD 2θ − *χ* scans:

$$
\frac{I_{random}}{I_{epitaxial}} = \frac{I_{ring}^{\exp} \bullet (360/\Delta \chi) \bullet 4\pi}{8 \bullet I_{epi}^{\exp}}
$$
(2)

Therefore, we simply evaluated the trend coefficient of epitaxy orientation,  $f_X$ , using the integration results of  $(103)$  *REBCO* reflection at  $\chi \neq 0^{\degree}(I_{103})$  and (006) REBCO reflection at  $\chi = 0^{\degree}(I_{006})$  in twodimensional (2D) XRD 2 $\theta$   $\chi$  scans:

$$
f_X = \frac{I_{epi\alpha xial}}{I_{epi\alpha xial} + I_{random}} = \frac{8 \bullet I_{006}}{8 \bullet I_{006} + I_{103} \bullet (360/\Delta \chi) \bullet 4\pi}
$$
(3)

The  $f_X$  values of various *REBCO* films as a function of the sintering temperature and ionic radius of *RE,* Fig. 1, reveal that both parameters have a significant influence on the formation of *c*-axis-oriented *RE*BCO. In YbBCO films with a small  $RE$  ionic radius,  $f_X$  reaches values higher than 40 % at medium sintering temperatures between 770 ◦C and

810 ◦C. These are the lowest temperatures among all *RE*BCO films investigated in this study. Considerably higher sintering temperatures above 850 °C are required to obtain similarly high  $f_X$  values in SmBCO films. This comparison indicates that *c*-axis textured growth tends to decrease with increasing rare earth ion radius at a certain temperature. Furthermore, in the high temperature region (i.e., above 820 ◦C), the appearance of BaCeO<sub>3</sub> is clearly evident from the XRD results, indicating serious interfacial reactions. As a result, a part of the well-oriented *REBCO* is consumed, seemingly reducing the  $f_X$  values.

According to the chemical reaction scheme 1 for the FF-MOD method, the relative proportion of *RE* in the Ba-Cu-O liquid phase should also have an effect on *δ* and thus on the preferential orientation of the films. Therefore, we investigated the relationship between *rE*-stoichiometry,  $x$ , the sintering temperature and the *c*-axis fraction,  $f_X$ , in  $RE_xBa_2Cu_3O_{7-y}$  films on the example of YBCO in order to establish a correlation between *x* and *δ*. The ratio of Ba:Cu was fixed to 2:3, while the Y content *x* in Y<sub>x</sub>Ba<sub>2</sub>Cu<sub>3</sub>O<sub>7-*y*</sub> was varied, with  $x = 0.8, 1.0, 1.2$  and 1.4. Fig. 2a shows the color-coded  $f_X$  values obtained for the four different levels of *x* in YBCO films sintered between 760  $\degree$ C and 860  $\degree$ C. At a temperature of 790  $\degree$ C, the  $f_X$  value of the yttrium-poor film is already about 30 %. Larger concentrations of yttrium in the film require increasing temperatures for similarly high degrees of the preferential *c*axis orientation. According to Fig. 2b [\[45\],](#page-7-0) *δ* increases as the proportion of yttrium increases. Combined with our results, lower degrees of *δ* are therefore beneficial for the growth of *c*-axis oriented films.

A closer look at the raw data underlying Fig. 2 (a) shows that at low yttrium concentration and therefore low  $\delta$ , a strong YBCO (006) peak appears, [Fig. 3](#page-3-0)b, while the YBCO (103) peak is almost negligible, [Fig. 3](#page-3-0)c. This indicates that low *δ* is favorable to promote the growth of *c*axis orientated nuclei and suppress the growth of random orientation. With increasing yttrium content and  $\delta$ , the intensity of the YBCO (006) peak decreases, [Fig. 3e](#page-3-0), while the intensity of the YBCO (103) peak increases, [Fig. 3](#page-3-0)f. This means that random alignment has a competitive advantage over *c*-axis-oriented nuclei with increasing *δ*. At even higher levels of *x* and *δ*, the YBCO (006) peak, [Fig. 3](#page-3-0)h, does not weaken any further, but the YBCO (200) peak, which represents *a*-axis-oriented grains, appears in addition to YBCO (103), [Fig. 3](#page-3-0)h and i. This implies that *RE*BCO films with a specific crystallographic orientation can be obtained by modulating *δ*.

#### *3.2. Effect of diffusion distance to the reaction site*

The yttrium concentration in the Ba-Cu-O liquid phase obviously plays an important role for the orientation of the growing YBCO film, Figs. 2a and [3](#page-3-0). During phase evolution in the FF-MOD route, yttrium segregates from the matrix as  $Y_2O_3$  prior to the actual YBCO formation, but also re-dissolves when the yttrium concentration or solubility

The phases in coexistence regions are labeled as follows: 200-Y<sub>2</sub>O<sub>3</sub>, 001-CuO, 011-BaCuO<sub>2</sub>, 211-Y<sub>2</sub>BaCuO<sub>5</sub>, 123-YBa<sub>2</sub>Cu<sub>3</sub>O<sub>x</sub>, 210-Y<sub>2</sub>BaO<sub>4</sub>.

**Fig. 4.** Schematic diagram of the effect of different concentrations on the *D* of yttrium at the reaction interface, where  $C_e$ ,  $C$  and  $\delta$  represent the equilibrium concentration, the concentration of yttrium at the reaction interface and the supersaturation, respectively.

changes; the former affected e.g., by the beginning YBCO formation, the latter depends on external conditions such as temperature. Under specific conditions, however, the equilibrium concentration, i.e., the maximum possible concentration of yttrium, *C*e, in Ba-Cu-O is a constant. Therefore, *δ* at the reaction site depends immediately on *C*. Besides, *D* also depends on *C*, Fig. 4, which shows a connection between *D* 

and *δ*. When the *D* increases from  $D_1$  to  $D_2$ , *δ* decreases to *δ*', which means that larger *D* values can be considered equivalent to a lower yttrium concentration. Therefore, regulation of *D* offers another possibility for the modulation of *δ*. In our experiment, we increased *D* artificially by a special Y-O/Ba-Cu-O stacked-layer architecture, [Fig. 5](#page-4-0)b, which we compared to a standard Y-Ba-Cu-O single-layer, [Fig. 5a](#page-4-0). Both types of samples were prepared via the same pyrolysis process. *D* is much smaller in the Y-Ba-Cu-O single-layer than in the Y-O/Ba-Cu-O stackedlayer architecture.

To investigate the effect of *D*, a comparative study was carried out on the two sets of films schematically depicted in [Fig. 5](#page-4-0)a and b. In the Y-Ba-Cu-O single-layer,  $Y_2O_3$  nanoparticles are mixed with other intermediate phases just after pyrolysis. During crystallization, the *D* of yttrium to the reaction site is extremely small within the Ba-Cu-O liquid phase in this case, practically negligible. In the early stage of the high-temperature process, nucleation at the interface is dominant, i.e., the Gibbs free energy at the interface is low compared to that in the film body.  $Y_2O_3$  close to the interface dissolves into Ba-Cu-O, and YBCO starts crystallizing. In contrast, in the case of the Y-O/Ba-Cu-O stacked-layer, the yttrium source is far away from the interface. Hence, yttrium must diffuse through the entire Ba-Cu-O layer before nucleation can begin at the interface. Compared to the Y-Ba-Cu-O single-layer, the Y-O/Ba-Cu-O stacked-layer precursor therefore allows to play with the *D* of yttrium by adjusting the thickness of the Ba-Cu-O layer. It provides a new angle to study the effect of the *D* on the orientation of YBCO superconducting films.

To further investigate the effect of *δ* on the *c*-axis orientation of YBCO, XRD and Raman spectroscopy, were used to characterize the orientation quality of the sintered films. Raman spectroscopy makes it easy to analyze the homogeneity of the films by determining the

<span id="page-4-0"></span>

**Fig. 5.** Sketch of the architectures of (a) the Y-Ba-Cu-O single-layer and (b) Y-O/Ba-Cu-O stacked-layer after pyrolysis.

Fig. 6. Y-Ba-Cu-O single-layer (black) and Y-O/Ba-Cu-O stacked-layer (red) films after sintering: (a)  $f_X$  calculated from XRD results, (b) Raman spectra results. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

distribution of *a*- and *c*-axis orientations. XRD with a two-dimensional detector allows the simultaneous observation of *a*- and *c*-axis orientations and other texture components of YBCO.

We first investigated the orientation at different sintering temperatures for both Y-Ba-Cu-O single-layer and Y-O/Ba-Cu-O stacked-layer films. As shown in Fig. 6a, the  $f_X$  values in both types of films gradually increase with temperature. Thereby, the Y-Ba-Cu-O single-layer ranges at a significantly lower level, but shows a steeper rise towards higher temperatures and reaches  $f_X$  values of just over 40 % at 820 °C. The curve of the Y-O/Ba-Cu-O stacked-layer flattens out at higher temperatures and approaches  $f_X$  values of 100 % at 820 °C. Above all, however, it is over 75 % in the entire temperature range studied and therefore considerably higher than in the Y-Ba-Cu-O single-layer films.

Fig. 6b shows the Raman spectra of the Y-Ba-Cu-O single-layer and Y-O/Ba-Cu-O stacked-layer films. Two distinct peaks at the Raman shift of  $\sim$ 336 cm<sup>-1</sup> and  $\sim$ 500 cm<sup>-1</sup> correspond to the vibrational modes of oxygen at the  $CuO<sub>2</sub>$  planes (O (2,3) out-of-phase) and into apical sites (O4) of orthorhombic YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub>  $_y$ , respectively. The wavenumber and the intensity ratio are consistent with a sharp *c*-axis crystal orientation [46–[48\]](#page-7-0). The *c*-axis oriented grain fraction can be calculated from the following equation [\[49\]](#page-7-0):

$$
I_R = f_R I_c + (1 - f_R)I_a \tag{4}
$$

$$
r = \frac{I_{B1g}}{I_{Ag}} = \frac{f_R I_{c_{B_{1g}}} + (1 - f_R) I_{a_{B_{1g}}}}{f_R I_{c_{Ag}} + (1 - f_R) I_{a_{Ag}}}
$$
(5)

where  $I_{B1g}$  and  $I_{Ag}$  are the Raman intensity of the O (2,3)- $B_{1g}$  and O (4)-*Ag* modes, respectively.

According to the Raman tensor elements reported in the literature  $[50]$ ,  $f_R$  can also be expressed by the following equation from a simple transformation of equation (5):

$$
r = \frac{f_R\left(x_{B_{1g}}^2 + y_{B_{1g}}^2\right) + (1 - f_R)(x_{B_{1g}}^2 + z_{B_{1g}}^2)}{f_R\left(x_{A_g}^2 + y_{A_g}^2\right) + (1 - f_R)(x_{A_g}^2 + z_{A_g}^2)}
$$
(6)

where the Raman tensor elements  $x_{A_g}^2 = y_{A_g}^2 = 2$ ,  $x_{B_{1g}}^2 = y_{B_{1g}}^2 = 8.5$ ,  $z_{A_g}^2 = 100$ , and  $z_{B_{1g}}^2 \approx 0$ . Therefore, equation (6) can be simplified and rearranged to:

$$
f_R = \frac{r\left(z_{A_s}^2 + x_{A_s}^2\right) - x_{B_{1g}}^2}{r\left(z_{A_s}^2 - x_{A_s}^2\right) + x_{B_{1g}}^2} = \frac{102 \cdot r - 8.5}{98 \cdot r + 8.5}
$$
(7)

Calculations based on the Raman spectra, Fig. 6b, give  $f_R$  values of *f*<sub>*R*− *single* = 0.82 and *f*<sub>*R*− *stacked* = 0.93 for the Y-Ba-Cu-O single-layer and the</sub></sub>

<span id="page-5-0"></span>

# Y-Ba-Cu-O single-layer Y-O/Ba-Cu-O stacked-layer

**Fig. 7.** TOF-SIMS 2D elemental images representing the distribution of Y and Ba signals. Top views of (a) Y-Ba-Cu-O single-layer film and (b) Y-O/Ba-Cu-O stackedlayer film, side views of (c) and (e) Y-Ba-Cu-O single-layer film, side views of (d) and (f) Y-O/Ba-Cu-O stacked-layer film. The region of interest is restricted to the black rectangular box.

Y-O/Ba-Cu-O stacked-layer film, respectively. From both the XRD and Raman spectra results, it is concluded that the Y-O/Ba-Cu-O stackedlayer structure of the precursor film can effectively increase *D* of yttrium in the Ba-Cu-O liquid phase, therefore suppressing random orientations, which is beneficial for the growth of *c*-axis orientated YBCO.

# *3.3. Elemental diffusion behaviors and crystallization*

In order to understand the elemental distribution along the film thickness direction during the reaction–diffusion process, we analyzed

films sintered from a Y-Ba-Cu-O single-layer and a Y-O/Ba-Cu-O stackedlayer by TOF-SIMS, as shown in Figs. 7 and 8. Both films were obtained by quenching at 780 ◦C. It can be clearly seen that yttrium is enriched on the surface layer, while barium is rather uniformly distributed, which agrees with our previous results of YBCO studied by TEM and SIMS. In the Y-O/Ba-Cu-O stacked-layer film, the concentration of yttrium (Fig. 7d and [Fig. 8](#page-6-0)b) decreases gradually from the film surface to the reaction site at the interface, indicating that the Ba-Cu-O precursor indeed increases *D* and thus reduces *δ* of the reaction. Besides, barium is mainly concentrated near the interface (Fig. 7f and [Fig. 8b](#page-6-0)), which is consistent with our precursor structure. Therefore, TOF-SIMS results

<span id="page-6-0"></span>

The data were acquired from the region of interest marked in [Fig. 7](#page-5-0) (central  $5 \times 5 \mu m^2$ ).

**Fig. 9.** (a) TEM image of a film sintered from a Y-O/Ba-Cu-O stacked-layer, (b) EDS line scans along the thickness direction for Y, Ba, Cu, and Ce, where dashed-line boxes represent the growth front.

again confirm the increase of *D* in Y-O/Ba-Cu-O stacked-layer films.

To further understand the interfacial nucleation behavior of the Y-O/ Ba-Cu-O stacked-layer film, TEM and EDS analyses were carried out, Fig. 9. A small and well crystallized YBCO grain is visible at the interface, which has an epitaxial relationship to the  $CeO<sub>2</sub>$  buffer layer underneath. A few tens of nanometers above the YBCO crystal nucleus, a large number of spherical particles are detected, which tend to increase in size, the closer they appear to the YBCO growth front. These particles have average diameters of  $\sim$  5 nm and can be identified as  $Y_2O_3$ , Fig. 9a inset. The EDS results along the film thickness direction, Fig. 9b, show that a Y-rich region is present just above the YBCO growth front. These results suggest that  $Y_2O_3$  particles dissolve in the Ba-Cu-O liquid phase and preferentially form YBCO nuclei at the interface, which is consistent with our previous results.

# **4. Conclusion**

We systematically studied the effect of supersaturation on the orientation in FF-MOD derived *RE*BCO films. According to the *RE*2O3- Ba-Cu-O phase diagram, different rare earth elements, sintering temperatures as well as concentrations of *RE*2O3 were adjusted to modulate supersaturation. The results reveal that low supersaturation is favorable to grow *c*-axis oriented *RE*BCO films by the FF-MOD method. Moreover, a stacked-layer architecture of Y-O/Ba-Cu-O was designed to modulate the diffusion distance to the reaction site *D* of yttrium through the Ba-Cu-O liquid phase to the reaction site at the interface. Cross-sectional

TEM analysis shows that the diffusion of yttrium indeed could pass through the Y-O/Ba-Cu-O stacked-layer. Combined XRD and Raman spectroscopy analyses suggest that large *D* values of yttrium allow to significantly reduce supersaturation, therefore, enhancing the *c*-axis orientation growth. This work sheds light on the reaction mechanism of YBCO derived from the FF-MOD route, and demonstrates the influence of supersaturation control on the growth of films with preferential orientations.

#### **Declaration of Competing Interest**

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

# **Data availability**

No data was used for the research described in the article.

#### **Acknowledgments**
