Kurzzusammenfassung

Nach Angaben der Internationalen Agentur für Krebsforschung, einer Einrichtung der Weltgesundheitsorganisation, wurden im Jahr 2020 schätzungsweise 19,3 Millionen Menschen Krebs diagnostiziert, von denen 9,96 Millionen den Kampf gegen diese Krankheit verlieren werden. Krebstherapien werden häufig durch schwere Nebenwirkungen beeinträchtigt, die die anwendbare Dosis einschränken und die Lebensqualität der Patienten stark einschränken können. Die Entwicklung neuer, effizienter Therapeutika, die selektiv wirken und weniger Nebenwirkungen haben, ist daher von großer Bedeutung. Die Photopharmakologie stellt ein vielversprechendes Forschungsgebiet dar, um diesen Anforderungen gerecht zu werden, indem neue Medikamente entwickelt werden, die lokal und bioorthogonal mit Licht aktiviert werden können.

In dieser Arbeit stelle ich die Identifizierung und Charakterisierung von 3-Aryliden-2,5-diketopiperazinen (Hemipiperazine, HPIs) als eine neue Klasse von molekularen Photoschaltern vor. Ein HPI ist in Plinabulin enthalten, einem zytotoxischen Wirkstoff, der auf Mikrotubuli abzielt und sich derzeit in einer Phase-III-Studie zur Krebsbehandlung befindet. Es wurde entdeckt, dass die Bioaktivität von Plinabulin mit sichtbarem Licht moduliert werden kann, was eine biorthogonale Aktivierung dieses Medikaments mit räumlicher und zeitlicher Präzision ermöglichen kann. Außerdem wurden Derivate mit verbesserten photophysikalischen und pharmakologischen Eigenschaften identifiziert.

Das photochrome Kernfragment von Plinabulin enthält ein zyklisches Dipeptid (2,5-Diketopiperazin, DKP), welches selbst ein wichtiges Pharmakophor darstellt und auch in zahlreichen biokompatiblen intelligenten Materialien zu finden ist. Der Photochromismus von HPIs und der Einfluss von elektronenziehenden und -schiebenden Gruppen auf die photophysikalischen Eigenschaften wurde systematisch untersucht.

Darüber hinaus wurde gezeigt, dass HPI-Photoschalter in andere molekulare Gerüste eingebaut werden können und eine reversible Photomodulation der Fluoreszenzintensität ermöglichen. Es wurde festgestellt, dass fluoreszierende Derivate von Zellen aufgenommen und mittels konfokaler Mikroskopie innerhalb dieser Zellen sichtbar gemacht werden können. Diese Ergebnisse könnten die Grundlage für die Entwicklung neuartiger photoschaltbarer Fluoreszenzmarker bilden.

Abstract

According to the International Agency for Research of Cancer, an institution of the World Health Organization, in 2020 an estimate of 19.3 million humans were diagnosed with cancer, of which 9.96 million will lose the fight against this disease. Cancer therapy is often impaired by severe side effects that limit the applicable dose and can enormously diminish the patients' quality of life. The development of new, efficient therapeutics that act selectively and have fewer side effects is therefore of pronounced relevance. Photopharmacology represents a promising area of research for addressing these needs, by developing new drugs that can be activated locally and bioorthogonally with light.

In this thesis, I present the identification and characterization of 3-arylidene-2,5-diketopiperazines (Hemipiperazines, HPIs) as a novel class of molecular photoswitches. An HPI is found in plinabulin, a microtubule targeting cytotoxic agent currently in the 3rd phase of clinical trials for cancer treatment. It was discovered that the bioactivity of plinabulin can be modulated with visible light, which can enable biorthogonal activation of this drug with spatial and temporal precision. Furthermore, derivatives with improved photophysical and pharmacological properties have been identified.

The core photochromic fragment of plinabulin contains a cyclic dipeptide core (2,5-diketopiperazine, DKP), which itself is an important pharmacophore and also found in numerous biocompatible smart materials. The photochromism of HPIs and influence of electron-withdrawing and -donating groups on the photophysical properties was investigated systematically.

It was additionally demonstrated that HPI photoswitches can be incorporated into other molecular scaffolds and enable reversible photomodulation of fluorescence intensity. Fluorescent derivatives were found to be taken up by cells and were visualized within these cells *via* confocal microscopy. These results might form the basis for the development of novel photoswitchable fluorescent labels.

1 Introduction

1.1 Photopharmacology

To enable the study or even the control of biochemical processes, it is of great interest to develop tools and protocols that allow precise manipulation of bioactivity in a biorthogonal and non-invasive manner. Given the complexity of biological systems, it is not possible to selectively target individual processes or species by altering parameters like temperature or pH without significantly affecting or even harming the surrounding species in cells or tissue. Photopharmacology, however, can overcome these barriers and allow external control of bioactivity with light.¹ Light as a trigger of drug activity does not lead to contamination, is not influenced by diffusion, can be applied reversibly, and can be varied by using different wavelengths. Additionally, it offers the unique advantage that it can be tuned in three dimensions: its location, timing and its intensity.² These properties even enable studies on systems that are not accessible to alternative methods like for example genetic manipulation.³⁻⁷

To enable light-mediated regulation of pharmacokinetic and pharmacodynamic properties, light-triggered molecular scaffolds are being introduced into biologically active compounds. Three approaches to light-dependent pharmacology have been investigated: photodynamic therapy (PDT), photouncaging and photopharmacology (Figure 1). Photosensitizers developed for PDT generate highly cytotoxic reactive oxygen species upon irradiation.⁸ The disadvantage of this method is the lack of specificity in the activity due to general toxicity. This is not the case with photouncaging, where photolabile protecting groups are introduced, yielding biologically inactive compounds. These prodrugs are then activated through light-induced cleavage of a covalent bond.⁹ A drawback of this method is its irreversibility, which allows for diffusion of bioactive compounds into non-targeted tissues and can also lead to excretion of bioactive substances, causing the emergence of resistances.¹⁰ Additional disadvantages include the formation of potentially harmful byproducts as well as uncontrolled enzymatic hydrolysis of the photolabile bond. Another concept of photopharmacology is based on the implementation of molecular photoswitches by covalent attachment to or direct incorporation into a pharmacophore. The photoswitchable motif allows for reversible changes in shape and/or polarity, which can enable the design of a pharmaceutical with significantly different biological activities in the light-dependent structural states. Ideally, one photoisomer does not interfere with the drug's functionality, whereas switching to the corresponding isomer allows deactivation of the compound to reduce systemic side effects while maintaining specificity.¹⁰

Especially in the past decade, interdisciplinary research including the fields of chemistry, medicine, pharmacy, and molecular biology facilitated the rapid evolution of photopharmacology towards clinical applications.¹ The efficacy at the cellular level has already been reported for possible applications including the treatment of pain¹¹⁻¹⁴, microbial infections^{15,16}, diabetes¹⁷⁻²¹, and cancer^{6,7,22-30}. In some cases, the applicability has been demonstrated in live animals.³¹

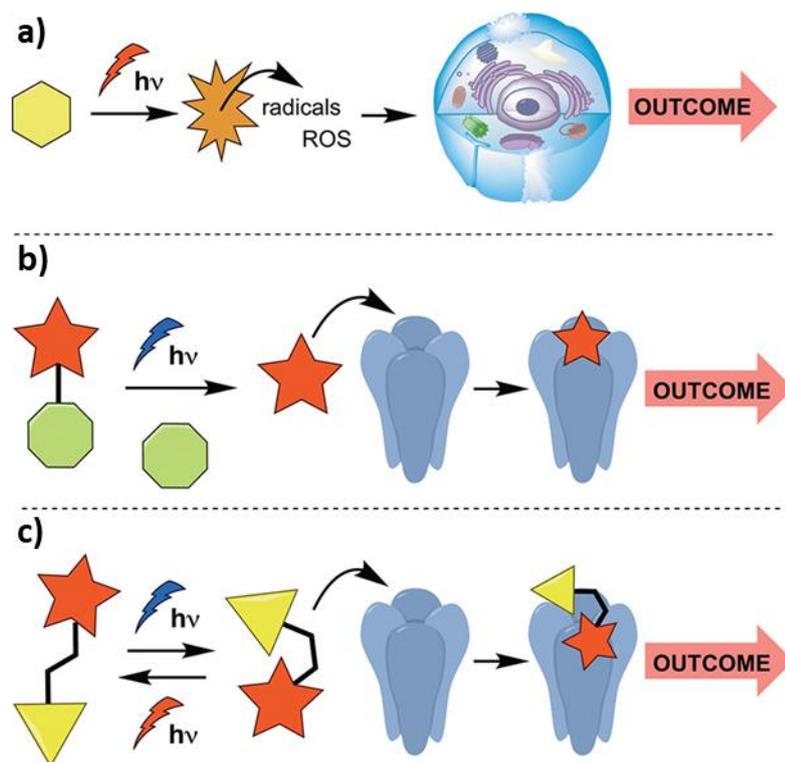

Figure 1: Principles of different approaches for light-dependent pharmacology: a) photodynamic therapy (ROS = reactive oxygen species), b) photouncaging, c) photopharmacology. Reprinted with permission from ³². Copyright 2020 American Chemical Society.

However, further developments are necessary to address all the limitations of the currently known examples. One problem is the commonly observed decrease in overall bioactivity due to a significant change in the pharmacokinetic and pharmacodynamic properties upon introduction of the molecular photoswitch.^{2,10} Additional properties like the polarity, solubility and metabolic stability may be altered and have to be evaluated and optimized for both photoisomers.¹⁰

To address these issues, the optimal position of the photoswitchable motif within the drug has to be identified in structure-activity relationship studies. As there are various molecular photoswitches with different photophysical properties available, it is also vital to choose one with characteristics that suit the intended application best.

1.2 Molecular Photoswitches

1.2.1 Characteristics of Molecular Photoswitches in the Context of Photopharmacology

Molecular photoswitches are molecules which can reversibly interconvert between two or more photoisomers upon irradiation with light. The photoisomers differ in their geometry and photophysical properties and, in some cases, also in their polarity.³³ In most cases, the photoconversion proceeds as *E/Z*-isomerization, which usually causes distinct structural modifications,³⁴ or as pericyclic reaction, which often leads to significant changes in electronic properties and/or polarity.³⁵ A distinction is made between T- and P-type photoswitches based on the relaxation process following photoexcitation, which can occur thermally (T) or photochemically (P). Additional classification concerns the observed change in color triggered by irradiation. Positive photochromism describes an increased intensity of color and negative photochromism the reversible color fading upon light irradiation.³⁶

When aiming at photomodulation of bioactivity, it is crucial to develop a system that responds to light irradiation with high efficiency. Hence, a distinct difference in potency between the irradiated and non-irradiated forms is fundamental. And for efficient photoactivation, irradiation must result in accumulation of the bioactive species. To achieve this, it has to be ensured that the thermal stability of the more active species is on a timescale that allows to elicit the biological effect. Additionally, a sufficient photoswitching quantum yield is required to harness the limited amount of light reaching the targeted tissue effectively.^{32,37}

Introducing a molecular photoswitch does not only influence the potency of a drug, but also its pharmacodynamic properties. Azobenzenes belong to the best studied molecular photoswitches and widely applied in photopharmacology. However, a serious drawback of azobenzene-based photoswitches is the metabolic instability of several derivatives. Especially electron-rich azobenzenes were found to be degraded by glutathione-catalyzed reduction of the N=N double bond in the cellular environment. This increases the required concentrations and – more importantly – yields mutagenic and cancerogenic arylhydrazines.³⁸

When developing molecular photoswitches for pharmacological applications or medicinal research, one has to consider the wavelengths required for photoisomerization. Although highly energetic UV-light (365 nm) is very often applied, it is not well suited in a biological context due to its potential phototoxicity and inefficient penetration of soft tissues due to absorption by biomolecules and optical scattering in cells or tissues.^{39,40} Since shortwave visible light normally only penetrates a few millimeters into tissue, an excitation in the range of 650 – 900 nm - the so-

called ‘therapeutic window’ - with the highest penetration depth of soft human tissues is aspired in photopharmacology.^{1,2}

1.2.2 Visible Light-triggered Photoswitches

The scientific community working on organic photoswitches successfully developed a variety of different photoswitchable compounds reversibly photoisomerizable with visible light.

The aforementioned azobenzenes reversibly undergo *E*-to-*Z*-isomerization at the N=N double bond. Because UV-light is required for an efficient isomerization of unsubstituted azobenzenes, several structural modifications have been investigated to tune their photophysical properties. Numerous derivatives that allow for selective *E*-to-*Z*- and *Z*-to-*E*-photoisomerization within the visible range of the electromagnetic spectrum with high or, in some cases, even complete photoconversion have been identified. Selected examples are presented in Figure 2.⁴¹⁻⁴⁵

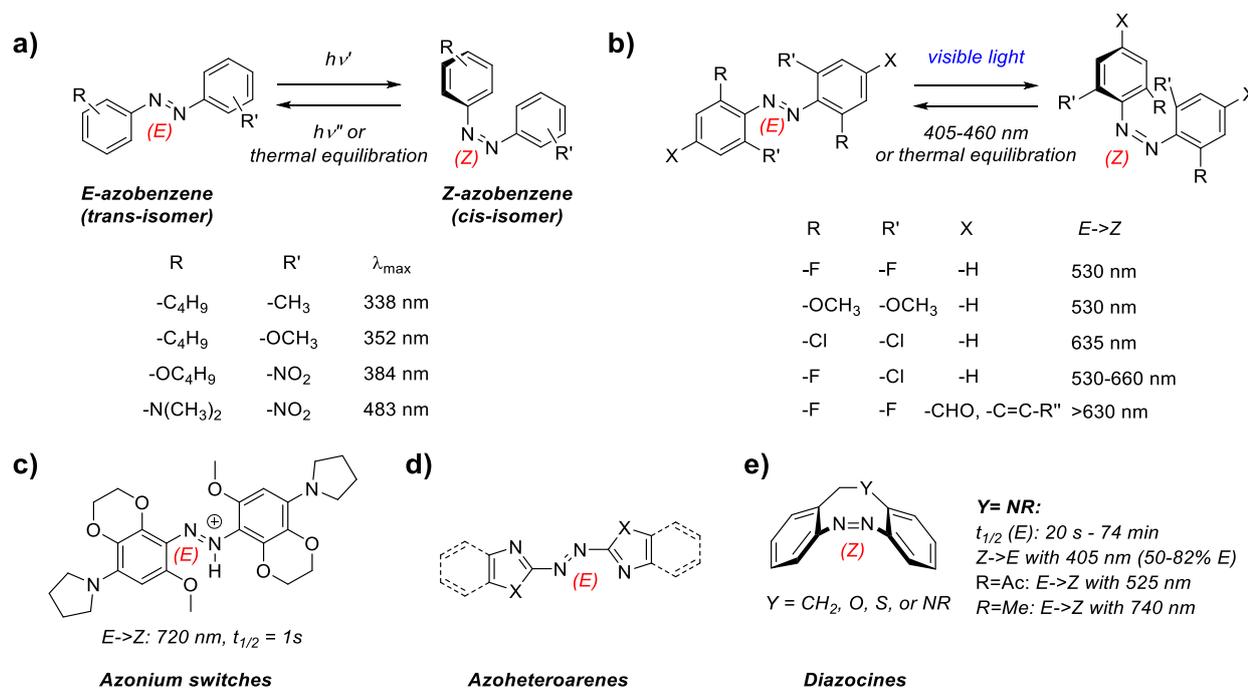

Figure 2: Structural modifications of azobenzenes that enable reversible photoisomerization with visible light. a) Push-pull azobenzenes and the corresponding absorption maxima (λ_{\max}) determined in chloroform^{46,47}, b) *ortho*-substituted azobenzenes and the wavelengths required for *E*-to-*Z* switching^{42-44,48,49}, c) azonium switches⁵⁰, d) azoheteroarenes⁵¹, e) diazocines^{52,53}. In c)-e) the thermodynamically stable forms are depicted. Reproduced from reference⁴⁵.

Various examples of visible light-responsive photoswitches undergoing *E*/*Z*-photoisomerization are derived from the dye indigo (Figure 3). Intramolecular hydrogen bonding stabilizes the *E*-isomer of indigo and prevents photoisomerization.^{54,55} Consequently, indigoid photoswitches were designed by introducing alkyl or aryl substituents that prevent hydrogen bond formation on the nitrogen atoms of indigo.⁵⁶ Other classes of indigoid photoswitches are obtained by combining

stilbene with indigo (hemiindigo)^{55,57} or thioindigo (hemithioindigo)⁵⁸⁻⁶¹. Optimization of the photophysical properties is feasible by installing electron-donating substituents (Figure 3b).^{45,60}

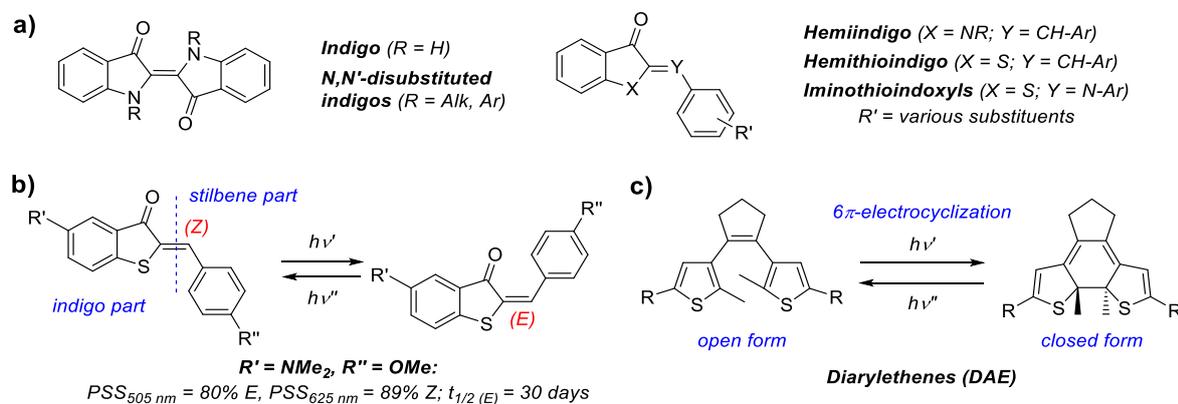

Figure 3: Indigoid and diarylethene photoswitches. a) Structural modifications of indigo yielding photochromic indigoids, b) By installing electron-donating substituents at both *para*-positions, visible-light responsive hemithioindigos with an increased lifetime of the respective *E*-isomer were obtained.⁶¹ Reproduced from reference ⁴⁵.

Diarylethenes are an established example for bistable molecular photoswitches undergoing reversible electrocyclization, which leads to considerable differences in the polarity of the respective photoisomers. Since photoisomerization of unsubstituted diarylethene requires UV-light, a variety of approaches, including extension of the conjugated π -system, have been investigated to shift the absorption spectrum bathochromically.⁶²⁻⁶⁶

Besides these more common examples, several other scaffolds, including spiropyrans⁶⁷, dihydropyrenes⁶⁸, norbornadienes⁶⁹⁻⁷¹ and donor-acceptor Stenhouse adducts⁷²⁻⁷⁴, have been found to undergo visible light induced photoisomerization.

1.3 Photoswitchable Antimitotic Agents

One of the most pursued applications for photopharmacology is cancer therapy, which is often impaired by severe side effects that limit the applicable dose and can enormously diminish the patients' quality of life.⁷⁵ This is frequently observed with pharmaceuticals that target microtubule dynamics, including clinically approved drugs such as vinca alkaloids, taxanes, and epothilone, which belong to the most important drug classes for cancer treatment.^{76,77}

1.3.1 Microtubules: Structure and Dynamics

Microtubules are a major component of the eukaryotic cytoskeleton and involved in essential biological processes including intracellular transport, motility, and cell proliferation. These noncovalent polymers are composed of α/β -tubulin heterodimers that first arrange head-to-tail to form long strands called protofilaments (Figure 4). Typically, 13 protofilaments assemble into

tube-like structures with a diameter of ~ 25 nm by lateral association.⁷⁸⁻⁸¹ The cellular microtubule network undergoes constant remodeling, required to fulfill the spatiotemporally-distinct functions of microtubules and is described as ‘dynamic instability’.⁸² The equilibrium between phases of dissociation (‘catastrophe’) and polymerization (‘rescue’) is guanosine triphosphate (GTP)-dependent and regulated by microtubule-associated proteins (MAPs).^{77,83-85}

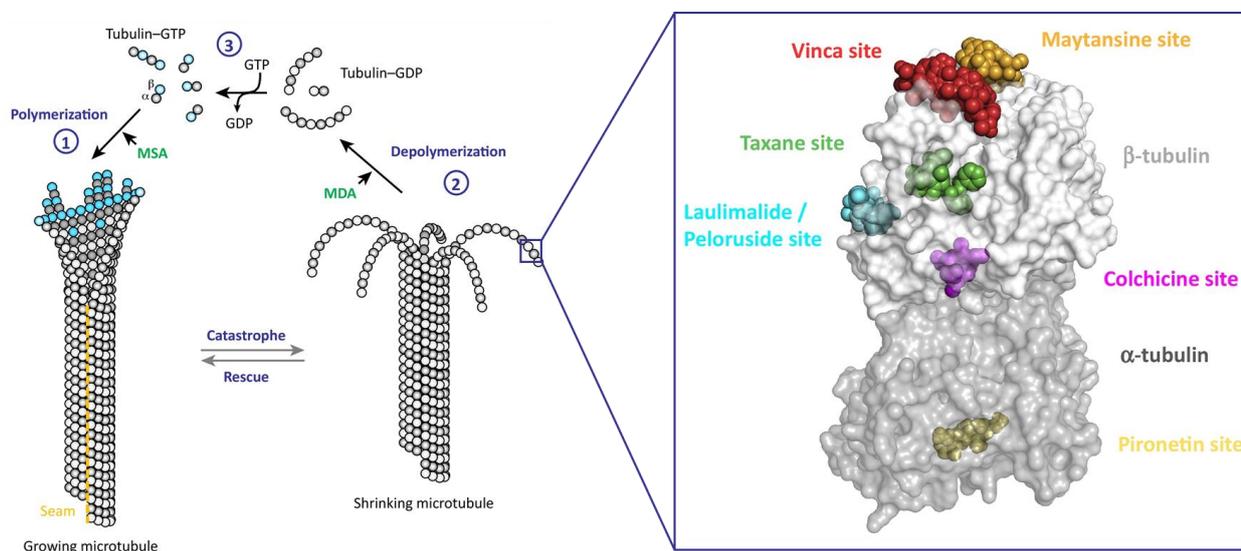

Figure 4: ‘Dynamic instability’ describes the GTP-dependent equilibrium of assembly and disassembly of α/β -tubulin heterodimers. Microtubule targeting agents either stabilize (microtubule stabilizing agents, MSAs) or destabilize microtubule polymers (microtubule destabilizing agents, MDAs). The identified binding sites have been named after the most prominent agents of classes of agents binding at this region. They are highlighted and assigned *via* color code. GTP = guanosine triphosphate, GDP = guanosine diphosphate. Adapted with permission from the reference ⁷⁷. Copyrights (2018) Elsevier.

1.3.2 Targeting the Microtubule Cytoskeleton

Microtubule-targeting agents interfere with the ‘dynamic instability’ of microtubules by promoting either microtubule polymerization (microtubule stabilizing agents, MSAs) or dissociation (microtubule destabilizing agents, MDAs) (Figure 4). Both classes of agents can severely impair cell viability by suppressing microtubule dynamics, which characteristically results in cell cycle arrest in the G₂/M phase.^{76,77,86,87} Six distinct ligand binding sites have been characterized by structural biology and assigned to the respective most prominent compound class that binds to this region, as presented in Figure 4.⁷⁷

Due to their antiproliferative effect, these agents are promising candidates for cancer therapy. However, from several hundred compounds found to be capable of inducing mitotic arrest, only a few have been clinically approved. The suitability of these compounds as pharmaceuticals is diminished by their nonspecific mode of action. They affect vital processes in all cells and can cause systemic side effects and leads to a low therapeutic index of the drugs. Consequently, therapy

suffers a compromise with limited applicable doses reducing the desired effect and severe adverse effects including myelosuppression and neutropenia that have to be endured.⁷⁶

Spatiotemporal control of the activity of these compounds could reduce side effects and allow for higher concentration in the targeted tissue. This goal is being pursued by developing photoswitchable analogues of these agents.

1.3.3 Photoswitchable Microtubule-Targeting Agents

A variety of photoswitchable microtubule-targeting agents based on different molecular photoswitches have been demonstrated as analogues of the naturally occurring alkaloid and microtubule-destabilizing agent colchicine (Figure 5 a).

Combretastatin A-4 (CA4) is a naturally occurring stilbene that acts as a microtubule-destabilizing agent. Whereas the thermodynamically less stable *Z*-isomer is structurally similar to colchicine, can bind efficiently to the colchicine binding site in tubulin, and is a very potent microtubule inhibitor, the corresponding *E*-isomer is 60-fold less potent.^{88,89} Although *E*-to-*Z*-isomerization of this compound is possible, the intrinsic characteristics of stilbenes prevent successful applications. Photoactivation of this compound requires UV-light and is not entirely reversible due to photochemical electrocyclization.⁹⁰

To enable reversible photoisomerization, a photopharmacological azologue of CA4 was designed by replacing the carbon atoms of the C=C double bond with nitrogen atoms, as independently reported by three groups (photostatin-1, PST-1, Figure 5).^{7,22,23} The biologically less active but thermodynamically more stable *E*-isomer can be efficiently and reversibly transformed into the colchicine-like *Z*-isomer with light in the range of 380-410 nm. A significantly increased potency against various cell lines and light-triggered G₂/M arrest were demonstrated. In addition, light-induced mitotic arrest in metaphase was shown *in vivo* with *C. elegans* embryos and it was found to be possible to target only selected single cells and reverse this process by green light-triggered *Z*-to-*E*-isomerization.⁷ However, PST-1 was found to be unstable under reducing conditions and it was further observed that the more active *Z*-isomer is degraded considerably faster by cellular glutathione. As mentioned in chapter 1.2.1, this is a commonly observed phenomenon with azobenzene photoswitches and severely limits their applicability in biological environments.

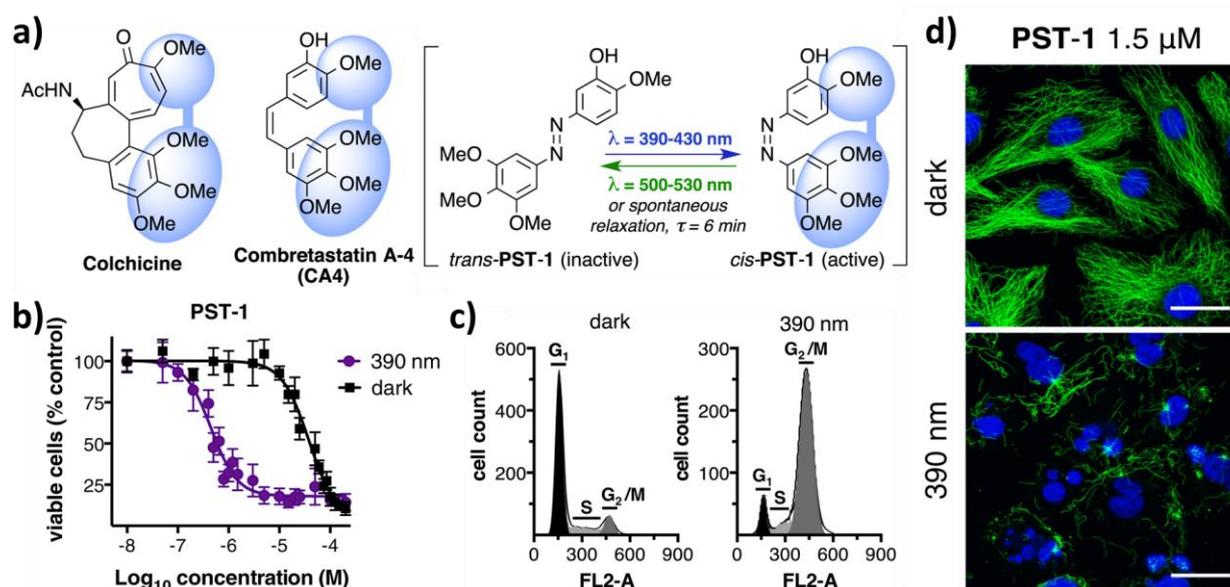

Figure 5: a) Photostatin-1 (PST-1) is a photoswitchable azobenzene derivative of combretastatin A-4 (CA4), b) Viability assays demonstrate the light-tunable potency of PST-1, c) Light-dependent cell-cycle analysis illustrates that irradiated PST-1 leads to G_2/M arrest, a characteristic observation for microtubule-targeting agents, d) PST-1 selectively causes disassembly of microtubules and nuclear fragmentation upon irradiation with 390 nm. Treatment with the same concentration but in the dark does not affect microtubule structure. (MDA-MB-231 cells; α -tubulin (green), DNA (blue); scale bars, 20 μ m). Adapted with permission from reference ⁷. Copyright 2015 Elsevier Inc.

The limitations of azobenzene photoswitches motivated scientists to expand the variety of photoswitchable colchicine-inspired designs, including alternative molecular photoswitches such as spiropyran⁹¹, benzodiazole *N*-substituted pyrrole⁹², hemithioindigos^{6,25}, pyrrole hemithioindigos²⁸ and heterostilbenes^{29,93}.

Photoswitchable pyrrole hemithioindigos reported by Sailer *et al.* (e.g. PHTub-7, Figure 6) overcome two factors that limit the photoswitchability of azobenzenes in biological assays. In contrast to the previously reported azobenzenes, these photoswitches can be photoisomerized nearly quantitatively in both directions within the biologically compatible light spectrum. Moreover, high photostationary states (PSSs) can be reached by applying fixed-wavelength lasers available in confocal microscopes.²⁸ Complementary to this, another series of photoswitchable microtubule-destabilizing agents based on the heterostilbene styrylbenzothiazole was developed, specifically designed to be orthogonal to common light frequencies applied for imaging with confocal microscopes. These compounds can be employed for photocontrol of microtubules in biological assays in combination with multichannel imaging. Fluorescence imaging of for example green fluorescent protein (GFP) labelled species is possible without affecting these photopharmacological agents. Further favorable characteristics of these compounds include their stability against degradation by cytoplasmic glutathione and the enhanced lifetime of the more

active species.⁹³ Two lead compounds, SBTub2M and SBTubA4 (Figure 6), with potencies in the mid-nanomolar range and 30- to 200-fold enhanced antimetabolic activity in the lit state have been identified.²⁹ Unfortunately, photomodulation of styrylbenzothiazole-based photoswitches is limited due to the low band separation between the two respective photoisomers in combination with the high thermal stability of the Z-isomers. These characteristics prevent photoactivation from being reversed thermally or by irradiation with another wavelength. However, it was found that diffusion of the photoactivated species enables recovery of microtubule dynamics after photoactivation with half-lives of ca. 20 s in 2D cell culture and ca. 10 min in organoids and *in vivo*. It was further demonstrated that reversible and spatiotemporal control of mitotic progression in zebrafish *D. rerio* is possible in repeatable cycles with the water-soluble prodrug SBTubA4P (Figure 6).²⁹

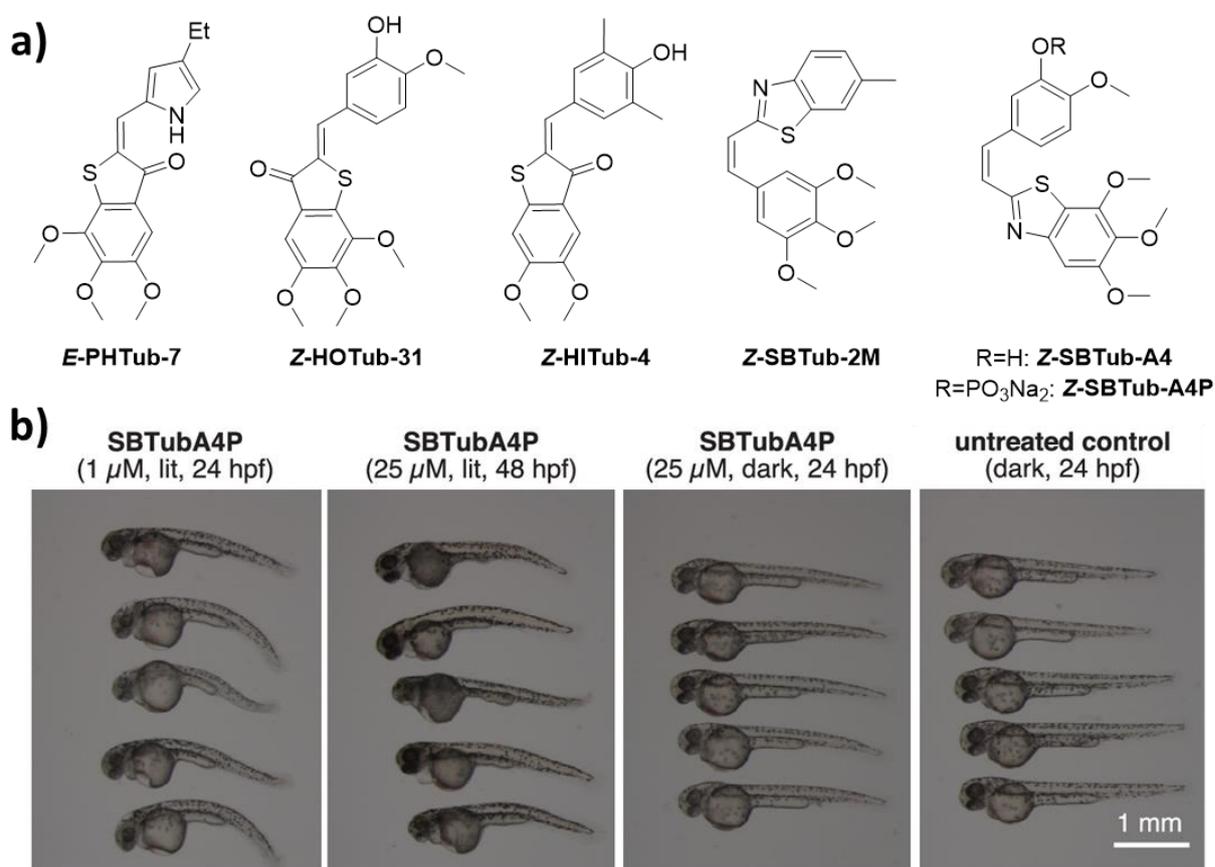

Figure 6: Examples of photoswitchable microtubule-destabilizing agents. a) Examples for active photoisomers of agents with photoswitchable antimetabolic activity, b) Heterostilbene **SBTubA4P** (1 or 25 μ M) causes morphological abnormalities in the development of *D. rerio* selectively in the lit state. hpf = hours post-fertilization. Reproduced and adapted with permission from reference ²⁹.

Further possible applications were realized by designing photoswitchable analogues of the microtubule-stabilizing agents paclitaxel and epothilone B and D, which provide access to a further

spectrum of biological effects. Compared to microtubule-destabilizing agents, they differ in their pharmacological properties and stoichiometry.²⁶

Müller-Deku *et al.* synthesized a library of 3'-azobenzamide-taxanes and identified AzTax3MP as the lead compound for which the structural alterations resulted in the smallest loss of overall potency and which was found to reach the highest dark/lit ratio of EC₅₀ values. In contrast to the previously described compounds, like for example PST-1, this compound does not inhibit but promotes tubulin polymerization with an enhanced potency in the lit state (Figure 7).²⁶

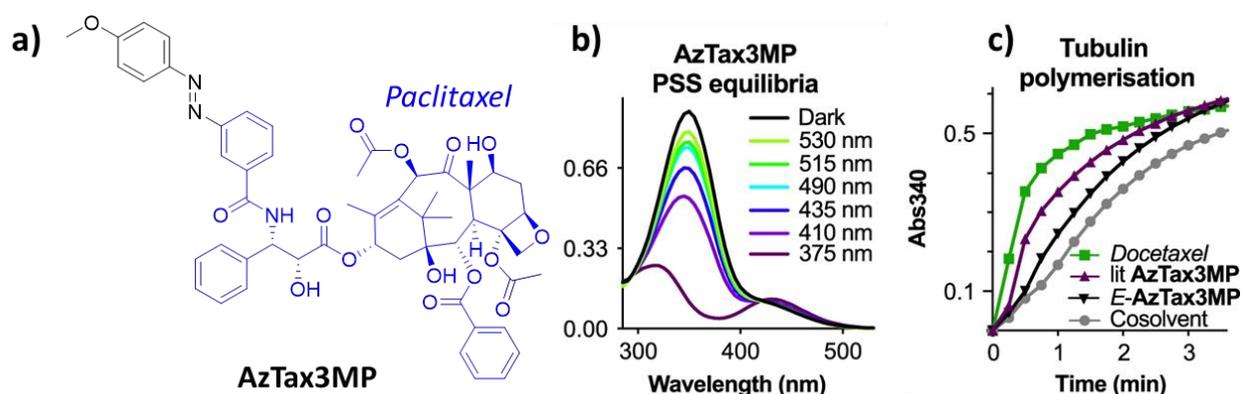

Figure 7: a) **AzTax3MP** was designed by installing a methoxy-substituted azobenzene on the microtubule stabilizing agent paclitaxel (marked in blue), b) UV-Vis absorption spectra of **AzTax3MP** in the photostationary states (PSSs) reached upon irradiation with selected wavelengths, c) Light-enhanced promotion of tubulin polymerization by **Z-AzTax3MP** was demonstrated in cell-free assays and compares to docetaxel. Panels b) and c) were reprinted under the terms of the Creative Commons CC BY license from reference ²⁶.

In another study Gao *et al.* installed a photoswitchable styrylthiazole (ST) moiety on epothilone D by either expanding the molecular scaffold or connecting the ST to the macrolactone *via* the phenyl ring (Figure 8). Interestingly, they obtained light-activated derivatives (Figure 8 a) as well as an agent that loses potency upon irradiation (Figure 8 b). Because the absorption spectra of both photoisomers do not overlap with the commonly applied laser lines 488 nm and 561 nm, it was possible to monitor the disorganized microtubule networks caused by photoactivated STEpo2 *in situ*.³⁰

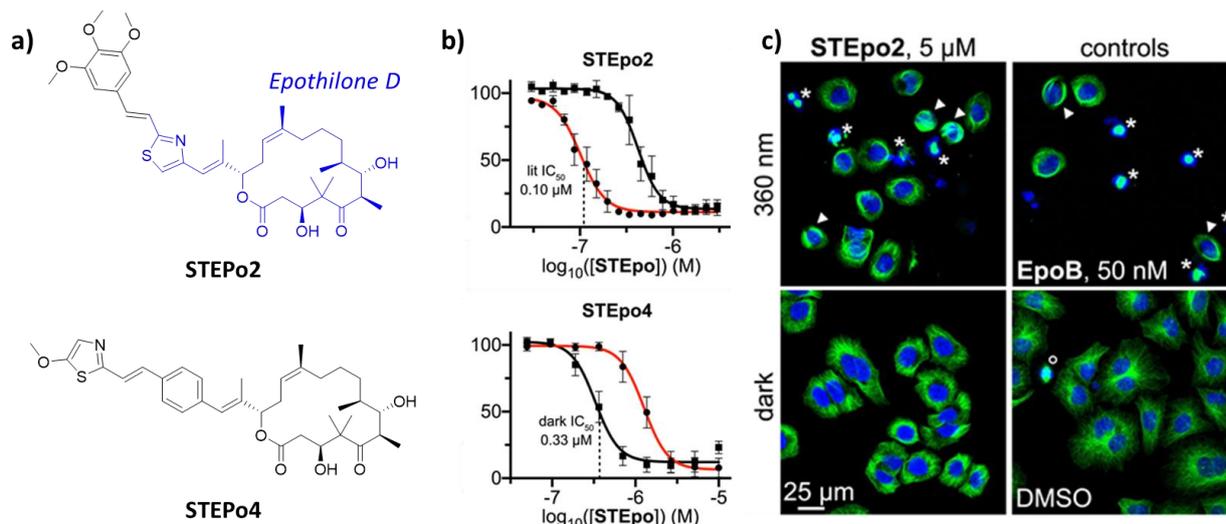

Figure 8: a) **STEp**os are photoswitchable microtubule-targeting agents derived from epothilone D (highlighted in blue) by either expanding the molecular scaffold (**STEp**o2) or inverting the introduced ST photoswitch (**STEp**o4), b) Photomodulation of the antiproliferative activity of **STEp**o2 and **STEp**o4 was investigated in cell viability assays. While **STEp**o2 is activated under lit conditions, **STEp**o4 loses potency upon irradiation, c) HeLa cells were treated with **STEp**o2 (20 hours incubation) and imaged *via* fluorescence microscopy (α -tubulin: green, DNA stained with DAPI: blue). Generation of a high population of the Z-isomer *via* 360 nm pulsing results in disorganized microtubule networks: spindle defects (asterisks) and bundled MTs (arrowheads). 1.3.4 Plinabulin

Plinabulin is a microtubule-destabilizing agent with low-nanomolar activity and it is currently being investigated in a global phase 3 clinical trial as an agent for the treatment of non-small cell lung cancer⁹⁴⁻⁹⁶ and chemotherapy-induced neutropenia.⁹⁷ It is a synthetic analogue of the natural product phenylahistin, discovered in cultures of the marine fungus *Aspergillus ustus* in 1997, which was found to induce cell cycle arrest in the G₂M phase with a significantly higher potency of the (*S*)-enantiomer.^{95,98-100} In systematic and extensive structure-activity relationship studies, plinabulin (also referred to as NPI-2358) was identified as a synthetically readily accessible derivative with optimized bioactivity.^{100,101} Plinabulin binds to the colchicine binding site of β -tubulin but differs in the nature of binding compared to colchicine and CA4. This is a possible explanation for its effect against chemotherapy-induced neutropenia, which has not been observed for the other two compounds.¹⁰²

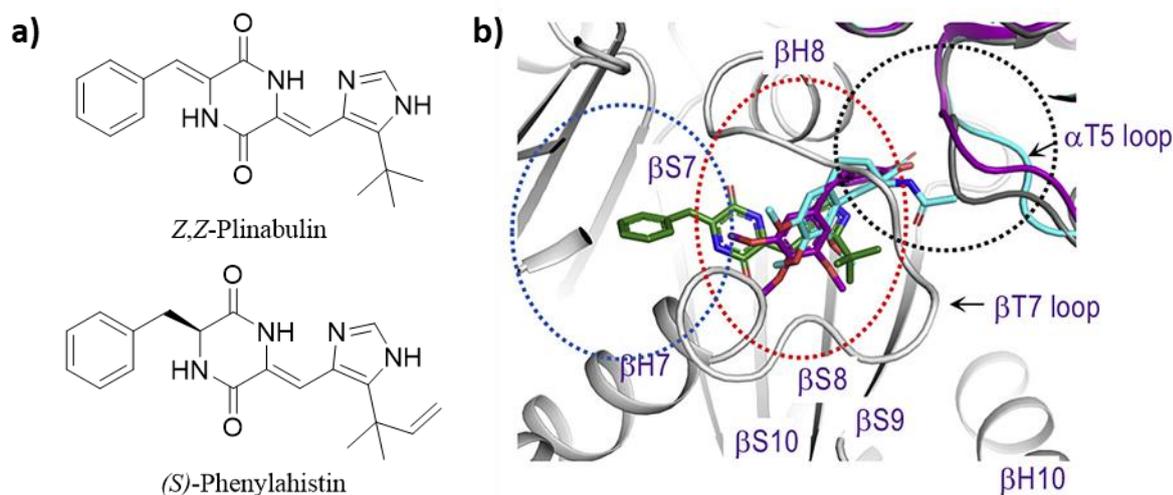

Figure 9: a) Plinabulin is a synthetic analogue of phenylahistin, which was isolated from the marine fungus *Aspergillus ustus*, b) An overlay of the X-ray crystal structure analyses revealed the different nature of binding of plinabulin (green sticks) compared to colchicine (cyan sticks) and CA4 (purple sticks). Panel b) was adapted from reference ¹⁰².

Plinabulin can be described as a cyclic dipeptide and consists of a 2,5-diketopiperazine (DKP) ring with two aryldiene substituents. The pseudo-tricyclic structure of the DKP ring and the imidazole moiety highlighted in Figure 10 are essential for its biological activity and should not be altered when designing new derivatives of plinabulin. However, the installation of functional groups on the phenyl ring is tolerated in some cases and the two derivatives depicted in Figure 10 b were found to be even more potent than plinabulin.¹⁰⁰

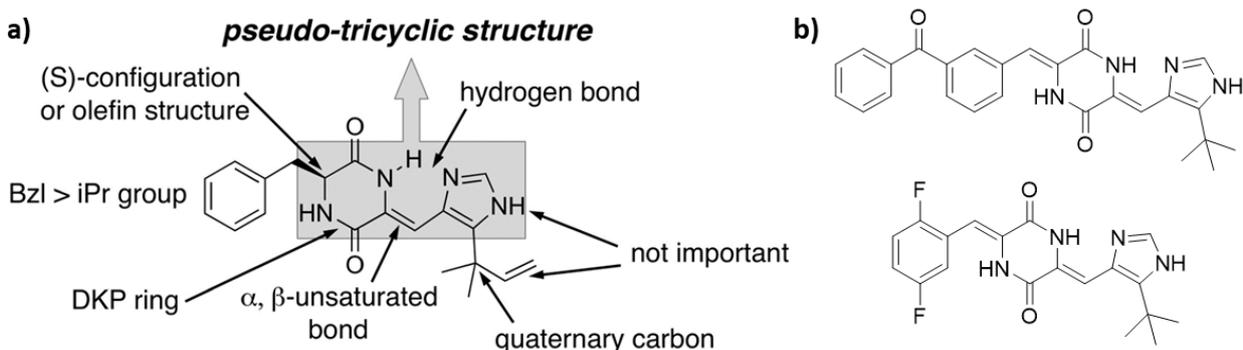

Figure 10: a) Structural features of plinabulin that are essential for its biological activity, b) Derivatives with an enhanced potency compared to plinabulin. Reproduced from. Panel a) was reprinted with permission from reference ¹⁰⁰. Copyright 2012 American Chemical Society.

Adverse effects of plinabulin include fever, tumor pain, transient hypertension, fever, fatigue, and nausea/vomiting.⁹⁶ To enable light-triggered release of this drug, plinabulin was encapsulated into DKP-based hydrogels and efficiently released upon irradiation with green light.¹⁰³ While working on this project, it was discovered that plinabulin itself can be reversibly photoisomerized with visible light.

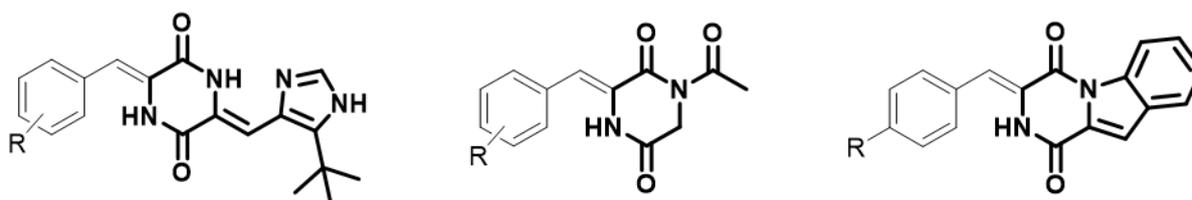

2 Objective

The newly discovered photoswitchability of plinabulin constitutes a previously unexplored characteristic of a potent agent currently in the 3rd phase of clinical trials. This sets the basis for the qualification of plinabulin as an alternative to previously described photoswitchable antimetabolic agents that suffer a dramatic loss in potency caused by the structural modifications made when introducing the respective molecular photoswitch.

This research work aims to gain an understanding on the nature of photoswitching of plinabulin and to introduce plinabulin and its derivatives as a new class of photopharmacological agents. For this purpose, first, the photoswitchable structural motif is identified by isolating and studying the respective photoisomers. To investigate possibilities for optimization of these agents, a series of derivatives is synthesized and investigated strategically with respect to their photophysical and photopharmacological properties.

The photochromism of plinabulin was never reported before. It also does not contain any established photoswitch within its structure. Therefore, the unexpected discovery in our group, that plinabulin can reversibly photoisomerize, opens up new interesting perspectives both in photopharmacology and in basic photochromism research. Consequently, the identified photoisomerizable structural motif – arylidene-2,5-dietopiperazine, abbreviated below as “hemipiperazine” or “HPI” - is studied systematically by installing electron-withdrawing and electron-donating substituents on a model compound. The photophysical properties are assessed and correlated with computational quantum mechanical modeling (applying the density-functional theory, DFT) calculations.

Finally, the new photoswitch – HPI - is introduced into another core structure to demonstrate the broader applicability and expand the scope of possible applications.

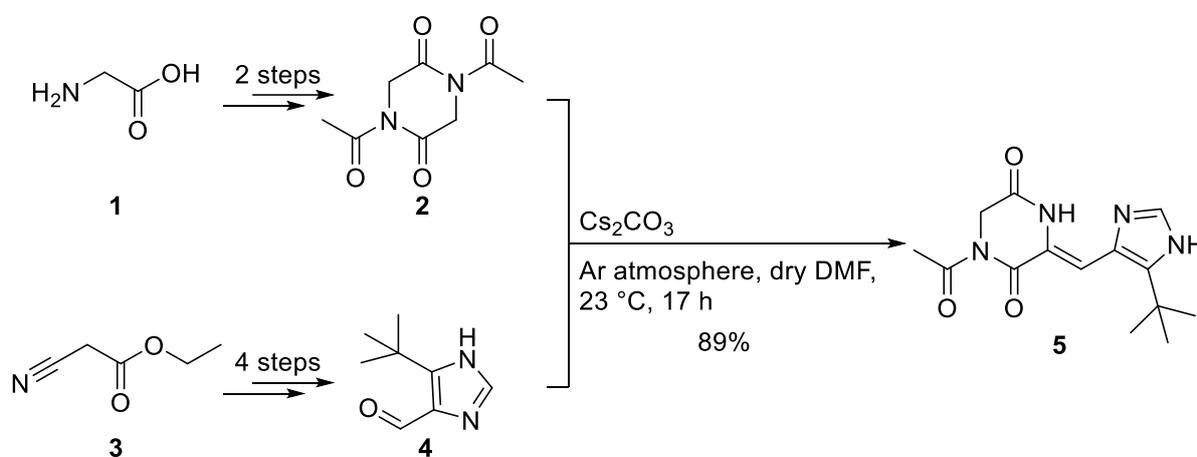

3 Results and Discussion

3.1 Plinabulin Derivatives

This work introduces plinabulin as a novel photoswitchable antimetabolic agent that comprises a previously unidentified molecular photoswitch suitable for photopharmacological applications. A library of plinabulin derivatives was synthesized in order to identify the scope of photochromism and the optimization potential of the photophysical and photopharmacological properties - for future human therapeutic applications.

3.1.1 Synthesis

The syntheses of plinabulin (**6**) and the investigated derivatives were achieved according to literature procedures in eight reaction steps, starting with the formation of the molecular building blocks *N,N'*-diacetyl-2,5-piperazinedione (**2**) and aldehyde **4** (Scheme 1). These two compounds are synthetically accessible starting from the commercially available substrates glycine (**1**) and ethyl isocyanoacetate (**3**) in two and four synthetic steps, respectively. In a subsequent condensation reaction, they are coupled, yielding arylidenepiperazinedione **5**.^{100,104-106}

Scheme 1: The synthetic intermediate diketopiperazine (DKP) **5** is accessible *via* a seven-step synthesis route, starting from the commercially available substrates glycine (**1**) and ethyl isocyanoacetate (**3**).

In the final reaction step, a series of carbocyclic aromatic and heteroaromatic aldehydes were coupled with intermediate **5** in a second condensation reaction. This aldol-type condensation is a common reaction for introducing arylidene substituents on diketopiperazines (DKPs) (Figure 11).¹⁰⁷⁻¹¹²

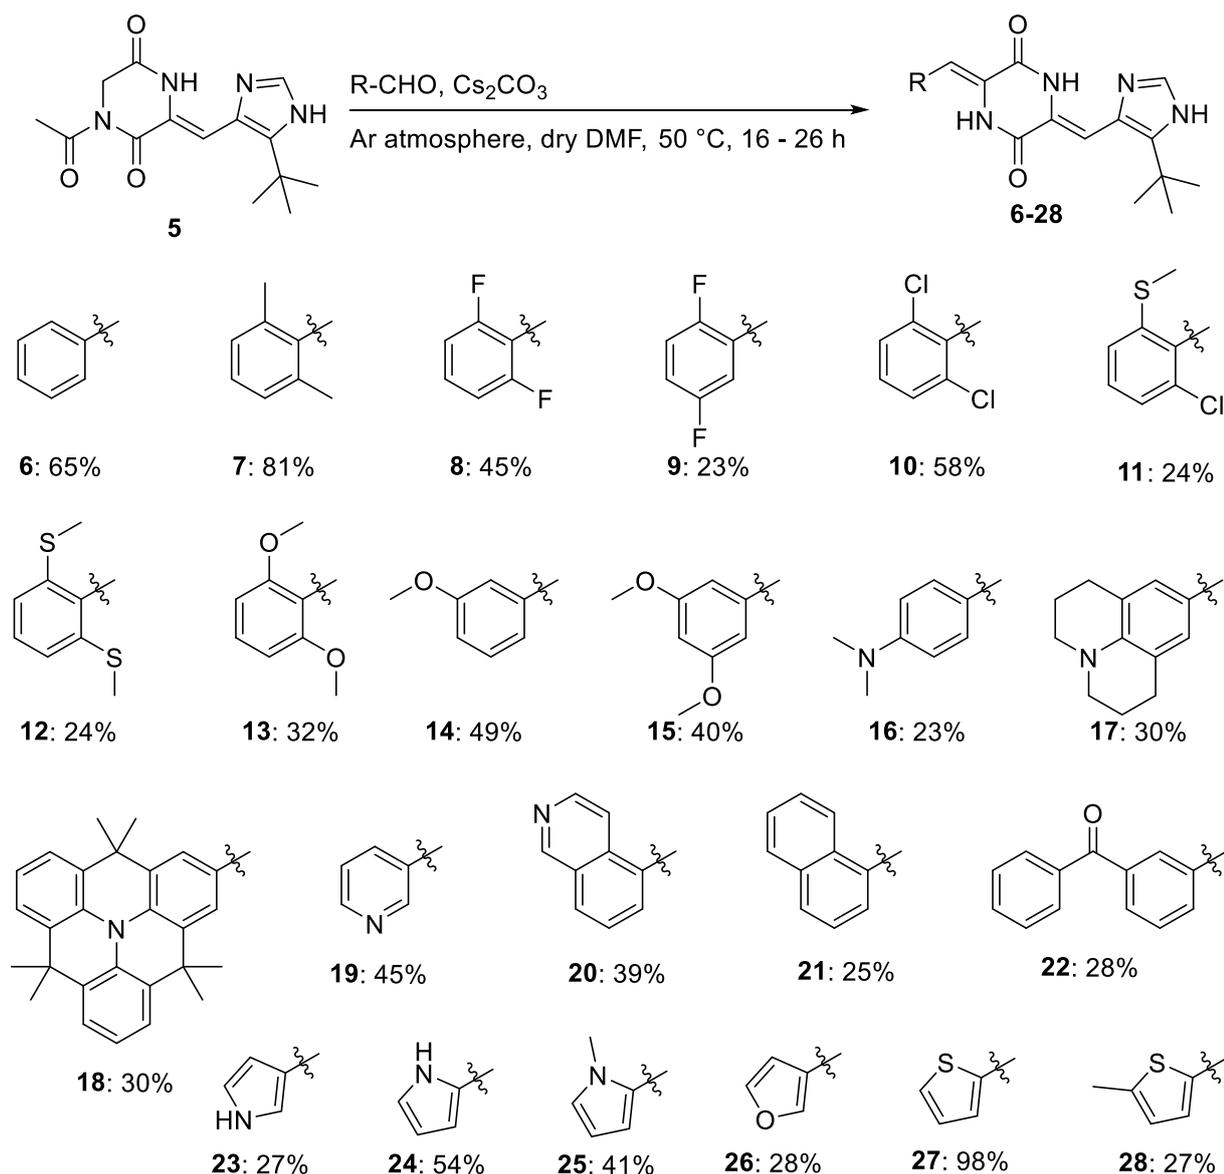

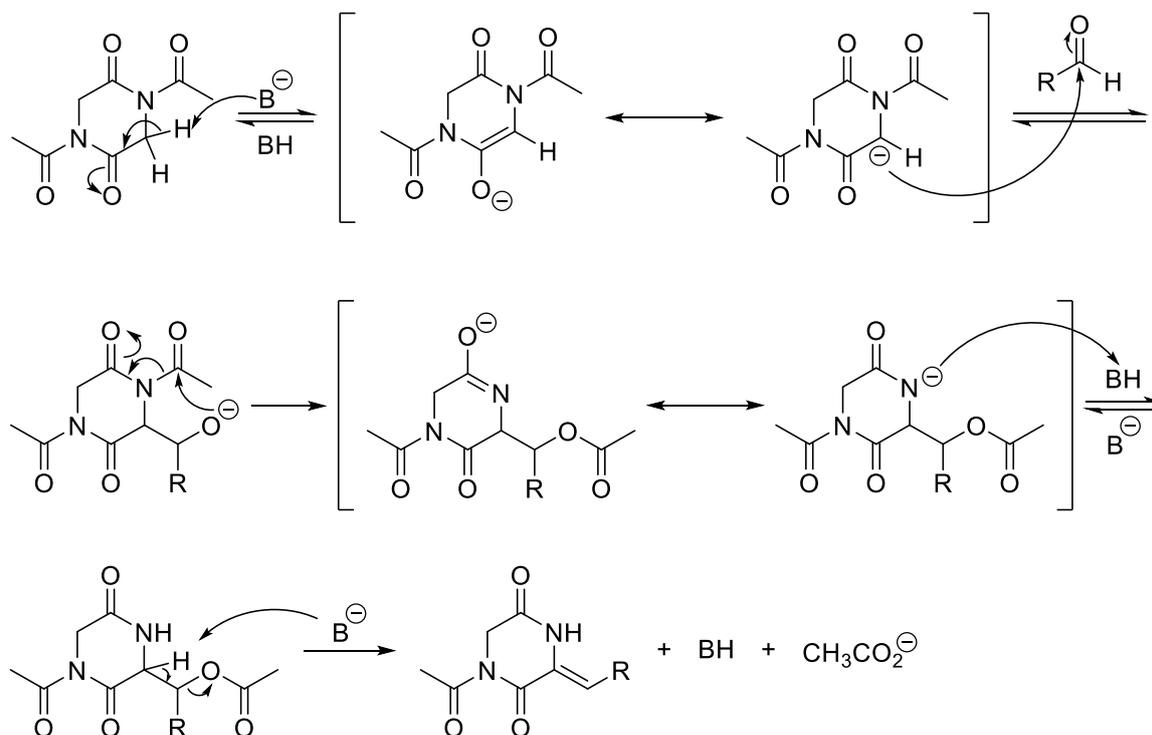

Figure 11: A library of plinabulin derivatives was synthesized by coupling carbocyclic aromatic and heteroaromatic aldehydes with intermediate **5** in an aldol condensation reaction.

The respective aldehydes were usually obtained commercially and only in a few cases synthesized in preparation for the respective condensation reaction (details in chapter 5.4.2). The aldehyde subjected to the reaction towards compound **23** (Figure 11) contained a *tert*-butyloxycarbonyl (Boc) protecting group NH which was removed in an additional, ninth reaction step.

As shown in Scheme 1, the condensation reactions were preceded by an activation of the diketopiperazine by an *N*-acetylation of the DKP. The acylated DKP can subsequently be subjected to aldol-type condensation reactions with aromatic and aliphatic aldehydes in the presence of a suitable base (e.g. triethylamine (Et₃N), caesium carbonate (Cs₂CO₃) or potassium *tert*-butoxide (KO^tBu)). The enhanced reactivity of the acylated derivative was rationalized by a greater acidity of the vicinal methylene proton, which is cleaved off by a base and leads to the enolate formation

in the first step of the proposed mechanism (Scheme 2).^{107,112} Yet, computational studies did not show a significant distance in the acidity of these protons in unsubstituted DKP ($pK_a = 24.0$) and the acetylated analogue ($pK_a = 24.1$).¹¹³ However, the acetylation additionally supports the condensation reaction by enabling a kinetically favored intramolecular *N*-*O* shift of the acyl group (step 3, Scheme 2).^{107,112}

Scheme 2: General reaction mechanism of the aldol-type condensation of acylated DKP **2** and aromatic or aliphatic aldehydes proposed by Gallina and Liberatori in 1973.¹⁰⁷

In the last step, the double bond is formed by elimination of acetate. The reaction is typically diastereoselective in favor of the respective *Z*-isomers, which may be explained by applying the Zimmermann-Traxler model to the second step of the mechanism, the aldol addition.^{111,112} The two competing transition states proposed by Balducci *et al.* are shown in Figure 12. The reaction proceeds *via* the transition state in which the relative orientation of the aldehyde to the acetyl group causes less steric hindrance.¹¹⁴

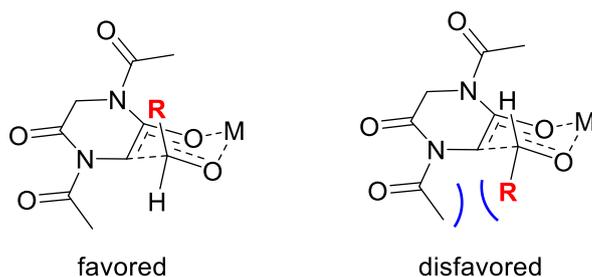

Figure 12: The diastereoselectivity of the aldol condensation can be rationalized by applying the Zimmerman-Traxler model to the aldol addition following the enolization of the DKP **2**. The reaction proceeds *via* the transition state depicted on the left with less steric hindrance. R = aliphatic or aromatic residue, M = Metal of the base applied in the reaction.¹¹⁴

When performing the aldol condensation with carbocyclic aromatic aldehydes the yield and/or the required reaction time is highly dependent on the substituents. In general, the reaction is significantly faster when coupling aldehydes bearing electron-withdrawing groups, which promote a nucleophilic attack of the intermediate enolate on the aldehyde group. The reaction conditions can be optimized by choosing a suitable combination of base and solvent.¹¹² During this work, it was studied whether the speed of the reaction with electron-rich aldehydes can be enhanced by raising the reaction temperature from room temperature to 50 °C when performing reactions. When monitoring these reactions *via* analytical HPLC, it was observed that an increased temperature lead to the formation of undesired side products which thus resulted in lower yields. Satisfactory yields were achieved when stirring at room temperature and prolonging the reaction up to several days.

For nine of the synthesized derivatives single crystals were grown successfully and subjected to single-crystal X-ray diffraction studies. The corresponding structures are shown in Figure 13. As expected, the *Z*-conformation of both C=C double bonds was confirmed for all these compounds, respectively.

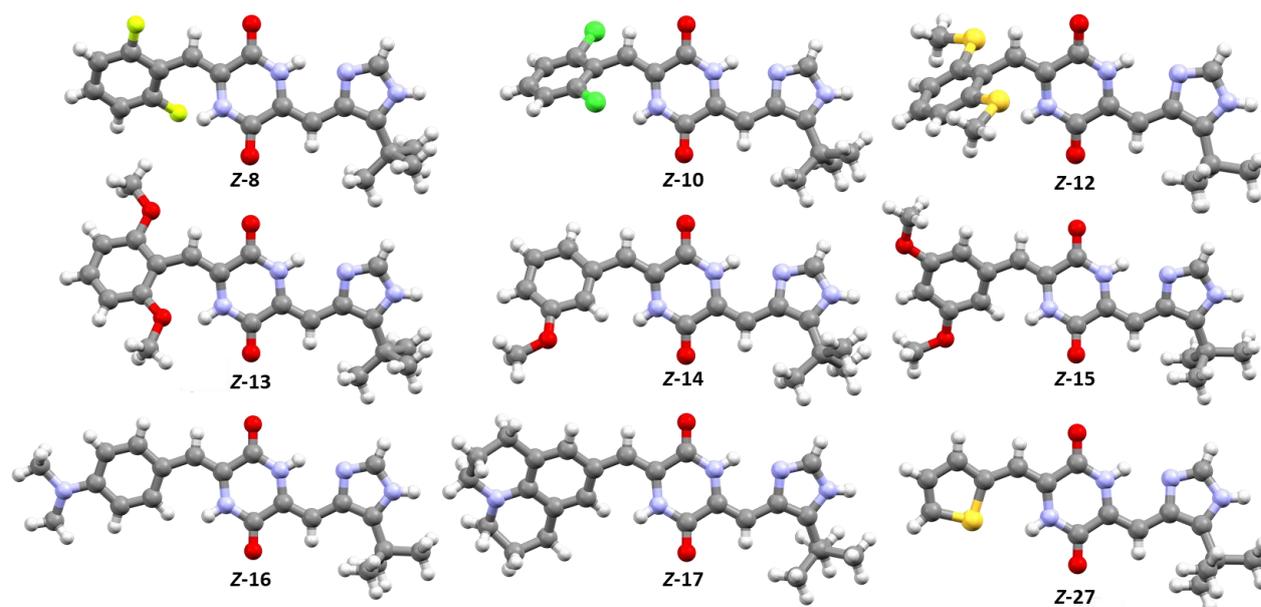

Figure 13: Single crystals of Z-8, Z-10, Z-12-17 and Z-27 were analyzed in single-crystal X-ray diffraction studies. The results were visualized with Mercury 2020.1 (CCDC). Additional atoms in the results of Z-8, Z-13, Z-27 (H₂O), Z-14 (disordered 3-methoxybenzylidene moiety) and Z-17 (disordered *tert*-butyl and julolidine moieties) were removed in this visual presentation. Atoms of carbon are depicted in grey, hydrogen in white, oxygen in red, nitrogen in blue, sulfur in deep yellow, fluorine in bright yellow and chlorine in green.

Also, the pseudo-tricyclic structure described by Yamazaki et al. (see also chapter 1.3.3)¹⁰⁰ was confirmed. The imidazole ring was found to be in plane with the diketopiperazine ring, which is presumably supported by an intramolecular hydrogen bond between the lone electron pair of the nitrogen atom on the imidazole ring and the amide proton on the DKP ring. It was additionally observed that the introduction of substituents in *ortho* position on the phenyl ring leads to a twist of the aromatic ring out of plane, which can be rationalized by steric repulsion.

3.1.2 Investigation of the Photoswitching

In course of our research on encapsulation and light-induced plinabulin (**6**) release as a bioactive cargo from photoswitchable supramolecular hydrogels based on azobenzene¹⁰³, our group discovered that in absence of the azobenzene-containing hydrogelator the cargo molecule itself also exhibited reversible photochromic behavior. Because plinabulin (**6**) does not contain any previously investigated photoswitchable structural motifs, the first major goal was to determine the conformation of the less stable photoisomer of plinabulin (**6**) that is being formed upon irradiation. When assuming that photoconversion proceeds as *E/Z*-isomerization, there are two double bonds that could hypothetically isomerize, leading to four possible photoisomers in total,

which are depicted in Figure 14. However, all collected results of NMR and HPLC measurements suggest that only one additional photoisomer is formed during photoisomerization.

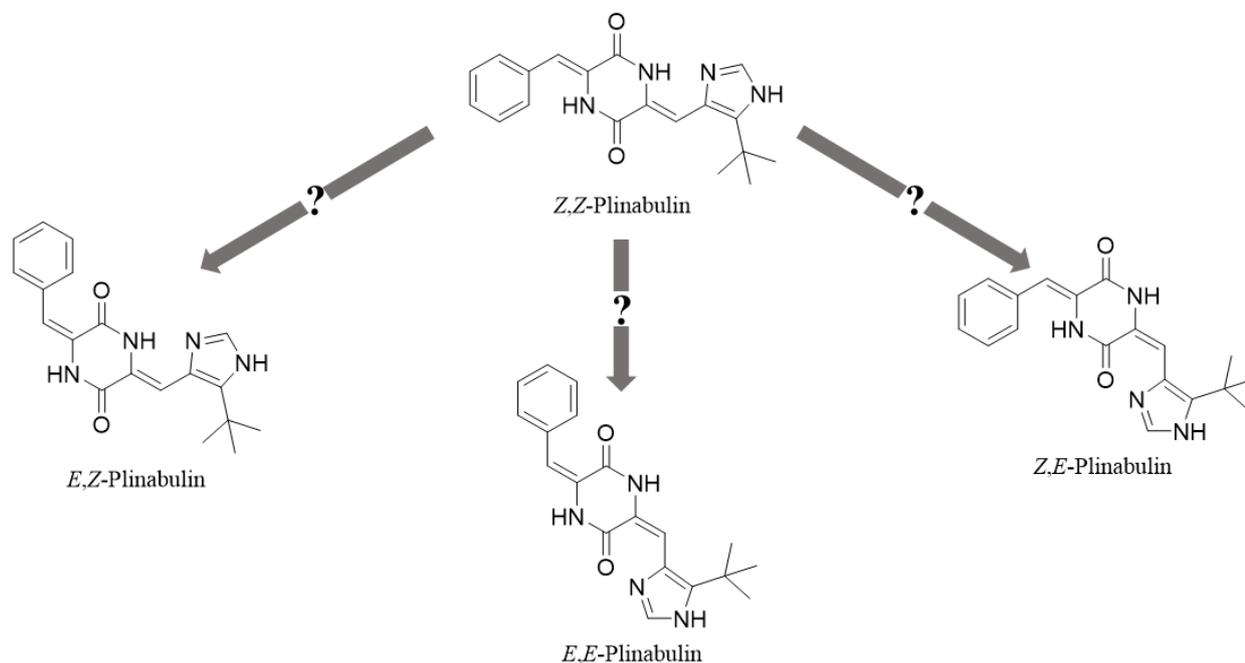

Figure 14: In theory, the thermally most stable *Z,Z*-isomer can be photoisomerized into the three other isomers when undergoing *E/Z*-isomerization.

To identify this photoisomer a method to separate the respective photoisomers *via* preparative HPLC was developed. It was found that both photoisomers are sufficiently stable to be analyzed *via* NMR spectroscopy. Sections of the respective ^1H NMR spectra are presented in Figure 15 and selected signals were assigned to the corresponding protons *via* color code. One of the two signals assigned to the two vinylic protons (blue) is shifted significantly more into the high field than the other one (green). This allows the conclusion that the proton on the side of the phenyl residue is subjected to a greater change in its electronic surroundings, than the proton on the side of the heterocycle. This is a first indication that the depicted *E,Z*-isomer is formed.

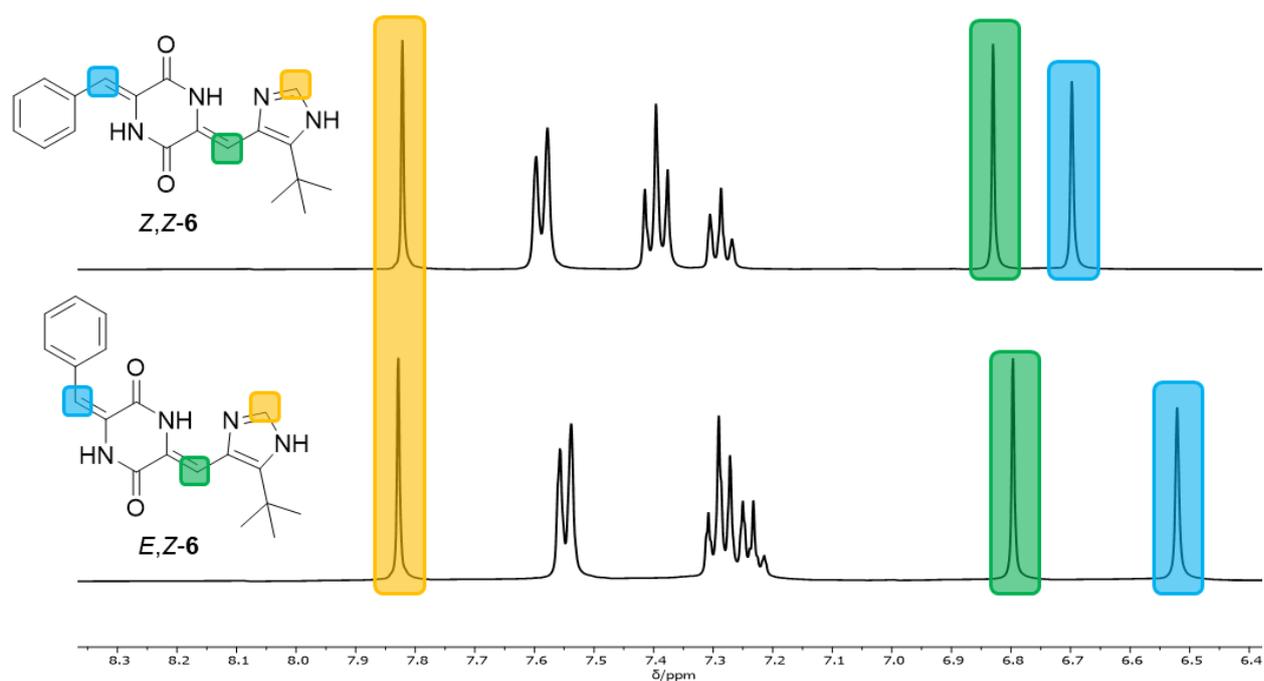

Figure 15: Comparison of sections of ^1H NMR spectra (400 MHz) in deuterated dimethyl sulfoxide ($\text{DMSO-}d_6$) of the photoisomers of plinabulin (**6**). Selected signals are assigned to the respective proton *via* color code.

Additionally, NOESY NMR spectra of both photoisomers of plinabulin (**6**), 3-methoxyplinabulin **14** and 3,5-dimethoxyplinabulin **15** were measured and analyzed. Sections of these spectra are presented in Figure 16 and important signals are assigned to the respective protons *via* color code. It is evident that after photoisomerization the signal, assigned to interactions of the NH proton with aromatic protons (highlighted in yellow, not detected for Z-**6**) is replaced by a signal that indicates close proximity of the NH proton to the vinylic proton. These results also support the light-triggered formation of the respective *E,Z*-isomers.

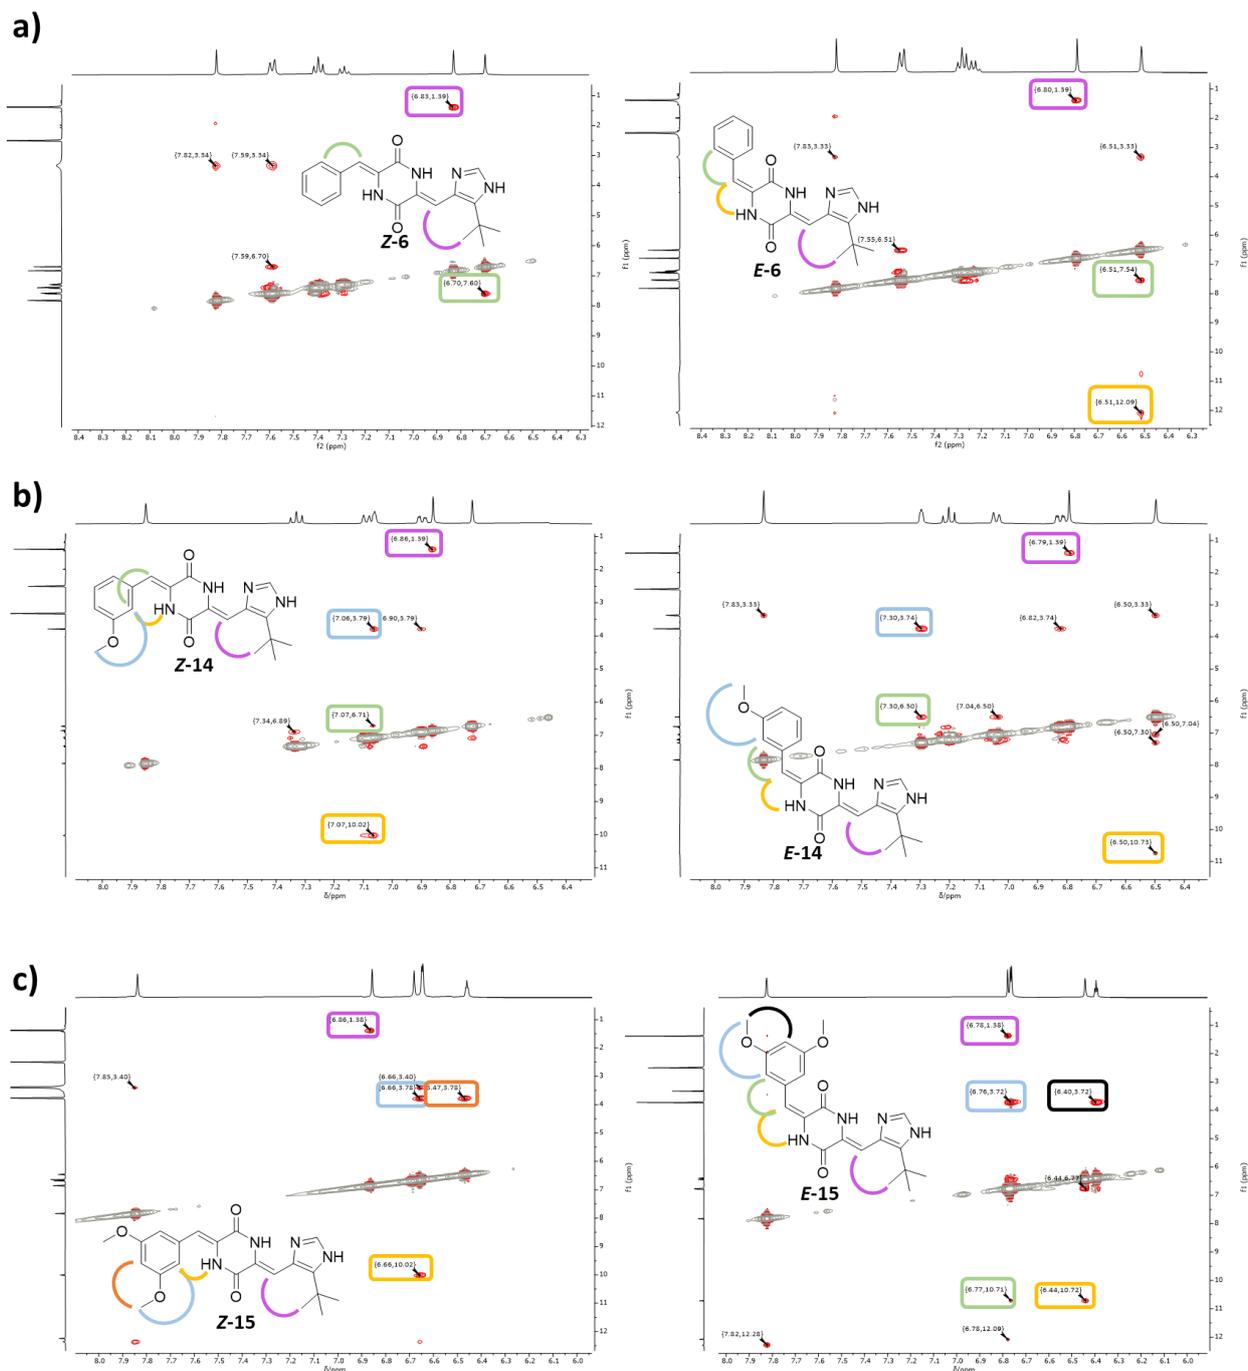

Figure 16: Sections NOESY NMR spectra in deuterated dimethyl sulfoxide ($\text{DMSO-}d_6$) of the two respective photoisomers of a) **6**, b) **14** and c) **15**. Selected signals are assigned to the respective protons *via* color code.

Furthermore, single crystals of both photoisomers of 2,6-dichloroplinabulin **10** were obtained and analyzed *via* X-ray diffraction analysis to determine their respective conformations. As depicted in Figure 17, the formation of the *E,Z*-isomer could be confirmed.

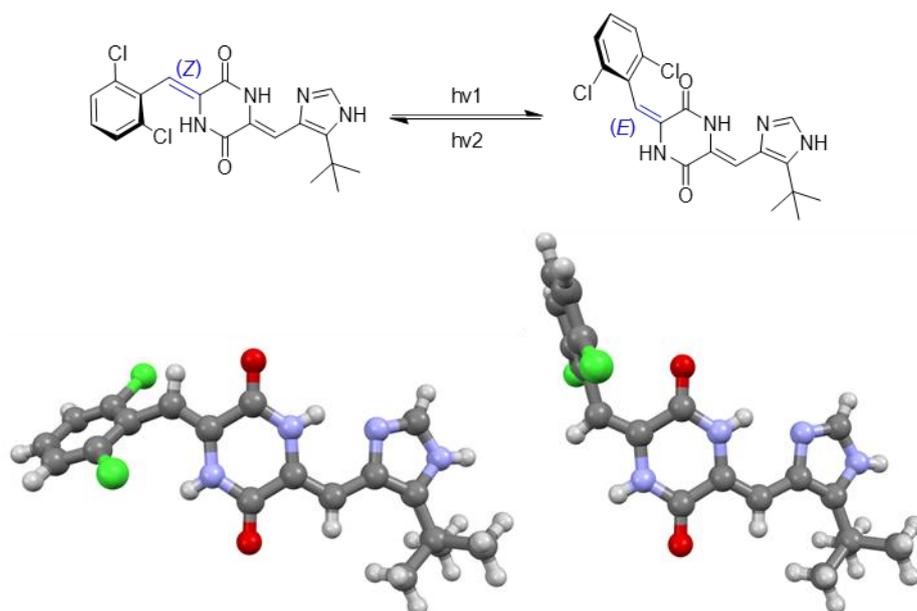

Figure 17: The conformations of the two photoisomers of 2,6-dichloroplinabulin **10** were determined *via* single-crystal X-ray diffraction analysis.

Based on the combined data it was concluded that the synthesized plinabulin derivatives undergo light-induced *E/Z*-isomerization of the carbocyclic arylidene group attached to the cyclic dipeptide. This *E/Z*-photoisomerization is analogous to the isomerization of arylidene substituents adjacent to heterocyclic five-membered-ring scaffolds of the previously described classes of molecular photoswitches indigoids¹¹⁵, hydantoins¹¹⁶, and isoindolinones¹¹⁷. The photosensitivity of arylidene groups attached to heterocyclic six-membered-rings has been mentioned in 1970¹¹⁸ and 1982¹¹⁹ and was also shortly described for an isolated natural product in a report that was published over the course of this work¹²⁰. Although these studies do not include any characterization of photochromism, they support the hypothesis of an *E/Z*-isomerization of the proposed C=C double bond. This novel molecular photoswitch is a combination of a hemistilbene and a 2,5-diketopiperazine and was thus named hemipiperazine (HPI).

Under the investigated conditions, no *Z/E*-photoisomerization of the C=C bond on the heterocyclic arylidene substituent of plinabulin (**6**), nor its derivatives, has been observed. Therefore, it was decided to split the original system on two halves – each with one arylidene-substituted DKP – in order to separately check if there is any inherent structural reason for such a behavior. The photochromism of two alternative monoarylidene synthetic intermediates of plinabulin (**6**) – the benzylidene-*N*-monoacetyl-DKP **29** and the imidazole-substituted *N*-monoacetyl-DKP **5** shown in Figure 18 were investigated. They both contain the rudimentary HPI motif. For compound **29**, the *Z*-configuration could be confirmed *via* single-crystal X-ray diffraction analysis (see chapter 5.5.11). Interestingly, both compounds were found to be reversibly photoswitchable with

UV- and violet light and the respective photoisomers were isolated successfully and analyzed *via* NMR spectroscopy. Sections of the respective NOESY NMR spectra are shown in Figure 18 and important signals are assigned to the respective protons *via* color code. In both cases, a signal that indicates close proximity of the NH proton on the DKP ring to the vinylic proton was identified in the spectrum of the respective thermodynamically less stable photoisomer formed upon irradiation.

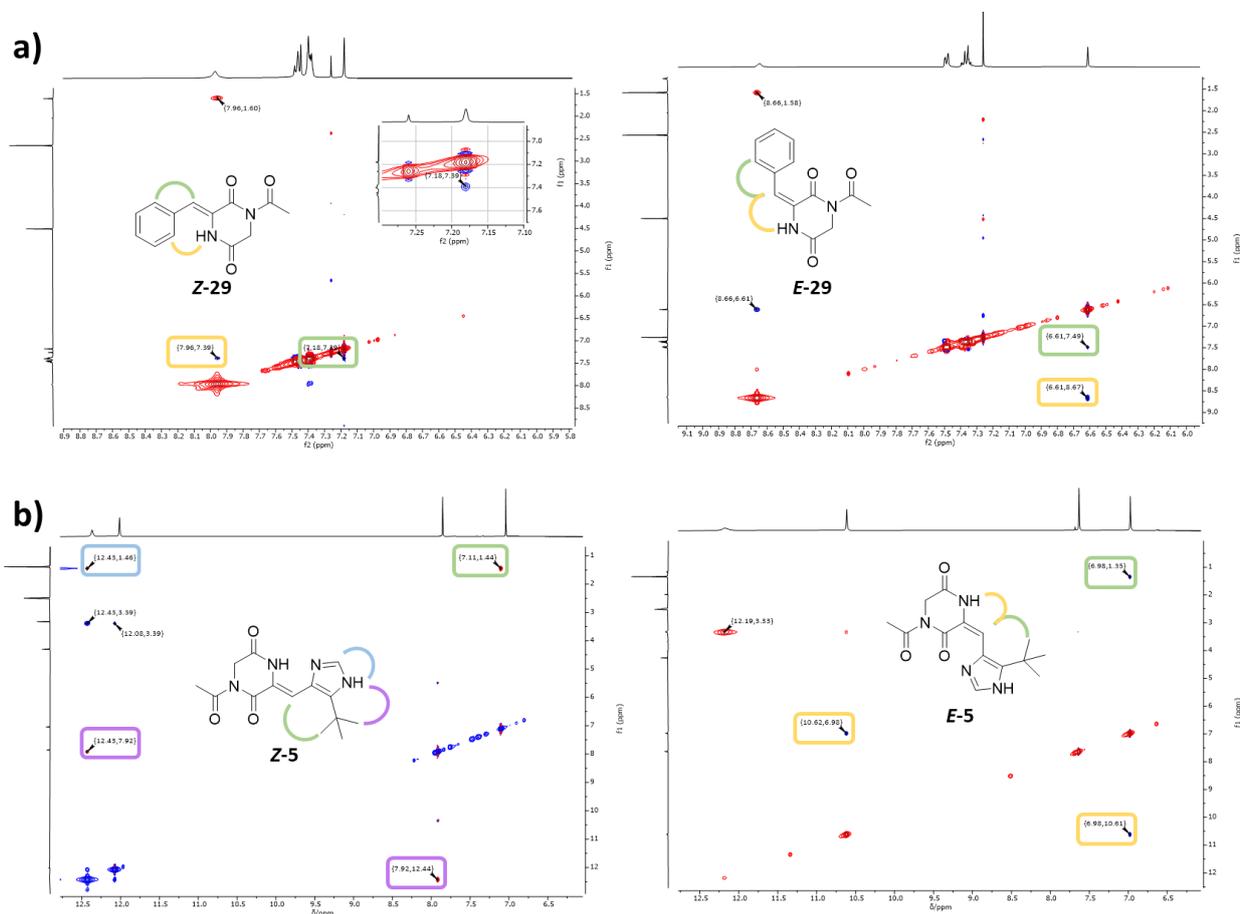

Figure 18: Sections NOESY NMR spectra in deuterated dimethyl sulfoxide (DMSO- d_6) of the two respective photoisomers of a) HPI **29** and b) HPI **5**. Selected signals are assigned to the respective protons *via* color code.

The collected data suggests that both intermediates – the carbocyclic aromatic **29** and the heteroaromatic **5** – are functional HPI photoswitches that separately undergo light-triggered *Z/E*-photoisomerization. This speaks against a preliminary working hypothesis, that it is the hydrogen bonding between the DKP amide bond and the imidazole nitrogen atom which stabilizes the *Z*-configuration of the heteroarylidene and prevents it from photoisomerization. Yet, in plinabulin (**6**), which comprises both a carbocyclic aromatic and a heteroaromatic HPI motif, the heterocyclic arylidene substituent is inert to light. Possible explanation for the stabilized *Z*-configuration is the particular relative geometric configuration of the two chromophores. A similar effect has been observed elsewhere for multiphotochromic azobenzenes.¹²¹

3.1.3 Photophysical and Photopharmacological Properties of Plinabulin (6)

When studying the photophysical properties of plinabulin (**6**), a minor solvatochromic effect was observed for both photoisomers. The absorption maxima of spectra measured in different solvents fluctuate between 355 and 371 nm (Figure 19). However, no direct correlation on the solvents' dipole moment and the shift of the absorption maxima was observed.

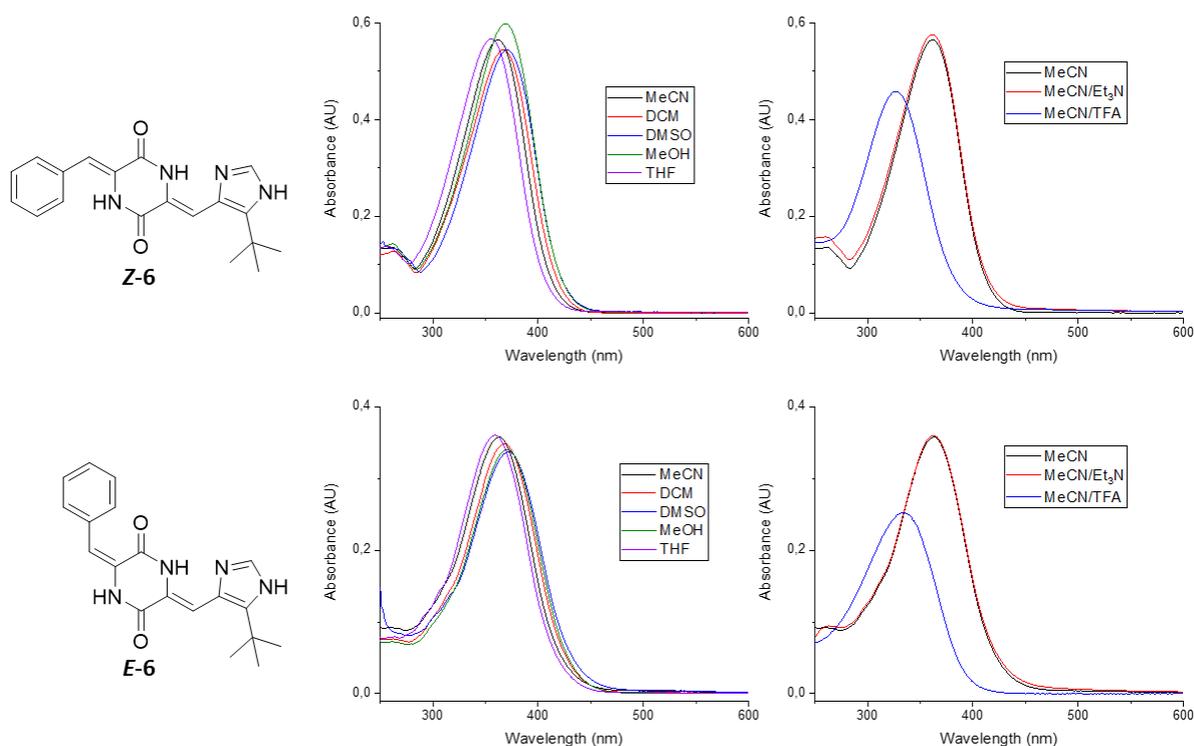

Figure 19: Solvatochromism and acidochromism was observed for both photoisomers **Z-6** (top) and **E-6** (bottom). Absorption spectra were measured ($c = 80 \mu\text{M}$, $d = 2 \text{ mm}$) and spectra are assigned to the respective solvents *via* color code.

Additionally, absorption spectra measured in acetonitrile without any additive were compared with those of solutions with the same concentration but with 1% (v/v) of an acid (trifluoroacetic acid, TFA) and a base (triethylamine, Et₃N), respectively (Figure 19). While the addition of Et₃N had no significant influence on the absorption spectra, TFA addition was found to lead to a hypsochromic shift of the absorption maximum of 35 nm (**Z-6**) and 41 nm (**E-6**), respectively. The shift in the absorption spectra is assumed to be caused by protonation and can be tuned by adding different amounts of TFA whereby saturation is reached at 2.0 equivalents TFA (Figure 20). When investigating the two HPIs and synthetic intermediates of plinabulin **5** and **29**, no acidochromism was observed for the carbocyclic aromatic HPI **29** but TFA addition lead to a hypsochromic shift in the absorption maximum of 45 nm in the spectra of compound **5**. These results suggest that plinabulin (**6**) is protonated on the imidazole moiety when TFA (pK_a in MeCN = 12.65)¹²² is

added, which is in accordance with a pK_a value of 15.07 for unsubstituted imidazole in MeCN.¹²³ In consequence of these findings, work-up after purification *via* preparative HPLC was adjusted: Because TFA was added to the mobile phase during purification all collected fractions were washed with saturated aqueous solution of sodium hydrogen carbonate to remove all TFA.

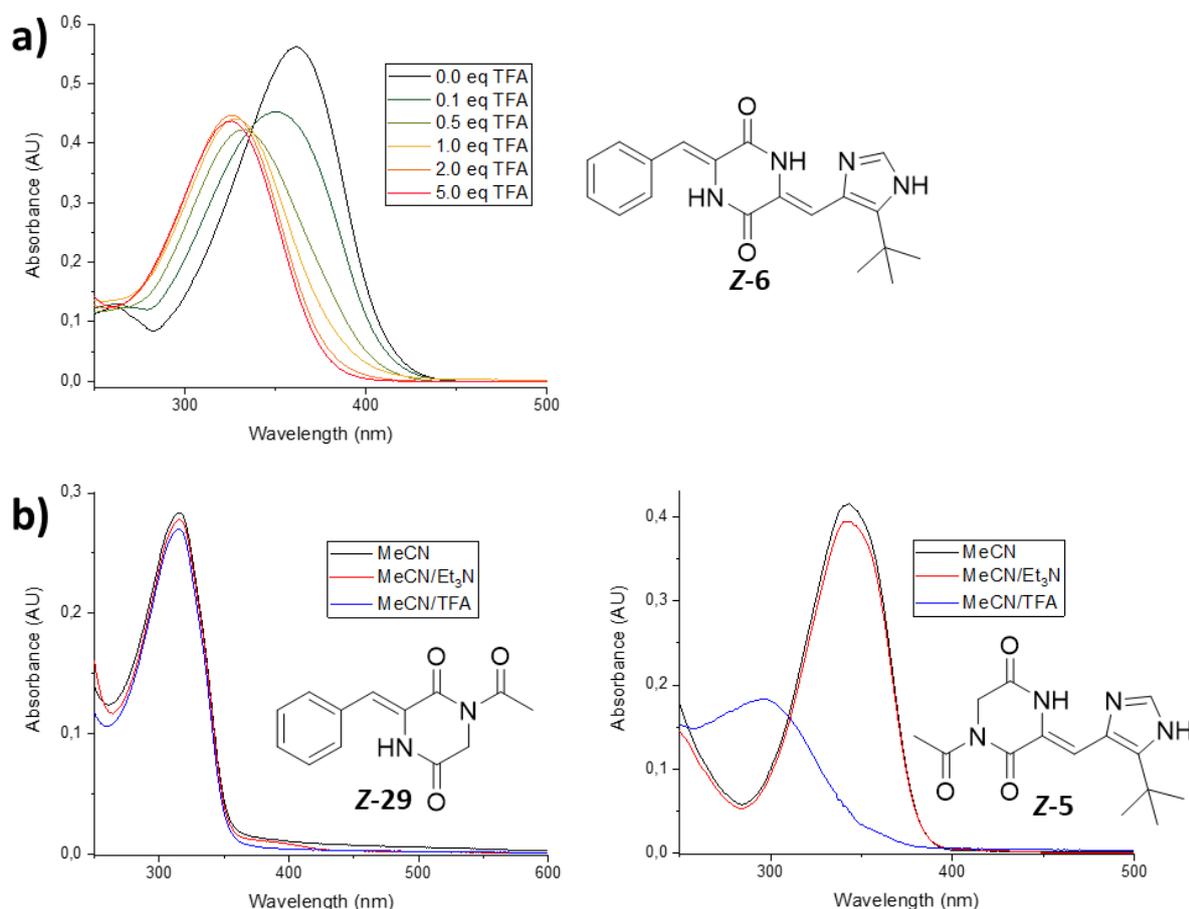

Figure 20: Results of investigations of the acidochromism of plinabulin (**6**) suggest a protonation on the imidazole ring. a) Absorption spectra of Z-6 with different amounts of TFA, b) Compounds **29** (left) and **5** (right) were dissolved in pure MeCN and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Acidochromism was not observed for Z-29 but for Z-5. Absorption spectra ($c = 80 \mu\text{M}$, $d = 2 \text{ mm}$) are assigned to the respective solvents and mixtures *via* color code.

After having assessed the photophysical properties of the isolated photoisomers the changes upon irradiation with selected wavelengths were investigated. The compositions of the photostationary states (PSSs) were determined *via* NMR spectroscopy in deuterated dimethyl sulfoxide (DMSO- d_6) (Figure 21).

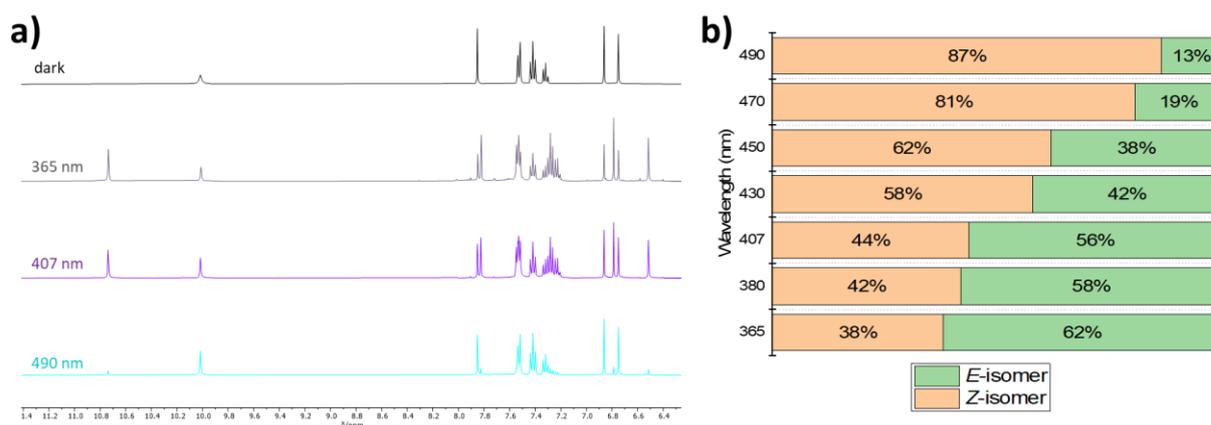

Figure 21: The compositions of the photostationary states (PSSs) of plinabulin (**6**) were determined *via* ^1H NMR spectroscopy. Samples in deuterated dimethyl sulfoxide ($\text{DMSO-}d_6$) were irradiated with selected wavelengths and photoisomerization was monitored until prolonged irradiation did not lead to further changes in the relative integrals of the signals assigned to the two photoisomers. a) Sections of NMR spectra obtained after irradiation with selected wavelengths and the PSS was reached. The spectra are assigned to the respective wavelengths *via* color code, b) Compositions of the respective PSSs for all applied wavelengths.

A PSS is reached once further irradiation does no longer induce a change in the ratio of *E*- and *Z*-isomer. It was found that the thermodynamically more stable *Z*-isomer can be photoisomerized to up to 62% of the corresponding *E*-isomer with UV-light (365 nm) and efficient back-isomerization to 87% *Z*-isomer is achieved upon irradiation with cyan light (490 nm).

In diluted samples, slight photodegradation was noticed upon irradiation at and below 430 nm. In presence of blue or cyan light (450-490 nm) however, plinabulin (**6**) was found to be stable. To investigate the photostability of plinabulin (**6**) in details, ten subsequent switching cycles in DMSO were performed by first irradiating the sample with violet light (407 nm, 2 min per cycle), then with cyan light (490 nm, 35 min per cycle). The resulting mixtures were analyzed after every irradiation step *via* analytical HPLC (Figure 22).

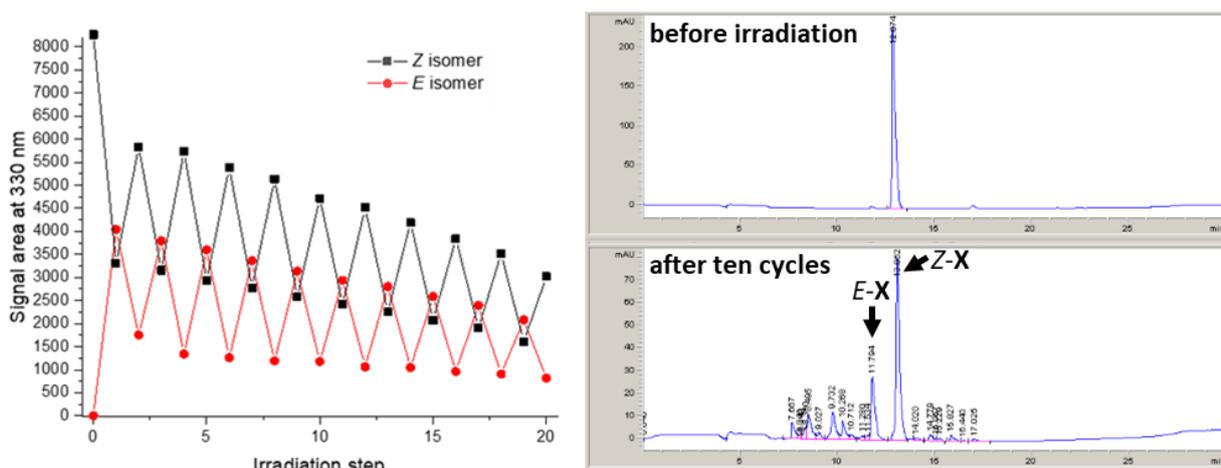

Figure 22: Photodegradation of plinabulin (**6**) in ten subsequent switching cycles. a) A solution of pure Z-**6** (1.0 mM) in DMSO was analyzed *via* analytical HPLC. The sample was first irradiated with 407 nm for 2 min, followed by with 490 nm for 35 min, respectively. The irradiation cycles were performed ten times and after every irradiation step the solution was analyzed *via* analytical HPLC, b) Two of the corresponding HPLC traces - before irradiation (top right) and after completing ten switching cycles (bottom right) - are depicted.

It was observed that the integrals of the signals assigned to both, the *E*- and the *Z*-isomer of plinabulin (**6**), continuously decrease with progressing irradiation time. After 20 irradiation steps, over ten additional signals besides those assigned to the photoisomers of plinabulin (**6**) were detected in the HPLC trace. This indicates a formation of multiple degradation products in reactions with low specificity and prevents the identification of a predominant degradation pathway. To investigate the influence of oxygen on the degradation, a 40 μ M solution of plinabulin (**6**) in DMSO was split into three separate samples: Whereas one sample was kept under ambient atmosphere, the other two were purged for five minutes with gases, one sample with oxygen and the other with argon. Subsequently, absorption spectra of these samples were measured before and after irradiation with first 490 nm, followed by 407 nm (Figure 23).

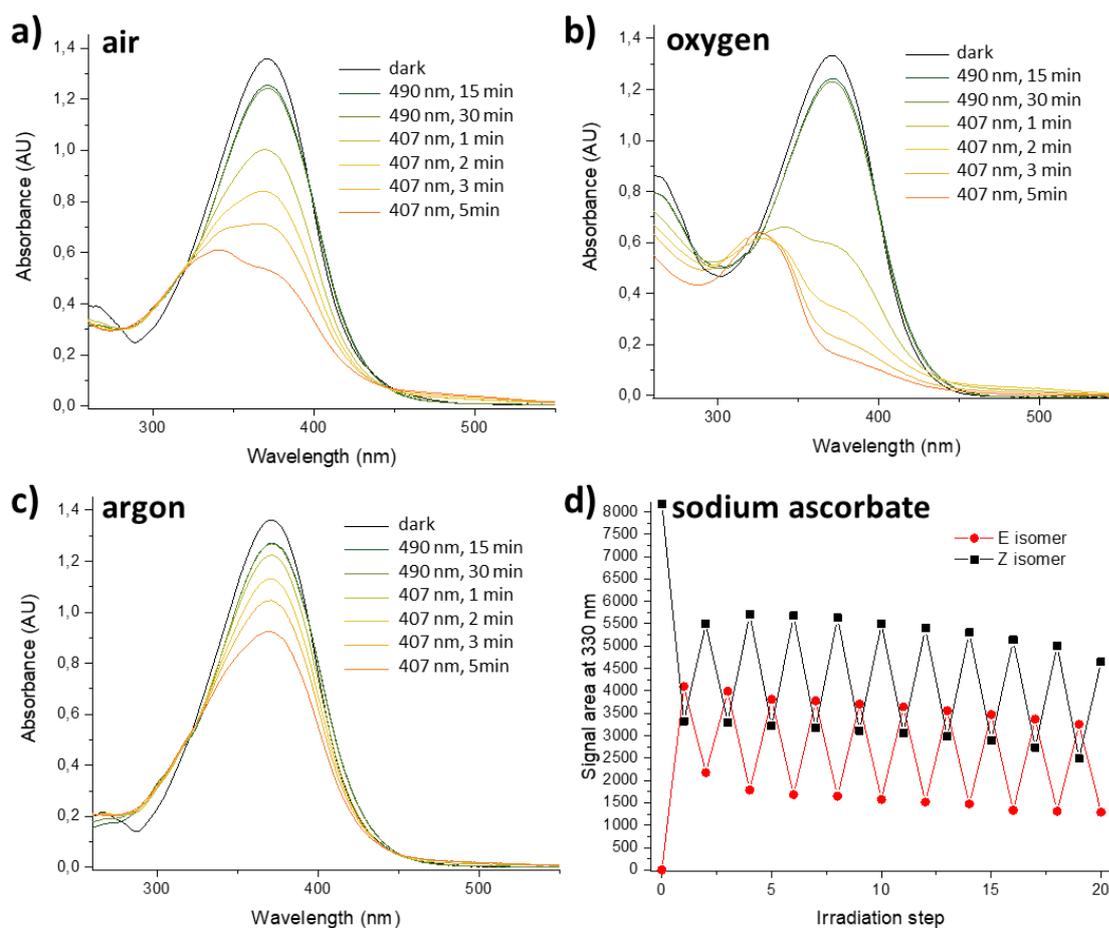

Figure 23: The photodegradation is promoted by oxygen and can be significantly reduced by the addition of the reactive oxygen species (ROS) quenchers, like sodium ascorbate. a)-c) A 40 μM solution of **6** in DMSO was prepared and split up into three samples. One sample a) was kept under ambient atmosphere, the other samples were purged for 5 min with b) oxygen or c) argon, respectively. Afterwards, the samples were first irradiated twice for 15 min with 490 nm and subsequently five times for 1 min with 407 nm. Absorption spectra were first recorded in the dark and then after each irradiation step. d) A solution of pure Z-**6** (1.0 mM) in a saturated solution of sodium ascorbate in DMSO was analyzed *via* analytical HPLC. The sample was irradiated with 407 nm for 2 min and with 490 nm for 35 min, respectively. The irradiation cycles were repeated ten times and after every irradiation step the solution was analyzed *via* analytical HPLC.

It was observed that irradiation with cyan light (490 nm) leads to a change in the absorption spectra, while doubling the irradiation time from 15 min to 30 min does not lead to further significant changes. Two isosbestic points are visible and it can be concluded that the PSS is reached after 15 min irradiation time and no photodegradation is detected. Subsequent irradiation with violet light (407 nm) induces changes in the absorption spectra of all three samples. Notably, already after 1 min irradiation time the spectra do not intersect at the isosbestic point anymore and further irradiation leads to a continuous decrease in the absorption maxima. This decrease in absorbance presumably correlates with progressing photodegradation. The enrichment of oxygen accelerates this process, while the degradation of the sample purged with argon is decelerated, which clearly indicates that the photoinduced degradation of plinabulin (**6**) is promoted by oxygen.

Therefore, it was concluded that the degradation products result from unspecific reactions with reactive oxygen species (ROS) formed upon irradiation. Consequently, sodium ascorbate – a known quencher of ROS¹²⁴ – was added to a sample to suppress the degradation process. It was found that this additive significantly slows down the decrease of the integrals of the signals assigned to both, the *E*- and the *Z*-isomer, when performing photoswitching cycles with indicates that it successfully reduces the amount of degradation (Figure 23).

The hypothesis of photodegradation caused by reaction with ROS is also supported by the known instability of natural products like guanosine or histidine against singlet oxygen. It has been reported by several groups that singlet oxygen attacks these compounds on the imidazole moiety and it is presumed that photooxidation of histidine is caused by singlet oxygen attacking the imidazole ring.^{125,126} Furthermore, in this work it was observed that irradiation of the carbocyclic HPI **29** – a synthetic intermediate of plinabulin (**6**) without the imidazole substituent – does not lead to photodegradation. Ten switching cycles were performed without any additive, monitored *via* analytical HPLC and no decrease of the areas of the signals assigned to the two photoisomers and no formation of any additional signals was observed (Figure 24).

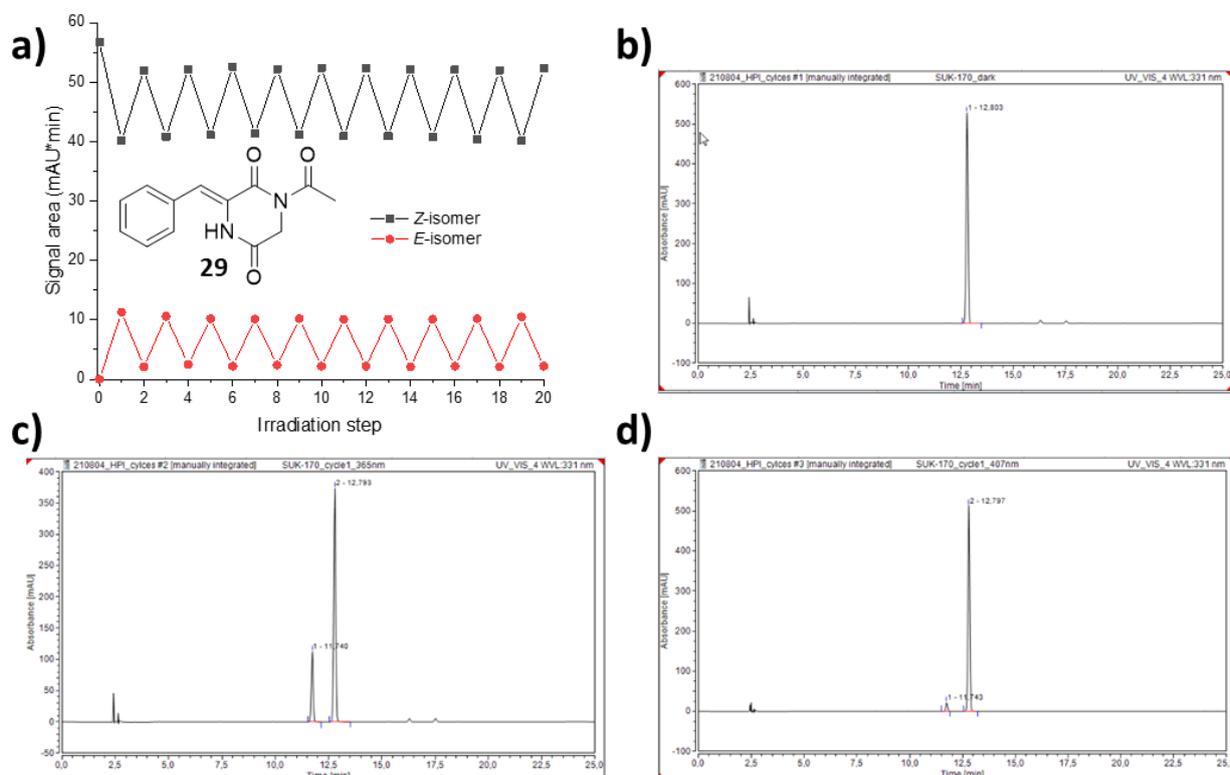

Figure 24: Switching stability of the carbocyclic HPI **29**. A solution of pure *Z*-**29** in DMSO (1.0 mM) were alternately irradiated with 365 nm for 2 min, followed by 407 nm for 10 min. a) After every irradiation step the solutions were analyzed *via* analytical HPLC. The corresponding HPLC traces b) before irradiation, c) after irradiation with 365 nm, and d) after irradiation with 407 nm are depicted.

Absorption spectra of PSSs of plinabulin (**6**) were recorded in presence of the ROS quencher sodium ascorbate (Figure 25 a), or alternatively in presence of the reducing agents glutathione and tris(2-carboxyethyl)phospine (TCEP) (Figure 25 b). The observed photoswitchability of plinabulin (**6**) in presence of these reducing agents is an enormous benefit compared to azobenzene-based photopharmacophores known to be prone to degradation under intracellular reducing conditions.³⁸ Plinabulin (**6**) however, is stable in presence of a mixture of reduced glutathione (10 mM) with TCEP (5 mM) without any detectable degradation for 14 hours at 37 °C (see chapter 5.4.11).

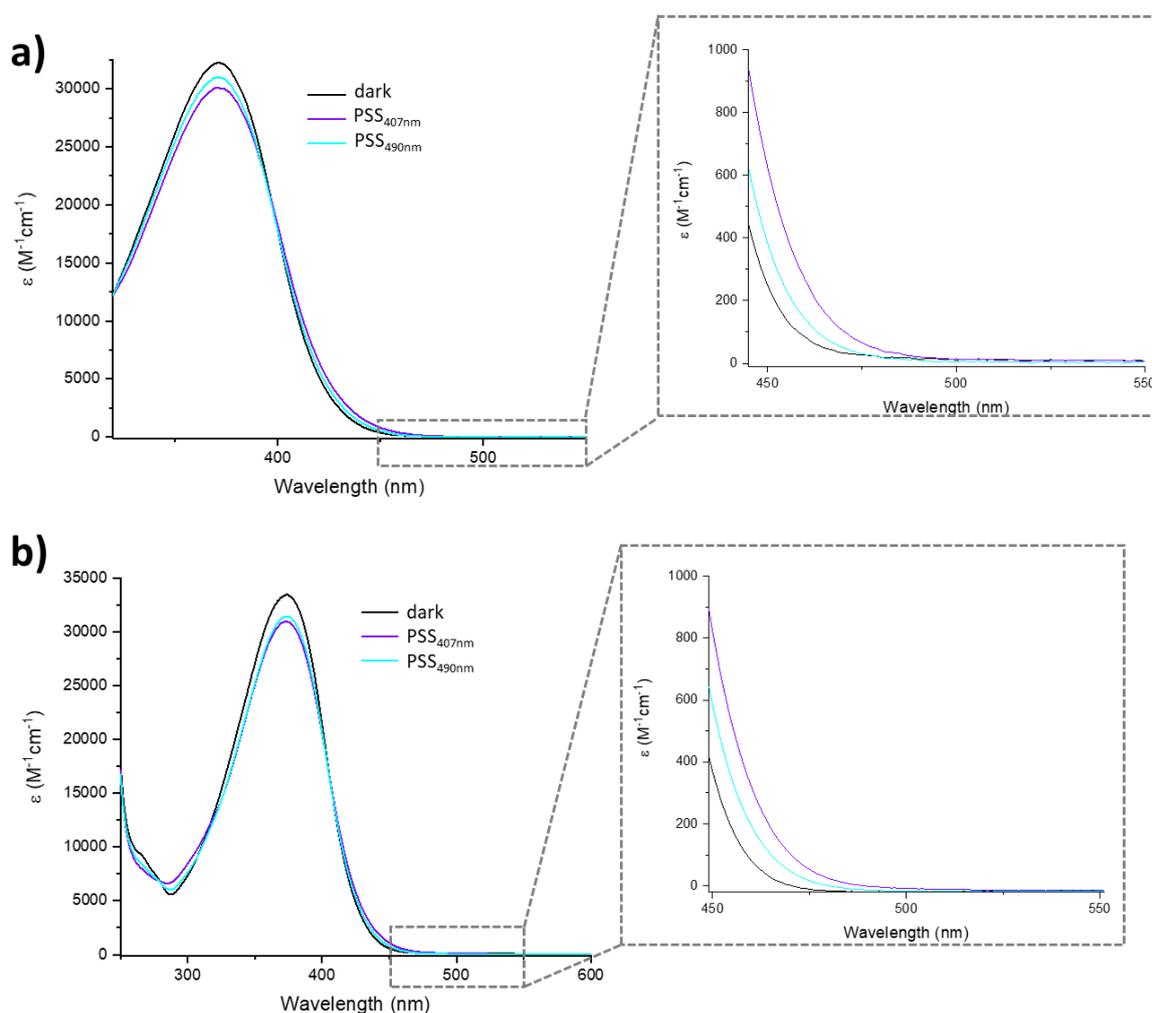

Figure 25: Absorption spectra of plinabulin (**6**) before and after irradiation in a) saturated solution of sodium ascorbate in DMSO and b) in 25% PBS in DMSO with 10 mM glutathione and 5.0 mM tris(2-carboxyethyl)phospine (TCEP).

The relatively small differences between the absorption spectra of plinabulin (**6**) before and after irradiation reveal a comparably low band separation between the two photoisomers. The spectrum obtained after irradiation with 407 nm corresponds to over 50% *E*-isomer, yet there is no noticeable shift in the absorption maximum. The observed differences in the extinction coefficients

in the absorption spectra caused by photoisomerization correlate with the composition of the photostationary states determined *via* NMR spectroscopy. The spectra intersect in an isosbestic point at 401 nm. At wavelengths in the range of 365 nm to 410 nm, a higher extinction coefficient was determined for the *Z*-isomer whereas above 401 nm the absorption coefficient of the *E*-isomer was found to be higher. This is a possible explanation for the effective *E*-to-*Z*-isomerization upon irradiation with cyan light.

It was additionally observed that solutions of plinabulin (**6**) exhibited isomer-dependent moderate yellow fluorescence emission. Compared to the *Z*-isomer (*Z*-**6**) the emission spectrum of *E*-plinabulin (*E*-**6**) is shifted bathochromically by 21 nm and the fluorescence quantum yield is lowered ($\Phi_F(Z\text{-}\mathbf{6}) = 4.5\%$, $\Phi_F(E\text{-}\mathbf{6}) = 2.0\%$).

During the characterization of both photoisomers of plinabulin (**6**) under ambient conditions no significant thermal *E*-to-*Z*-isomerization was observed for at least one day. Therefore, the thermal stability was first investigated at 60 °C in MeCN (Figure 26) by monitoring a solution of *E*-plinabulin (*E*-**6**) *via* analytical HPLC. It was found that even at this elevated temperature less than 5% *E*-plinabulin (*E*-**6**) had been thermally relaxed after 25 hours.

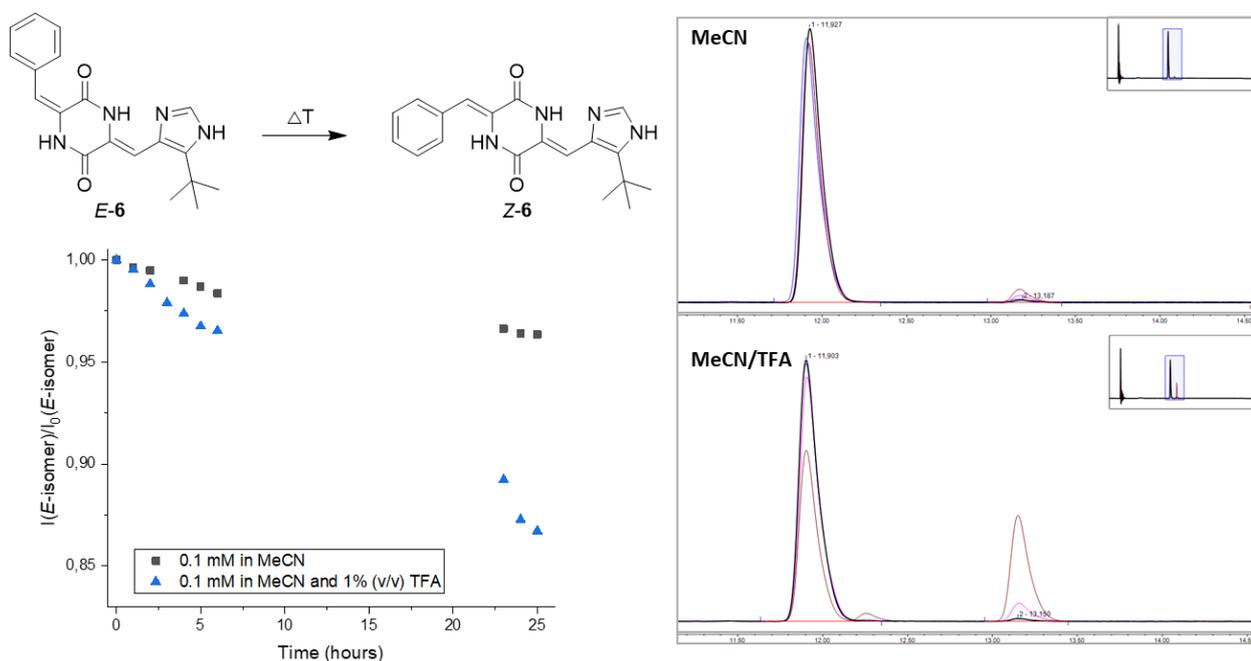

Figure 26: The thermal relaxation of *E*-plinabulin (*E*-**6**) in MeCN at 60 °C in absence and presence of TFA was monitored *via* analytical HPLC, respectively. The integrals of the signals assigned to the respective *E*-isomer were determined at 330 nm: I_0 = initial integral area, I = integral area at given point in time. A comparison of the overlays of the HPLC traces collected for the sample with TFA (bottom right) and without (top right) clearly demonstrate an accelerated backisomerization in an acidic medium.

Additionally, the thermal relaxation of the protonated species was followed by repeating the experiment with an acidified sample (1% (v/v) of TFA in MeCN). It was found that protonation significantly reduces the lifetime of *E*-plinabulin (**6**) and almost 15% of *E*-**6** was thermally isomerized to the *Z*-isomer after 25 hours. In preparation for biological assays, samples were dissolved in DMSO and – if needed – irradiated. It was found that these samples could be stored in a freezer for over two months without significant changes in the photoisomer composition.

After the photophysical properties had been successfully assessed, the cytotoxicity of both photoisomers was investigated by performing cell viability MTT assays against HT-29 human colon cancer cells with the isolated photoisomers in the dark. The results shown in Figure 27 clearly demonstrate that the geometry changes upon photoisomerization affect bioactivity and an >300-fold enhanced potency of the *Z*-isomer was determined ($IC_{50}(Z-6) = 0.3 \text{ nM}$, vs. $IC_{50}(E-6) = 92 \text{ nM}$). In summary, these results demonstrate the successful photomodulation of bioactivity by applying plinabulin (**6**) as a photopharmacological agent. The high thermal stability of the less active *E*-isomer allows for isolation and storage. It can be considered as a prodrug and photoactivation of *E*-plinabulin (*E*-**6**) by irradiation with cyan light (490 nm) gives a mixture with 87% *Z*-plinabulin (*Z*-**6**) with a 20-fold higher cytotoxicity against HT-29 cells.

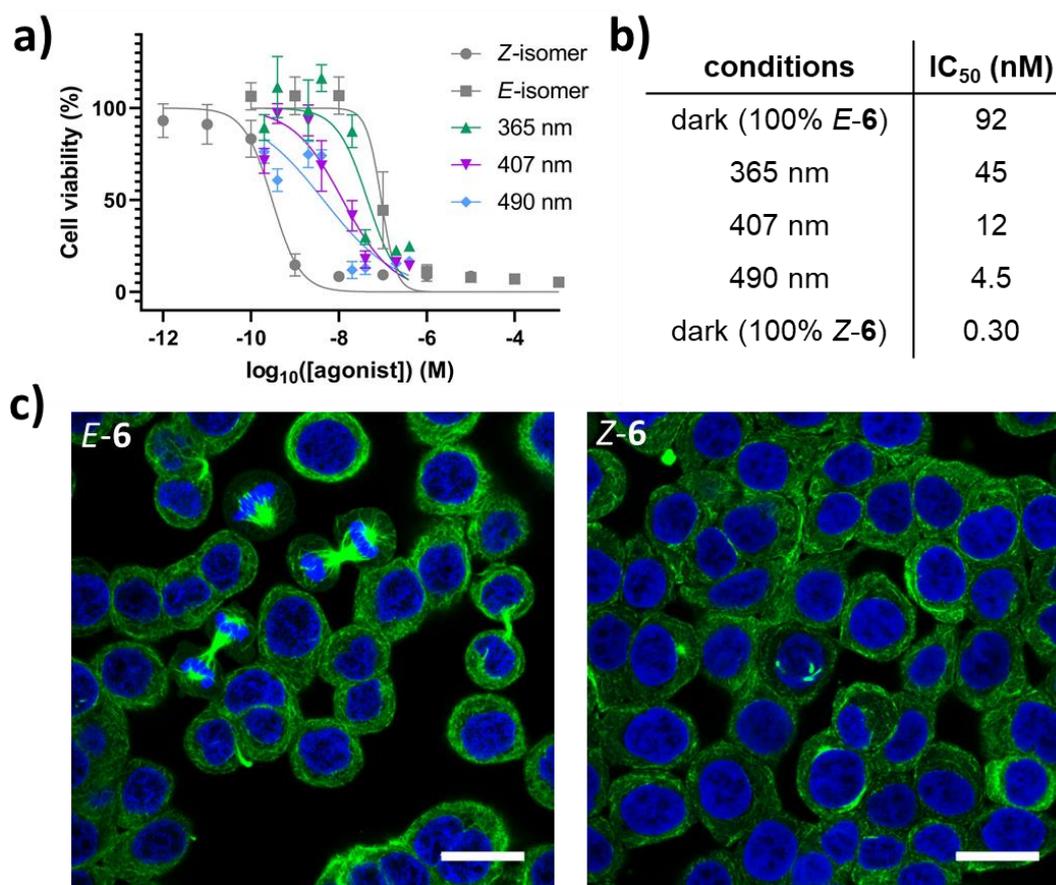

Figure 27: Photomodulation of the bioactivity of plinabulin (**6**). a) Viability of HT-29 cells after treatment with the HPLC-purified Z- and E-isomers of plinabulin (**6**) and with the respective mixtures of the isomers generated upon equilibration under 490 nm irradiation (cyan light), 407 nm (violet light) or 365 nm (UV-light) for 48 hours, b) Light-dependent IC₅₀ values for plinabulin (**6**) were determined *via* viability assays with HT-29 cells after treatment with the respective pure photoisomers and mixtures that resulted from irradiation with the listed wavelengths, c) HT-29 cells were treated for six hours with E- (left) or Z-plinabulin (right) at 2 nM concentrations, then fixed, and stained for α -tubulin (green) and DNA (blue). Scale bars, 20 μ m.

Photoisomer dependent inhibition of microtubule dynamics was confirmed by immunofluorescence imaging of endogenous tubulin. HT-29 cells were treated separately with the same concentration of E- and Z-plinabulin (**6**) (2nM) and incubated for 6 hours. After six hours incubation time the microtubule networks were visualized *via* immunostaining. As expected, significant differences were observed because the applied concentration lies in between the respective IC₅₀ values of the two photoisomers. No cell proliferation was detected after treatment with Z-plinabulin (Z-6) whereas mitosis was proceeding in the sample treated with the same concentration of E-plinabulin (E-6) (Figure 27 c). This difference in activity supports that the potency of plinabulin (**6**) as an inhibitor of tubulin polymerization can be tuned by photoisomerization.

It was noticed that there was a reproducible discrepancy between the IC_{50} value obtained for *Z*-plinabulin (**6**) (0.30 nM) and the IC_{50} reported in literature (15 nM)¹⁰⁰ for the same cell type. To investigate this, a sample of the more active *Z*-isomer was – contrary to the usual procedure – not protected from daylight exposure one day before as well as during the viability assay. It was found that during this time 15% of the less active *E*-isomer had been formed and that this led to a decrease in activity ($IC_{50} = 1.08$ nM, see also chapter 5.4.12). It was additionally observed that prolonged exposure to daylight resulted in an equilibrium containing 32% *E*-isomer in the sample mixture. These results support the assumption that the higher values reported in literature resulted from unintentional exposure to daylight before or while performing viability assays.

In summary, it was discovered that plinabulin (**6**) was a novel photoswitchable microtubule targeting agent. In contrast to previously reported compounds presented in chapter 1.3.3, it has not been synthetically modified, which in turn preserves its' potency completely. It can be reversibly photoisomerized within the visible light spectrum (by alternating 407 nm and 490 nm irradiation) and contrary to many azobenzene-based photopharmacological agents it is stable under reducing conditions. The photophysical properties are compatible with fixed wavelengths of lasers commonly applied in confocal microscopy. Violet (405 nm) and cyan (488 nm) light are expected to enable *in situ* photomodulation while light frequencies of the green (561 nm) and the red (642 nm) channel are not absorbed and can be applied for parallel imaging without affecting the photoswitchable compound.

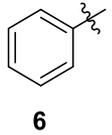

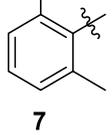

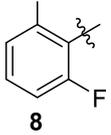

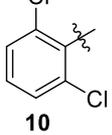

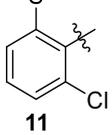

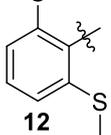

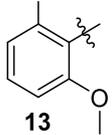

3.1.4 Investigation of Plinabulin Derivatives 7-28

After having thoroughly investigated the characteristics of plinabulin (**6**), the identification of structural features that enable tuning the photophysical and/or the photopharmacological properties was pursued. Three main characteristics were aspired for enhancing applicability of the plinabulin (**6**) photopharmacophore: a bathochromic shift in the absorption spectrum – to enable photoswitching with green or even red light that enable deeper penetration of soft human tissues, a larger band separation between the two photoisomers to enable better photoconversions, and an increased difference in potency between the two photoisomers that would enlarge the therapeutic window.

A library of plinabulin analogues bearing various functional groups on the phenyl ring or heteroaromatic substituents instead of the phenyl ring were synthesized and characterized (see chapter 0, Figure 11).

First, various substituents were introduced in *ortho* position of the phenyl ring. This position was chosen for two reasons: many *ortho*-modifications are not detrimental for plinabulin (**6**) activity¹⁰⁰, and *ortho*-modifications of azobenzenes are known for substantial bathochromic shift combined with high thermal stability. Yet, the absorption spectra of *ortho*-substituted plinabulin derivatives are very similar to the original plinabulin (**6**). In that instance, they resemble much closer hemithioindigo switches.¹²⁷ The absorption maxima in MeCN are presented in Table 1 and differ only by a few nanometers, compared to plinabulin (**6**) and neither of them absorbs green light (> 500 nm). Thus, no substantial bathochromic shift in the absorption spectra was observed.

Table 1: Comparison of the absorption maximum of plinabulin (**6**) with those of derivatives **7-13** bearing functional groups in *ortho* position of the phenyl ring.

Compound							
$\lambda_{\text{abs,max}}$ (MeCN)	362	351	362	358	358	359	366

The bioactivities of the respective photoisomers were – analogous to plinabulin (**6**) – evaluated in cell viability assays against HT-29 cells. For all *ortho* substituted derivatives a similar or lower potency of the *E*-isomers compared to the corresponding *Z*-isomers was assessed. A significant loss in potency of both photoisomers was observed for compounds bearing more bulky substituents (see chapter 5.4.12). It can be assumed that these substituents lead to steric repulsion in the

colchicine binding pocket and prevent efficient binding.¹⁰⁰ *Z*-2,6-Difluoroplinabulin **8**, however, showed an activity similar to that of *Z*-plinabulin ($IC_{50}(Z-8) = 0.27$ nM) and a 1555-fold difference in potency between the two photoisomers, which is considerably higher than for plinabulin (306-fold). As shown in Figure 28, irradiation of the isolated metastable *E*-**8** with cyan light (490 nm) gives a mixture containing 44% of *Z*-**8** and leads to a 107-fold enhanced potency. Unfortunately, a very low band separation between the two photoisomers of **8** results in negligible *E/Z*-isomer ratio differences upon irradiation with different wavelengths (maximal difference between 64% *E*-**8** at 380 nm and 56% *E*-**8** at 490 nm). Hence, efficient therapeutically conceivable photoactivation of *E*-2,6-difluoroplinabulin **8** is possible with cyan light, but practically irreversible.

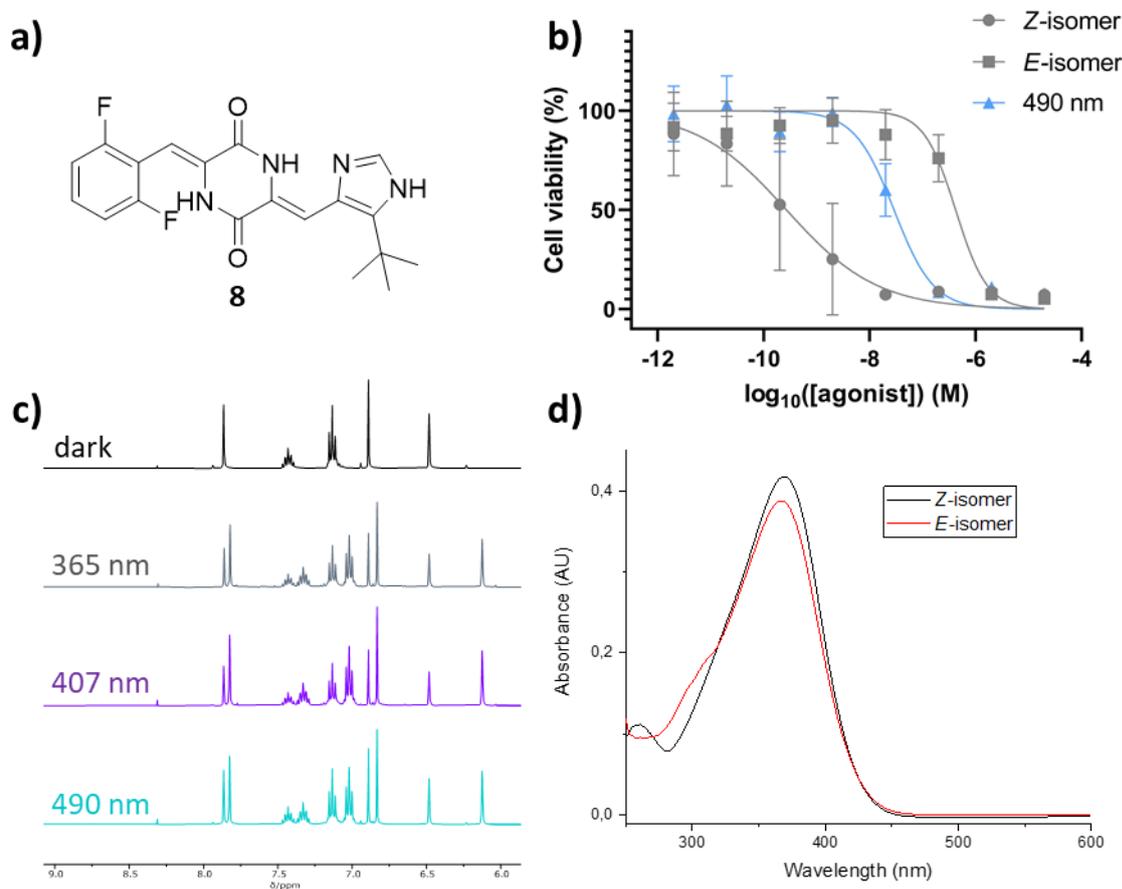

Figure 28: Photomodulation of bioactivity of *Z*-2,6-difluoroplinabulin **8**. a) After synthesis in the dark the thermodynamically more stable *Z*-**8** is obtained, b) Cell viability assays against HT-29 cells showed a 1555-fold higher potency of *Z*-**8** compared to *E*-**8** and a 107-fold enhanced potency after irradiation of *E*-**8** with cyan light (490 nm), c) The compositions of the photostationary states were determined by NMR spectroscopy and revealed a low difference between the applied wavelengths, d) The low band separation between the two photoisomers of **8** becomes apparent when comparing the corresponding absorption spectra.

An alternative substitution pattern was investigated by synthesizing and characterizing *Z*-2,5-difluoroplinabulin **8**. It was found that moving one fluorine substituent from *ortho* to *meta* position

leads to an overall loss in potency ($IC_{50}(Z-9) = 5.47$ nM) and a lower difference between the two photoisomers (13.8-fold). Consequently, even quantitative photoisomerization would not allow for improved photomodulation of bioactivity. In that case, significant reversible photoisomerization has been observed with alternating 407 and 490 nm irradiation with UV-Vis spectroscopy, but the exact composition of the respective photostationary states remains to be determined.

In contrast to its fluorinated analogue, 2,6-dichloroplinabulin **10** can be reversibly photoisomerized with significant differences in the *E/Z*-isomer ratios (62% *E-10* at 365 nm; 13% *E-10* at 490 nm). However, it is significantly less potent overall and a much lower difference in potency (27.5-fold) between the isolated photoisomers was determined.

As mentioned before, for the derivatives **11-13**, bearing more bulky substituents, the potency loss was even more significant ($IC_{50} > 1$ μ M) and therefore they were not considered for further investigations as candidates for optimized plinabulin (**6**) analogues.

Considerable bathochromic shifts of the absorption spectra up to 62 nm were determined when electron-donating amino substituents (compounds **16**, **17** and **18**; Figure 29 and Figure 30) were introduced in *para* position of the phenyl ring. This effect was even more pronounced for the julolidine-bearing derivative **18**. The latter substituent was also embedded into the structure of hemithioindigo photoswitches with similar consequences (see Figure 29 a) and Table 2).^{45,60} In contrast to plinabulin (**6**), all three compounds absorb green light (> 500 nm) and in case of *para*-(*N,N*-dimethylamino)-plinabulin (*p*-NMe₂-plinabulin) **16** irradiation with 523 nm yields 90 % *Z*-isomer. The corresponding NMR and absorbance spectra are shown in Figure 29.

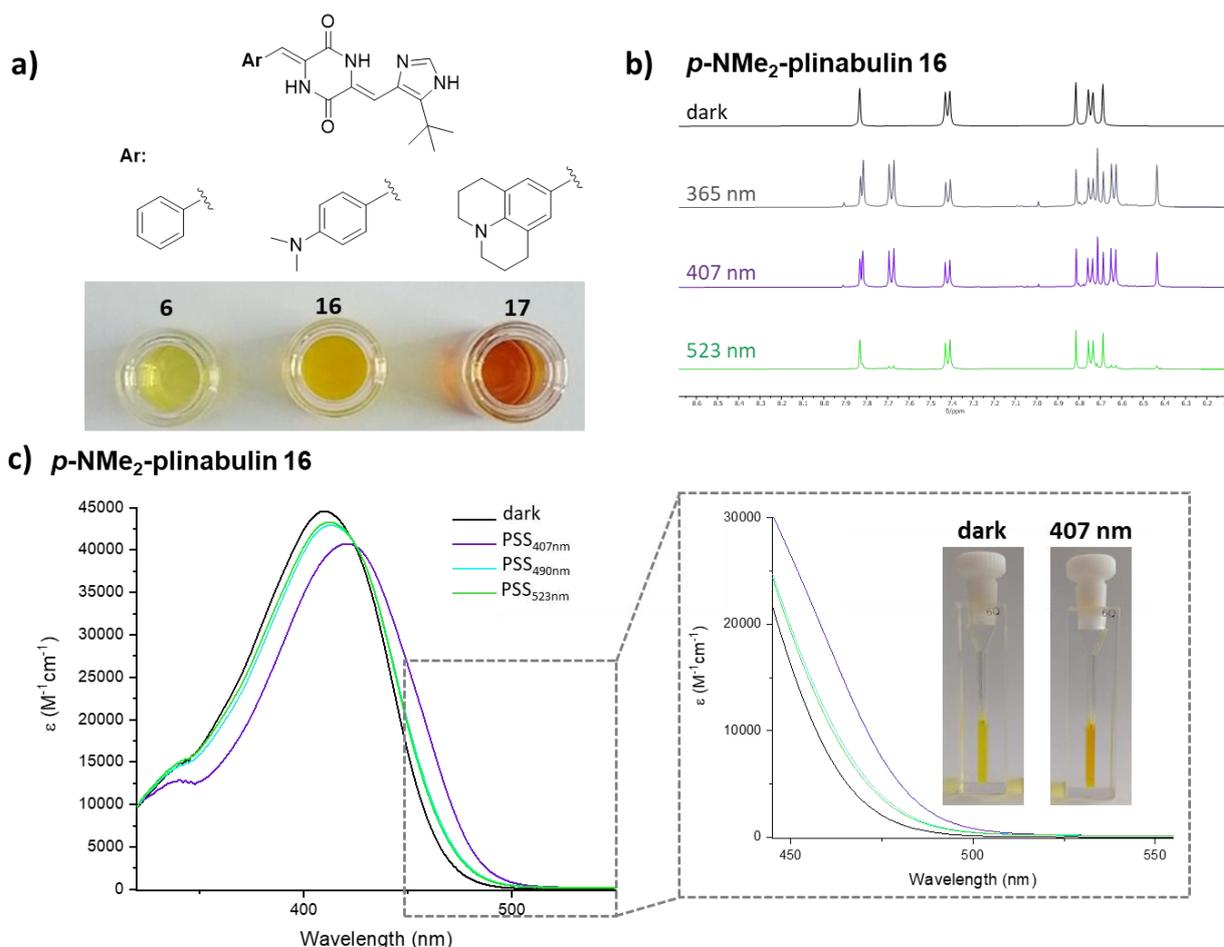

Figure 29: a) Electron-donating substituents in *para* position of plinabulin (**6**) lead to a distinctive bathochromic shift in the absorption spectra in DMSO visible with the bare eye, b) The bathochromic shift in the absorbance of **16** enables efficient photoisomerization with green light (523 nm). Photostationary states were characterized *via* ^1H NMR spectroscopy in $\text{DMSO-}d_6$ (61% *E*-**16** at 365 nm; 55% *E*-**16** at 407 nm; 10% *E*-**16** at 523 nm), c) Absorption spectra of **16** a saturated solution of sodium ascorbate in DMSO (80 μM) reveal an enhanced band separation when compared to plinabulin (**6**). Irradiation of pure *Z*-**16** (dark) with violet light (407 nm) is accompanied by a visible change in color from yellow to orange.

It was furthermore observed that these electron-donating substituents lead to a bigger band separation, which is clearly visible in the absorption spectra as well as the pictures of *p*- NMe_2 -plinabulin **16** in Figure 29 c and explains the efficient *E*-to-*Z*-isomerization with green light. While *p*- NMe_2 -plinabulin **16** proved to be superior to plinabulin (**6**) in the aforementioned photophysical properties it does not meet requirements of an optimized photopharmacological agent due to a significantly shorter thermal half-life of the metastable stable *E*-isomer and – more importantly – an undesired pronounced loss in activity (also observed for compound **17**). The IC_{50} values of *E*-**16** and *E*-**17** were not determined because the limited solubility in aqueous media prevented the application of the necessary, higher concentrations.

The derivatives bearing electron-donating amino substituents also include compound **18**, which comprises a planarized triphenylamine. The dimethylmethylene-bridges lead to an enhanced π -

conjugation and prevent twisting of the phenyl rings around the C–N bonds.¹²⁸ Besides the bathochromic shift, a significantly enhanced fluorescence quantum yield of 23.6% has been observed (Table 2).

Table 2: Electron-donating amino substituents lead to significant bathochromic shifts in absorption and emission spectra of the respective plinabulin (**6**) derivatives. Planarized triarylamine **18** additionally showed a strongly enhanced fluorescence intensity.

Compound	6	16	18	17
$\lambda_{\text{abs,max}}$ (MeCN)	362 nm	400 nm	413 nm	424 nm
$\lambda_{\text{em,max}}$ (MeCN)	512 nm	534 nm	554 nm	-
Φ_{F} (MeCN)	4.5%	2.7%	23.6%	-

Compared to plinabulin (**6**), the solvatochromism of **18** is slightly more pronounced with a maximal difference of 25 nm between the absorbance maxima (for plinabulin (**6**) 16 nm). A solvatochromic effect was additionally found to influence the fluorescence spectra considerably, causing a bathochromic shift in the emission maximum of 77 nm in MeOH when compared to the spectrum measured in tetrahydrofuran (THF) (Figure 30).

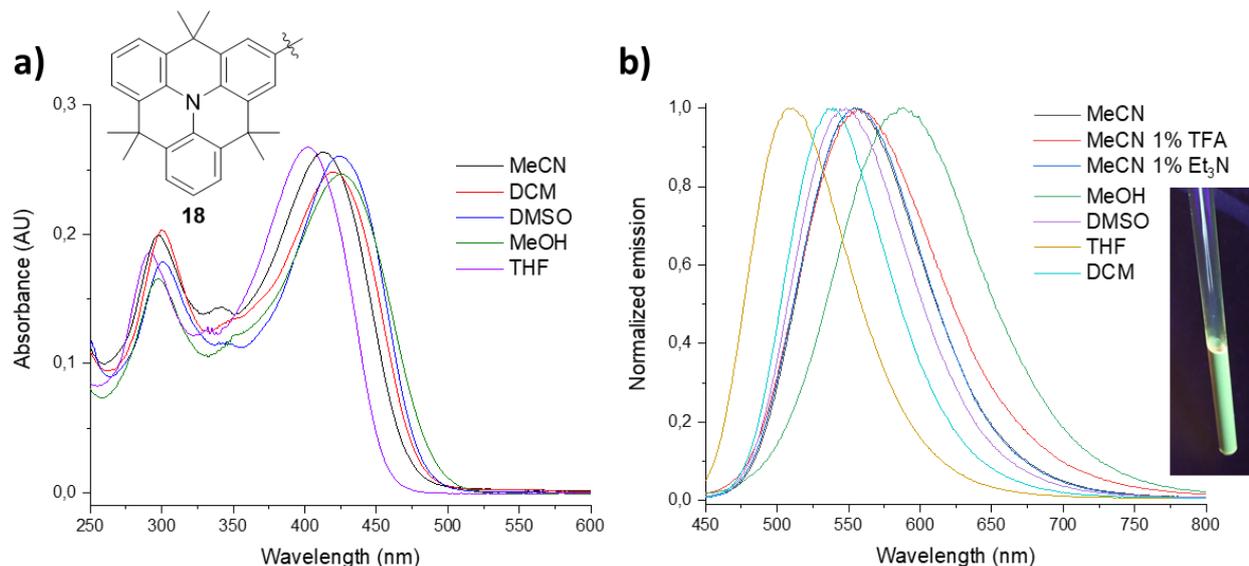

Figure 30: Photochromism of plinabulin derivative **18**. Compound **Z-18** was dissolved in different solvents (80 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et_3N in MeCN, respectively. a) Absorption and b) emission spectra were measured ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

Eventually, two derivatives – 3-methoxyplinabulin **14** and 3,5-dimethoxyplinabulin **15** – with superior pharmacological properties were identified. The potencies of respective *Z*-isomers are similar but those of the *E*-isomers are significantly reduced compared to *E*-plinabulin (*E-6*). Since absorption spectra and band separation are also comparable to those of plinabulin (**6**) reversible

photoswitching is possible within the visible light spectrum. Consequently, the achievable photomodulation of bioactivity is considerably enhanced.

For 3,5-dimethoxyplinabulin **15** an over 2900-fold difference in potency between the two photoisomers was determined (Figure 31). The less active, metastable *E*-**15** was found to be stable in aqueous medium at 37 °C for at least 32 hours without any detectable thermal backisomerization. Photoactivation of cytotoxicity was demonstrated in cell viability assays. Irradiation of the less active *E*-**15** ($IC_{50} = 618$ nm) with cyan light (490 nm) yields an over 1800-fold more potent mixture that contains 89% *Z*-**15**. It was additionally confirmed that irradiation with violet light generates a mixture with over 50% *E*-**15** and an over 100-fold lower potency.

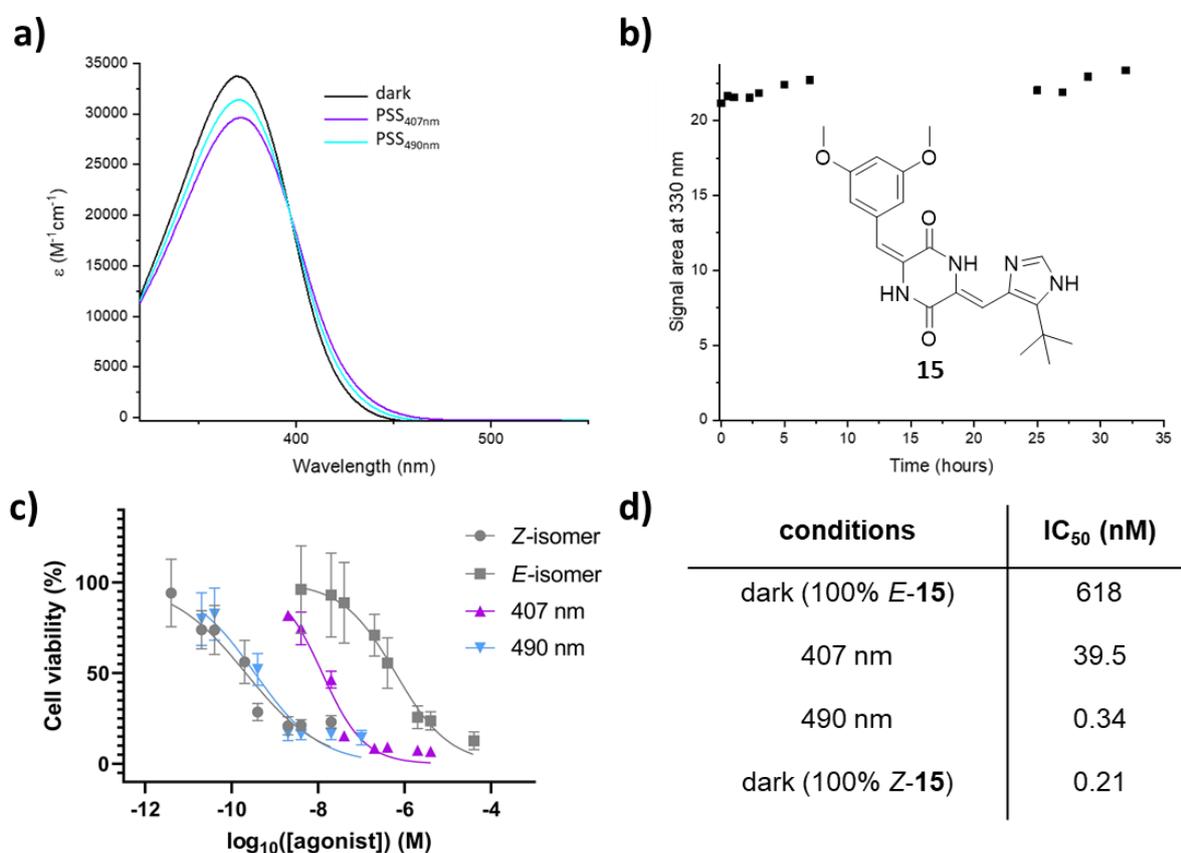

Figure 31: Characterization of 3,5-dimethoxyplinabulin **15** a) Compound **15** was dissolved in a saturated solution of sodium ascorbate in DMSO (80 μ M). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (2 min), then with 490 nm (15 min) and an absorption spectrum was measured after each irradiation step, b) Solutions of compounds *E*-**15** in PBS/DMSO (1:1) with a concentration of 33 μ M were incubated at 37 °C for 32 hours. Samples were taken after certain time intervals and analyzed *via* analytical HPLC at 330 nm, c) Viability of HT-29 cells after treatment with the HPLC-purified *Z*- and *E*-isomers of **15** or with the respective mixtures of the *E*- and *Z*-isomers generated upon equilibration under 490 nm irradiation (cyan light) or 407 nm (violet light) for 48 hours, d) Light-dependent IC_{50} values for **15** were determined *via* viability assays with HT-29 cells after treatment with the respective pure photoisomers or mixtures that resulted from irradiation with the listed wavelengths.

Further studies focused on design strategies towards plinabulin derivatives with bathochromically shifted absorption spectra with sufficient potency for photopharmacological applications. Because electron-donating groups in *para* position on the phenyl ring were found to lead to an almost complete loss in bioactivity, two alternative strategies were investigated: 1) Expanding the π -system, 2) replacing the phenyl ring with five-membered heterocycles. To ensure sufficient bioactivity the investigated compounds were selected from a previously reported library of compounds subjected to structure-activity-relationship studies by Yamazaki *et al.*¹⁰⁰

Three derivatives with an expanded π -system were synthesized and characterized (Figure 32). However, the pursued bathochromic shift in the absorption spectra was not observed. The absorbance maxima of these compounds vary only by 3 nm and all three compounds were not photoisomerizable with wavelengths above 500 nm. A stronger bathochromic shift of 14-36 nm was observed in the corresponding fluorescence spectra shown in Figure 32 (Φ_F of plinabulin (**6**) in DMSO = 521 nm).

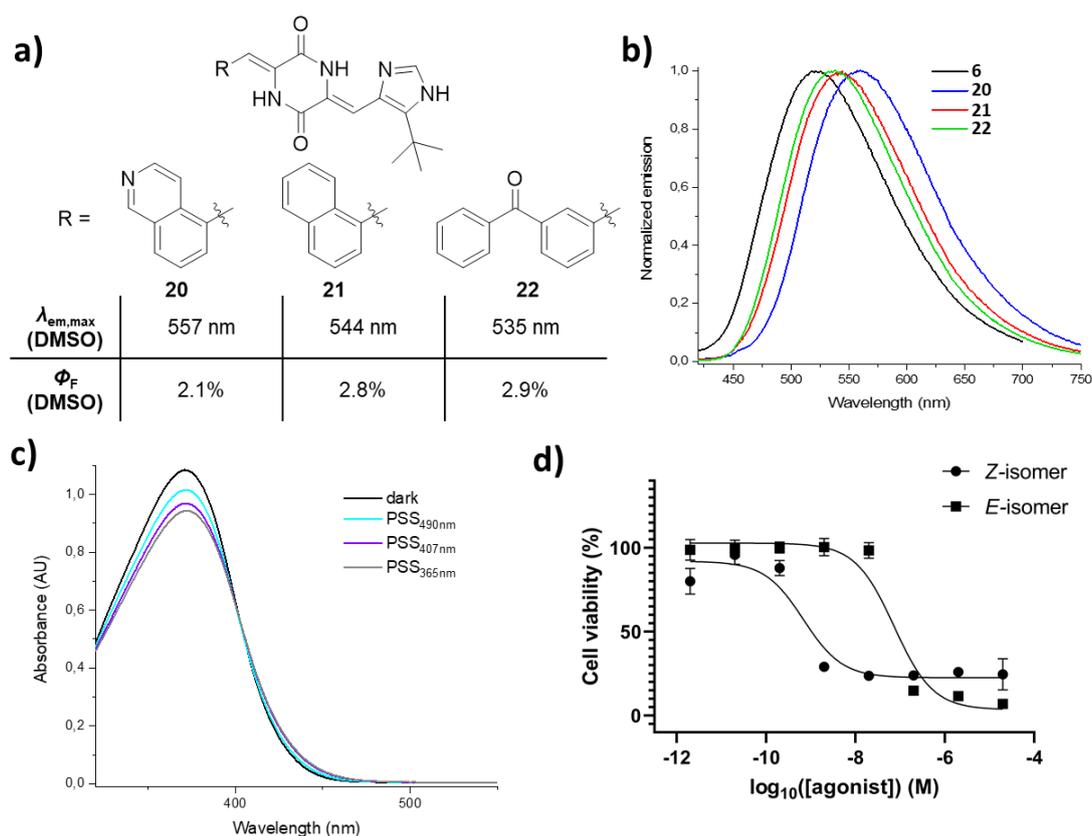

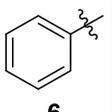

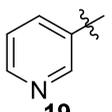

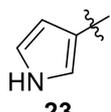

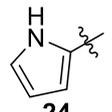

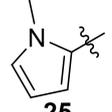

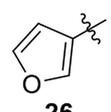

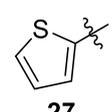

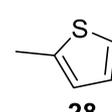

Figure 32: Characterization of plinabulin derivatives **20-22** with an expanded π -system. a), b) The emission maxima of the investigated compounds are shifted bathochromically compared to that of plinabulin (**6**) (Φ_F (DMSO) = 521 nm) with a slightly lower fluorescence quantum yield, c) Compound **22** was dissolved in a saturated solution of sodium ascorbate in DMSO (80 μ M). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (2 min), then with 490 nm (15 min) and an absorption spectrum was measured after each irradiation step, d) Viability of HT-29 cells after treatment with the HPLC-purified *Z*- and *E*-isomers of compound **22** for 48 hours.

When evaluating the cytotoxicity of both respective compounds *via* cell viability assays against HT-29 cells the best results were obtained for the benzophenone derivative **22**. In accordance with the literature, it was found to be highly potent in the *Z*-configuration ($IC_{50} = 0.68$ nM) and a 108-fold difference in cytotoxicity between the two photoisomers was determined.

Following the second design strategy towards bathochromically shifted plinabulin derivatives, seven heterocyclic plinabulin derivatives were synthesized and investigated regarding their photophysical behavior. For five derivatives, bathochromically shifted absorbance maxima were determined with a maximal shift of 28 nm. However, the bathochromic shifts were lower than that of *p*-NMe₂-plinabulin **16** ($\lambda_{\text{abs,max}}$ (DMSO) = 410 nm) and none of these plinabulin analogues were photoswitchable with light above 500 nm (Table 3).

Table 3: Comparison of the absorption maximum of plinabulin (**6**) with those of analogues bearing a five-membered heterocyclic substituent.

compound								
$\lambda_{\text{abs,max}}$ (DMSO)	371 nm	369 nm	374 nm	398 nm	399 nm	368 nm	387 nm	387 nm

When then phenyl ring in plinabulin (**6**) was replaced by 2-pyrrole or 2-thiophene substituents the most pronounced bathochromic shifts were determined. Additionally, the absorption spectra showed a larger band separation between the two respective photoisomers with the most pronounced separation for *N*-methyl-2-pyrrole-plinabulin **25** (Figure 33 a). This was found to enable almost quantitative *E*-to-*Z*-isomerization upon irradiation with cyan light (490 nm).

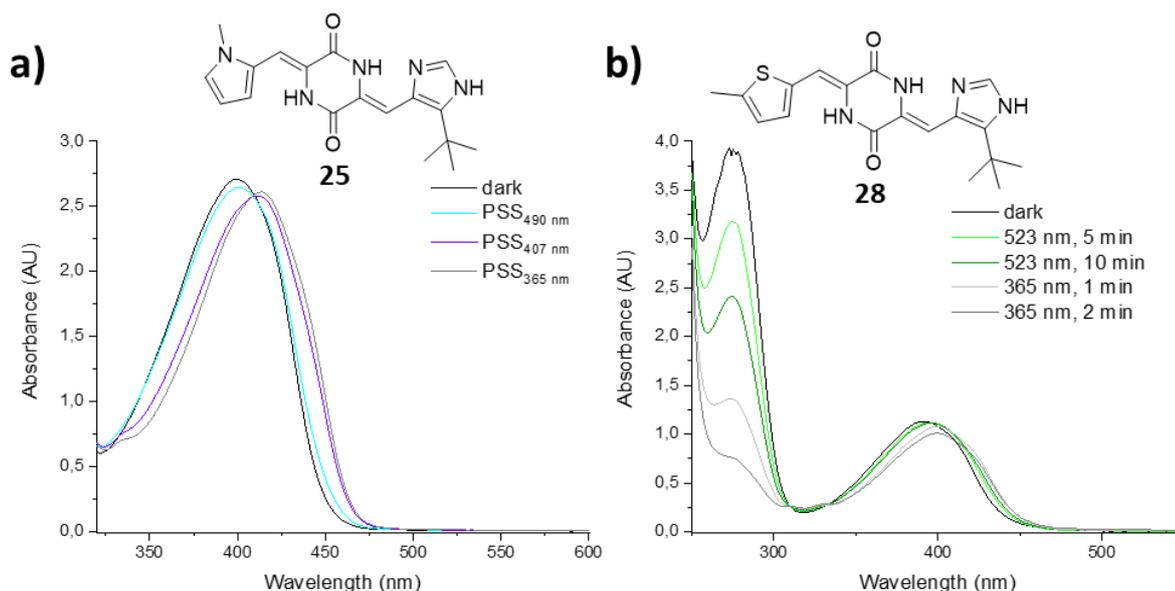

Figure 33: Absorption spectra of two plinabulin derivatives that contain a second five-membered heterocycle. a) *N*-Methyl-2-pyrrole-HPI **25** was dissolved in a saturated solution of sodium ascorbate in DMSO (81 μ M) and purged with argon. An absorption spectrum ($d = 10$ mm) was first measured in the dark. The sample was then irradiated with 490 nm (15 min), 407 nm (2 min) and 365 nm (2 min) in succession and an absorption spectrum was measured after each irradiation step, b) 5-Methyl-2-thiophene-HPI **28** was dissolved in a saturated solution of sodium ascorbate in DMSO (160 μ M). An absorption spectrum ($d = 10$ mm) was first measured in the dark. The sample was then first irradiated with 523 nm, then with 365 nm and an absorption spectrum was measured after each irradiation step. To demonstrate the photoinduced consumption of sodium ascorbate the spectra were not blanked to the solution of ascorbate.

However, an acceleration of the consumption of the added ROS quencher sodium ascorbate was observed when performing light-dependent absorption spectroscopy. This is clearly visible in the spectra of 5-methyl-2-thiophen **28** shown in the right panel in Figure 33. To demonstrate the continuous decrease of the absorption band of sodium ascorbate these spectra were not blanked to the solution of ascorbate. To obtain satisfactory spectra it was necessary to additionally purge the samples with argon before starting irradiation. It was concluded that the second heterocycle leads to an enhanced formation of singlet oxygen which is presumed to be the cause for photodegradation of plinabulin derivatives. Consequently, plinabulin derivatives bearing a second heterocycle were not considered for further investigations as candidates for optimized plinabulin analogues. Future studies should be started with investigations of the formation of singlet oxygen *via* colorimetric singlet oxygen detection assays, by monitoring the bicyclic ozonide formation from 2,5-diphenylfuran.^{129,130}

After having investigated the whole library of compounds it was found that the thermal half-life, the composition of the photostationary states and the absorption spectra can be tuned by installing different substituents on the phenyl ring of plinabulin (**6**). 3,5-Dimethoxyplinabulin **15** was identified as a derivative with optimized photopharmacological characteristics allowing for efficient photomodulation of bioactivity.

3.2 Hemipiperazines: Model Compounds

3-Arylidene-2,5-diketopiperazines – abbreviated as hemipiperazines (HPIs) – are novel photoswitchable motifs first identified within the microtubule targeting compound plinabulin (**6**). To characterize this molecular photoswitch, the core photochromic fragment of plinabulin (**6**), which contains only one double bond and no heterocycle, was chosen to serve as a model system. A panel of derivatives were synthesized and characterized systematically to investigate the influence of electron-withdrawing and -donating groups on their photophysical properties.

3.2.1 Synthesis

A series of carbocyclic benzaldehyde derivatives were coupled with acetylated DKP **2** in aldol condensation reactions under basic conditions (Figure 34), also applied for the synthesis of the plinabulin derivatives discussed in the previous chapter. Usually, mild conditions were preferred and the reaction was performed with Cs_2CO_3 in DMF at room temperature. For the synthesis of compounds **36** and **38**, where electron-rich aldehydes are used, Cs_2CO_3 was replaced by the stronger base KO^tBu in THF. In case of compound **38**, a Boc-protected aldehyde was subjected to the reaction and the protecting group was removed in a subsequent, additional reaction step (see chapter 5.5.1).

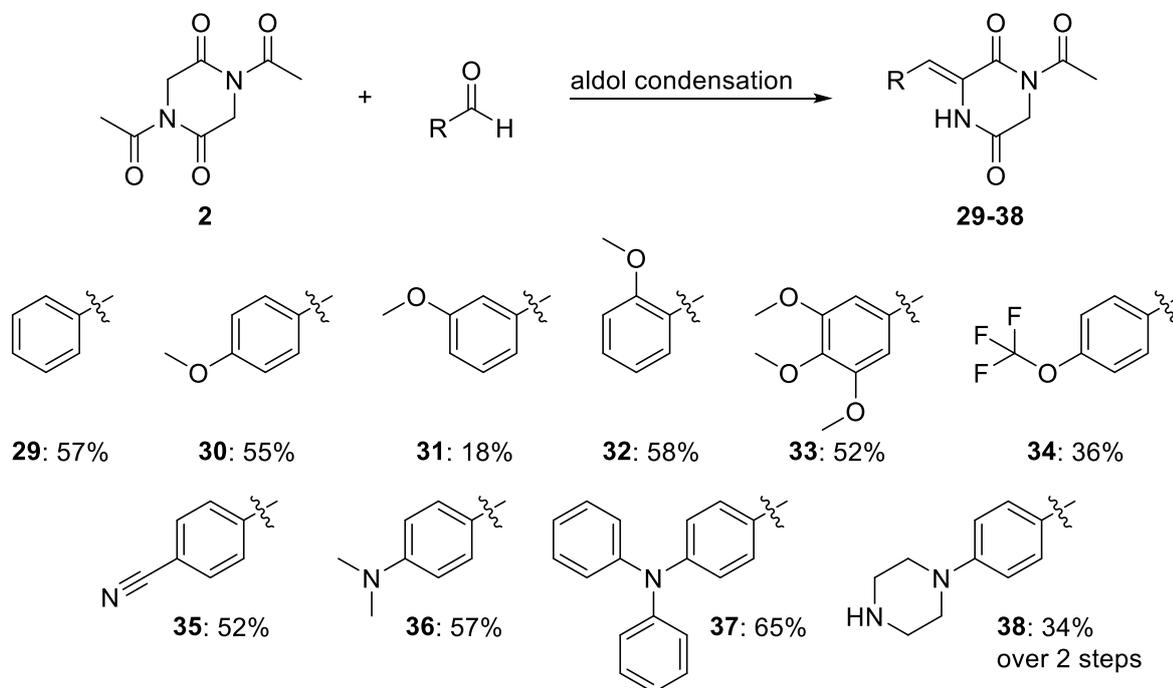

Figure 34: A library of HPIs was synthesized by coupling carbocyclic aldehydes with acetylated DKP **2** in a base aldol condensation reaction under basic conditions.

All compounds were isolated in the respective thermodynamically more stable *Z*-configuration, which was verified *via* NMR spectroscopy and for five derivatives additionally in single-crystal X-ray diffraction studies (Figure 35).

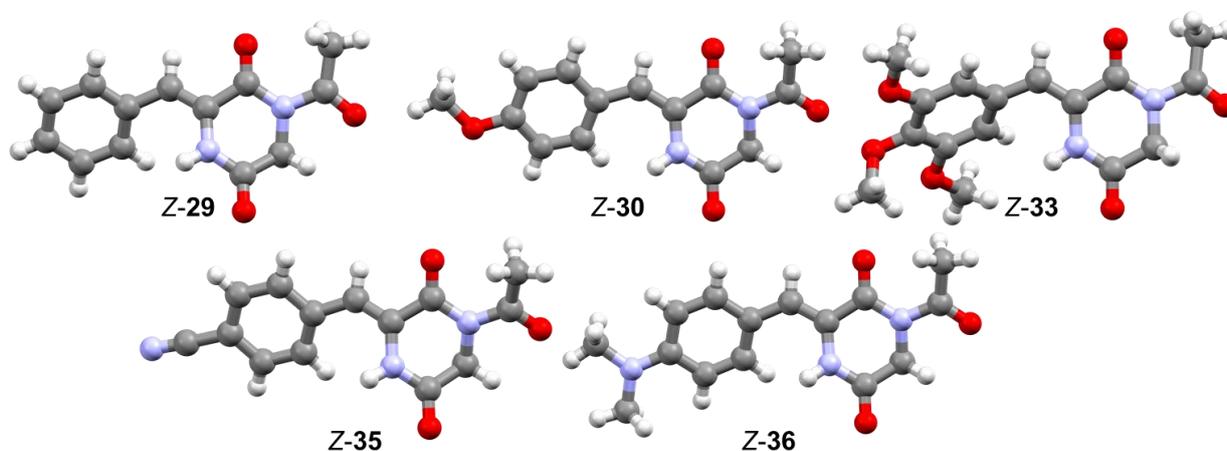

Figure 35: Single crystals of *Z*-**29**, *Z*-**30**, *Z*-**33**, *Z*-**35**, and *Z*-**36** were analyzed in single-crystal X-ray diffraction studies. The results were visualized with Mercury 2020.1 (CCDC). Additional atoms in the results of *Z*-**35** (H₂O) and *Z*-**29** (three additional crystallographic independent molecules, also in *Z*-configuration) were removed in this visual presentation. Atoms of carbon are depicted in grey, hydrogen in white, oxygen in red and nitrogen in blue.

3.2.2 Photophysical Properties

First, the absorption spectra of the respective *Z*-isomers in DMSO were compared. In general, most of the absorption spectra are shifted hypsochromically compared to those of the previously discussed plinabulin derivatives, which might be explained by a smaller expansion of the π -system due to the missing conjugation with the imidazole substituent. It was found that both, electron-withdrawing and electron-donating substituents in *para* position, cause a bathochromic shift relative to unsubstituted HPI **29** in the respective absorption spectra. The conjugated *ortho*-methoxy substituent (compound **32**, see resonance structures in Figure 36 b) also leads to a significantly bathochromically shifted absorbance maximum while the non-conjugated *meta*-substituted **31** only showed a slight bathochromic shift (Figure 36).

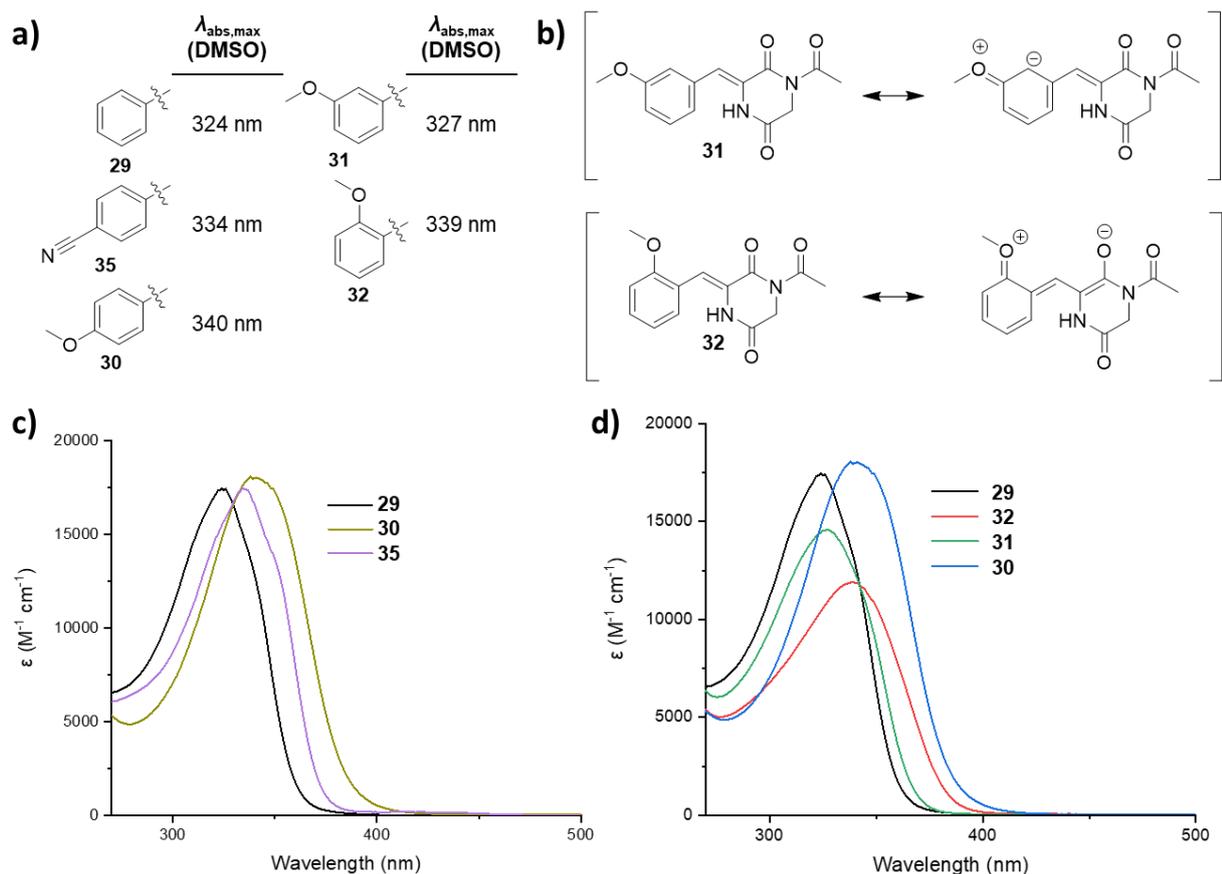

Figure 36: Installation of electron-withdrawing (compound **35**) and electron-donating (compounds **30-32**) substituents on the phenyl ring of carbocyclic aromatic HPI photoswitches causes a bathochromic shift in the absorbance spectra relative to unsubstituted HPI **29**. The respective *Z*-isomers were dissolved in DMSO (80 – 160 μM) and absorption spectra were measured in the dark. a) Absorbance maxima of compounds **29-32** and **35** on DMSO, b) A comparison of the resonance structures of HPIs **31** and **32** demonstrates that *ortho*-substituted **32** is additionally mesomerically stabilized, c) When comparing the same substitution pattern, the bathochromic shift of the absorbance maximum is generally more pronounced for electron-donating substituents (HPI **30**) than electron-withdrawing substituents (HPI **35**), d) Comparison of the absorbance spectra in different substitution patterns of methoxy-substituted HPIs. The bathochromic shift is very low for non-conjugated *meta*-substituted **31** and most pronounced conjugated *para*-methoxy substituted **32**.

All the synthesized HPIs showed reversible photochromic behavior and for three compounds (**29**, **30** and **36**) the respective photoisomers were separated *via* flash column chromatography. Sections of the corresponding NOESY NMR spectra of **30** and **36** are shown in Figure 37 and important signals are assigned to the respective protons *via* color code. Analogous to the observations made for plinabulin derivatives, after *Z*-to-*E*-isomerization, the signals assigned to interactions of the NH proton with aromatic protons (highlighted in green) are replaced by signals that indicate close proximity of the NH proton to the vinylic proton. These results support again the light-triggered formation of the respective *E*-isomers.

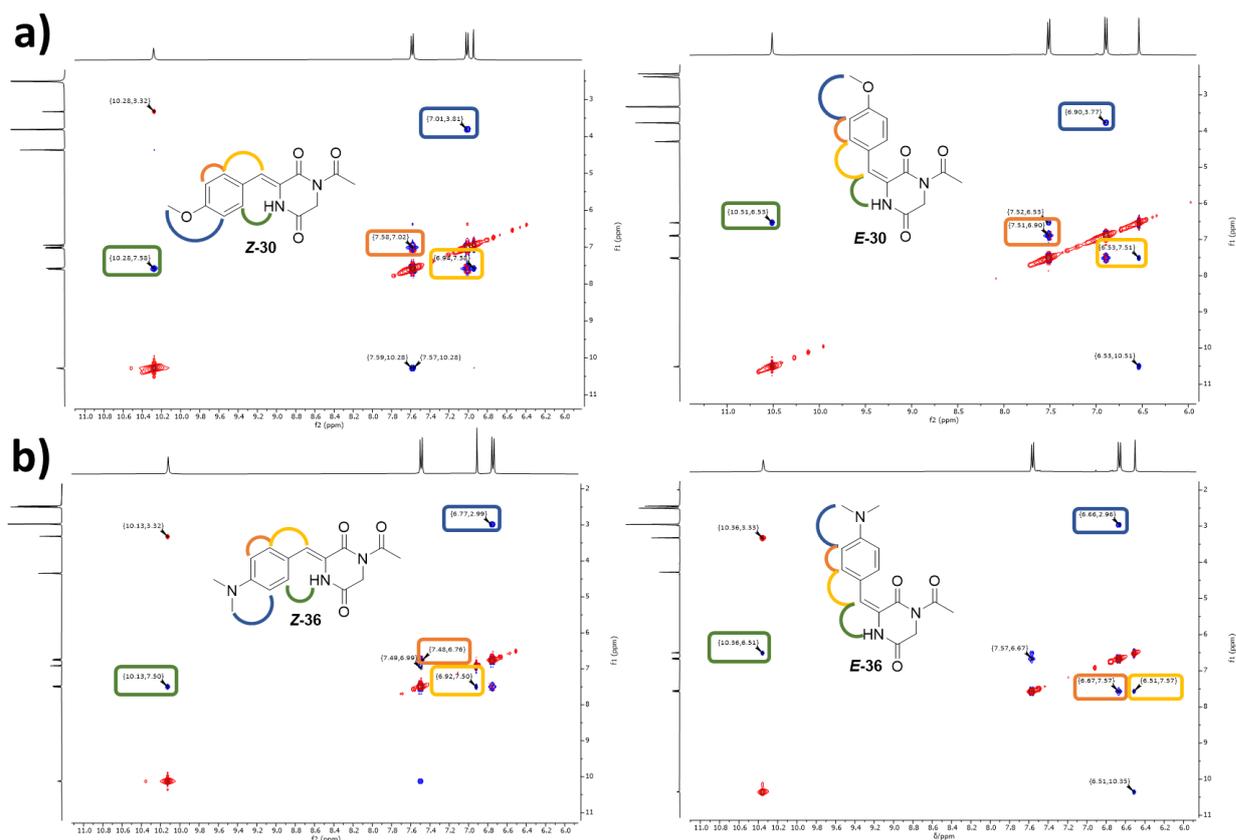

Figure 37: Sections of NOESY NMR spectra in DMSO- d_6 of the two respective photoisomers of a) **30** and b) **36**. Selected signals are assigned to the respective protons *via* color code.

All compounds were found to be photoswitchable and reversible photoisomerization without significant fatigue upon ten isomerization cycles was demonstrated (see e.g. Figure 38 and chapter 5.5.9). However, the photochromism of unsubstituted HPI **29** and the electron-poor cyano-substituted HPI **35** was low and irradiation with UV-light (365 nm) produced only 12% of *E*-**29** (in CD_2Cl_2) and 19% of *E*-**35** (in DMSO- d_6), respectively (Figure 38). However, it has to be noted that the absorbance maxima of these compounds could not be addressed with the available light-emitting diodes (LEDs) used for photoisomerization. Conceivably, irradiation with wavelengths in the range of 320 nm could result in the formation of higher amounts of the respective *Z*-isomers.

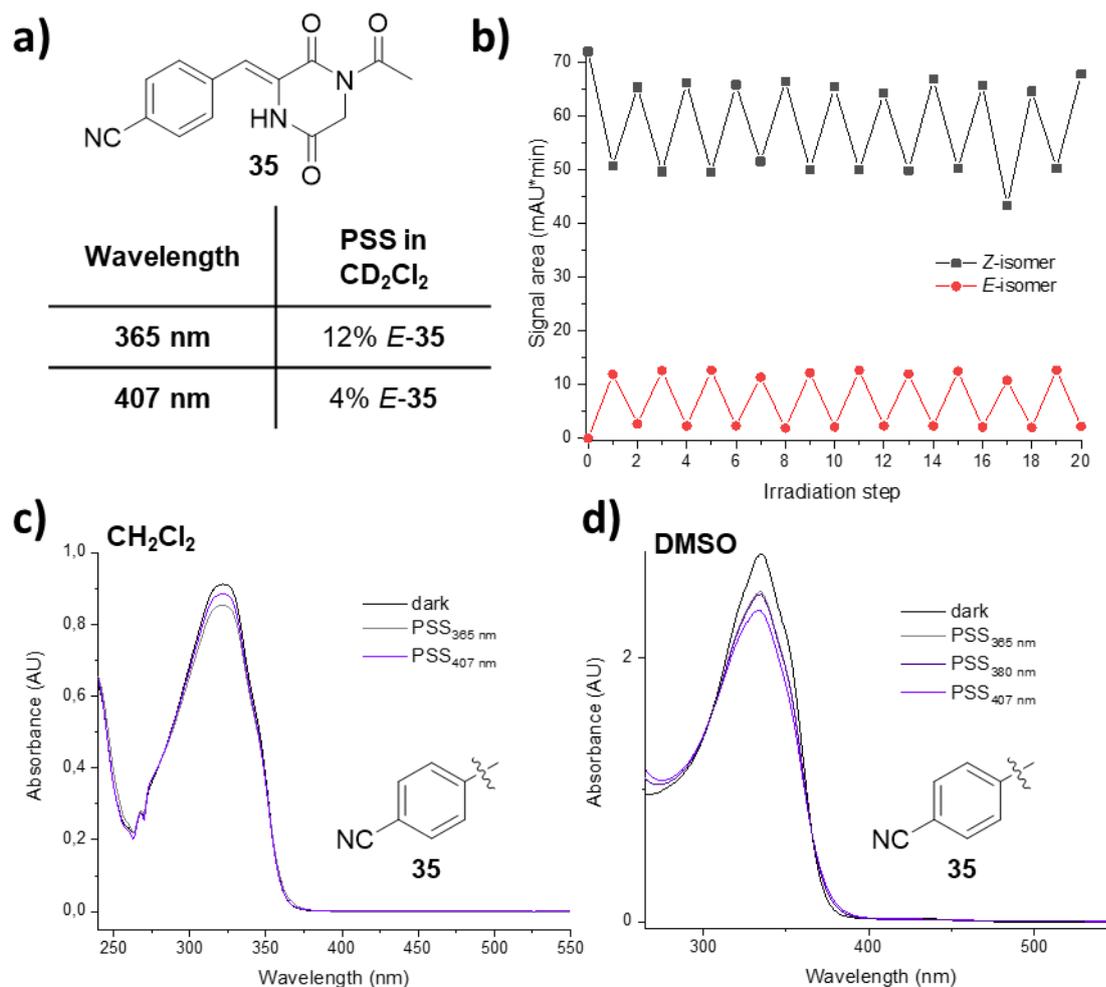

Figure 38: Reversible photoisomerization of electron-poor HPI **35**. a) PSS composition in CD₂Cl₂ determined by measuring ¹H NMR spectra of the respective compounds after irradiation. b) A solution of pure *Z*-**35** in DMSO (1.0 mM) was alternately irradiated with 365 nm for 4 min and with 430 nm for 45 min. After every irradiation step the solution was analyzed *via* analytical HPLC. c),d) Compound **35** was dissolved in CH₂Cl₂ (80 μM, c)) and DMSO (160 μM, d)), respectively. Absorption spectra (d = 10 mm) were first measured in the dark. The samples were then irradiated with 365 nm, 380 nm and 407 nm. An absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

Photoisomerization of *para*-methoxy substituted HPI **30** was investigated *via* absorption spectroscopy in CH₂Cl₂ and the compositions of the PSSs were determined *via* ¹H NMR spectroscopy in CD₂Cl₂ (Figure 39). Irradiation of this derivative with UV-light (365 nm) gave 29% of the corresponding *E*-isomer and irradiation with indigo light (430 nm) enabled quantitative backisomerization (<1% *E*-isomer). An interesting observation has been made when performing these measurements in DMSO. Here, a new isosbestic point at 410 nm occurred and the extinction coefficient of *Z*-**30** was found to be higher than that of *E*-**30** at wavelengths above this point. Whereas irradiation with light above 400 nm induced *E*-to-*Z*-isomerization in CH₂Cl₂, the reversed process was triggered when the compound was irradiated in DMSO. The progressing *Z*-to-*E*-

isomerization upon irradiation with blue light (470 nm) was followed by absorption spectroscopy (Figure 39). The photoisomerization process was relatively slow – presumably because of the low extinction coefficient at this wavelength – and the PSS was reached after one hour irradiation time.

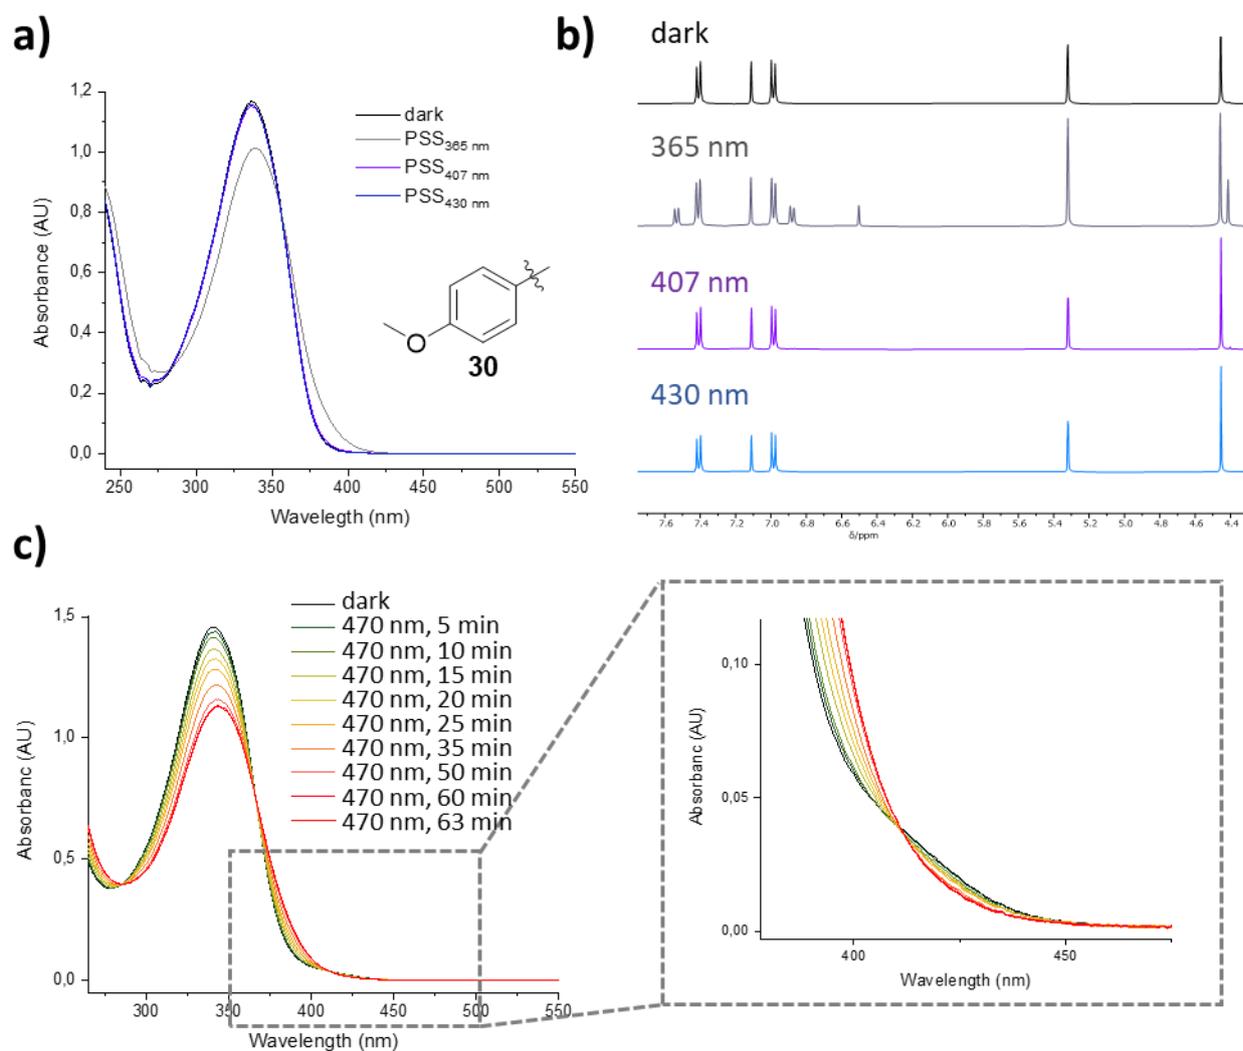

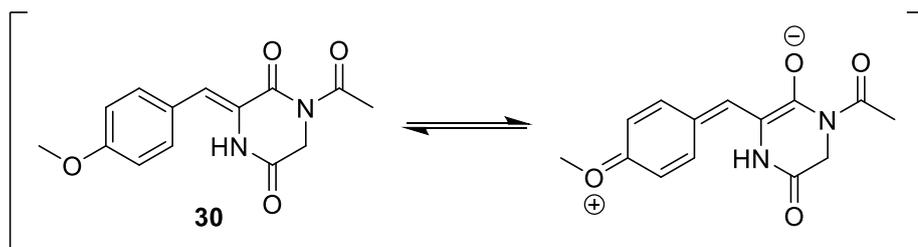

Figure 39: Photophysical properties of *para*-methoxy substituted HPI **30**. a) Compound **30** was dissolved in CH_2Cl_2 (80 μM) and an absorption spectrum ($d = 10$ mm) was measured. The sample was then irradiated with 365 nm, 407 nm and 430 nm and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively, b) Sections of ^1H NMR spectra of compound **30** in CD_2Cl_2 in the dark (top) and after reaching the PSS upon irradiation with 365 nm, 407 nm and 430 nm. The spectra are assigned to the corresponding irradiation wavelength *via* color code, c) Compound **30** was dissolved DMSO (80 μM) and an absorption spectrum ($d = 10$ mm) was first measured in the dark. The sample was then irradiated with 470 nm and photoisomerization over time was followed *via* absorption spectroscopy.

Unexpectedly, the shoulder in the absorption spectrum did not recover upon back-isomerization with shorter wavelengths and the isosbestic point at 410 nm was not retained. In consequence, a repetition of the switching cycle was not possible. With lower wavelengths however, photoisomerization was found to be repeatable over ten cycles and no photodegradation was

observed. The origin of this phenomenon has not yet been identified. DMSO and CH_2Cl_2 are both non-protic solvents that differ significantly in their respective dielectric constant (ϵ_r) ($\epsilon_r(\text{DMSO}) = 47$ versus $\epsilon_r(\text{CH}_2\text{Cl}_2) = 9.1^{131}$). It is conceivable that in DMSO a tautomer of *Z*-**30** with a higher dipole moment or even charge separation is stabilized (Scheme 3). Excitation with light might diminish this tautomer, which is not recovered within the timescale of subsequent backisomerization. However, further investigations are needed before reliable explanations for this phenomenon can be found.

Scheme 3: A possible explanation for the solvent-dependent shoulder observed in the absorbance spectrum of **30** is the stabilization of a zwitterionic tautomer of HPI **30** in DMSO.

The highest bathochromic shifts in combination with high PSSs were achieved by introducing the strongly electron-donating dimethylamino (NMe_2) group in *para*-position on the phenyl ring (compound **36**, Figure 40). HPI **36** can be efficiently photoisomerized in DMSO within the range of 365-523 nm with PSSs up to 71% of *E*-**36** with UV light (365 nm), and as much as 97% *Z*-**36** with green light (523 nm). The results of ten subsequent switching cycles suggest that the presence of the NMe_2 group enables or promotes photodegradation, which was not observed for the unsubstituted compound (Figure 40). When dissolved in CH_2Cl_2 , both *para*-amino-substituted HPIs **36** and **37** were found to be less photostable and degradation was observed upon irradiation with wavelengths below 450 nm (see chapter 5.5.4). However, an enhanced solubility in aqueous media – more of relevance for potential photopharmacological applications – allowed for reversible photoisomerization in phosphate-buffered saline (PBS, pH 7.4) doped with 25% DMSO without any detectable degradation (Figure 40).

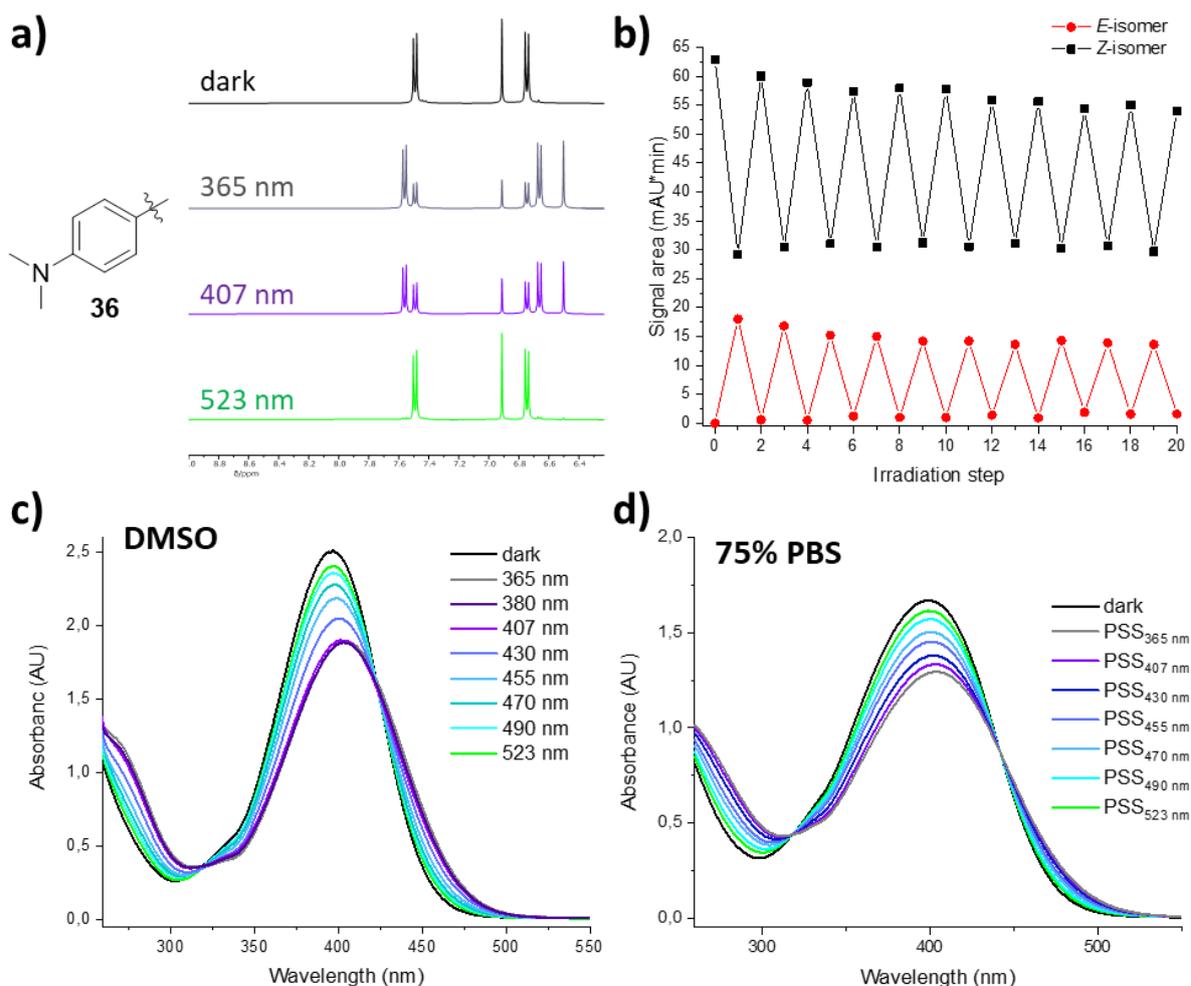

Figure 40: Reversible photoisomerization of electron-rich *p*-NMe₂ HPI **36** in different media. a) Sections of ¹H NMR spectra (DMSO-*d*₆) of compound **36** in the dark (top) and after reaching the PSS upon irradiation with 365 nm, 407 nm and 523 nm. The spectra are assigned to the corresponding irradiation wavelength *via* color code, b) A solution of pure *Z*-**36** in DMSO (1.0 mM) was alternately irradiated with 407 nm for 4 min and with 523 nm for 10 min and after every irradiation step the solution was analyzed *via* analytical HPLC, c) Compound **36** was dissolved in DMSO (80 μM), as well as d) 75% PBS in DMSO (v/v) (80 μM), respectively. Absorption spectra (d = 10 mm) were first measured of the dark-state, then the samples were irradiated with 365 nm, 380 nm, 407 nm, 430 nm, 455 nm, 470 nm, 490 nm and with 523 nm. An absorption spectrum was measured after each irradiation step until the PSS at the respective wavelength was reached.

A second electron-rich HPI, the *para*-bisphenylamino (*p*-NPh₂)-substituted HPI **37**, was found to have very similar characteristics as HPI **36** in absorbance (Figure 41) as well as the compositions of the photostationary states (see also chapters 5.5.4 and 5.5.6). However, a bathochromic shift of 49 nm and significantly enhanced intensity was determined when comparing the fluorescence spectra of both compounds. A change from green fluorescence (HPI **36**: $\lambda_{em,max}(DMSO) = 516$ nm) with very low intensity (HPI **36**: $\Phi_F(DMSO): 0.004$) to a much brighter yellow fluorescence (HPI **37**: $\lambda_{em,max}(DMSO) = 565$ nm, $\Phi_F(DMSO): 0.030$) was observed (Figure 41).

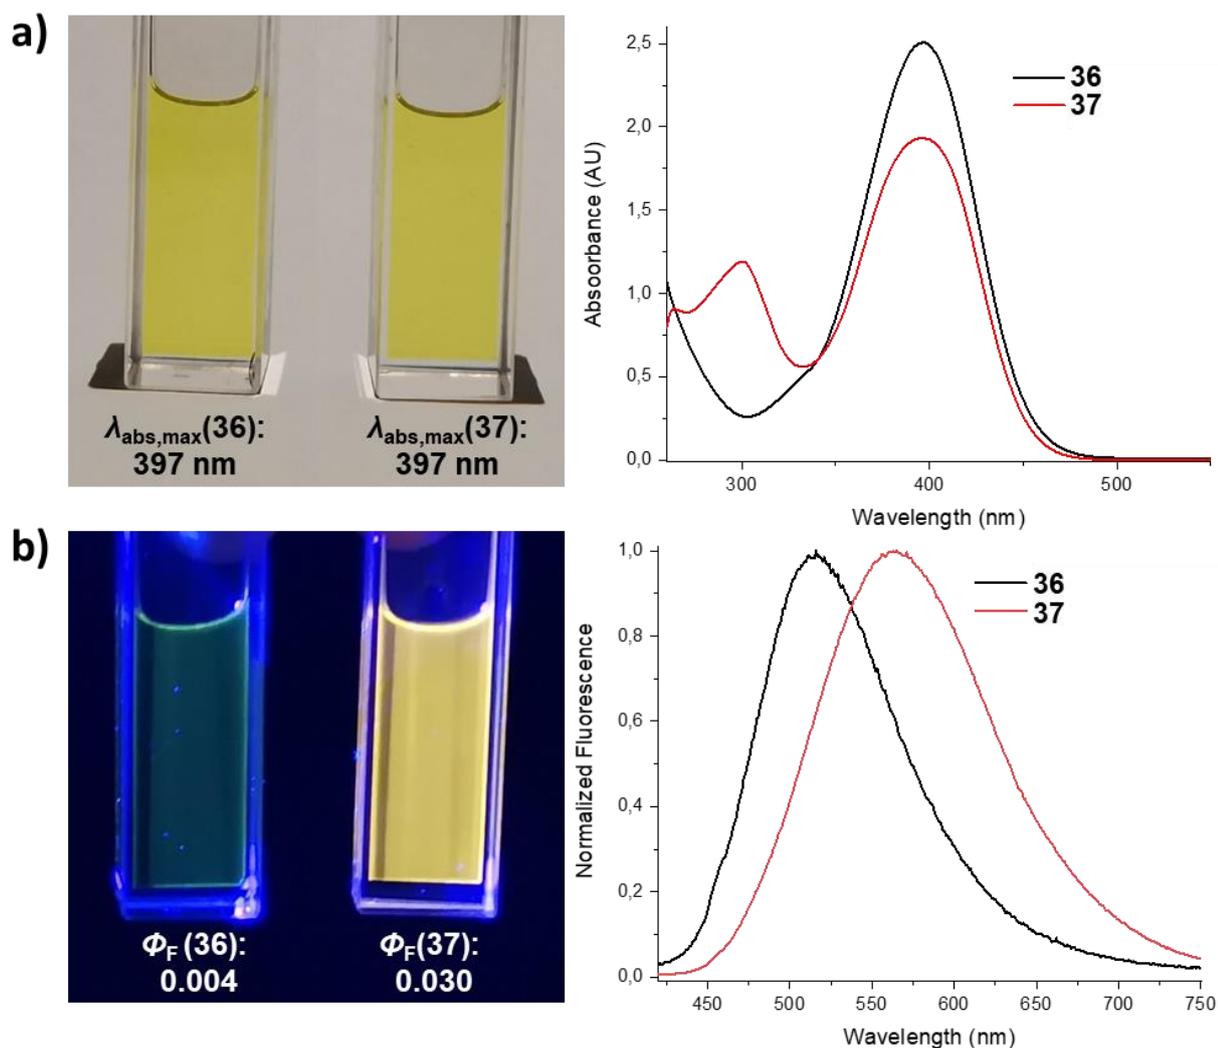

Figure 41: Comparison of the photophysical properties of the electron-rich HPIs **36** and **37**. a) The absorption spectra of both compounds in DMSO (80 μM , $d = 10 \text{ mm}$) reveal a very similar absorption maximum at 397 nm. B) The fluorescence of *para*-diphenylamino-substituted HPI **37**, however, is bathochromically shifted compared to HPI **36** and a significantly increased fluorescence quantum yield was determined.

For *p*-NPh₂-substituted HPI **37** the photoisomerization quantum yields were determined using a setup developed by the group of Riedle (details in chapter 5.5.7).¹³² The quantum yields were found to be comparable to those determined for hemithioindigo photoswitches¹³³ with values of $\Phi_{(Z \rightarrow E)} = 16 \pm 1 \%$ (398 nm) and $\Phi_{(E \rightarrow Z)} = 15 \pm 1 \%$ (520 nm). As the values were found to be in the same range for both directions of photoisomerization, it can be concluded that the different compositions of the photostationary states correspond to the differences in the extinction coefficients of both photoisomers.

The thermal stability of the *E*-isomers of all the investigated HPIs was found to be very high, analogous to the plinabulin derivatives discussed in the previous chapter. The thermal *E*-to-*Z*-isomerization was monitored *via* analytical HPLC and even at an elevated temperature of 60 °C in

MeCN only 0.8% to 12% of the respective *E*-isomers had been thermally relaxed to the corresponding *Z*-configuration within one week (Figure 42).

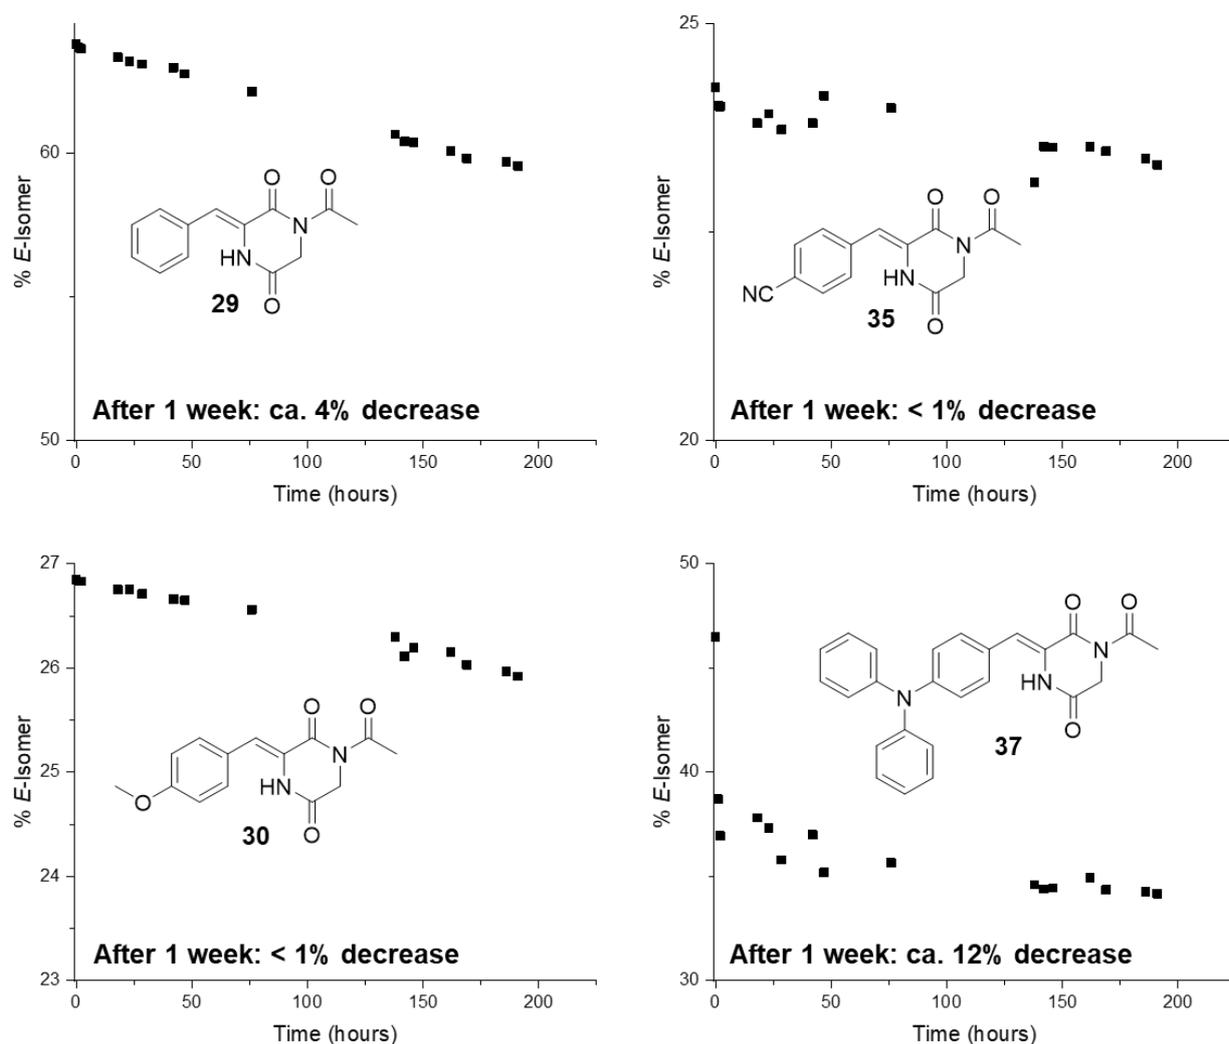

Figure 42: Thermal relaxation of the *E*-isomers of HPIs **29**, **30**, **35** and **37** in MeCN at 60 °C was monitored *via* analytical HPLC. The percentage of *E*-isomer was determined with the integrals of the signals assigned to the respective isomer.

One additional HPI bearing a piperazine ring in *para* position (compound **38**) was synthesized to further optimize HPI photoswitches for biomedical applications, by enhancing solubility in aqueous media while maintaining a significant bathochromic shift, compared to the unsubstituted HPI **29**. The characterization of this compound was not completed yet. However, a qualitative comparison of the absorbance spectra of *para*-piperazine-HPI **38** and *p*-NMe₂-HPI **36** obtained *via* analytical HPLC measurements indicates that the absorbance of **38** compound is in a similar range as those of the other two electron-rich *para*-amino derivatives (Figure 43). It was furthermore observed that after purification *via* preparative HPLC the compound was obtained as the corresponding TFA salt (pK_a of piperazine in MeCN = 18.69)¹³⁴ and neutralization of this compound by washing with a saturated aqueous solution of sodium bicarbonate gave the neutral

compound and led to a color change from yellow to orange. Consequently, it can be presumed that the spectrum obtained from analytical HPLC corresponds to a protonated species and neutralization might lead to a more pronounced bathochromic shift in the absorption spectrum.

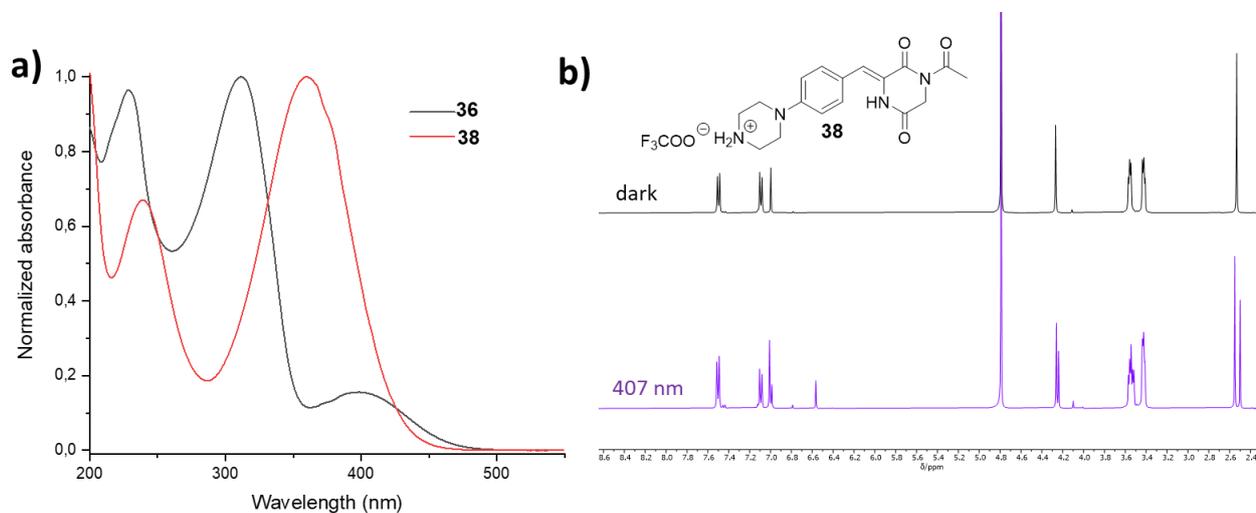

Figure 43: Results of first investigations of the photophysical properties of the water-soluble HPI **38**. a) Qualitative comparison of the normalized absorption spectra of *p*-NMe₂-substituted HPI **36** and *para*-piperazine-substituted HPI **38**. The spectra were obtained from the analytical HPLC and consequently measured in different mixtures of MeCN and H₂O containing 1% TFA (v/v), b) Sections of ¹H NMR spectra (400 MHz, D₂O) of compound **38** in the dark (top) and after irradiation 407 nm for 15 min (bottom).

The piperazine-HPI **38** was found to be soluble in water and was characterized *via* NMR spectroscopy in D₂O. In first investigations it was furthermore demonstrated that this derivative can be photoisomerized in D₂O with violet light (407 nm) (Figure 34). These first results indicate that compound **38** is a promising candidate for *in vivo* switching and further investigations of its photomodulation in aqueous media will be done in the future.

3.2.3 Theoretical Calculations

To investigate HPI photoswitches further, theoretical calculations for HPIS **29-38** have been performed by employing the B3LYP-GD3BJ/6-311G(d,p) PCM(DMSO) level of theory, which previously proved to be suitable for modelling of hemithioindigo photoswitches.¹³⁵ First, theoretical calculations have been conducted to obtain structures and orbital energies for both respective photoisomers in the ground state. The resulting electron distribution of the highest occupied molecular orbitals (HOMOs) and lowest unoccupied molecular orbitals (LUMOs) for compounds Z-**29**, Z-**35** and Z-**36** are shown in Figure 44. The shapes of the calculated HOMOs and LUMOs are similar, but slight shifts that correspond with the electron-donating or -withdrawing properties of the substituents are observed.

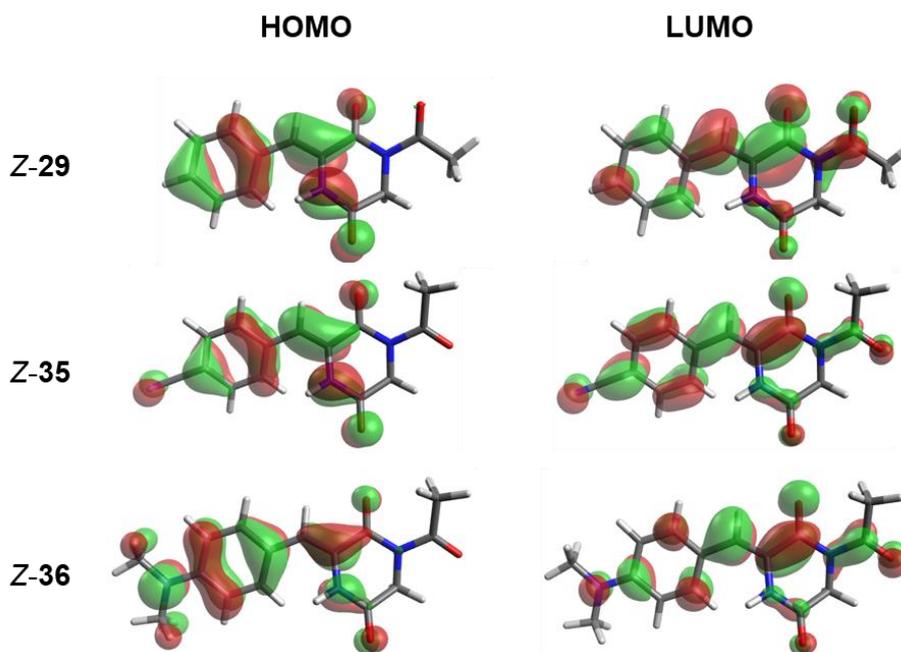

Figure 44: The electron distribution of HOMO and LUMO orbitals have been calculated for *Z*- and *E*-isomers of all discussed HPIs using B3LYP-GD3BJ/6-311G(d,p) PCM(DMSO) level of theory. The orbitals of the unsubstituted HPI **Z-29** are compared with those of the electron-poor HPI **35** and the electron-rich HPI **36**.

To investigate the differences between electron-rich and electron-poor HPIs the *p*-CN-substituted HPI **35** and *p*-NMe₂-substituted **36** have been selected and compared to the unsubstituted HPI **29** (Figure 45). It was found that an electron-withdrawing substituent in *para*-position leads to stabilization of both, the HOMO and the LUMO. Because the stabilization of the LUMO is less pronounced, the HOMO-LUMO gap is reduced. Also, a smaller band separation was determined for the electron-poor derivative. All these results are in agreement with an experimentally observed bathochromic shift in the absorption spectra and less pronounced changes in the absorbance spectra upon photoisomerization of *p*-CN-substituted HPI **35**. For the electron-rich derivative **36** a destabilization of both, the HOMO and the LUMO was observed. Here, the energy of the HOMO is significantly more increased compared to that of the LUMO and an even smaller HOMO-LUMO gap was determined. These results are again consistent with a more pronounced bathochromic shift determined for electron-rich HPIs observed *via* absorption spectroscopy. It was also found that based on the calculated HOMO-LUMO gaps the band separation between the two photoisomers of the unsubstituted HPI **29** is in the same range as for the electron-rich HPI **36**, which could be efficiently and reversibly photoisomerized. These results suggest, that also HPI **29** might be photoswitchable with high PSSs when irradiated with wavelengths below 365 nm.

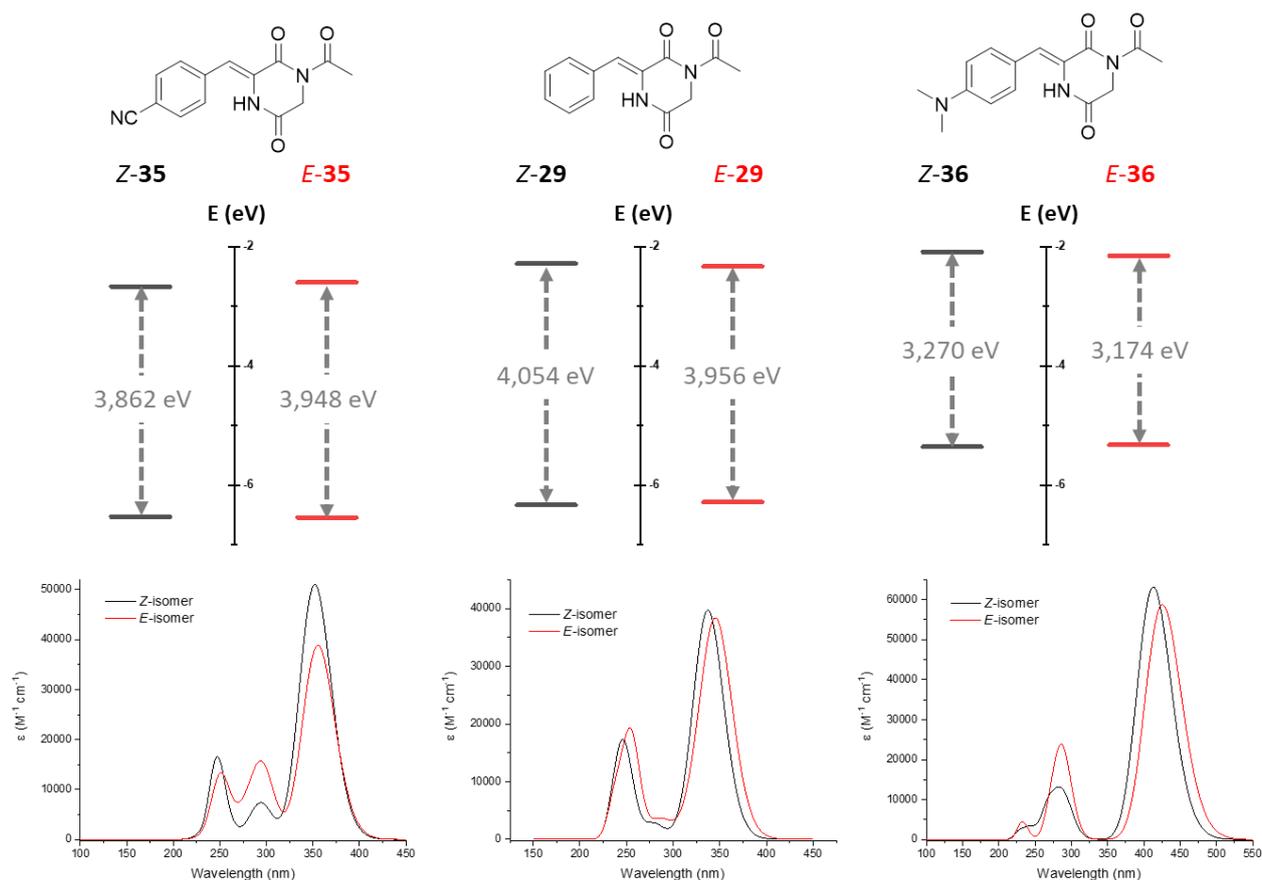

Figure 45: Theoretical description and comparison of electronic transitions of both respective photoisomers of HPIs **29**, **35** and **36**. Orbitals and associated energies were obtained at the B3LYP-GD3BJ/6-311 G(d,p) PCM(DMSO) level and corresponding absorption spectra on the TD-B3LYP-GD3BJ/6-311+G(d,p) PCM(DMSO) level of theory based on the optimized structures.

Furthermore, time-dependent B3LYP-GD3BJ/6-311G(d,p) calculations were performed based on the previously obtained structures. Solvent interactions were simulated using a polarizable continuum model (PCM), with parameters taken for DMSO. Absorption spectra were calculated based on these results (using 10 states) and were found to support the experimental data (Figure 45). In general, the calculated absorbance maxima are slightly higher compared to the results from absorption spectra measurements. However, the trend in the absorbance maxima matches the experimental data well (Table 4). Calculations for the not fully characterized water-soluble HPI **38** suggest that this compound – analogous to the other two amino-substituted HPIs **36** and **37** – absorbs green light (>500 nm).

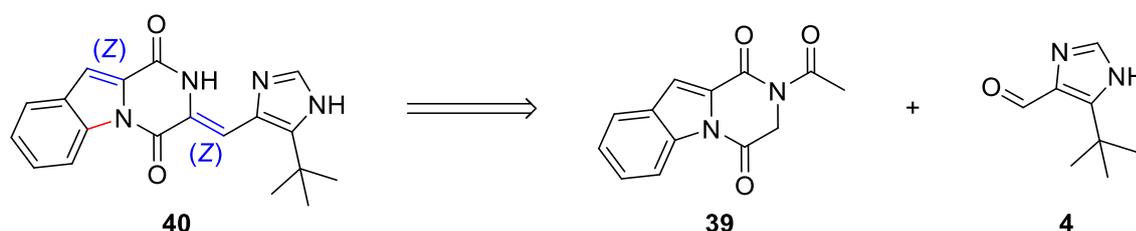

Table 4: Comparison of calculated absorbance maxima (TD-B3LYP-GD3BJ/6-311+G(d,p) PCM(DMSO) level of theory) of selected HPIs with experimental data in measured in DMSO.

Compound	29	30	35	36	37	38
Calculated $\lambda_{\text{abs,max}}$ (DMSO)	337 nm	362 nm	352 nm	413 nm	449 nm	409 nm
Experimental $\lambda_{\text{abs,max}}$ (DMSO)	324 nm	341 nm	335 nm	397 nm	397 nm	n.d.

In summary, all theoretical calculations are well in agreement with the experimental data and the applied level of theory was found to be suitable for describing and potentially predicting photophysical characteristics of HPI photoswitches.

3.3 'Locked' Plinabulin Analogue and Derivatives

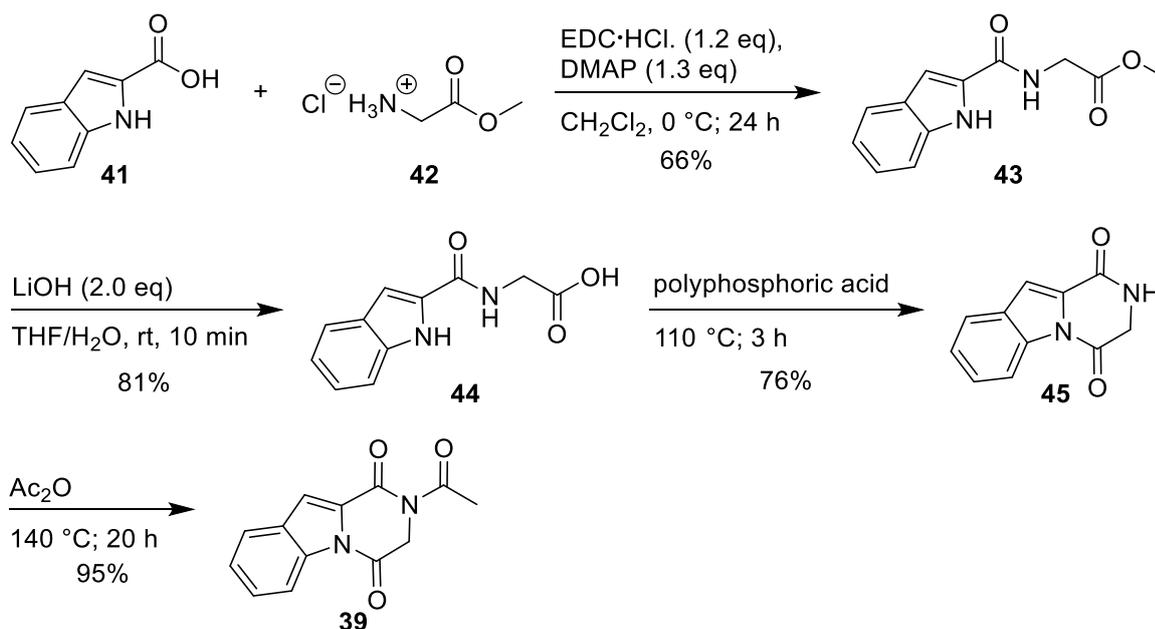

To further clarify the initial observation, that the photoisomerization of plinabulin (**6**) and its derivatives occurs only at the carbocyclic arylidene C=C double bond but not on the heteroarylidene site, a synthesis route towards a plinabulin analogue with a 'locked' carbocyclic arylidene in *Z*-configuration was developed by adding another single bond in the *ortho*-position (highlighted in red, compound **40** in Scheme 4). The double bond formation between the DKP scaffold and the imidazole substituent was planned analogous to the synthesis of plinabulin (**6**) in an aldol condensation of the newly designed intermediate DKP **29** and imidazole aldehyde **4**.

Scheme 4: Plinabulin analogue **40** with a 'locked' carbocyclic arylidene can be obtained by an aldol condensation of acetylated DKP **39** and imidazole aldehyde **4**.

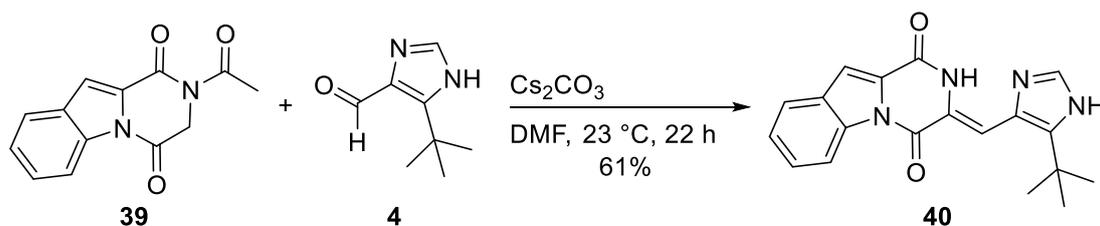

3.3.1 Synthesis

The synthetic intermediate acetylated DKP **39** is a cyclic dipeptide that consists of the two amino acids 2-carboxyindole (**41**) and glycine (Scheme 5). The synthesis was started with a peptide bond formation, in which the coupling agent EDC·HCl and DMAP were applied successfully to couple carboxyindole **41** and methyl 2-aminoacetate hydrochloride (**42**).

Scheme 5: Four-step synthesis route towards synthetic intermediate **39**.

After a subsequent ester saponification, the resulting dipeptide **44** was heated for three hours in polyphosphoric acid which promotes cyclization of *N*-(2-indoyl carbonyl)amino acids as previously reported by Pigulla and Röder.¹³⁶ Analogous to the synthesis of other HPI scaffolds, the resulting DKP **45** was then activated by acetylation and the synthesis of target compound **39** was achieved in a subsequent aldol condensation applying mild conditions by using Cs₂CO₃ in DMF (Scheme 6).

Scheme 6: ‘Locked’ plinabulin analogue **40** was synthesized by coupling acetylated DKP **39** and imidazole aldehyde **4** in an aldol condensation reaction.

Because of a lower solubility of plinabulin analogue **40** in aqueous solutions, the purification was more challenging than for plinabulin (**6**). Purification *via* preparative HPLC was successful with significantly reduced loading and ‘locked’ plinabulin analogue **40** was obtained in a satisfactory yield of 61% as a yellow solid. By single-crystal X-ray diffraction studies of intermediate **39** as well as derivative **40** (Figure 46) the planarity of these compounds was demonstrated. It was assumed that the decreased solubility is explained by the planar structure that facilitates intermolecular stacking forces of adjacent π -planes.

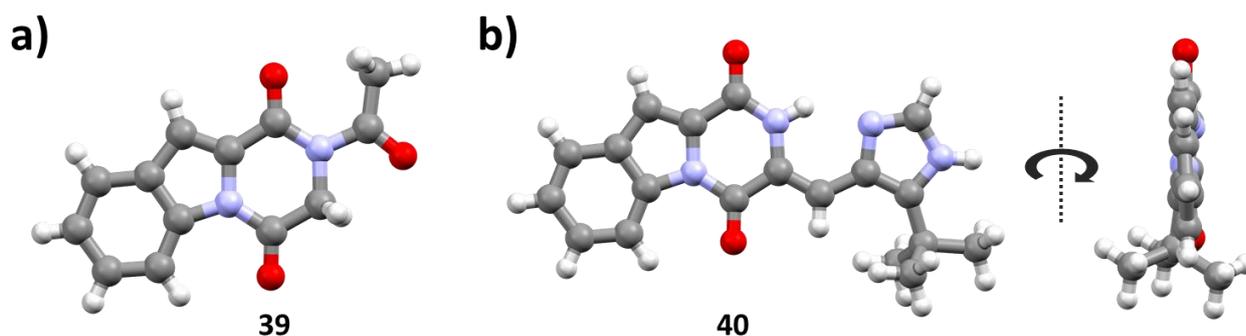

Figure 46: Single crystals of a) **39** and b) **40** were analyzed in single-crystal X-ray diffraction studies and the results were visualized with Mercury 2020.1 (CCDC). Atoms of carbon are depicted in grey, hydrogen in white, oxygen in red and nitrogen in blue.

3.3.2 Photophysical Properties of ‘Locked’ Plinabulin Analogue **40**

When investigating the photophysical properties of compound **40**, it was found that the introduction of the single bond in the *ortho*-position leads to pronounced changes in the photophysical properties. In case of intermediate DKP **39**, the absorbance maximum was found to be shifted hypsochromically ($\lambda_{\text{abs,max}}(\text{MeCN}) = 299 \text{ nm}$) compared to the analogue with a

photoswitchable C=C double bond, HPI **29** ($\lambda_{\text{abs,max}}(\text{MeCN}) = 316 \text{ nm}$). However, for the ‘locked’ plinabulin analogue **40** a bathochromic shift of the absorbance maximum of 27 nm in MeCN (Figure 47 b) compared to plinabulin (**6**) was determined. A contrary trend was observed for the emission maximum, which was shifted 42 nm hypsochromically. Whereas a yellow fluorescence was observed for all previously discussed plinabulin derivatives, the ‘locked’ analogue **40** was found to emit cyan light (Figure 47 a). Interestingly, the fluorescence quantum yield of **40** ($\Phi_{\text{F}} = 24\%$) was significantly increased compared to plinabulin (**6**) ($\Phi_{\text{F}} = 4\%$) and most of the previously investigated derivatives.

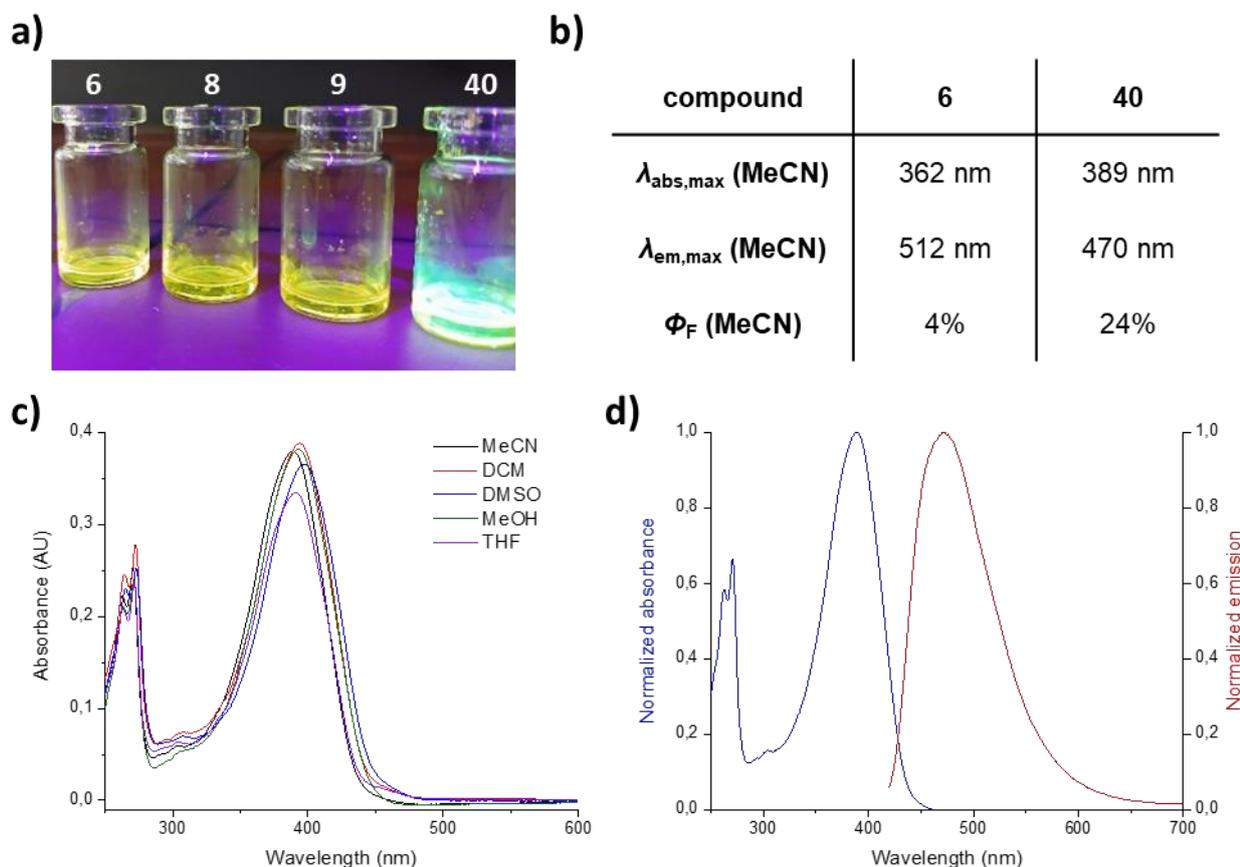

Figure 47: Photophysical properties of ‘locked’ plinabulin analogue **40**. a) A yellow fluorescence was observed for all previously discussed plinabulin derivatives, including compounds **6**, **8** and **9**. In contrast to that, the ‘locked’ plinabulin analogue **40** was found to emit cyan light, b) Comparison of the absorption and emission maxima as well as the fluorescence quantum yields determined for plinabulin (**Z-6**) and its analogue (**Z-40**), c) Compound **Z-40** was dissolved in different solvents (80 μM), respectively. Absorption spectra were measured ($d = 2 \text{ mm}$) and the spectra are assigned to the respective solvents *via* color code, d) Normalized absorption (blue) and emission (red) spectra of solutions of **Z-40** in MeCN.

To investigate if the heteroarylidene group is undergoing *Z*-to-*E*-isomerization once the carbocyclic arylidene is ‘locked’ in *Z*-configuration, solutions of compound **40** in $\text{DMSO-}d_6$ were analyzed *via* NMR spectroscopy and analytical HPLC before and after irradiation. It was found that **40** can be photoisomerized and that under the applied conditions isomerization is accompanied

by photodegradation. In contrast to observations made with plinabulin (**6**), the formation of one primarily degradation product was observed: the corresponding ^1H NMR spectra and HPLC traces (Figure 48) clearly demonstrated the development of two additional species upon irradiation. Whereas the intensity of one of the signals reduced upon irradiation with longer wavelengths, the intensity of the second signal (highlighted in red) continuously increased upon prolonged irradiation. To date, the degradation product has not yet been isolated or identified.

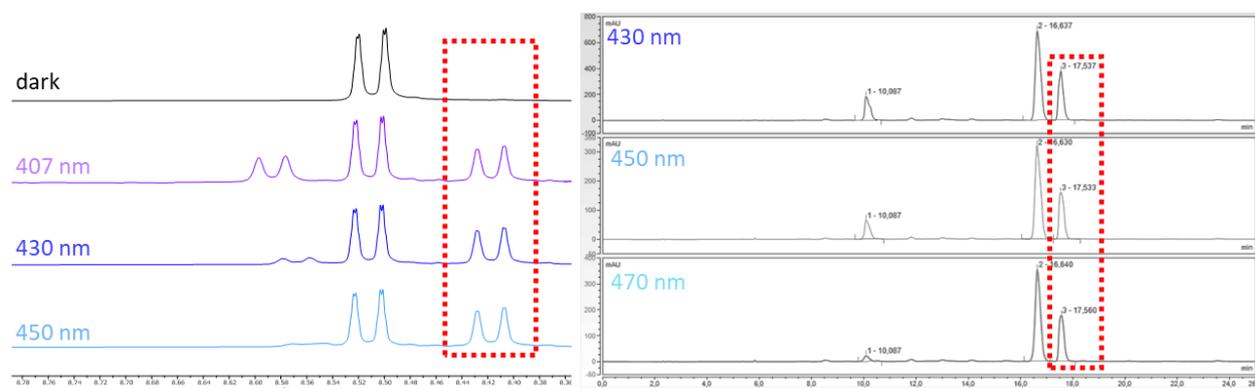

Figure 48: Irradiation of **Z-40** lead to the formation of two additional species that were detected in the corresponding a) ^1H NMR spectra and b) HPLC traces. Whereas the amount of one species decreased upon irradiation with longer wavelengths, the intensity of signals assigned to a second compound (highlighted in red) continuously increased.

Based on the observations made in previous studies on plinabulin derivatives (see chapter 3.1.2), ascorbic acid was used as an additive for all further investigations of ‘locked’ plinabulin analogue **40** to inhibit photodegradation. After the addition of ascorbic acid, a hypsochromic shift in the absorption spectrum was detected, accompanied by a fade of color of the solution (Figure 49 a,b). Reversible photoisomerization of **40** in presence of ascorbic acid was demonstrated by performing ten subsequent switching cycles while monitoring the absorbance spectra before and after every irradiation step (Figure 49 d). Only a slight decrease in absorbance was detected in the course of this experiment. In contrast to plinabulin (**6**), there is a pronounced change in the absorbance spectrum upon irradiation with violet light (410 nm), which enables efficient *Z*-to-*E*-isomerization resulting in a photoequilibrium with 93% *E-40* (see chapter 5.6.7). Backisomerization with cyan light (490 nm) however, was not as efficient and gave 33% *Z-40*.

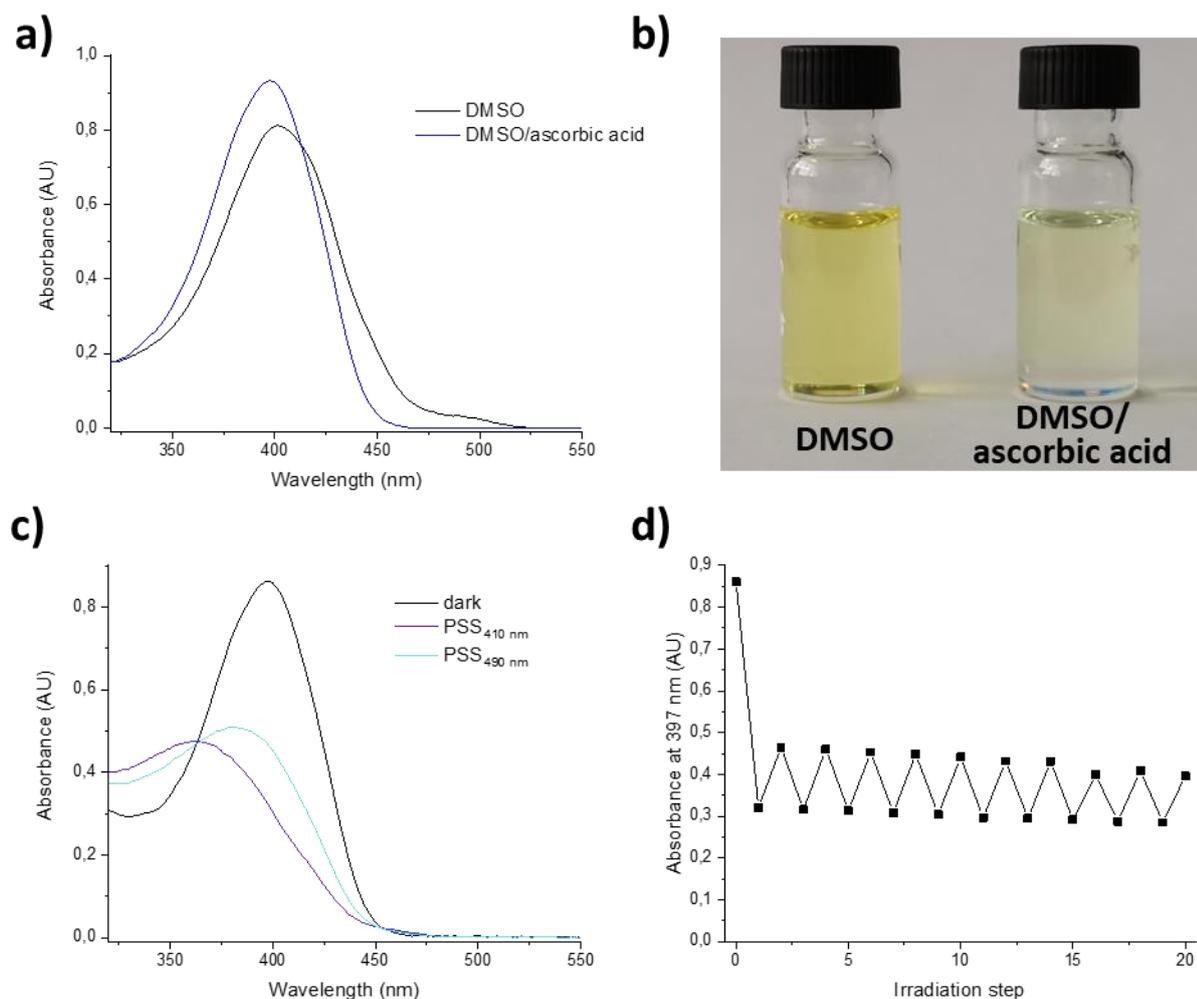

Figure 49: Reversible photoisomerization of **40** is possible in presence of ascorbic acid and was monitored *via* absorbance spectroscopy. a) Compound **Z-40** was dissolved in DMSO and in a saturated solution of ascorbic acid in DMSO (DMSO/ascorbic acid), respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code, b) The additive ascorbic acid leads to a hypsochromic shift in the absorbance of **Z-40** visible by a fade of yellow color, c) A solution of pure **Z-40** in a saturated solution of ascorbic acid in DMSO ($200 \mu\text{M}$) was irradiated and an absorption spectrum ($d = 2$ mm) was measured after each irradiation step until the PSS was reached, respectively, d) A solution of pure **Z-40** in a saturated solution of ascorbic acid in DMSO ($200 \mu\text{M}$) was irradiated with 410 nm for 30 s and with 490 nm for 12 min, respectively. The irradiation cycle was repeated ten times and after every irradiation step the absorbance at 397 nm was determined.

The photoisomerization of **40** was additionally followed *via* fluorescence spectroscopy. When analyzing the fluorescence spectra before and after irradiation with specific wavelengths (410 nm and 490 nm) it was found that the fluorescence intensity after excitation with UV-light (380 nm) can be modulated reversibly by irradiation with visible light (Figure 50). *Z*-to-*E*-Isomerization with violet light (410 nm) leads to a significant decrease in fluorescence intensity, which can be subsequently increased by *E*-to-*Z*-isomerization triggered with cyan light (490 nm). It was furthermore observed, that the PSS was reached more quickly upon irradiation with 410 nm, which

can be explained by a lower intensity of the 490 nm LED as well as a lower extinction coefficient of **40** at this wavelength.

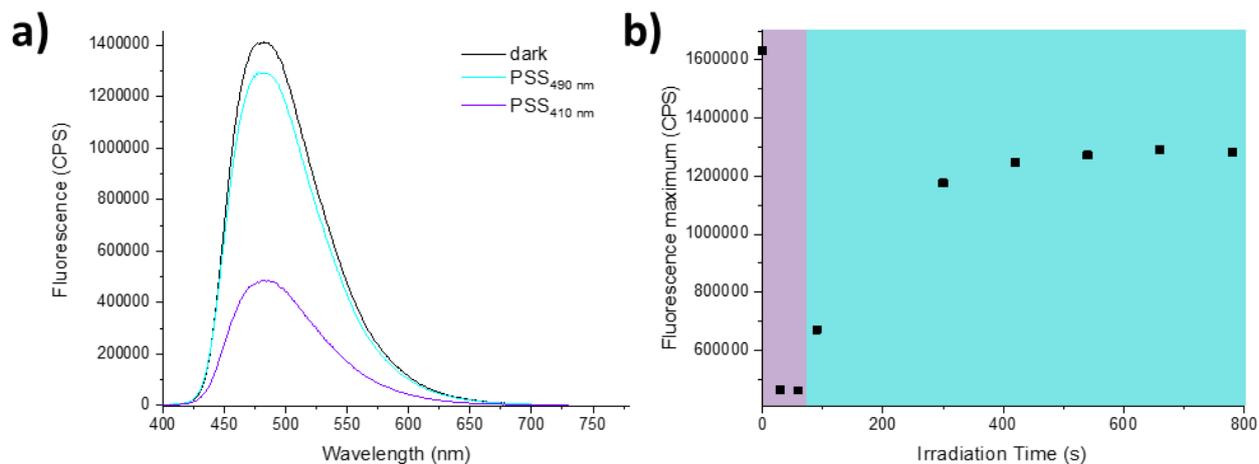

Figure 50: a) Fluorescence spectra of compound **40** (200 μ M) in saturated solution of ascorbic acid in DMSO before and after irradiation (excitation at 380 nm). The spectra are assigned to the respective mixture *via* color code, b) Compound **40** (200 μ M) in saturated solution of ascorbic acid in DMSO was analyzed *via* fluorescence spectroscopy before and after irradiation with first 410 nm and subsequently 490 nm (indicated by the color of the background). The maximal fluorescence was plotted against the irradiation time.

The thermal half-life of *E*-**40** at room temperature exceeds several days, which is in accordance with observations made for the *E*-isomers of the other investigated HPI photoswitches discussed in the previous chapters. The thermal relaxation of *E*-**40** in a mixture of water and DMSO ($v/v = 1:1$) at 37 $^{\circ}$ C was monitored *via* analytical HPLC. After 6 hours less than 1% of the isomer have undergone thermal backisomerization (Figure 51).

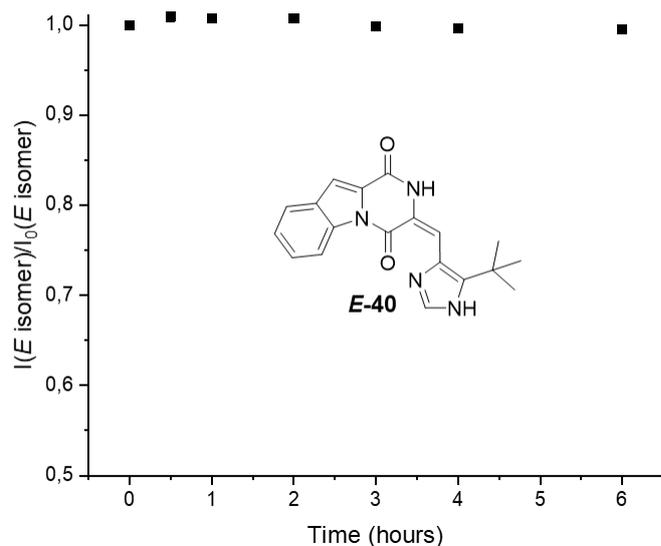

Figure 51: The thermal relaxation of *E*-**40** in H₂O/DMSO (1:1) at 37 $^{\circ}$ C was monitored *via* analytical HPLC. The integrals of the signals assigned to the respective *E*-isomer were determined at 330 nm: I_0 = initial integral, I = integral at given time point.

Further studies concentrated on the identification of the structural motif that is required for an enhanced fluorescence quantum yield compared to plinabulin (**6**). For this purpose, two new derivatives have been prepared with the same synthetic procedure as applied for ‘locked’ plinabulin analogue **40** in aldol condensation reactions with the suitable aldehydes (see also chapter 5.6.2): Compound **46** also contains an imidazole ring but without a *tert*-butyl substituent, whereas in compound **47** the imidazole substituent is replaced by a phenyl ring with a *tert*-butyl group in *para* position relative to the vinyl group (Figure 52).

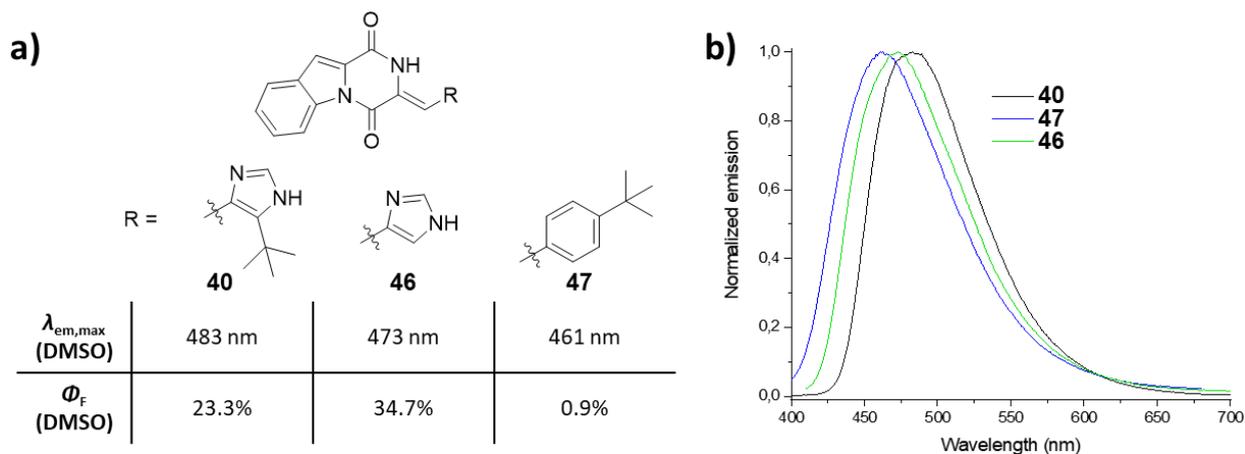

Figure 52: a) Comparison of the emission maxima and the fluorescence quantum yields of compounds **40**, **46** and **47** in DMSO, b) Normalized emission spectra of **40** in a saturated solution of ascorbic acid in DMSO and compounds **46** and **47** in DMSO. The spectra are assigned to the compounds *via* color code.

Compared to plinabulin analogue **40** the emission maxima of both of these compounds are shifted hypsochromically. Interestingly, it was found that the fluorescence quantum yield is significantly increased when the compounds contain an imidazole ring and the electron-donating *tert*-butyl group is removed (compound **46**) and below 1% for carbocyclic compound **47**. This trend might be explained by an increasing fluorescence intensity with more electron deficient substituents. Whereas imidazole substituents are known to have an electron-withdrawing character, phenyl substituents are slightly electron-donating substituents.^{137,138} This leads to the assumption that the imidazole substituent is required for an enhanced fluorescence quantum yield.

3.3.3 Carbocyclic Analogous of ‘Locked’ Plinabulin **40**

The ‘locked’ plinabulin analogue **40** represents a new structure that contains an HPI photoswitch. After having established and characterized HPIs within the plinabulin (**6**) scaffold as well as in a model system, it was now investigated whether the observed trends in photophysical properties can also be transferred to this third molecular scaffold. For this purpose, benzaldehyde and other, functionalized carbocyclic aromatic aldehydes were coupled to DKP **39** in an aldol condensation

reaction under basic conditions (Figure 53). In case of compound **55**, a Boc-protected aldehyde was subjected to the reaction and the protecting group was removed in a subsequent, additional reaction step (see chapter 5.6.2).

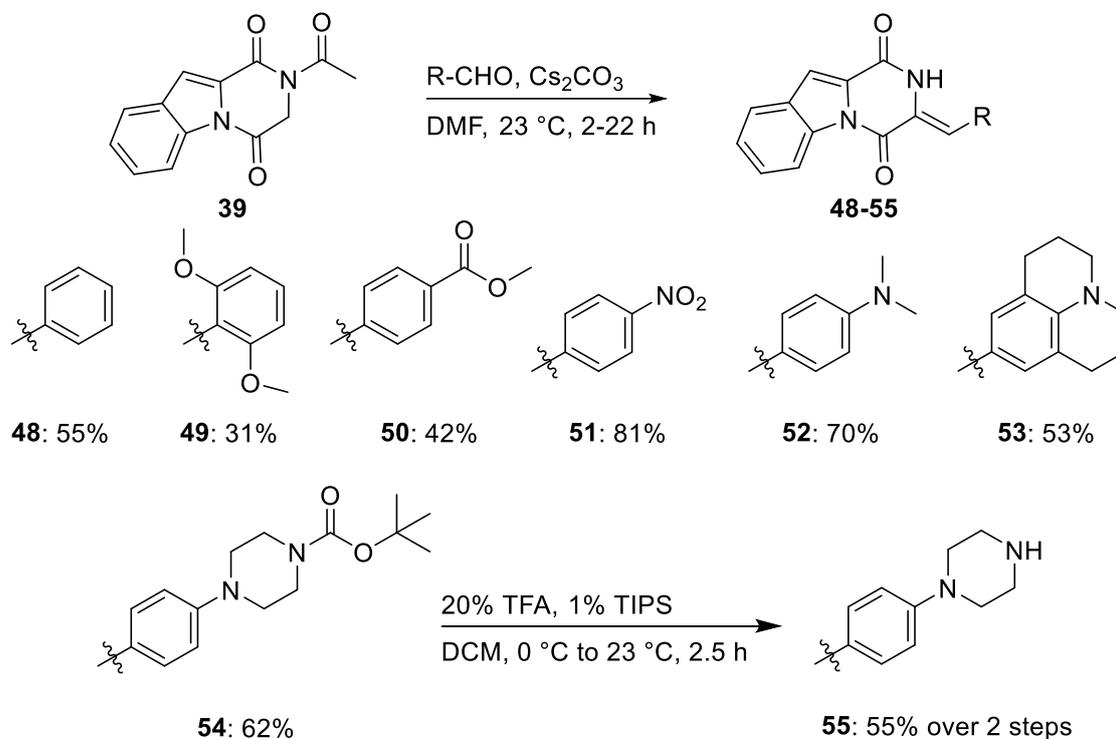

Figure 53: A short series of HPIs was synthesized by coupling carbocyclic aldehydes with acetylated DKP **39** in a base-catalyzed aldol condensation reaction.

In course of testing different methods for purifying these compounds, a generally low solubility in organic solvents was observed. It was found that the solubility can be significantly improved by installing substituents in *ortho* position relative to the vinyl bond. Whereas the concentration of saturated solutions of unsubstituted carbocyclic **48** in $\text{DMSO-}d_6$ was too low for ^{13}C NMR measurements, the spectra from measurement with *ortho*-dimethoxy-substituted **49** were found to have a satisfactory signal-to-noise ratio. It can be presumed that the methoxy substituents prevent a planar arrangement of the phenyl ring and consequently an efficient $\pi\text{-}\pi$ stacking of the molecules, which can limit solubilization of compound **48**. An enhanced solubility was also observed for compounds that contain other bulky substituents, such as a *tert*-butyl group (compound **54** as well as compound **47** presented in chapter 3.3.2) and the electron-rich *para*-amino substituted derivatives **52**, **53** and **55**.

First, absorption spectra of *ortho*-dimethoxy-substituted **49** were measured in various solvents and mixtures analogous to experiments performed with plinabulin derivatives (Figure 54). Similar to plinabulin (**6**), a minor solvatochromic effect was observed with absorbance maxima ranging from

364 nm in THF to 371 nm in DMSO. Analogous to the observations made in the previous chapters, TFA addition was found to lead to a hypsochromic shift of the absorption maximum of compound **46**, which bears an imidazole ring. However, only slight differences were observed when comparing absorption spectra of carbocyclic **49** measured in acetonitrile without any additives with those of solutions with the same concentration but with 1% (v/v) of TFA and Et₃N, respectively. The reversible photoisomerization of *ortho*-dimethoxy-substituted **49** was demonstrated *via* absorption spectroscopy in DMSO and no photodegradation was observed (Figure 54).

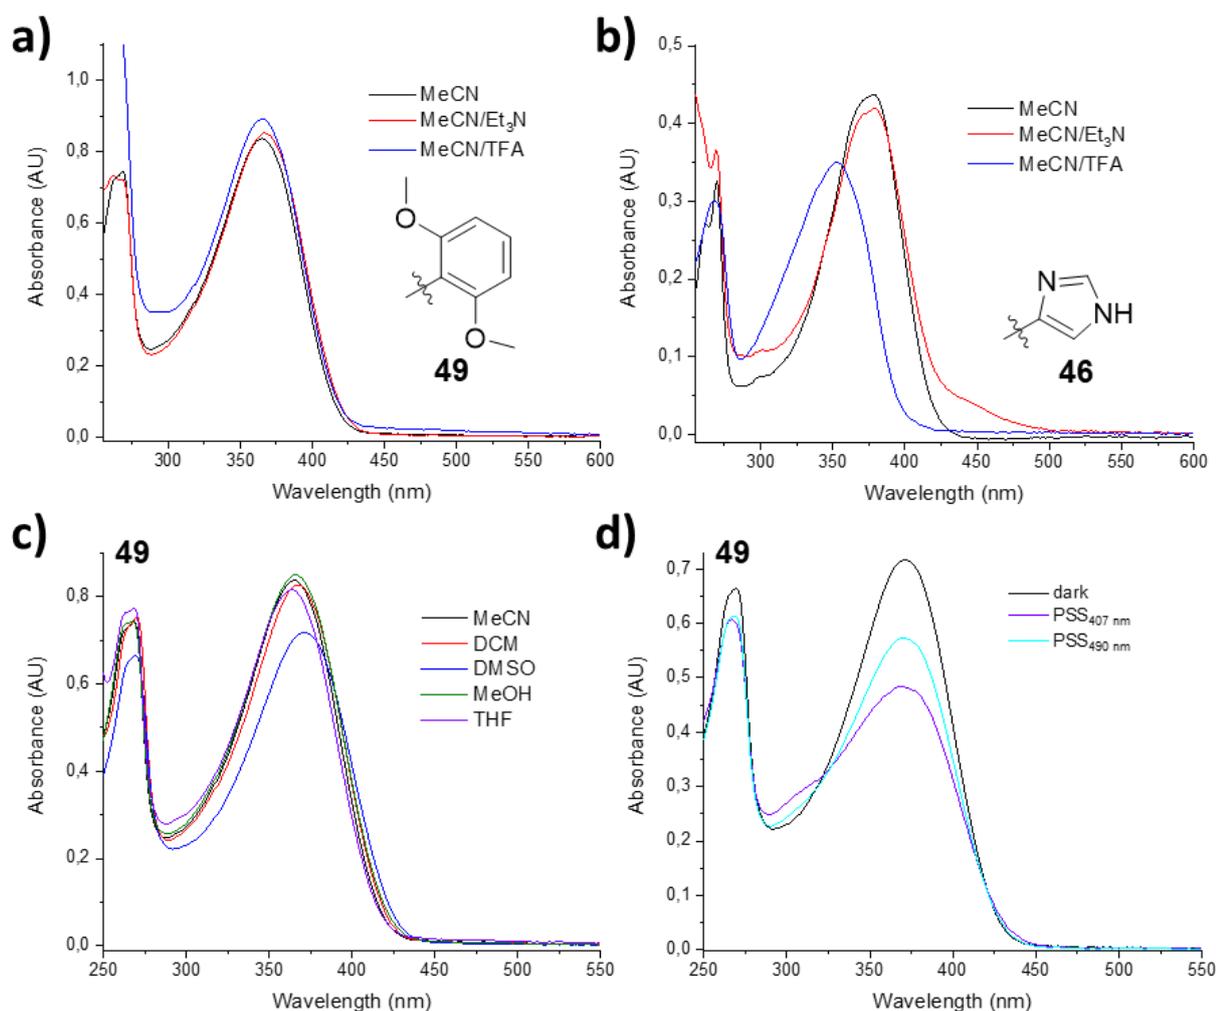

Figure 54: Photophysical properties of *ortho*-dimethoxy-substituted **49**. a) Compound Z-**49** was dissolved in MeCN and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively and absorption spectra were measured (d = 2 mm), b) Compound Z-**46** was dissolved in MeCN and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively and absorption spectra were measured (d = 2 mm). The spectra are assigned to the respective solvents *via* color code. c) Left: Compound Z-**49** was dissolved in different solvents (160 μM) and absorption spectra were measured in the dark (d = 2 mm). Right: Compound **49** was dissolved in DMSO (160 μM) and an absorption spectrum (d = 2 mm) was measured. The sample was then irradiated with 407 nm and 490 nm and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

Subsequently, the influence of electron-withdrawing (compounds **50** and **51**) and electron-donating (e.g. compound **52**) substituents in the *para* position on the photophysical properties of these derivatives were compared (Figure 55). Analogous to the model system and to the theoretical calculations discussed in chapter 3.2.3, the absorbance was found to be shifted bathochromically for all the functionalized derivatives, with a more pronounced effect for electron-donating substituents. It was additionally observed that the trends in bathochromic shifts are analogous to the hammett parameters of the substituents. For electron withdrawing substituents a higher hammett parameter ($\sigma^+(\text{COOCH}_3) = +0.49$, $\sigma^+(\text{NO}_2) = +0.78$) and for electron-donating substituents a lower hammett parameter ($\sigma^+(\text{N}(\text{CH}_3)_2) = -1.70$, $\sigma^+(\text{Julolidine}) = -2.03$) corresponds to a more pronounced bathochromic shift.^{133,137,138} Furthermore, a lower band separation was observed for electron-poor derivatives, analogous to the one observed in theoretical calculations for simple mono-substituted HPIs, discussed in the previous chapter 3.2.3. Additionally, for compounds **50** and **51** significant photodegradation was observed, and no photoequilibria were reached upon irradiation with violet light (410 nm). It should be tested whether ascorbic acid could be added and enable reversible photoisomerization and determination of the composition of different PSSs.

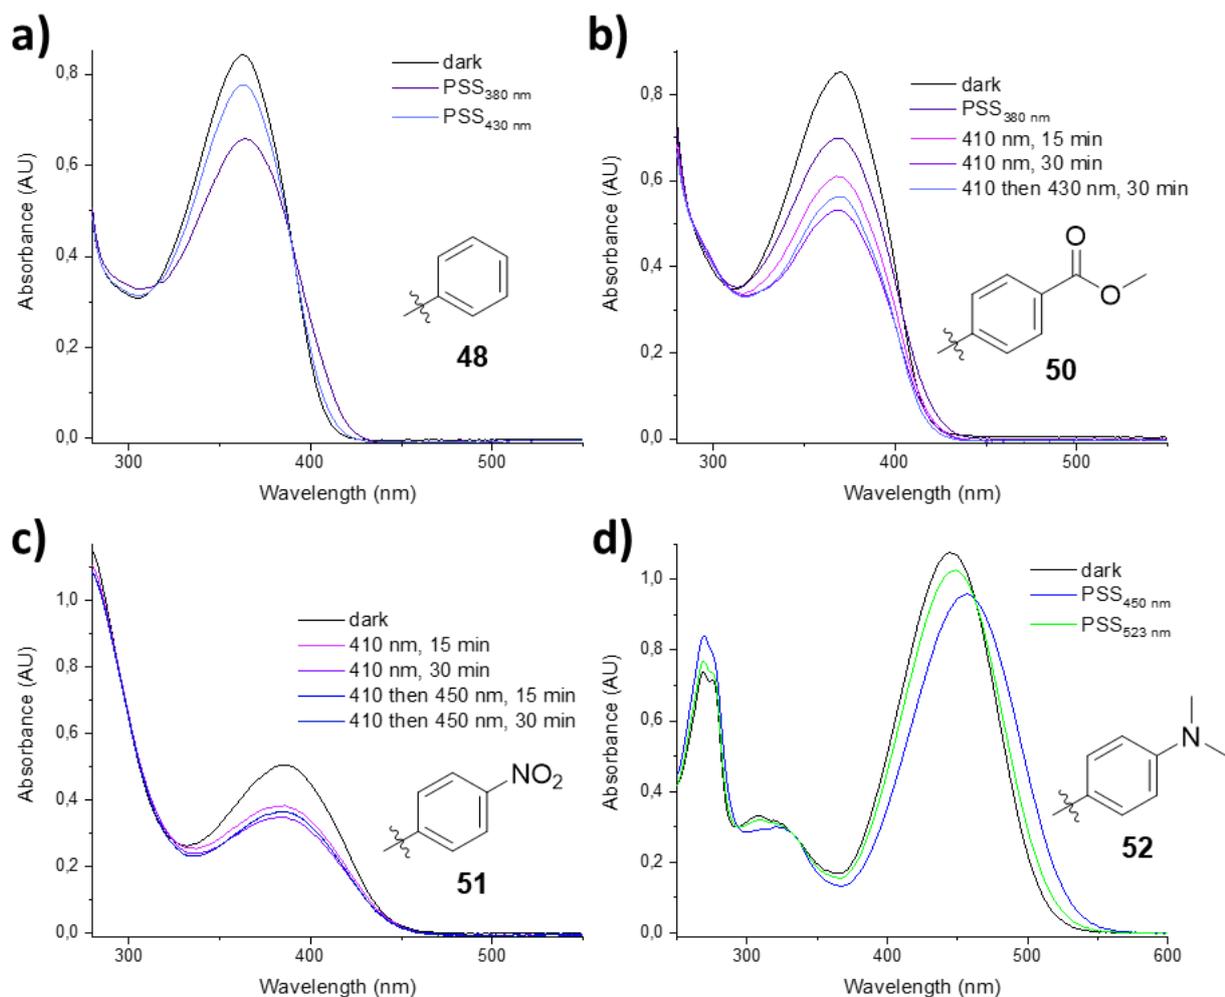

Figure 55: Compounds **48-52** were dissolved in DMSO (160 μ M) and absorption spectra ($d = 2$ mm) were measured. The samples were then irradiated and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively. Photodegradation was observed for compounds **50** and **51** and consequently, no PSS was reached.

A noticeable bathochromic shift with an absorbance maximum at 444 nm was observed in the spectrum of *p*-NMe₂-substituted **52**. This shift is more pronounced than that of the model compound **36** ($\lambda_{\text{abs,max}}(\text{DMSO}) = 397$ nm) as well as the plinabulin derivative **16** ($\lambda_{\text{abs,max}}(\text{DMSO}) = 410$ nm), that both also contain electron-donating *p*-NMe₂ substituents. The composition of the PSS was determined *via* ¹H NMR spectroscopy in DMSO-*d*₆ after irradiation with selected wavelengths. It was found that the thermodynamically more stable *Z*-**52** can be isomerized to 64% *E*-isomer with indigo light (430 nm) and subsequent irradiation with green light (523 nm) resulted in 83% *Z*-isomer (see chapter 5.6.7).

Furthermore, the fluorescence spectra of the electron-rich and electron-poor derivatives were compared (Figure 56). Analogous to the trend observed in the absorbance spectra, a bathochromic shift was observed for all derivatives. The shift correlated with the hammett parameters (σ^+) of

the respective functional groups and was generally more pronounced for electron-donating substituents.

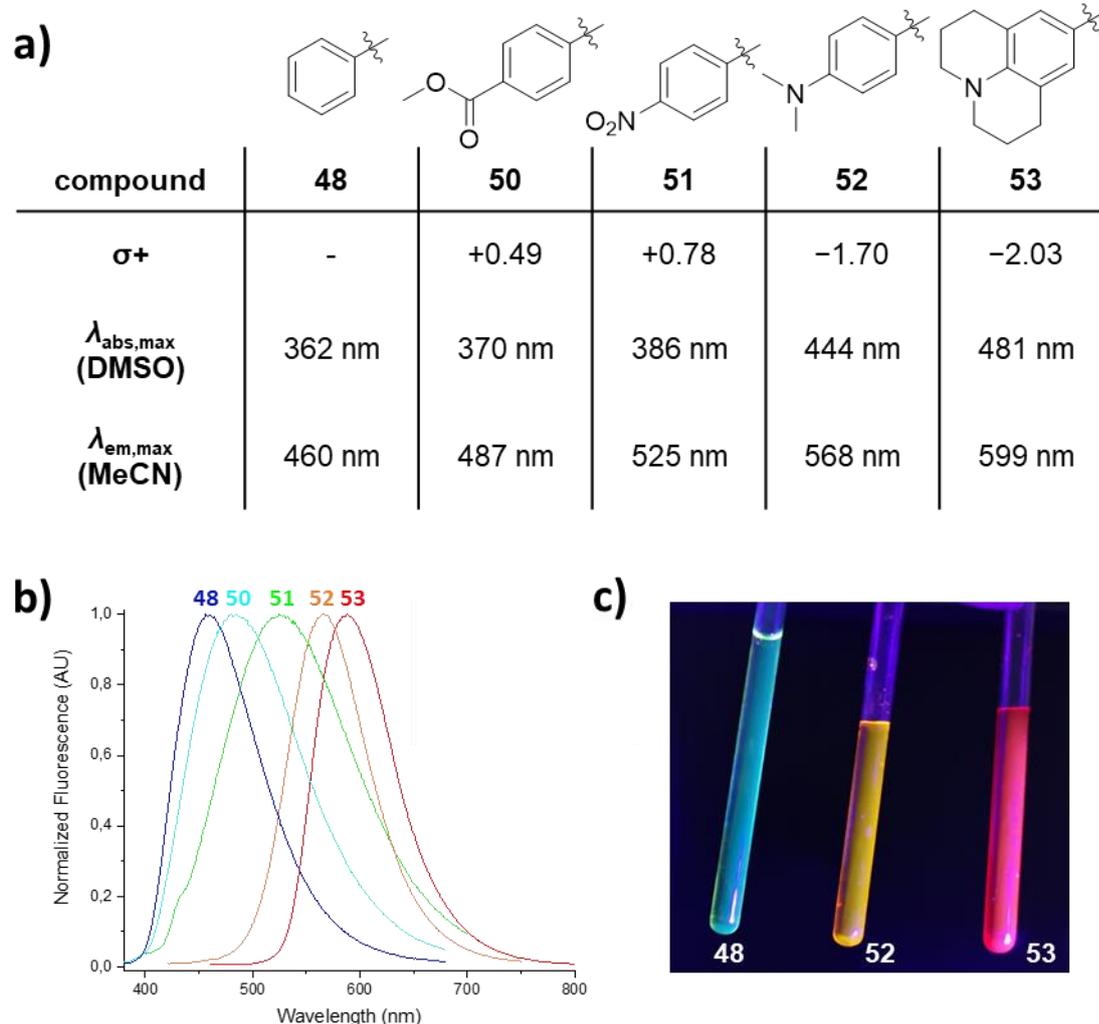

Figure 56 a) Comparison of absorbance and fluorescence maxima of compounds bearing electron-withdrawing or -donating substituents. Bathochromic shifts were found to correlate with the hammett parameters (σ^+) of the respective functional groups, b) Comparison of normalized emission spectra of the *Z*-isomers of compounds **48** and **50-53** in DMSO, c) Electron-donating substituents lead to a significant shift in the emission spectra from cyan (**48**) to orange (**52**) and even red (**53**). The compounds were dissolved in DMSO- d_6 and excited with 365 nm.

An impressive shift was observed for julolidine derivative **53**, which was the first HPI photoswitch found to be photoconverted with red light (623 nm), within the ‘therapeutic window’ (Figure 57). To investigate the compounds suitability for *in vivo* experiments, its behavior in aqueous media was investigated. It was found that an increasing amount of water in mixtures with DMSO led to a continuous bathochromic shift in the absorbance, which even could be observed with the bare eye. At 160 μM concentration the compound started to precipitate at a water content above 30%.

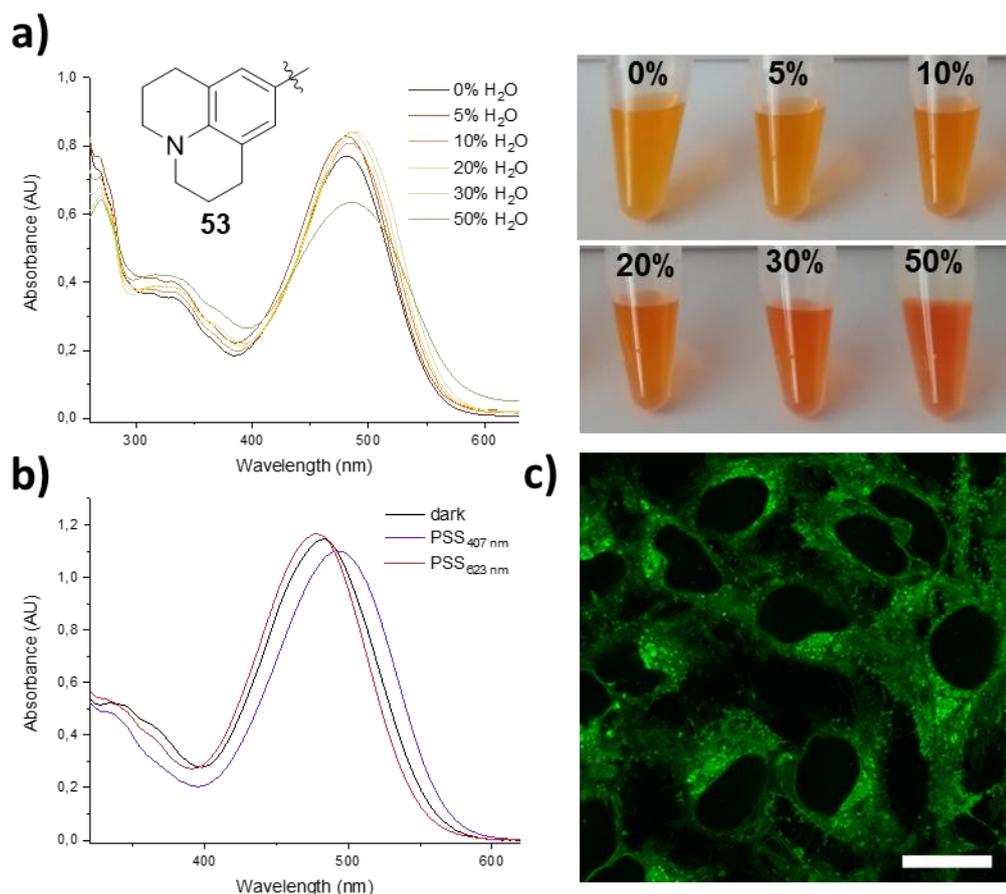

Figure 57: a) The absorption spectra of compound Z-**53** (160 μM) in DMSO and different mixtures of water and DMSO ($d = 2$ mm) were measured and a bathochromic shift was observed with an increasing amount of water in the mixture. The spectra are assigned to the corresponding solvent mixture *via* color code. A water content of 30% or higher resulted in precipitation of the compound, b) Compound **53** was dissolved in DMSO (80 μM) and an absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then irradiated and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively. The spectra are assigned to the corresponding wavelength *via* color code. c) Imaging of compound **53** in HeLa cells *via* confocal microscopy (scale bars 20 μm , excitation laser line: 488 nm, 2.2% intensity, detection at 500-600 nm, gain 854) after 15 h treatment (8.0 μM). The results were processed and visualized with Leica Application Suite X 3.7.4.23463 from Leica Microsystems CMS GmbH.

Subsequently, it was tested whether julolidine derivative **53** has cell-penetrating properties. For this purpose, HeLa cells were incubated with **53** (8 μM) for 15 hours and then the cells were washed with PBS buffer and fixed. Afterwards, the fluorescent compound **53** was detected *via* confocal microscopy applying the selected laser wavelength of 488 nm (Figure 57). Fluorescence was detected in the cells, but not inside the nucleus. The fluorescence was not distributed homogeneously in the cytoplasm, but some line-shaped structures and round shaped fluorescent spots were detected with a higher concentration close to the nucleus. It was concluded that compound **53** can cross cell membranes of HeLa cells, but the exact localization within the cells has not been identified yet.

Because the solubility of julolidine derivative **53** in aqueous media was found to be limited, another derivative bearing a piperazine substituent in *para* position (compound **55**) was synthesized. When investigating HPI model compounds (chapter 3.2.2) this functional group was found to enhance solubility in aqueous media while maintaining a significant bathochromic shift in the absorbance compared to an unsubstituted analogue. After purification *via* preparative HPLC, the TFA salt of compound **55** was obtained (Figure 58). The salt was found to be significantly bathochromically shifted in absorbance and emission ($\lambda_{\text{abs,max}}(\text{DMSO}) = 413 \text{ nm}$, $\lambda_{\text{em,max}}(\text{DMSO}) = 543 \text{ nm}$) compared to the unsubstituted analogue **48** ($\lambda_{\text{abs,max}}(\text{DMSO}) = 362 \text{ nm}$, $\lambda_{\text{em,max}}(\text{DMSO}) = 460 \text{ nm}$). After addition of Et_3N a bathochromic shift in the absorbance spectrum in MeCN of 23 nm was detected, which is presumed to correspond to the formation of uncharged compound **55**. Reversible photoisomerization in DMSO with visible light was observed *via* absorbance spectroscopy without any detectable photodegradation (Figure 58). Cell penetration assays were performed analogous to the experiments with julolidine derivative **53** and it was found that also piperazine **55** can penetrate cell membranes of HeLa cells. However, the distribution of the detected fluorescence differed from the compound **53**. There was a more homogeneous distribution within the cytoplasm, which might be explained by an enhanced solubility in aqueous media. Additionally, fluorescent circles are found predominantly close to the cell membrane. It can be presumed that these structures are vesicles being transported to the cell membrane during exocytosis. Interestingly, fluorescence was also observed inside of the nuclei in round-shaped structures, which might correspond to a localization of piperazine **55** in the nucleoli. However, this is yet to be verified in co-staining experiments.

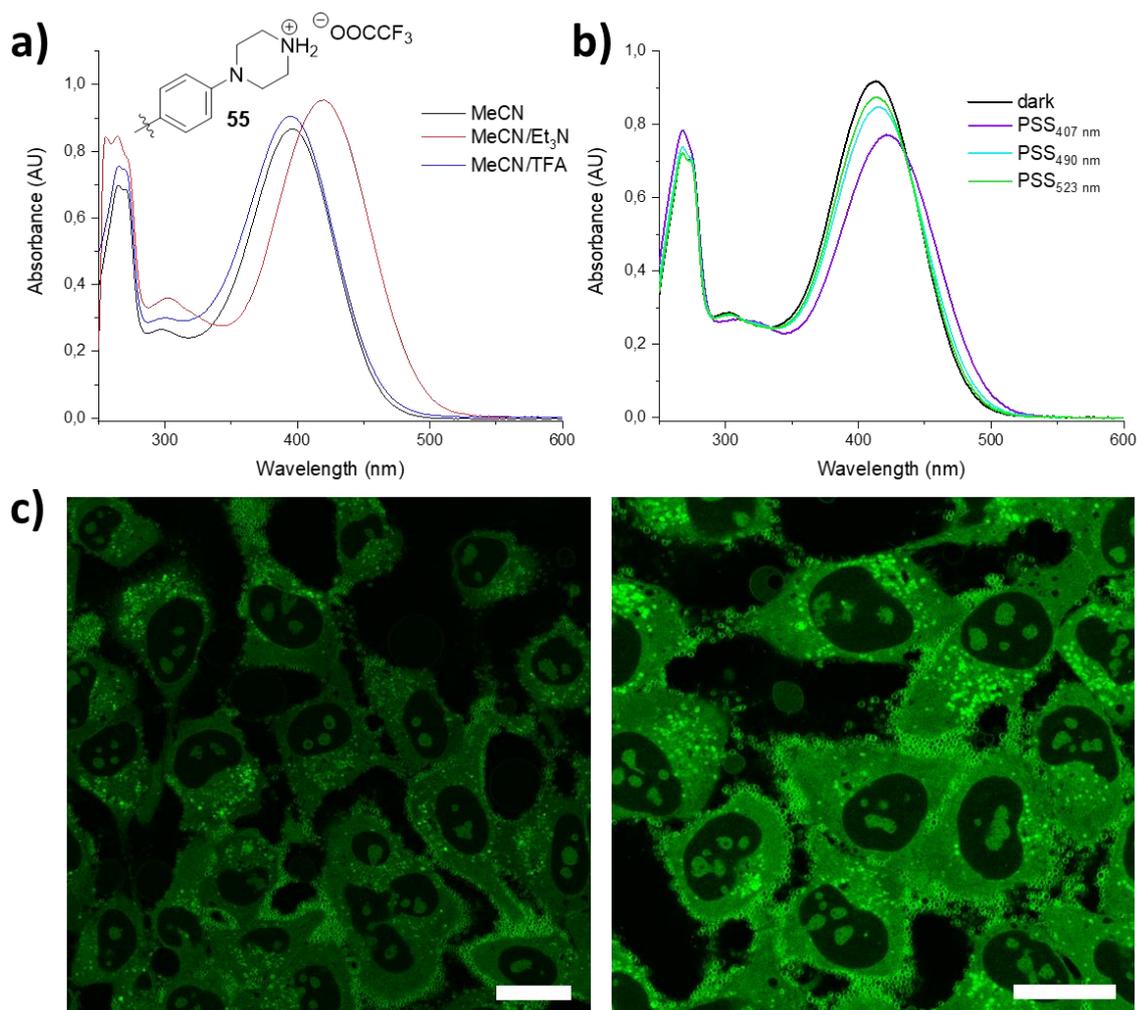

Figure 58: The TFA salt of compound **Z-55** was dissolved MeCN (160 μM) and mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured ($d = 2$ mm) and the spectra are assigned to the respective solvents *via* color code, b) the TFA salt of compound **55** was dissolved in DMSO (160 μM) and an absorption spectrum ($d = 2$ mm) was first measured, the sample was then irradiated and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively, c) Imaging of compound **55** in HeLa cells *via* confocal microscopy (scale bars 20 μm, excitation laser line: 488 nm, 2.2% intensity, detection at 530-603 nm, gain 1044) after 15 h treatment (8.0 μM). The results were processed and visualized with Leica Application Suite X 3.7.4.23463 from Leica Microsystems CMS GmbH.

These results set basis for further experiments that will be conducted in the future. First, the cytotoxicity of both respective photoisomers should be assessed *via* cell viability assays to determine the applicable concentration range. In co-staining experiments, the location of the photoswitches within the cells can be determined and parameters including the incubation time as well as the concentration of the fluorescent compounds should be screened. Further studies should be conducted to evaluate whether there is a difference in cell-penetrating activity or location within the cells between two photoisomers, which would enable photomodulation of these characteristics. Lastly, the structures can be further modified to enhance solubility in aqueous media by installing functional groups like e.g. a phosphate group.

4 Conclusion and Outlook

A novel molecular photoswitch was identified in the microtubule targeting agent plinabulin (**6**) and found to enable light-triggered activation of bioactivity as well as photomodulation of fluorescence intensity.

4.1 Plinabulin Derivatives

A panel of plinabulin derivatives (**6-28**) was synthesized successfully and characterized in respect to their photophysical and photopharmacological properties. Unmodified plinabulin (**6**) was found to be reversibly photoswitchable within the visible light spectrum and it was demonstrated that light-triggered *E/Z*-isomerization of plinabulin (**6**) enables the photomodulation of antimetabolic bioactivity. In contrast to previously reported photoswitchable microtubule-targeting agents, it has not been synthetically modified, which in turn preserves its' potency completely and contrary to many azobenzene-based photopharmacological agents it is stable under reducing conditions. The photophysical properties are compatible with fixed wavelengths of lasers commonly applied in confocal microscopy. Violet (405 nm) and cyan (488 nm) light are expected to enable in situ photomodulation while light frequencies of the green (561 nm) and the red (642 nm) channel are not absorbed and can be applied for parallel imaging without affecting the photoswitchable compound. Furthermore, properties including the composition of the PSSs, the absorption spectra and the difference in potency between two photoisomers were tuned by installing different substituents on the phenyl ring of plinabulin (**6**).

By installing electron-donating amino substituents on the phenyl ring, considerable bathochromic shifts of the absorption maxima up to 62 nm were determined, which resulted in green light-responsive (> 500 nm) photoswitches. Additionally, and bigger band separation between the two respective photoisomers was observed for these derivatives allowing for efficient reversible photoisomerization within the visible light spectrum.

Furthermore, 3,5-dimethoxyplinabulin **15** (Figure 59) was found to possess superior pharmacological properties with an over 2900-fold difference in potency between the two photoisomers, which considerably enhanced the achievable photomodulation of bioactivity. The less active, metastable *E*-**15** can be isolated *via* preparative HPLC. *E*-**15** was found to be stable in aqueous medium at 37 °C for at least 32 hours and it could be stored in a freezer without any detectable thermal backisomerization. Photoactivation of cytotoxicity was demonstrated in cell viability assays. Irradiation of the less active *E*-**15** (IC₅₀ = 618 nm) with cyan light (490 nm) yields an over 1800-fold more potent mixture that contains 86% *Z*-**15**. It was additionally confirmed that

the mixture can be deactivated by irradiation with violet light, which generates a mixture with over 50% *E*-**15** and an over 100-fold lower potency.

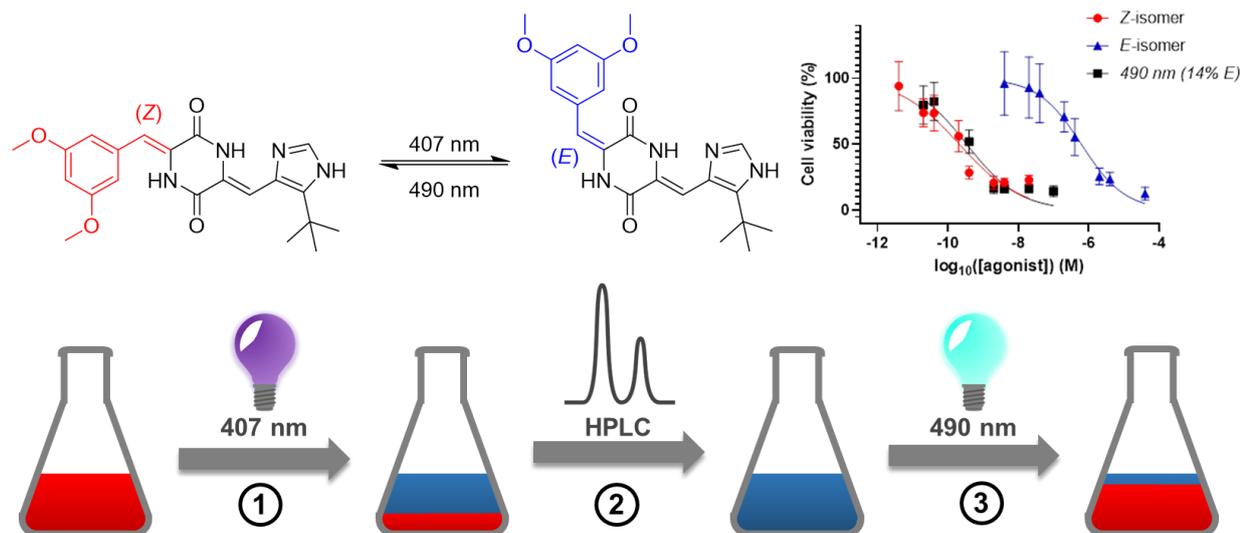

Figure 59: The photoswitchable 3,5-dimethoxyplinabulin **15** was found to possess superior pharmacological properties with an over 2900-fold difference in potency. Less active, metastable *E*-**15** is formed upon irradiation with violet light (407 nm) (①) and can be isolated *via* preparative HPLC (②) and stored in a freezer for at least two months. It can be considered as a prodrug, that can be activated by irradiation with cyan light (490 nm) (③), which gives a mixture with 89% *Z*-**15** (*Z*-6) with 1800-fold higher cytotoxicity against HT-29 cells.

Plinabulin derivatives consist of two arylidene residues attached to a cyclic dipeptide core (2,5-diketopiperazine, DKP). Because of structural analogies to linear peptides and appearance in numerous bioactive natural products, DKP became an important structural motif for drug design and discovery and a constitutive part of numerous biocompatible smart materials.^{110,139-141} Consequently, the results of this work can be applied for designing photoswitchable analogues of other DKP-based drugs and materials.

4.2 Hemipiperazines: Model Compounds

3-Arylidene-2,5-diketopiperazines – abbreviated as hemipiperazines (HPIs) – are novel photoswitchable motifs first identified within the microtubule targeting compound plinabulin (**6**). These photoswitches are based on the cyclic dipeptide motif (DKP), which is also found in other bioactive compounds and biocompatible materials and may be applied in various applications in the field of photopharmacology. To clarify the scope and limitations of these novel molecular photoswitches, the core photochromic fragment of plinabulin (**6**), which contains only one double bond and no heterocycle, was chosen to serve as a model system. A panel of derivatives were synthesized and characterized systematically to investigate the influence of electron-withdrawing and -donating groups on their photophysical properties (examples shown in Figure 60).

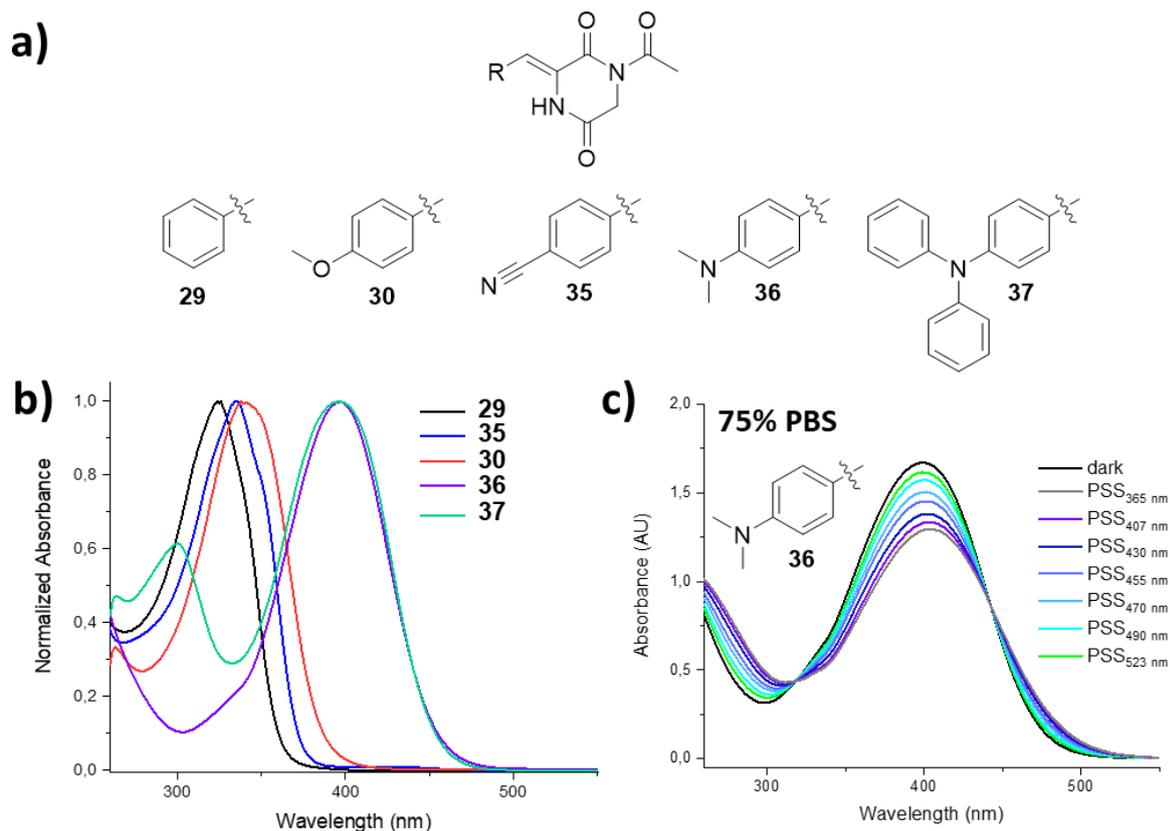

Figure 60: a) A panel of derivatives, including compounds **29**, **30**, and **35-37**, were synthesized and characterized systematically to investigate the influence of electron-withdrawing and -donating groups on their photophysical properties, b) Normalized absorbance spectra of compounds **29**, **30**, and **35-37** in DMSO, c) Electron-rich HPI **36** exhibits a bathochromically shifted absorbance and was found to be reversibly photoswitchable in aqueous media containing up to 75% PBS buffer.

Both, electron-withdrawing and -donating groups were found to lead to a bathochromic shift in absorbance, but this effect was much more pronounced for electron-donating substituents. Photochromism was observed for all derivatives, however with low photoconversion for unsubstituted HPI **29** as well as the electron-poor cyano-HPI **35**. The electron-rich HPIS **36** and **37** were found to be reversible photoisomerizable with visible light frequencies (green and violet light) in aqueous media. Furthermore, the switching quantum yields determined for **37** are comparable with established classes of photoswitches. Additionally, theoretical calculations were performed and found to be well in agreement with the experimental data. For future research, theoretical calculations can be applied to predict photophysical properties of HPI derivatives. The piperazine-HPI **38** was found to be soluble in water and was characterized *via* NMR spectroscopy in D₂O. In first investigations it was furthermore demonstrated that this derivative can be photoisomerized in D₂O with violet light (407 nm). These preliminary results indicate that compound **38** is a promising candidate for *in vivo* switching and further investigations of its photomodulation in aqueous media will be done in the future.

4.3 ‘Locked’ Plinabulin Analogue and Derivatives

To further clarify the initial observation, that the photoisomerization of plinabulin (**6**) and its derivatives occurs only at the carbocyclic arylidene C=C double bond but not on the heteroarylidene site, a plinabulin analogue **40** with a ‘locked’ carbocyclic arylidene in *Z*-configuration was synthesized (Figure 61). It was found that **40** exhibits a significantly enhanced fluorescence quantum yield can be reversibly photoisomerized with visible light frequencies. The fluorescence intensity can be modulated reversibly by irradiation with visible light. *Z*-to-*E*-Isomerization with violet light (410 nm) leads to a significant decrease in fluorescence intensity, which can be subsequently increased by *E*-to-*Z*-isomerization triggered with cyan light (490 nm) (Figure 61).

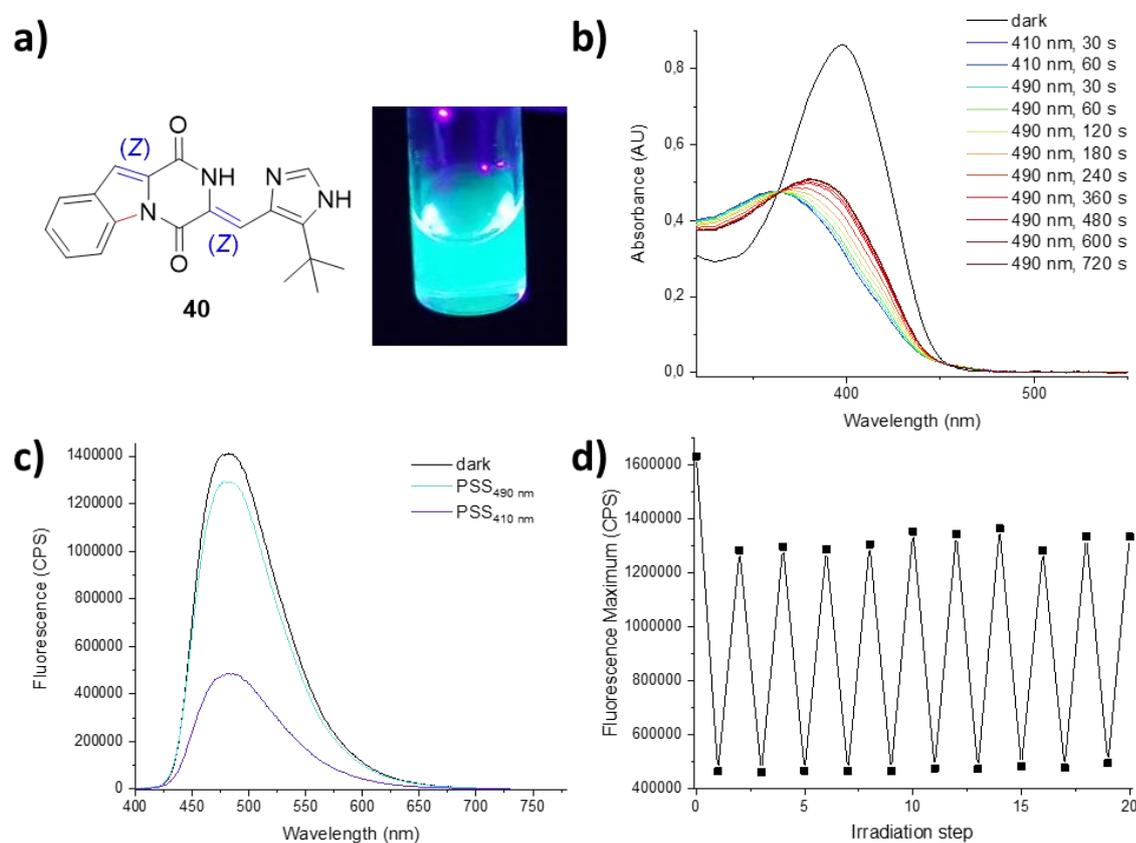

Figure 61: a) The emission of ‘locked’ plinabulin analogue **40** was found to be shifted hypsochromically and cyan fluorescence was observed with a fluorescence quantum yield of 24%, b) **40** in a saturated solution of ascorbic acid in DMSO (200 μ M) can be photoisomerized reversibly with visible light frequencies. The solution was irradiated and an absorption spectrum ($d = 2$ mm) was measured after each irradiation step until the PSS was reached, respectively. The spectra are assigned to the irradiation wavelength and time *via* color code, c) Fluorescence spectra of compound **40** (200 μ M) in saturated solution of ascorbic acid in DMSO before and after irradiation (excitation at 380 nm) The spectra are assigned to the irradiation wavelength *via* color code, d) A solution of pure *Z*-**40** in a saturated solution of ascorbic acid in DMSO (200 μ M) was irradiated with 410 nm for 30 s and with 490 nm for 12 min, respectively. The irradiation cycle was repeated ten times and after every irradiation step the solution was analyzed *via* fluorescence spectroscopy.

The ‘locked’ plinabulin analogue **40** represents a new structure that contains an HPI photoswitch. After having established and characterized HPIs within the plinabulin (**6**) scaffold as well as in a model system, it was now investigated whether the observed trends in photophysical properties can also be transferred to this third molecular scaffold. For this purpose, carbocyclic aromatic derivatives (examples shown in Figure 62) were synthesized and characterized with respect to their photophysical properties.

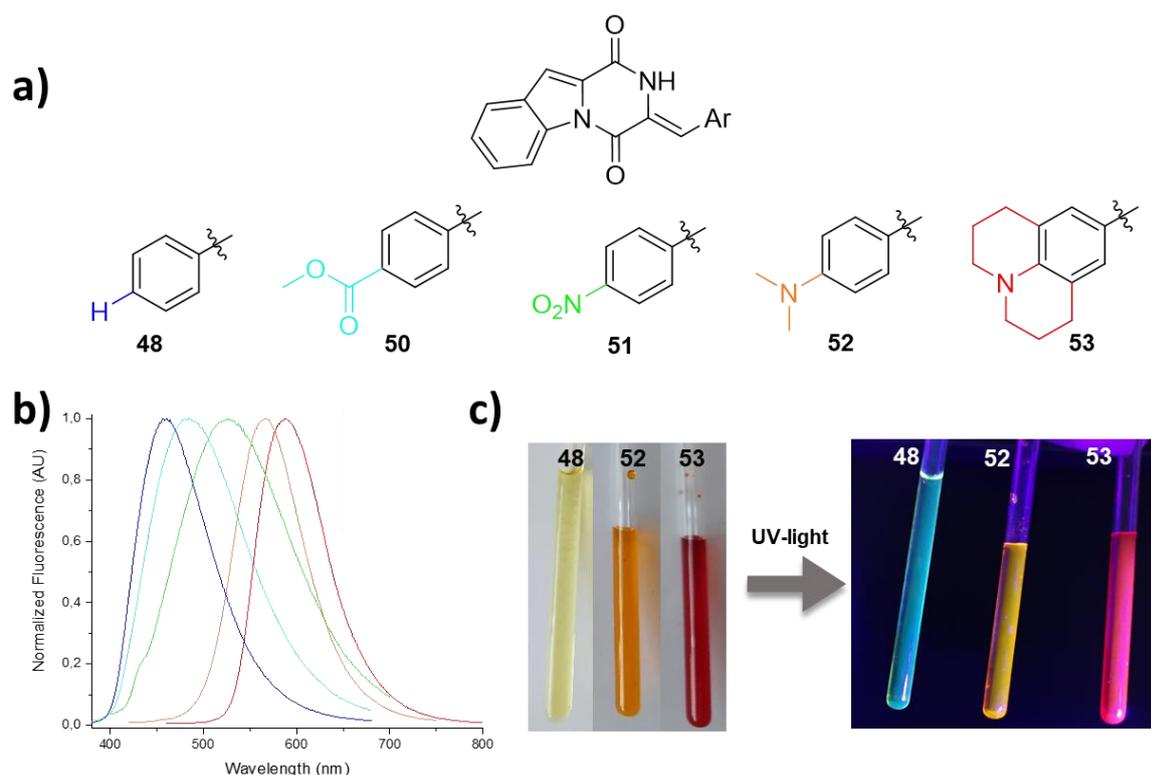

Figure 62: a) A panel of carbocyclic derivatives of ‘locked’ plinabulin analogue **40**, including compounds **48** and **50-53**, were synthesized and characterized systematically to investigate the influence of electron-withdrawing and -donating groups on their photophysical properties, b) Comparison of normalized emission spectra of the Z-isomers of compounds **48** and **50-53** in DMSO. The spectra are assigned to the compounds *via* color code (see panel a), c) Electron-donating substituents lead to a significant shift in the absorption (left) and emission (right) spectra. The observed fluorescence changes from cyan (**48**) to orange (**52**) and even red (**53**). The compounds were dissolved in DMSO- d_6 and excited with 365 nm.

Cell-penetrating properties of **53** and **55** were investigated *via* confocal microscopy. HeLa cells were incubated with the fluorescent compounds **53** and **55** and fluorescence was detected inside the cells after excitation at 488 nm (Figure 63). The distribution of the compounds inside the cells was found to differ between the two derivatives. **53** was not distributed homogeneously in the cytoplasm, but some line-shaped structures and round shaped fluorescent spots were detected with a higher concentration close to the nucleus. In contrast to that, there was a more homogeneous distribution of **55** within the cytoplasm, which might be explained by an enhanced solubility in aqueous media. Additionally, fluorescent round-shaped structures were observed inside of the

nuclei in, which might correspond to a localization of piperazine **55** in the nucleoli. However, the exact localization of both derivatives within the cells has not been identified yet and this is yet to be verified in co-staining experiments.

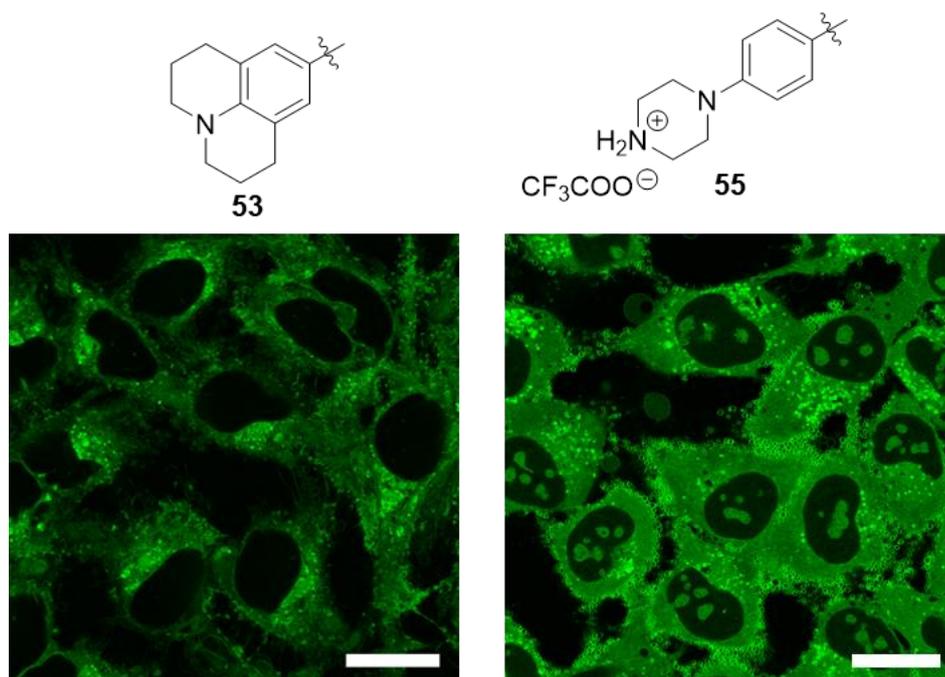

Figure 63: Imaging of compounds **53** (left) and **55** (right) in HeLa cells *via* confocal microscopy (scale bars 20 μm, excitation laser line: 488 nm, 2.2% intensity, **53**: detection at 500-600 nm, gain 854, **55**: detection at 530-603 nm, gain 1044) after 15 h treatment (8.0 μM). The results were processed and visualized with Leica Application Suite X 3.7.4.23463 from Leica Microsystems CMS GmbH.

Further investigations of these fluorescent cell-penetrating compounds will be conducted in the future. First, the cytotoxicity of both respective photoisomers should be assessed *via* cell viability assays to determine the applicable concentration range. In co-staining experiments the location of the photoswitches within the cells can be determined and parameters including the incubation time as well as the concentration of the fluorescent compounds should be screened. Further studies should be conducted to evaluate whether there is a difference in cell-penetrating activity or location within the cells between two photoisomers, which would enable photomodulation of these characteristics. Lastly, the structures can be further modified to enhance solubility in aqueous media by installing functional groups like e.g. a phosphate group.

5 Experimental Section

5.1 General Remarks

All reagents and starting materials are commercially available (Sigma-Aldrich, Fluorochem, chemPur, Alfa Aesar or BLDpharm) and were used as supplied unless otherwise indicated. Solvents of technical quality were distilled prior to use.

All experiments were conducted in air and in deionized water (Millipore) unless otherwise noted. In the experiments where physiological conditions were required, Dulbecco's Phosphate-Buffered Saline (DPBS) buffer pH 7.4, (-/-): no calcium, no magnesium, Gibco™ from Thermofisher, cat.#: 14190136, abbreviated below and in the thesis simply as “PBS buffer”, was used.

All experiments with photoisomerizable molecules in the visible light spectrum were performed in absence of sunlight, for example with brown glassware, or colourless glassware wrapped with aluminium foil, working in a room with dimmed light. All experiments were conducted in air unless otherwise noted and all reactions containing air- and moisture-sensitive compounds were performed under argon using oven-dried glassware applying common Schlenk-techniques. Liquids were added *via* steel cannulas and solids were added directly in powdered shape. For the aqueous extraction, for all analytic samples and for the HPLC deionized water (diH₂O) from Millipore was used unless otherwise noted. For certain reactions, flat-bottom crimp neck vials from CHROMAGLOBE with aluminum crimp cap were used. Reactions at low temperatures were cooled using flat dewars produced by Isotherm (Karlsruhe) with water/ice or isopropanol/dry ice mixtures.

5.2 Methods and Instruments

5.2.1 Analytical Balance

Used devices: SARTORIUS Basic (0.001 g), METTLER TOLEDO AE163 or RADWAG AS220.X2 (0.0001 g) and Sartorius M2P Micro Balance (0.001 mg).

5.2.2 Thin Layer Chromatography (TLC)

Analytical thin layer chromatography was carried out using silica coated aluminum plates (silica 60, F₂₅₄, layer thickness: 0.25 mm) with fluorescence indicator by Merck. The TLC plates with a size of 20 × 20 cm were cut into pieces according to demand. UV active compounds were detected with a UV lamp at $\lambda=254$ nm and $\lambda=365$ nm. When required, ninhydrin (1.5 g in 100 mL ethanol and 3.0 mL acetic acid), potassium permanganate (0.45 g potassium permanganate and 2.35 g of

sodium carbonate in 90 ml of water) or 2,4-DNP (1.2 g 2,4-dinitrophenylhydrazin in 8.0 mL water, 20 mL ethanol and 6.0 mL conc. H₂SO₄) was used as TLC-stain.

5.2.3 Chromatography

Flash column chromatography was performed using Merck silica 60 (0.040 × 0.063 mm, 230–400 mesh ASTM) and quartz sand (glowed and purified with hydrochloric acid).

5.2.4 High-Performance Liquid Chromatography (HPLC)

Analytical High Performance Liquid Chromatography (HPLC) was performed using two different instruments: (1) The 1200 Series from Agilent Technologies. The flow rate was 1.0 mL/min on an YMC C18-column JH08S04-2546WT with 250 mm length × 4.8 mm diameter and a column bead of 4 μm diameter. ChemStation for LC 3D systems (Agilent Technologies) was used for data extraction. (2) A Thermofisher UltiMate 3000 system containing a degasser, pump, autosampler, column compartment and diode array detector. The flow rate was 1 mL/min on a stationary PerfectSil Target (MZ-Analytik) C18 column (3-5 μm, 4.0 mm × 250 mm). Chromeleon 7 software was used for data extraction.

Preparative Reversed Phase High Performance Liquid Chromatography (RP-HPLC) was performed on the Puriflash™ 4125 system from Interchim. A VDSpher® C18-M-SE precolumn (10 μm, 40 x 16 mm) followed by a VDSpher® C18-M-SE separation column (10 μm, 250 x 20 mm, VDS Optilab) was used as the stationary phase. A linear gradient of acetonitrile and double distilled water, both supplemented with 0.1% trifluoroacetic acid (TFA), at a flow rate of 15 mL/min served as the mobile phase.

5.2.5 Nuclear Magnetic Resonance Spectroscopy (NMR)

NMR spectra were recorded using the following devices: ¹H NMR: Bruker 300 (300 MHz), Bruker Avance 400 (400 MHz), Bruker Ascend 500 (500 MHz), ¹³C NMR: Bruker 300 (75 MHz), Avance 400 (101 MHz), Ascend 500 (126 MHz), ¹⁹F NMR: Avance 400 (377 MHz) or Ascend 500 (471 MHz). The following solvents from Eurisotop were used: CDCl₃, acetic acid-*d*₄, DMSO-*d*₆, and D₂O. Chemical shifts δ were expressed in parts per million (ppm) and referenced to CDCl₃ (¹H: δ = 7.26 ppm, ¹³C: δ = 77.2 ppm), acetic acid-*d*₄ (¹H: δ = 2.04 ppm, ¹³C: δ = 179.0 ppm), DMSO-*d*₆ (¹H: δ = 2.50 ppm, ¹³C: δ = 39.5 ppm) and D₂O (¹H: δ = 4.79 ppm).¹⁴² ¹⁹F NMR were not referenced. For the characterization of centrosymmetric signals, the signal's median point was chosen, for multiplets the signal range. The signal structure is described as follows: s=singlet, d=doublet, t=triplet, q=quartet, quin=quintet, bs=broad singlet, m=multiplet, dt=doublet of

triplets. The spectra were analyzed according to the first order. All coupling constants are absolute values and expressed in Hertz (Hz). All NMR spectra were processed using MestReNova v14.1.2 (Mestrelab Research S.L.).

5.2.6 Mass Spectrometry (MS)

Mass spectra were recorded on a Finnigan MAT 95 mass spectrometer using electron ionization-mass spectrometry (EI-MS) or fast atom bombardment-mass spectroscopy (FAB-MS). For FAB measurements *m*-nitrobenzyl alcohol (3-NBA) was used as the matrix. The software used for FAB and EI measurements adds the mass of one electron. The molecular ion is abbreviated [M] for EI-MS and FAB-MS, the protonated molecular ion is abbreviated [M+H] for FAB-MS. Electrospray ionization-mass spectrometry (ESI-MS) spectra were recorded on a Thermo Fisher Scientific Q Executive mass spectrometer. Calibration was carried out using premixed calibration solutions (Thermo Fisher Scientific). The molecular fragments are stated as ratio of mass per charge *m/z*.

5.2.7 Infrared Spectroscopy (IR)

The infrared spectra were recorded with a Bruker, Alpha P instrument. All samples were measured by attenuated total reflection (ATR). The positions of the absorption bands are given in wavenumbers $\tilde{\nu}$ in cm^{-1} and were measured in the range from 3600 cm^{-1} to 500 cm^{-1} .

Characterization of the absorption bands was done in dependence of the absorption strength with the following abbreviations: vs (very strong, 0–9%), s (strong, 10–39%), m (medium, 40–69%), w (weak, 70–89%), vw (very weak, 90–100%).

5.2.8 Elemental Analysis (EA)

Elemental analysis was done on an Elementar vario MICRO instrument. The weight scale used was a Sartorius M2P. Calculated and found percentage by mass values for carbon, hydrogen, nitrogen, and sulfur are indicated in fractions of 100%.

5.2.9 LED Irradiation

Sample irradiation for photoisomerization and measurements of photostationary states was performed using LEDs with emission maxima of 523 nm, 407 nm and 365 nm from LED Engin, with 380 nm, 430 nm, 450 nm and 490 nm from Avonec and with 470 nm from OSRAM. For the time of irradiation, samples were maintained at constant temperature ($22 \pm 2 \text{ }^\circ\text{C}$) using a metal cooling block. Irradiation intensities of the respective LEDs were determined using the PowerMax USB (type PS19Q) sensor device (Coherent®) in five independent measurements. The detector

(diameter 19 mm) was located at a distance of 55 mm from the light source, identical to the position of irradiated samples. The results are presented in Table 5.

Table 5: Irradiation intensities of the LEDs. The LEDs applied to irradiate the photoswitchable compounds were determined using the PowerMax USB (type PS19Q) sensor device (Coherent®).

λ_{max} of the LED diode [nm]	Max Power [mW/cm ²]	Max mean power measured [W]	Min Power [mW/cm ²]	Min mean power measured [W]
365 nm	-	-	5.61E-01	1.59E-03
380 nm	8.67E-02	2.46E-04	-	-
407 nm	9.39E+01	2.66E-01	8.59E+01	2.43E-01
430 nm	1.85E+01	5.23E-02	1.19E+01	3.38E-02
450 nm	1.13E+00	3.21E-03	8.86E-01	2.51E-03
470 nm	1.69E+01	4.80E-02	1.59E+01	4.52E-02
490 nm	7.64E+00	2.17E-02	4.98E+00	1.41E-02
523 nm	7.08E+00	2.01E-02	6.56E+00	1.86E-02

5.2.10 Absorption Spectroscopy

UV-Vis absorption spectra between 200 nm and 800 nm were recorded on a Lambda 750 (PerkinElmer) UV-Vis spectrophotometer and an UV/Vis/NIR spectrometer Cary 500 (Varian), referenced against pure solvent. The spectra were measured in Quartz cuvettes of 10 mm or 2 mm optical path length at 20 °C. Baseline correction was performed manually to correct for solvent composition.

5.2.11 Fluorescence Spectroscopy

Fluorescence spectra were recorded on a Fluoromax-4 (Jobin Yvon - HORIBA) equipped with a Haake AC200 thermostat from Thermo Scientific at 20 °C. The spectra were recorded using FluorEssence v3.5.

5.2.12 Fluorescence Quantum Yield

Fluorescence quantum yield (Φ_F) measurements (absolute values) were performed on a Hamamatsu Quantaaurus-QY absolute PL quantum yield spectrometer C11347.

5.2.13 Photoswitching Quantum Yield

The maximum reaction quantum yields Φ_{\max} for either isomerization direction (*Z*-isomer to *E*-isomer $\Phi_{Z \rightarrow E}$ and the reverse process $\Phi_{E \rightarrow Z}$) were determined, using the experimental setup previously published by the working group around Riedle (LMU).¹³²

5.2.14 Crystal Structure Determinations

The single-crystal X-ray diffraction studies were carried out by Dr. Martin Nieger at the University of Helsinki (Finland) on a Bruker D8 Venture diffractometer with a PhotonII detector at 123(2) K, 173(2) K, or 298(2) K using Cu-K α radiation ($\lambda = 1.54178 \text{ \AA}$). Dual space methods (SHELXT)¹⁴³ were used for structure solution and refinement was carried out using SHELXL-2014 (full-matrix least-squares on F2)¹⁴⁴. Hydrogen atoms were localized by difference electron density determination and refined using a riding model (H(N, O) free). Semi-empirical absorption corrections were applied. All measurement parameters and further details are presented in the chapters 5.4.14, 5.5.11 and 5.6.11.

5.2.15 Quantum Chemical Calculations

All calculations were performed with the GAUSSIAN09 program package¹⁴⁵, employing the B3LYPGD3BJ/6-311G(d,p) PCM(DMSO) level of theory (these parameters were successfully applied for calculations in another arylidene-substituted heterocyclic photochromic system – hemiindigos¹³⁵). The global minima geometries were first optimized on the MPW1K/6-311G(d,p) and subsequently on the B3LYP-GD3BJ/6-311G(d,p). Frequency analysis confirmed all structures to be minimum structures since no imaginary frequencies have been found. Visualization of minimized structures, molecular orbitals, and calculated extinction spectra were done with GaussView 6.1.1. Excitation energies were calculated on TD-B3LYP-GD3BJ/6-311G(d,p) level of theory, using previously obtained structures. Solvent interactions were simulated using a polarizable continuum model (PCM), with parameters taken for DMSO. More detailed information and all results can be found in chapter 5.5.10.

5.3 Cell Experiments

All viability assays were performed by Anna-Lena Leistner and Angelika Seliwjorstow.

5.3.1 Cell Cultivation

HT-29 cells (Caucasian colon adenocarcinoma, ATCC HTB-38TM) and HeLa cells (Human cervix carcinoma) were grown separately in DMEM (Dulbecco's Modified Eagle Medium) which was modified with 10% FCS (fetal calf serum) and 1% penicillin/streptomycin solution (10,000

units/mL of penicillin and 10,000 µg/mL of streptomycin) in a humid incubator at 37 °C with 5% CO₂. Cells were washed with PBS (Phosphate-Buffered Saline) from Gibco®. Cells were detached from the surfaces with Trypsin-EDTA (0.25%) from Gibco®. The cells were tested negative for mycoplasma contamination.

5.3.2 Viability Assays

Method A: HT-29 cells were seeded in 96-well plates at 3,000 cells/well and incubated overnight to ensure cell attachment to the well-bottom and cell growth. The tested compounds were added in the dark and the cells were incubated for 48 h (final well volume 100 µL, 0.25% DMSO; six technical replicates). To ensure the same treatment to the control rows, the DMEM was removed from the wells and 0.25% DMSO in DMEM (100 µL) was added to the corresponding wells. The positive control was treated with 5 µL of Triton™ X-100 detergent (10% solution (w/v)) per well for at least 5 min to induce cell death before adding 15 µL of MTT dye-solution (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazoliumbromid in water / CellTiter 96®Non-Radioactive Cell Proliferation Assay from Promega or Invitrogen™ CyQUANT™ MTT Cell Viability Assay) to all sample wells and incubating for 3 h in the dark. 100 µL of Solubilization Solution/Stop Mix (CellTiter 96®Non-Radioactive Cell Proliferation Assay from Promega / Invitrogen™ CyQUANT™ MTT Cell Viability Assay) were added after incubation to stop the reduction of MTT to formazan, therefore prevent overreaction and solubilize the formazan crystals. Alternatively, a freshly prepared stop solution (10% sodium dodecyl sulfate, 0.01 M HCl in water) was used. After 24 h of solubilization in the incubator, the plate was read out with a plate reader (SpectraMax® iD3, Molecular Devices) by measuring the absorption of each well at 570 nm or 590 nm. Data points were only excluded from the analysis when errors were observed during execution of the experiment (e.g. pipetting to a wrong well). In the experiment where a sample of compound **15** was irradiated at 490 nm, a complete row of wells (one concentration) was excluded. Otherwise only single wells were excluded. Absorbance data was averaged over the technical replicates, the positive control subtracted as background, then normalized to viable cell count from negative control cells (% control) as 100%. Three independent experiments were performed. Data were plotted against the log of agonist concentration (log₁₀([agonist]) (M)) with mean and SD in GraphPad Prism Version 9.1.1 for Windows, GraphPad Software, San Diego, California USA, www.graphpad.com.

Method B: Following changes apply for viability assay with more detailed concentration range (compounds **14** and **15**): The tested photoisomers or irradiated mixtures were added in the dark

and the cells were incubated for 48 h (final well volume 100 μL , *E*-isomer: 0.5% DMSO / *Z*-isomer and 490 nm PSS: 0% DMSO; three to six technical replicates). To ensure the same treatment to the control rows, the DMEM was removed from the wells and *E*-isomer: 0.5% DMSO / *Z*-isomer and 490 nm PSS: 0% DMSO in DMEM (100 μL) was added to the corresponding wells. The positive control was treated with 5 μL of Triton™ X-100 detergent (10% solution (w/v)) per well for at least 5 min before adding 10 μL of MTT dye-solution (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazoliumbromid in water / Cell Proliferation kit I (MTT) from Roche) to all sample wells and incubating for 4 h in the dark. 100 μL of Solubilization Solution/Stop Mix (Cell Proliferation kit I (MTT) from Roche) were added after incubation to stop the reduction of MTT to formazan, therefore prevent overreaction and solubilize the formazan crystals.

5.3.3 Cell Penetration Assays

HeLa cells (Human cervix carcinoma cells, 4×10^4 cells/well) were seeded in 8 well μ -slides (IBIDI® μ -Slide 8 well) with 200 μL Dulbecco's modified Eagle's medium (DMEM, 5 high glucose, Gibco) supplemented with 10% fetal calf serum (FCS, PAA) and 1 U/mL Penicillin/Streptomycin and incubated overnight at 37 °C, 5% CO₂ and 95% humidity. The medium was replaced by 200 μL test solution per well, diluted in DMEM medium containing 0.25% (v/v) DMSO and incubated at 37 °C, 5% CO₂ and 95% humidity for 15 hours.

Fixation was performed by removing the medium after the incubation time and each well washed with 200 μL PBS and 200 μL /well of a 4% *para*-formaldehyde solution in PBS were added. After incubation for 10 min the fixing solution was removed, the cells were washed ten times with PBS. 200 μL PBS/well were added and imaging was performed with a DMi8 inverted microscope (LEICA). The added compounds were excited at 488 nm and detected at wavelengths in the range of 500 - 650 nm. The results were processed and visualized with LEICA Application Suite X 3.7.4.23463 from LEICA Microsystems CMS GmbH.

5.3.4 Immunofluorescence Imaging

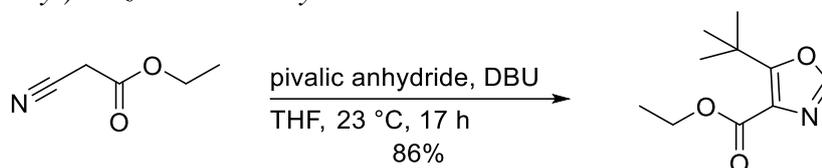

HT-29 cells were seeded in 8 well μ -slides from Ibi and incubated overnight. The medium was replaced by 200 μL test solution per well, diluted in DMEM medium containing 0.25% DMSO. Based on the results of the viability assays, a concentration between the two IC₅₀-values of the respective photoisomers was chosen: plinabulin (**6**): 2 nM; compound **8**: 20 nM; compound **10**: 200 nM. After 6 h of incubation in the dark, the medium was removed, each well washed with 200 μL PBS and 200 μL /well of a 4% *para*-formaldehyde solution in PBS were added. After incubation for 10 min the fixing solution was removed, the cells were washed with PBS and 200 μL of a 1%

Triton-X100 solution in PBS was added to each well and incubated for 4 min. Then the solution was removed, and the cells were washed again with PBS. To avoid false positive staining of the antibody, all binding sites were blocked by a CAS-Block™ histochemical reagent solution (ThermoFisher). For this purpose, PBS was removed and the CAS-Block™ solution was added (200 µL per well) and incubated for 30 min. For tubulin staining a fluorescein (FITC)-labeled monoclonal anti- α -tubulin antibody produced in mice (Sigma; F2168-2ML) was used. 200 µL of a 1:500 dilution of the antibody in PBS was added and the cells were incubated overnight in the fridge. The next day, the solution was replaced by 1:5000 Hoechst 33342 (Promega) in PBS. After 5 min of incubation, the cells were washed with PBS and imaged using a TCS SPE microscope (LEICA) microscope. The FITC-fluorescence was detected at 525 nm after irradiation at 470 nm, the Hoechst dye was irradiated at 361 nm and its emission was detected at 497 nm. The results were processed and visualized with LEICA Application Suite X 3.5.7.23225 from Leica Microsystems CMS GmbH.

5.4 Synthesis and Characterization of Plinabulin Derivatives

5.4.1 Precursor Synthesis

Ethyl 5-(*tert*-butyl)oxazole-4-carboxylate

Ethylisocyanoacetate (**3**) (10.0 g, 88.4 mmol, 1.00 equiv.) was dissolved in THF (80 mL), and pivalic anhydride (19.7 mL, 18.1 g, 97.3 mmol, 1.10 equiv.) and DBU (14.8 g, 97.3 mmol, 1.10 equiv.) were added. The reaction mixture was stirred overnight at 23 °C. Subsequently, the solvent was removed *in vacuo* and the residue was dissolved in ethyl acetate (150 mL). Brine (110 mL) and saturated aq. Na₂CO₃ solution (55 mL) were added and the phases were separated, and the aqueous phase was extracted three more times with ethyl acetate. After washing the organic phase with saturated aq. Na₂CO₃ solution (75 mL), citric acid (75 mL, 0.1 M) and drying over Na₂SO₄, the solvent was removed *in vacuo*. The residual oil was purified by flash column chromatography (cyclohexane:ethyl acetate, 20:1 → 9:1 → 6:1) to yield 15.0 g (76.1 mmol, 86%) of ethyl 5-(*tert*-butyl)oxazole-4-carboxylate as a yellow oil.¹⁰⁰

¹H NMR (400 MHz, CDCl₃): δ = 7.69 (s, 1H, CH), 4.38 (q, *J* = 7.1 Hz, 2H, CH₂), 1.45 (s, 9H, C(CH₃)₃), 1.40 (t, *J* = 7.1 Hz, 3H, CH₃) ppm.

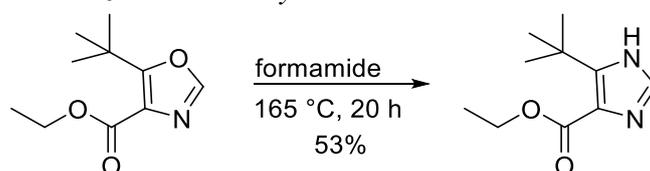

¹³C NMR (101 MHz, CDCl₃): δ = 166.1 (C-C(CH₃)₃), 162.2 (COOEt), 147.3 (CH), 126.1 (C-COOEt), 61.3 (CH₂), 33.4 (C(CH₃)₃), 28.2 (C(CH₃)₃), 14.4 (CH₃) ppm.

TLC: R_f = 0.34 (cyclohexane:ethyl acetate, 4:1).

IR (ATR): ν = 3118 (vw), 2975 (w), 2962 (w), 2938 (w), 2908 (w), 2874 (vw), 1718 (m), 1572 (m), 1527 (m), 1504 (w), 1482 (w), 1463 (w), 1448 (w), 1397 (w), 1368 (m), 1333 (m), 1302 (m), 1254 (m), 1221 (w), 1204 (w), 1180 (m), 1160 (m), 1129 (m), 1098 (m), 1052 (s), 1023 (m), 1006 (m), 942 (w), 864 (w), 844 (m), 820 (w), 793 (m), 773 (w), 708 (w), 649 (m), 606 (w), 541 (w), 401 (w) cm⁻¹.

HRMS (EI): *m/z* calcd. for C₁₀H₁₅NO₃ [M], 197.1051; found, 197.1052.

Ethyl 5-(*tert*-butyl)-1H-imidazole-4-carboxylate

Ethyl 5-(*tert*-butyl)oxazole-4-carboxylate (15.0 g, 76.0 mmol, 1.00 equiv.) was dissolved in formamide (90.0 mL, 102 g, 2.27 mol, 29.8 equiv.) and the mixture reacted at 165 °C overnight. After cooling down, ethyl acetate (180 mL) and brine (90 mL) were added and the aqueous phase was extracted with ethyl acetate (2×90 mL). Subsequently, the organic layer was washed with saturated aq. Na₂CO₃ solution (3×75 mL) and brine (3×75 mL), dried over Na₂SO₄ and concentrated *in vacuo*. The residual oil was purified by flash column chromatography (10% MeOH in toluene) to yield 7.98 g (40.7 mmol, 53%) of ethyl 5-(*tert*-butyl)-1*H*-imidazole-4-carboxylate as a yellow solid.¹⁰⁰

¹H NMR (400 MHz, CDCl₃): δ = 9.76 (s, 1H, NH), 7.47 (d, *J* = 1.7 Hz, 1H, CH), 4.44 – 4.09 (m, 2H, CH₂), 1.44 (s, 9H, C(CH₃)₃), 1.32 – 1.22 (m, 3H, CH₃) ppm.

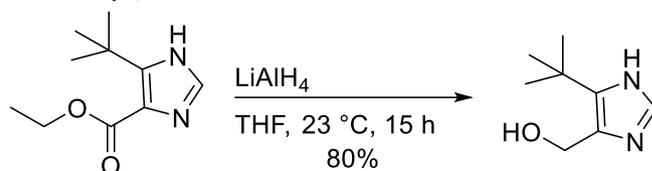

¹³C NMR (101 MHz, CDCl₃): δ = 162.4 (COOEt), 150.8 (C-C(CH₃)₃), 133.4 (CH), 123.5 (C-COOEt), 60.5 (CH₂), 32.6 (C(CH₃)₃), 29.2 (C(CH₃)₃), 14.3 (CH₃) ppm.

TLC: R_f = 0.15 (10% MeOH in toluene).

IR (ATR): ν = 3119 (vw), 3033 (vw), 2955 (w), 2907 (w), 2871 (w), 2840 (w), 2747 (vw), 2630 (vw), 1700 (w), 1560 (vw), 1499 (vw), 1434 (w), 1394 (vw), 1366 (vw), 1296 (m), 1271 (w), 1224 (vw), 1198 (w), 1171 (w), 1147 (w), 1096 (vw), 1058 (m), 1024 (w), 952 (w), 935 (w), 864 (w), 847 (w), 793 (w), 711 (vw), 663 (w), 605 (vw), 564 (vw), 483 (vw), 401 (vw) cm⁻¹.

HRMS (EI): *m/z* calcd. for C₁₀H₁₆N₂O₂ [M], 196.1212; found, 196.1212.

(5-(*tert*-Butyl)-1*H*-imidazol-4-yl)methanol

Ethyl 5-(*tert*-butyl)-1*H*-imidazole-4-carboxylate (4.40 g, 22.4 mmol, 1.00 equiv.) was dissolved in THF (140 mL). LiAlH₄ (1.70 g, 44.8 mmol, 2.00 equiv.) was added in small portions over 45 min, while cooling the mixture in an ice water bath to 0 °C. The reaction mixture was stirred overnight at 23 °C and subsequently ethyl acetate (100 mL) and water (50 mL) were added at 0 °C. After another 1 hour of stirring, the precipitate was filtered off, the filtrate was dried over Na₂SO₄ and the solvent was removed *in vacuo*. The residual solid was purified by flash column chromatography (20% MeOH in CH₂Cl₂) to yield 2.78 g (18.0 mmol, 80%) of (5-(*tert*-butyl)-1*H*-imidazol-4-yl)methanol as a pale yellow solid.¹⁰⁶

¹H NMR (400 MHz, DMSO-*d*₆): δ = 7.35 (s, 1H, CH), 4.46 (s, 2H, CH₂), 1.28 (s, 9H, C(CH₃)₃) ppm.

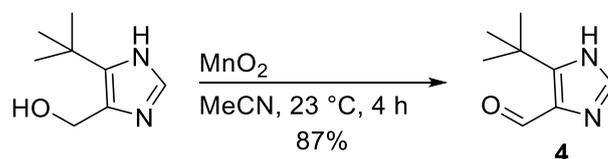

¹³C NMR (101 MHz, DMSO-*d*₆): δ = 139.7 (C-C(CH₃)₃), 131.8 (CH), 129.1 (C-CH₂), 56.0 (CH₂), 31.9 (C(CH₃)₃), 30.7 (C(CH₃)₃) ppm.

TLC: R_f = 0.25 (20% MeOH in CH₂Cl₂, stained with KMnO₄).

IR (ATR): ν = 3159 (vw), 3119 (w), 3106 (w), 3067 (w), 3019 (w), 2959 (w), 2901 (w), 2894 (w), 2884 (w), 2840 (w), 2730 (w), 2694 (w), 2670 (w), 2630 (w), 1578 (w), 1492 (w), 1469 (w), 1390 (vw), 1356 (w), 1332 (vw), 1298 (w), 1262 (w), 1230 (vw), 1204 (vw), 1187 (w), 1163 (w), 1094 (w), 1026 (w), 1013 (m), 953 (w), 901 (w), 858 (w), 823 (w), 765 (w), 715 (w), 649 (w), 595 (w), 520 (w), 473 (w), 405 (vw), 399 (vw), 380 (w) cm⁻¹.

HRMS (EI): m/z calcd. for C₈H₁₄N₂O [M], 154.1106; found, 154.1104.

5-(tert-Butyl)-1H-imidazole-4-carbaldehyde (4)

(5-(*tert*-Butyl)-1*H*-imidazol-4-yl)methanol (751 mg, 4.87 mmol, 1.00 equiv.) was dissolved in acetonitrile (50 mL). Subsequently, activated MnO₂ (4.23 g, 48.7 mmol, 10.0 eq, c.a. 85%, <10 μ m) was added and the mixture was stirred at room temperature for 4 hours. Subsequently, the mixture was filtered through celite® and the solvent was removed *in vacuo* to yield 644 mg (4.23 mmol, 87%) of 5-(*tert*-butyl)-1*H*-imidazole-4-carbaldehyde (**4**) as a yellow solid.¹⁰⁶

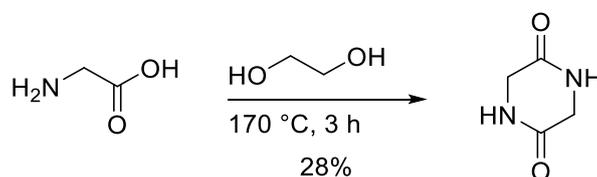

¹H NMR (400 MHz, CDCl₃): δ = 10.06 (s, 1H, CHO), 7.74 (s, 1H, CH), 1.48 (s, 9H, C(CH₃)₃) ppm.

¹³C NMR (101 MHz, CDCl₃): δ = 181.9 (CHO), 137.5 (CH), 34.1 (C(CH₃)₃), 31.3 (C(CH₃)₃) ppm.

IR (ATR): ν = 3121 (vw), 3053 (vw), 2963 (w), 2902 (vw), 2864 (vw), 1670 (w), 1558 (vw), 1507 (w), 1465 (vw), 1435 (w), 1398 (vw), 1377 (w), 1370 (w), 1349 (vw), 1336 (vw), 1295 (w), 1271 (w), 1204 (vw), 1186 (vw), 1057 (vw), 1023 (vw), 950 (w), 933 (vw), 864 (w), 837 (w), 786 (w), 666 (w), 582 (vw), 445 (vw) cm⁻¹.

Piperazine-2,5-dione

Glycine (**1**) (100 g, 1.33 mol, 1.00 equiv.) was dissolved in ethylene glycol (500 mL, 557 g, 8.97 mmol, 6.73 equiv.) and stirred at 170 °C for 3 hours. Afterwards, the solution was cooled at 5 °C for 20 hours and the precipitate was filtered off and washed with methanol (500 mL). Subsequently, the crude product was recrystallized from water and the solution was cooled overnight. The residual solid was filtered off and washed with methanol to yield 42.2 g (370 mmol, 28%) of piperazine-2,5-dione as a beige solid.¹⁰⁴

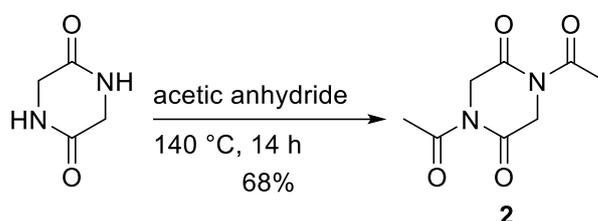

¹H NMR (400 MHz, DMSO-*d*₆): δ = 8.01 (s, 2H, CONH), 3.70 (d, J = 1.9 Hz, 4H, CH₂) ppm.

¹³C NMR (101 MHz, DMSO-*d*₆): δ = 166.1 (CONH), 44.3 (CH₂) ppm.

IR (ATR): ν = 3173 (vw), 3041 (vw), 2980 (vw), 2912 (vw), 2874 (vw), 1662 (w), 1591 (w), 1519 (w), 1468 (w), 1411 (w), 1333 (w), 1251 (w), 1132 (w), 1116 (w), 1072 (w), 1038 (w), 996 (vw), 914 (w), 892 (w), 829 (w), 805 (w), 701 (w), 605 (w), 518 (w), 479 (w), 445 (w), 408 (w), 397 (w) cm⁻¹.

5.4.2 Synthesis of Aldehydes

2,6-Bis(methylthio)benzaldehyde and 2-chloro-6-(methylthio)benzaldehyde

2,6-Dichlorobenzaldehyde (300 mg, 1.71 mmol, 1.00 equiv.) was dissolved in dry DMF (2 mL) under argon atmosphere. Sodium methanethiolate (252 mg, 3.60 mmol, 2.10 equiv.) was added at 15 °C portionwise to the mixture. After 20 min of stirring, the solution was heated to 60 °C and stirred for an additional 60 min. Subsequently, the mixture was cooled to room temperature, diluted with ethyl acetate (6 mL) and washed with water (3×3 mL). The solution was dried over Na₂SO₄ and the solvent was removed *in vacuo*. The crude residue was purified by flash column chromatography (cyclohexane:CH₂Cl₂, 1:1) to yield 200 mg (1.01 mmol, 59%) of 2,6-bis(methylthio)benzaldehyde as a yellow solid and 89.0 mg (0.477 mmol, 28%) of 2-chloro-6-(methylthio)benzaldehyde as a yellow solid.¹⁴⁶

2,6-Bis(methylthio)benzaldehyde

¹H NMR (400 MHz, CDCl₃): δ = 10.71 (s, 1H, CHO), 7.42 (t, J = 8.0 Hz, 1H, H_{arom}), 7.11 (d, J = 7.9 Hz, 2H, H_{arom}), 2.48 (s, 6H, CH₃) ppm.

¹³C NMR (101 MHz, CDCl₃): δ = 190.2 (CHO), 145.9 (C-SCH₃), 133.1 (C_{arom}), 129.3 (C-CHO), 122.0 (C_{arom}), 16.3 (CH₃) ppm.

IR (ATR): ν = 2989 (w), 2975 (w), 2912 (w), 2860 (w), 2840 (w), 2758 (w), 1663 (m), 1560 (w), 1547 (w), 1509 (w), 1502 (w), 1442 (w), 1432 (w), 1412 (w), 1390 (w), 1324 (w), 1310 (w), 1281 (w), 1203 (m), 1193 (w), 1174 (w), 1102 (w), 1086 (w), 972 (w), 960 (w), 846 (w), 776 (w), 758 (m), 720 (w), 704 (w), 669 (w), 475 (w), 415 (w) cm⁻¹.

HRMS (EI): m/z calcd. for C₉H₁₀OS₂ [M], 198.0173; found, 198.0172.

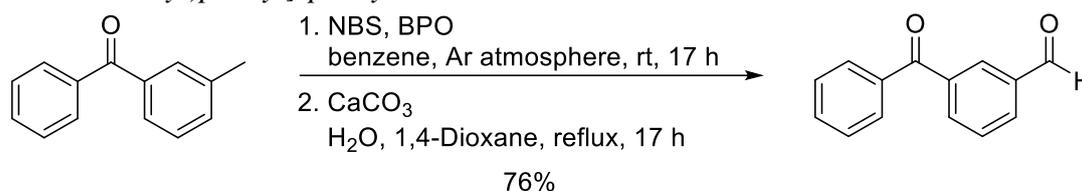

2-Chloro-6-(methylthio)benzaldehyde

¹H NMR (400 MHz, CDCl₃): δ = 10.64 (s, 1H, CHO), 7.42 (t, J = 8.0 Hz, 1H, H_{arom}), 7.24 – 7.16 (m, 2H, H_{arom}), 2.46 (s, 3H, CH₃) ppm.

¹³C NMR (101 MHz, CDCl₃): δ = 190.7 (CHO), 147.0 (C_{arom}-SCH₃), 140.5 (C_{arom}-Cl), 133.7 (C_{arom}), 128.3 (C_{arom}-CHO), 125.7 (C_{arom}), 123.1 (C_{arom}), 15.7 (CH₃) ppm.

IR (ATR): ν = 1666 (w), 1571 (w), 1557 (w), 1543 (w), 1490 (vw), 1434 (w), 1409 (w), 1395 (w), 1326 (vw), 1317 (w), 1283 (vw), 1194 (m), 1162 (w), 1092 (w), 1079 (w), 990 (vw), 972 (vw), 962 (w), 945 (w), 894 (vw), 877 (vw), 837 (w), 775 (m), 704 (w), 663 (w), 545 (vw), 523 (vw), 428 (w), 412 (w) cm⁻¹.

[3-(Dibromomethyl)phenyl]-phenylmethanone

3-Methylbenzophenone (2.00 g, 1.83 mL, 10.2 mmol, 1.00 equiv.), *N*-bromosuccinimide (4.53 g, 25.5 mmol, 2.50 equiv.) and benzoyl peroxide (39.5 mg, 163 μ mol, 0.0160 equiv.) in benzene (20.0 mL) were refluxed under argon atmosphere for 17 h. The mixture was allowed to cool down to room temperature, washed twice with 50 mL of distilled H₂O and dried over anhydrous Na₂SO₄. The solvent was then removed *in vacuo* to yield 4.28 g of crude [3-(dibromomethyl)phenyl]-phenylmethanone as a grey solid.

The crude [3-(dibromomethyl)phenyl]-phenylmethanone (4.28 g, 12.1 mmol, 1.00 equiv.) was combined with CaCO₃ (5.00 g, 50.0 mmol, 4.13 equiv.) in 60 mL H₂O/dioxane (1:1) and refluxed overnight for 17 h. After the reaction mixture has been cooled down, the solvent was removed *in vacuo*. Subsequently, 40 mL of CH₂Cl₂ and 80 mL of 1 mol/L HCl were added under continued stirring to dissolve the solid. The organic phase was isolated and the aqueous phase extracted twice with 20 mL of CH₂Cl₂. The organic fractions were combined, washed twice with 40 mL sat. aq. NaHCO₃ and dried over anhydrous Na₂SO₄. The crude residue was purified by flash column chromatography (diethyl ether:cyclohexane, 1:1) to yield 1.63 g (7.77 mmol, 76%) of 3-benzoylbenzaldehyde as colorless oil.¹⁴⁷

TLC: R_f = 0.45 (cyclohexane:diethyl ether 1:1)

¹H NMR (400 MHz, CDCl₃): δ = 10.06 (s, 1H, CHO), 8.25 (t, *J* = 1.8 Hz, 1H, *H*_{arom}), 8.09 (dt, *J* = 7.6, 1.5 Hz, 1H, *H*_{arom}), 8.05 (dt, *J* = 7.7, 1.5 Hz, 1H, *H*_{arom}), 7.81 – 7.76 (m, 2H, *H*_{arom}), 7.66 (t, *J* = 7.7 Hz, 1H, *H*_{arom}), 7.63 – 7.58 (m, 1H, *H*_{arom}), 7.53 – 7.41 (m, 2H, *H*_{arom}) ppm.

tert-Butyl 3-formylpyrrole-1-carboxylate

Boc₂O (1.24 g, 5.68 mmol, 1.08 equiv.) dissolved in dry CH₂Cl₂ (7.5 mL) was added dropwise to a solution of 3H-pyrrole-3-carbaldehyde (500 mg, 5.26 mmol, 1.00 equiv.) in dry CH₂Cl₂ (7.5 mL) at 0 °C. After 15 min a solution of DIPEA (734 mg, 5.68 mmol, 1.08 equiv.) and DMAP (19.3 mg, 158 μ mol, 0.0300 equiv.) in dry CH₂Cl₂ (7.5 mL) was added dropwise over 30 min. The reaction was stirred for 1 h at 0 °C and then allowed to warm to room temperature over the course of 1.5 h.

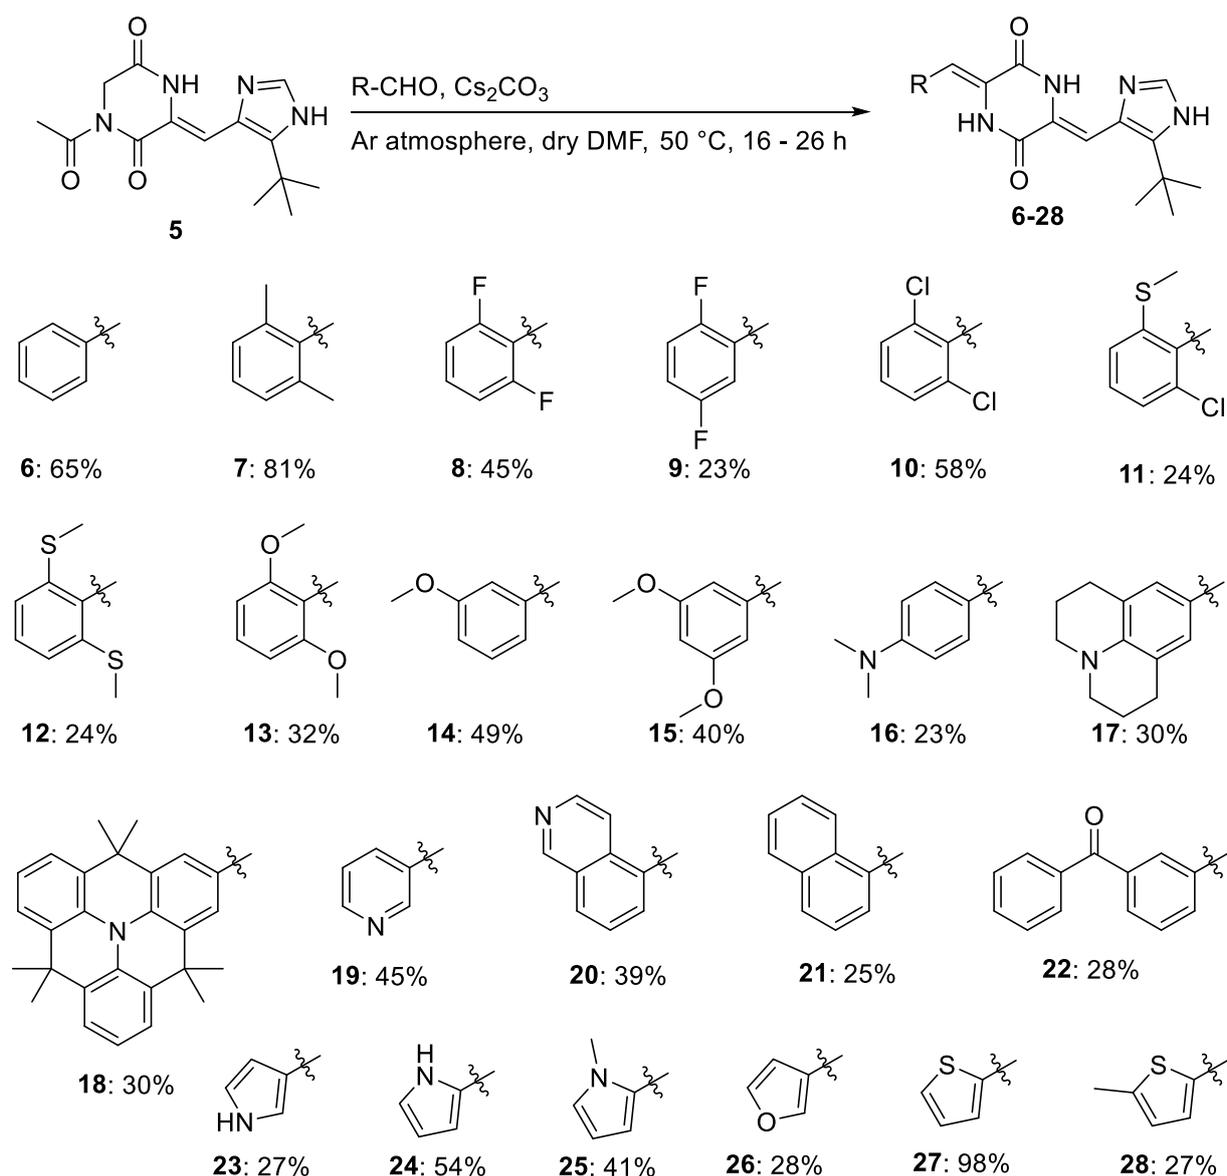

The mixture was washed with a sat. aq. solution of NH_4Cl (30 mL), extracted with CH_2Cl_2 (30 mL) and purified by flash chromatography (cyclohexane/ethyl acetate 9:1). The reaction yielded 896 mg of *tert*-butyl 3-formylpyrrole-1-carboxylate as a colorless oil (4.59 mmol, 87%).¹⁴⁸

^1H NMR (400 MHz, CDCl_3): δ = 9.83 (s, 1H), 7.83 (t, J = 1.9 Hz, 1H), 7.25 – 7.27 (m, 1H), 6.64 (dd, J = 3.4, 1.7 Hz, 1H), 1.62 (s, 9H) ppm.

^{13}C NMR (101 MHz, CDCl_3): δ = 185.8, 148.1, 129.0, 128.4, 122.3, 109.5, 85.7, 28.0 ppm.

5.4.3 Synthesis of Plinabulin Derivatives

The following compounds were synthesized under my supervision by students working on their bachelor thesis: **7**, **11**, **12** and **13** by Angelika Seliwjorstow; **9**, **19-22** by Jonas Springer; **23**, **25**, **26** and **28** by Sven Schenk.

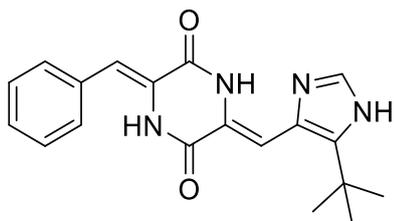

(*Z*)-1-Acetyl-3-((5-(*tert*-butyl)-1*H*-imidazol-4-yl)methylene)piperazine-2,5-dione (**5**) (100 mg, 344 μmol , 1.00 equiv.) was dissolved in 1.0 mL of dry DMF under an argon atmosphere. The respective aldehyde (517 μmol , 1.50 equiv.) was dissolved in the mixture and Cs_2CO_3 (168 mg, 517 μmol , 1.50 equiv.) was added. The mixture was stirred for 17-23 h under an argon atmosphere at $50\text{ }^\circ\text{C}$. The reaction mixture was subsequently poured on ice water (20 mL) and the precipitate was filtered off. The crude product was purified *via* HPLC (gradient of 20-80% MeCN in H_2O within 40 min, 0.1% TFA (v/v) in the solvents) and washed with sat. aq. solution of NaHCO_3 .

For selected compounds the respective *E*-isomers were isolated. This was achieved by irradiating a solution of the respective compound in DMSO with 407 nm for 1 hour followed by the separation of the two photoisomers *via* HPLC and washing with sat. aq. solution of NaHCO_3 .

In case of compounds **7**, **11**, **12** and **13** the neutralization step after the purification was omitted.

For the synthesis of compound **23** a Boc-protected aldehyde was used and an additional deprotection step was included before the purification as described in the respective subchapter. The aldehyde applied for the synthesis of compound **18** was synthesized and provided by the group of Prof. Dr. Milan Kivala from Heidelberg University.

Plinabulin (**6**)

5.4.5 Absorption Spectra of Non-Irradiated Samples

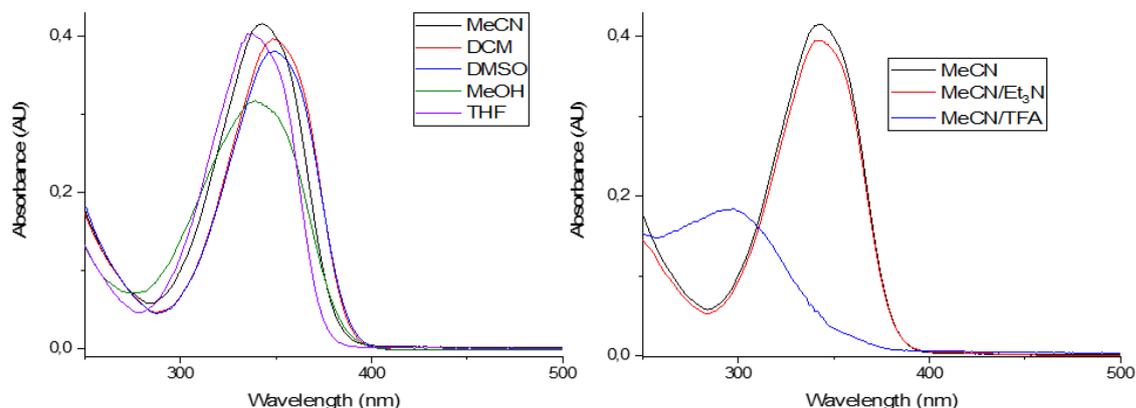

Figure 125: Compound Z-5 was dissolved in different solvents (80 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

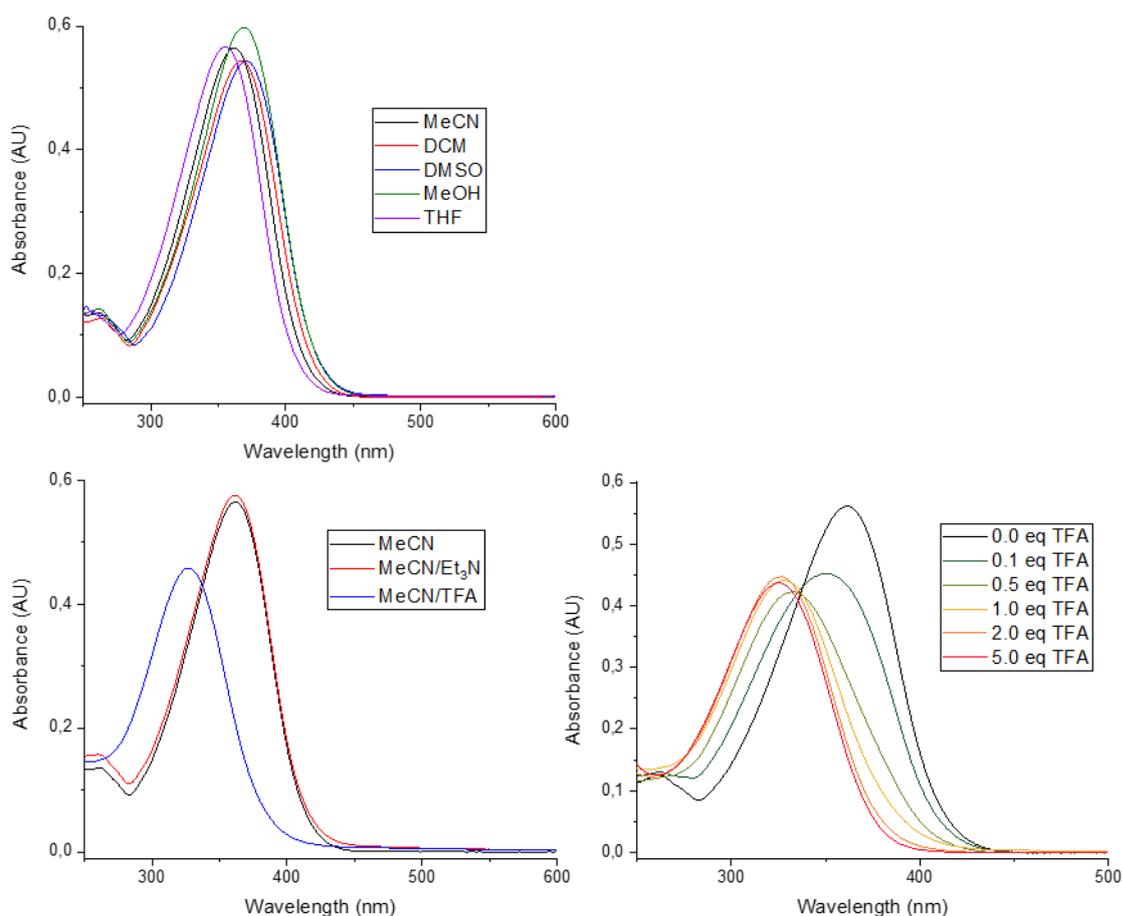

Figure 126: Compound Z-6 was dissolved in different solvents (80 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code. Additionally, absorption spectra of 80 μM solutions ($d=2$ mm) of **6** in MeCN with different amounts of TFA were measured.

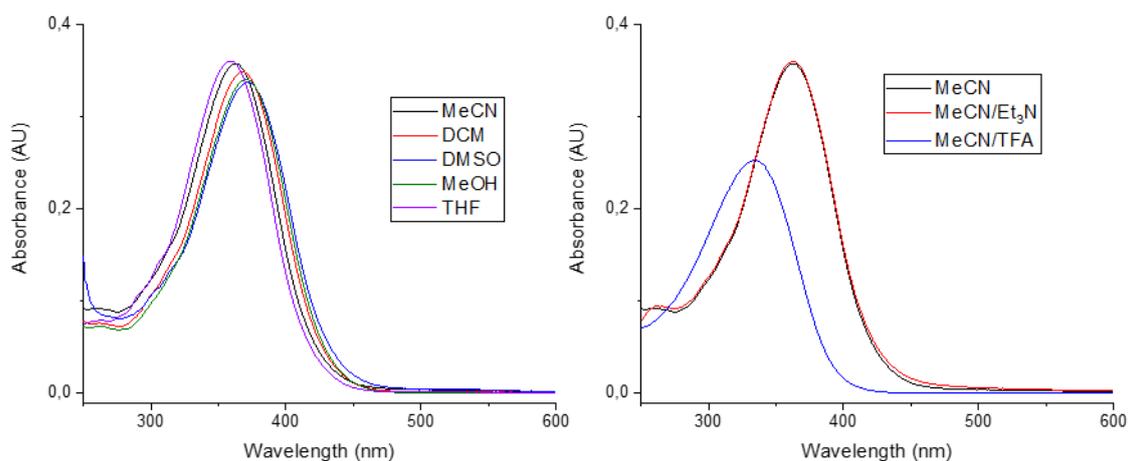

Figure 127: Compound *E-6* was dissolved in different solvents (80 μ M) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

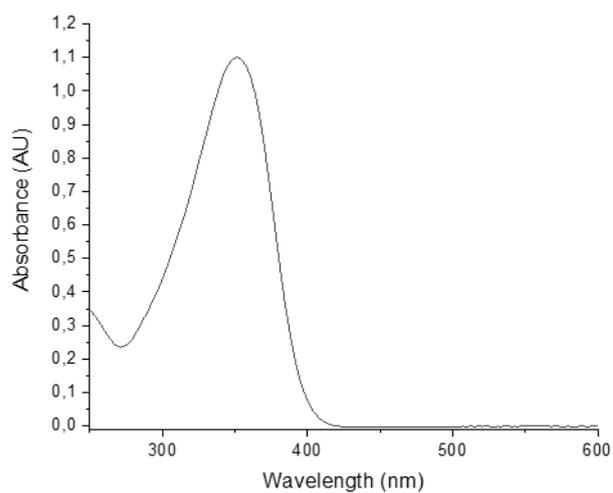

Figure 128: Absorption spectrum of compound *Z-7* (52 μ M) MeCN ($d = 10$ mm).

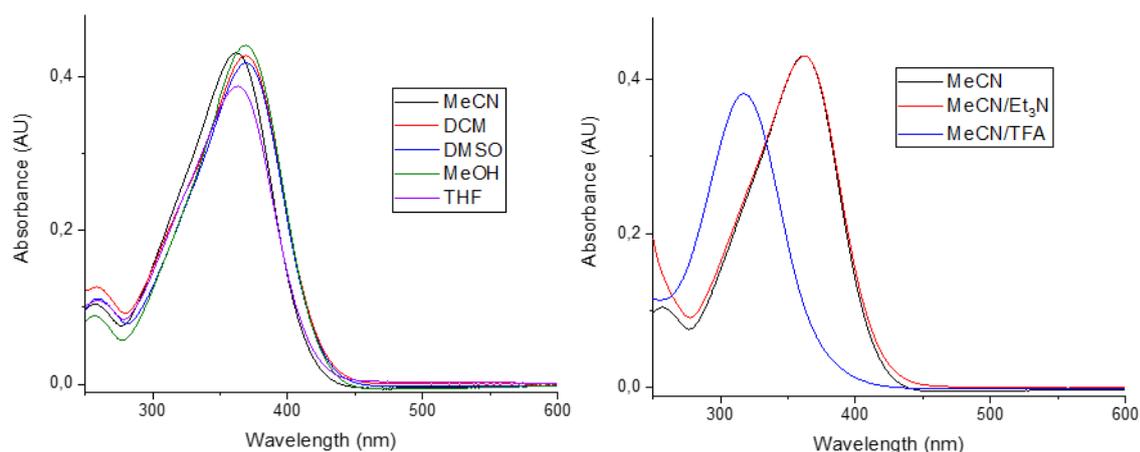

Figure 129: Compound Z-8 was dissolved in different solvents (80 μ M) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

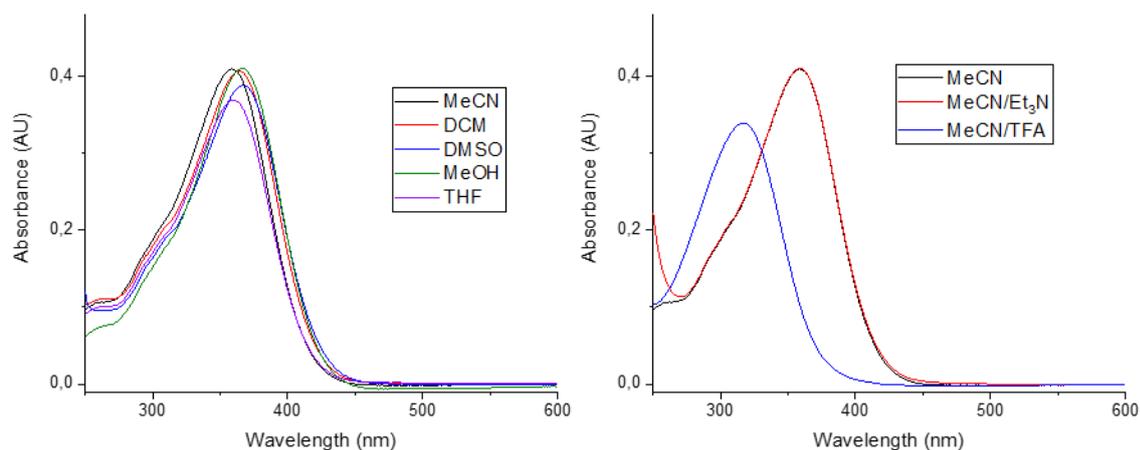

Figure 130: Compound E-8 was dissolved in different solvents (80 μ M) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

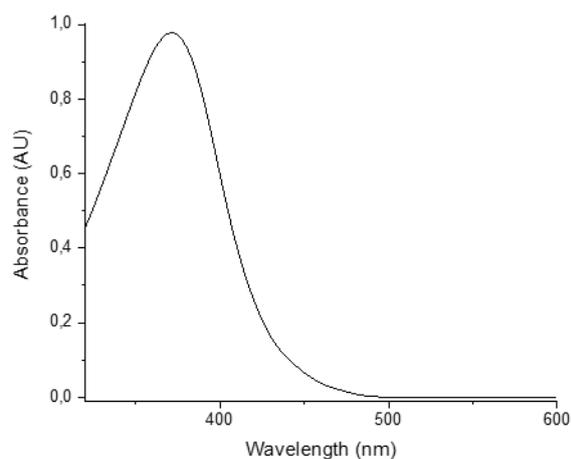

Figure 131: Absorption spectrum of compound Z-9 (160 μ M) DMSO ($d = 2$ mm).

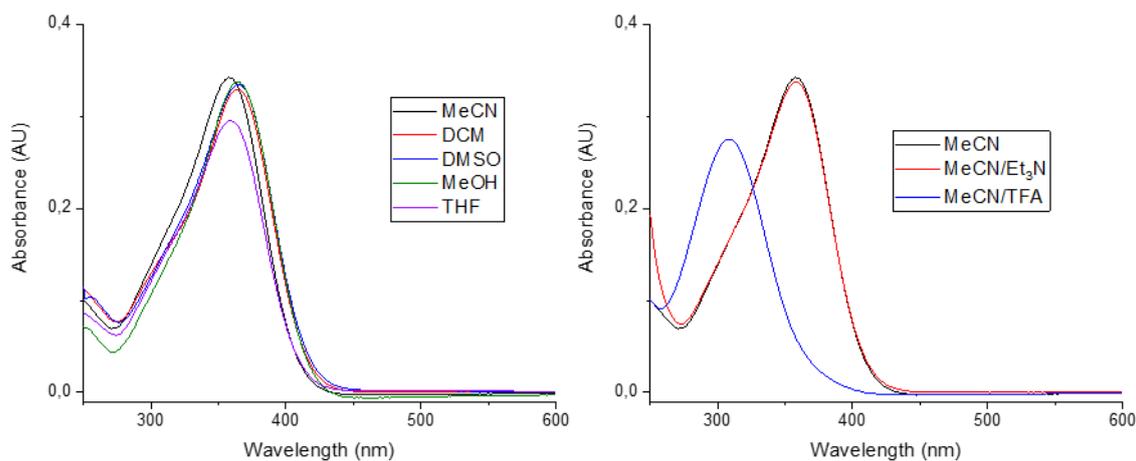

Figure 132: Compound **Z-10** was dissolved in different solvents (80 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

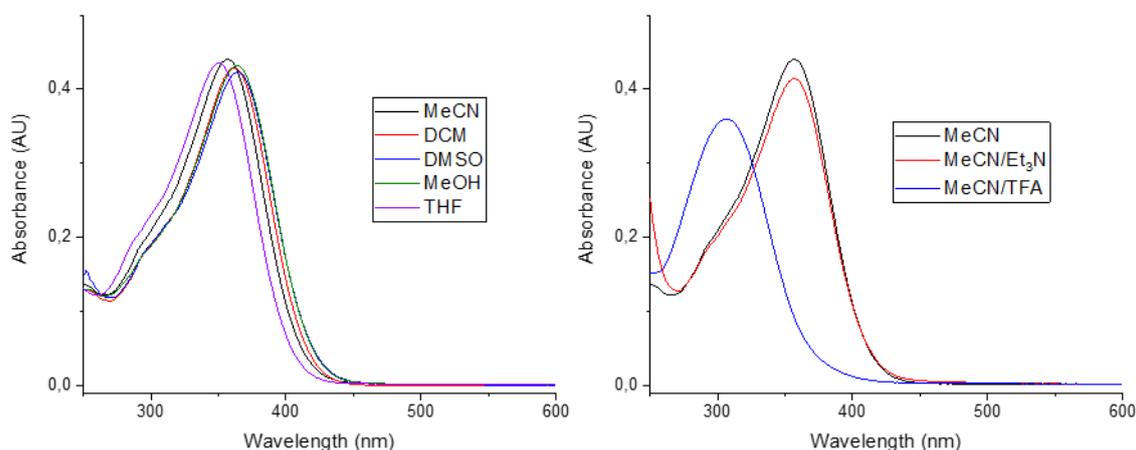

Figure 133: Compound **E-10** was dissolved in different solvents (80 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

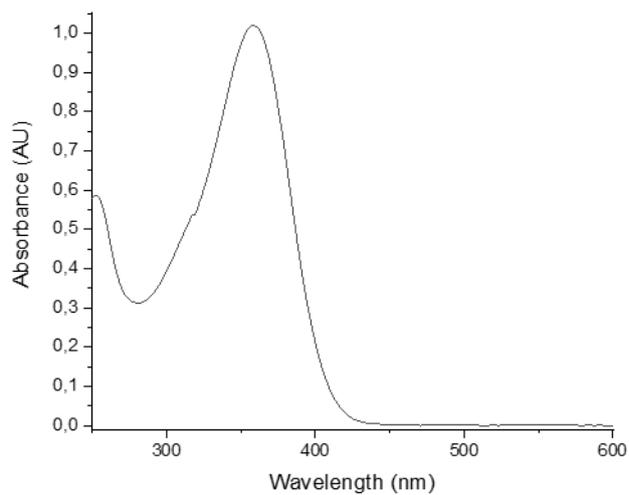

Figure 134: Absorption spectrum of compound Z-11 (42 μ M) MeCN (d = 10 mm).

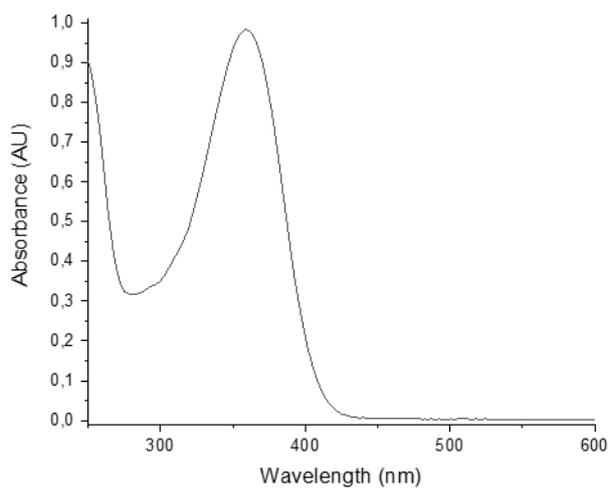

Figure 135: Absorption spectrum of compound Z-12 (41 μ M) MeCN (d = 10 mm).

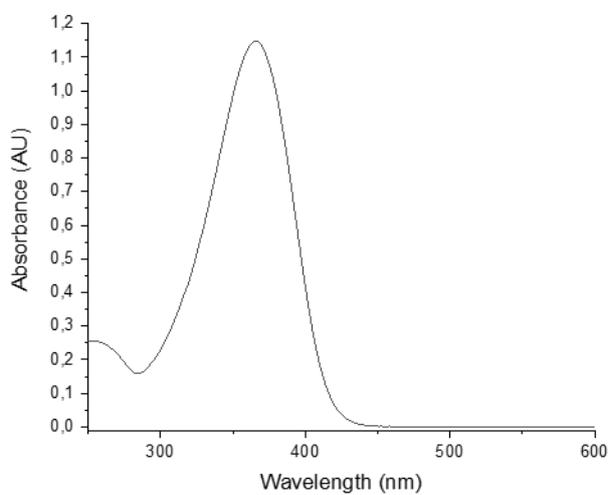

Figure 136: Absorption spectrum of compound Z-13 (45 μ M) MeCN (d = 10 mm).

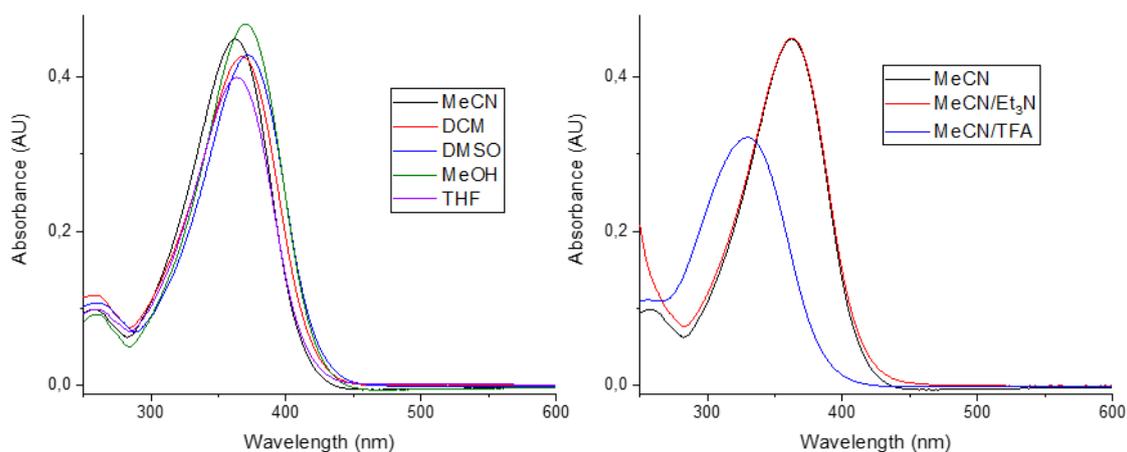

Figure 137: Compound **Z-14** was dissolved in different solvents (80 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

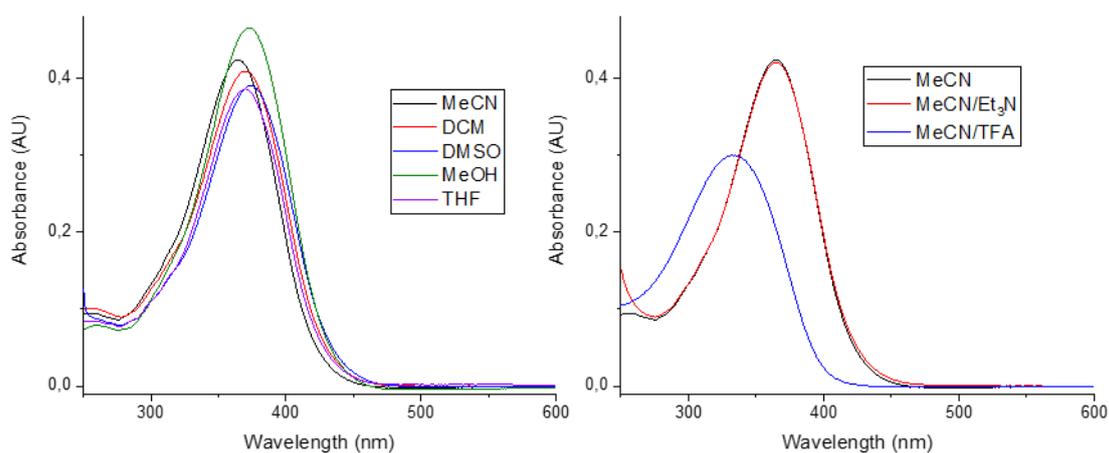

Figure 138: Compound **E-14** was dissolved in different solvents (80 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

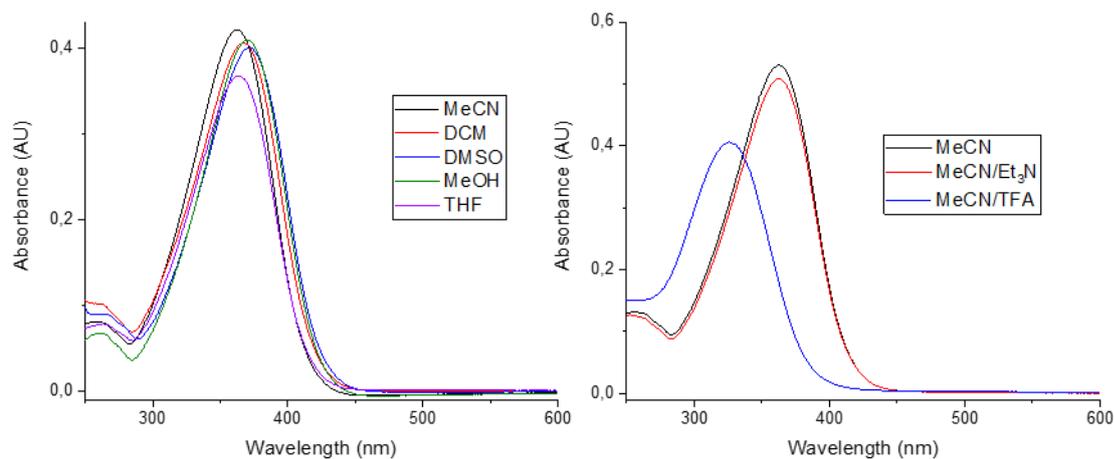

Figure 139: Compound Z-15 was dissolved in different solvents (80 μ M) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

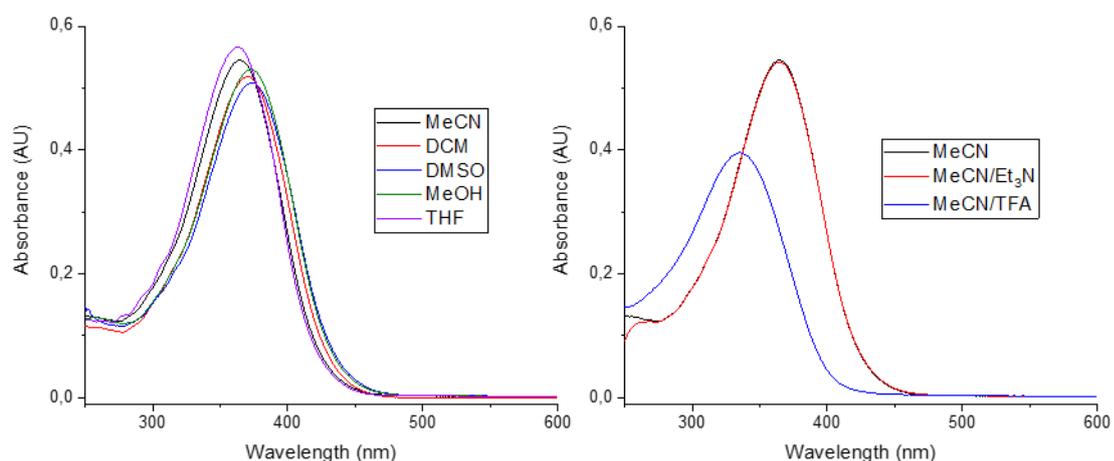

Figure 140: Compound E-15 was dissolved in different solvents (80 μ M) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

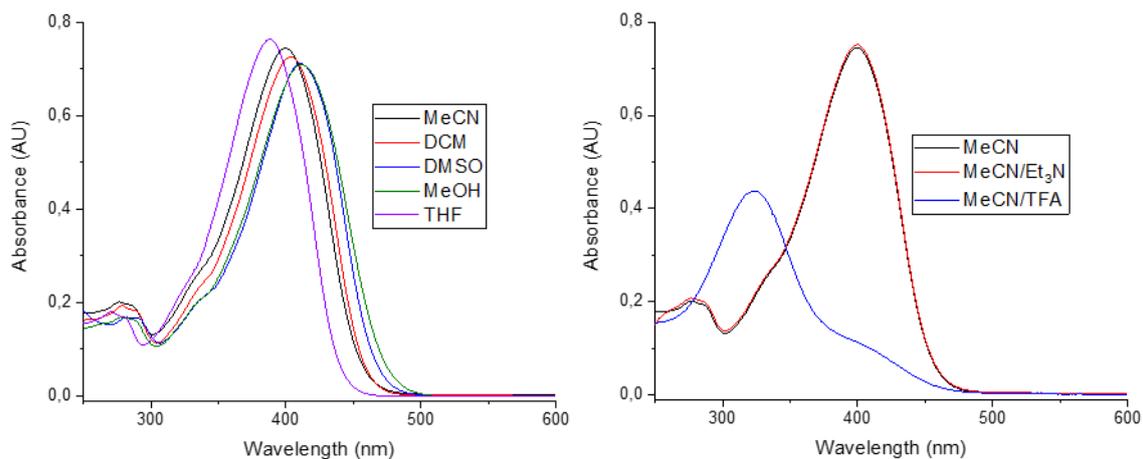

Figure 141: Compound Z-16 was dissolved in different solvents (80 μ M) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

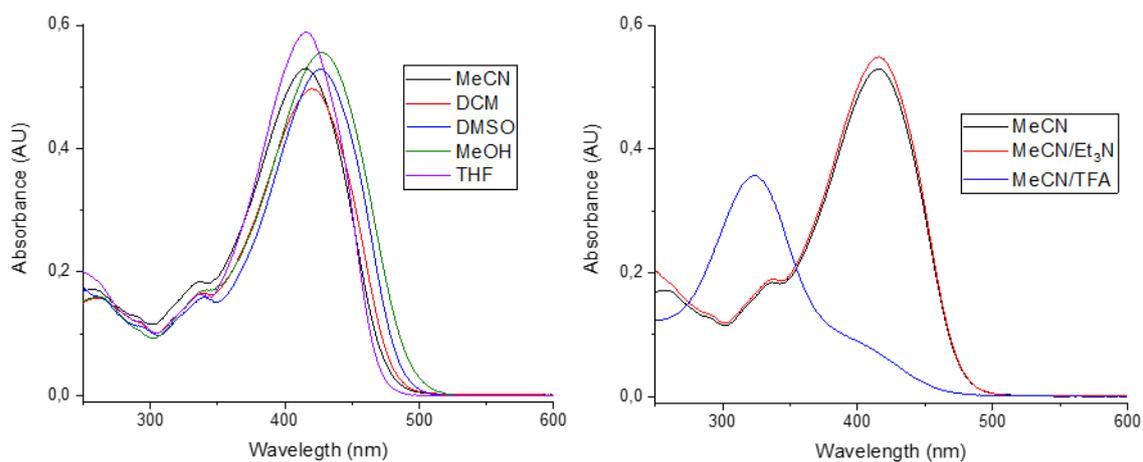

Figure 142: Compound E-16 was dissolved in different solvents (80 μ M) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

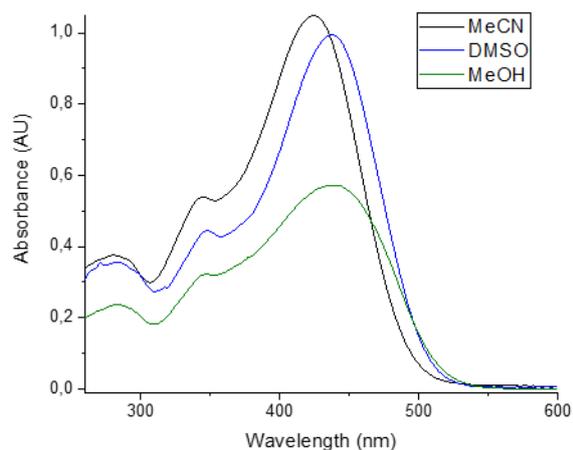

Figure 143: Compound Z-17 was dissolved in different solvents (80 μ M), respectively. Absorption spectra were measured in the dark ($d = 10$ mm). The spectra are assigned to the respective solvents *via* color code.

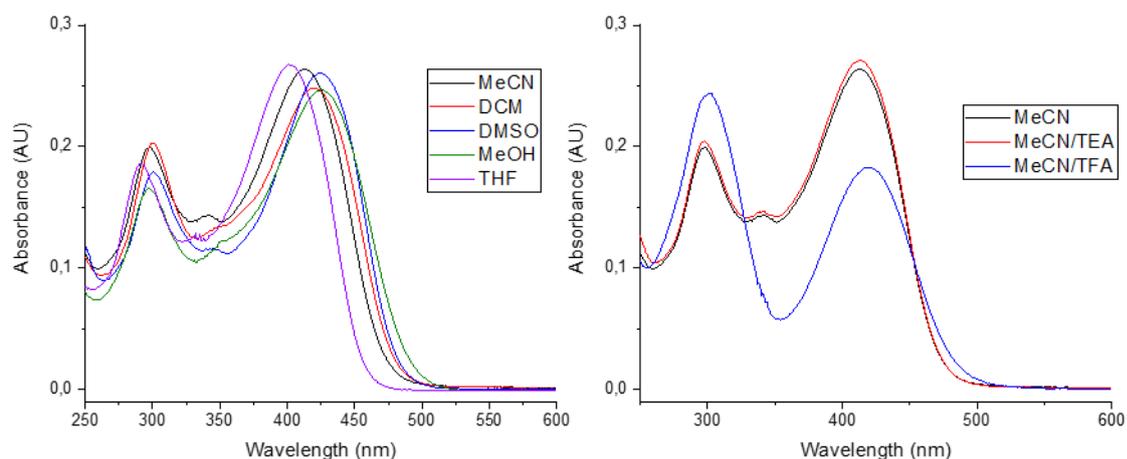

Figure 144: Compound Z-18 was dissolved in different solvents (80 μ M) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

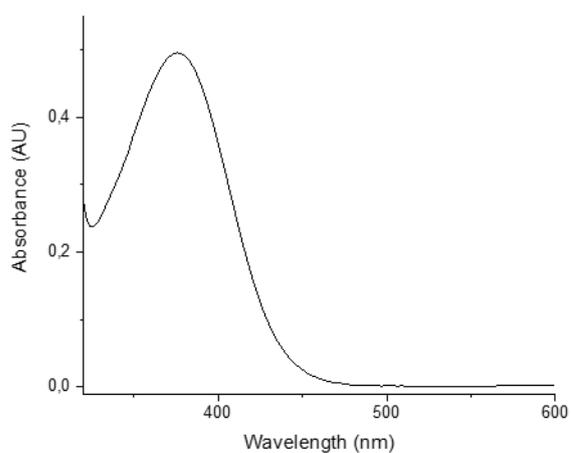

Figure 146: Absorption spectrum of compound Z-20 (160 μM) in a saturated solution of sodium ascorbate in DMSO ($d = 2$ mm).

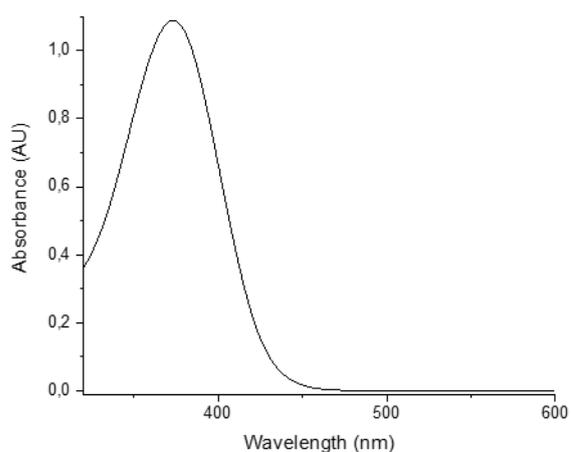

Figure 147: Absorption spectrum of compound Z-21 (160 μM) in a saturated solution of sodium ascorbate in DMSO ($d = 2$ mm).

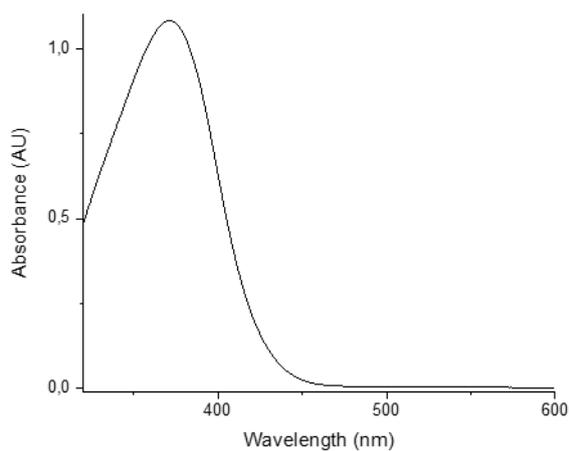

Figure 148: Absorption spectrum of compound Z-22 (160 μM) in a saturated solution of sodium ascorbate in DMSO ($d = 2$ mm).

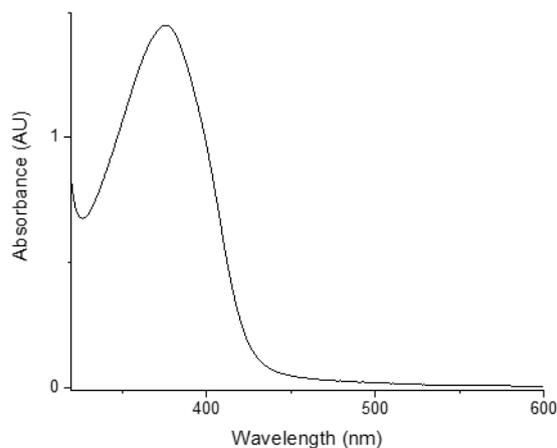

Figure 149: Absorption spectrum of compound Z-23 (48 μM) in a saturated solution of sodium ascorbate in DMSO ($d = 10$ mm).

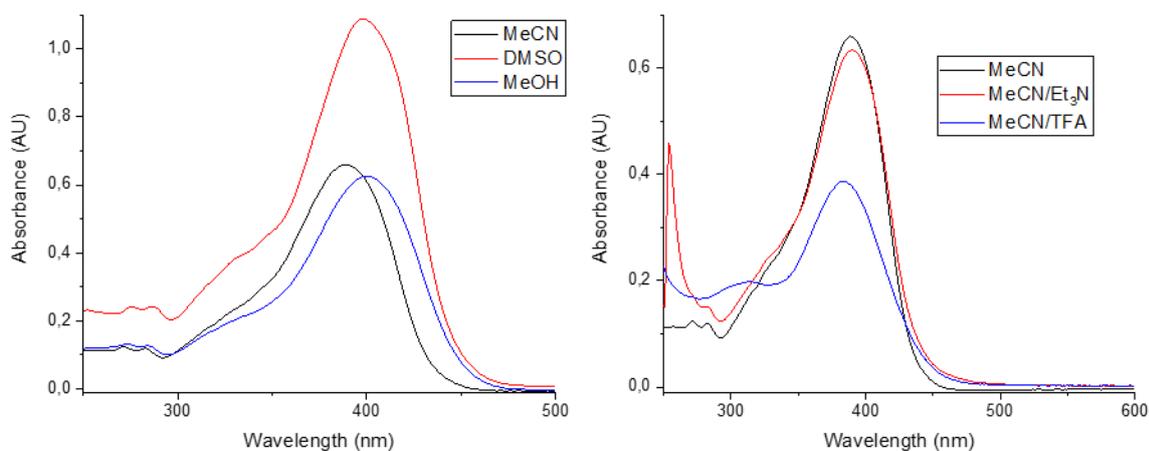

Figure 150: Compound Z-24 was dissolved in different solvents (160 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

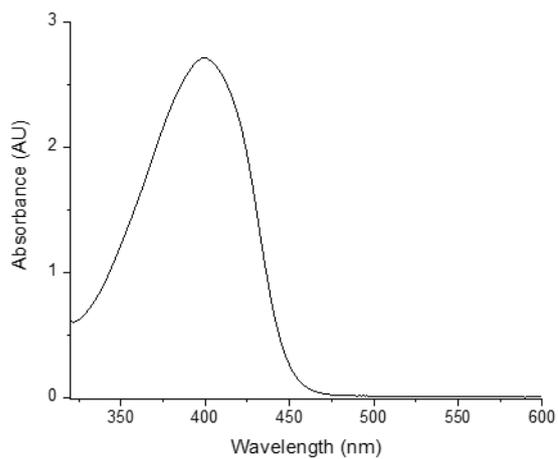

Figure 151: Absorption spectrum of compound Z-25 (81 μM) in a saturated solution of sodium ascorbate in DMSO ($d = 10$ mm).

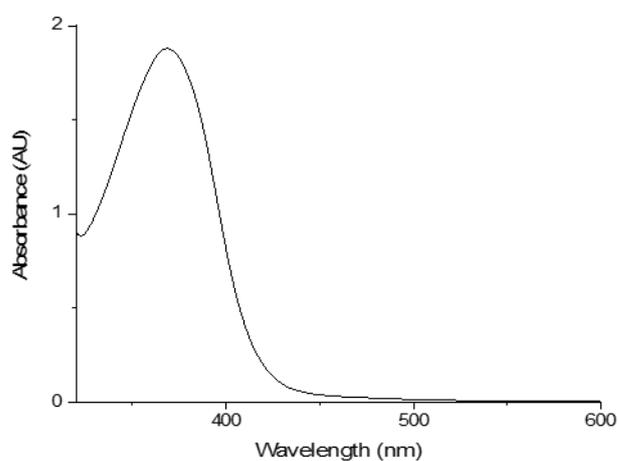

Figure 152: Absorption spectrum of compound Z-26 (48 μM) in a saturated solution of sodium ascorbate in DMSO ($d = 10$ mm).

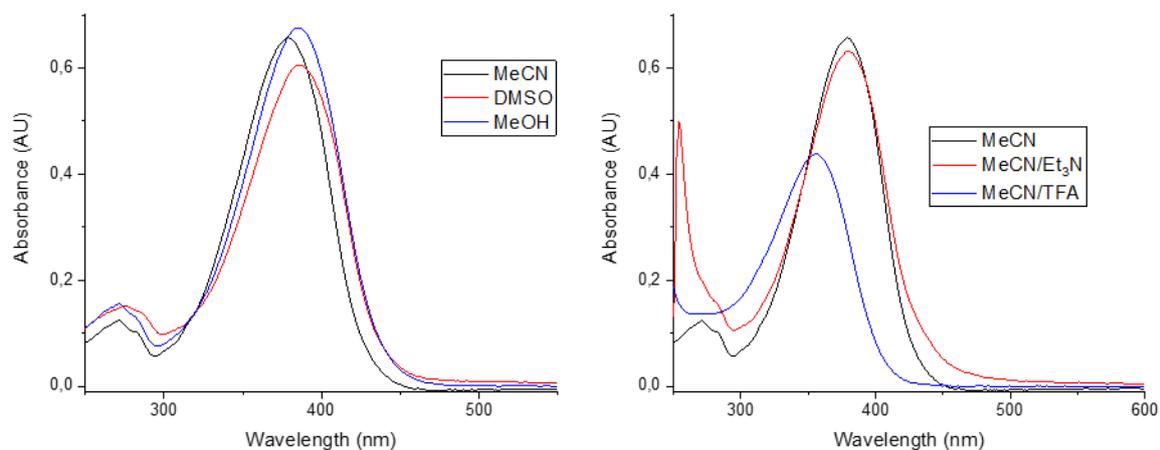

Figure 153: Compound Z-27 was dissolved in different solvents (160 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

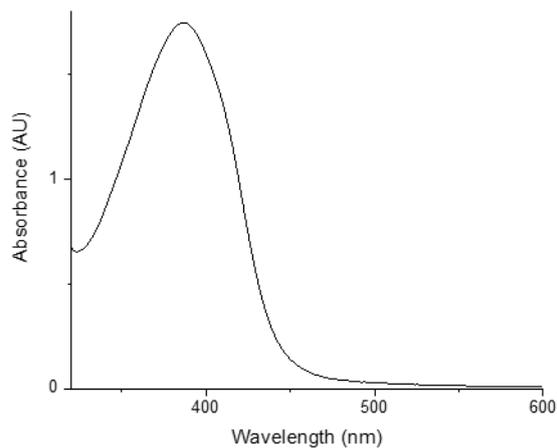

Figure 154: Absorption spectrum of compound Z-28 (48 μM) in a saturated solution of sodium ascorbate in DMSO ($d = 10$ mm).

5.4.6 Absorption Spectra of Irradiated Samples

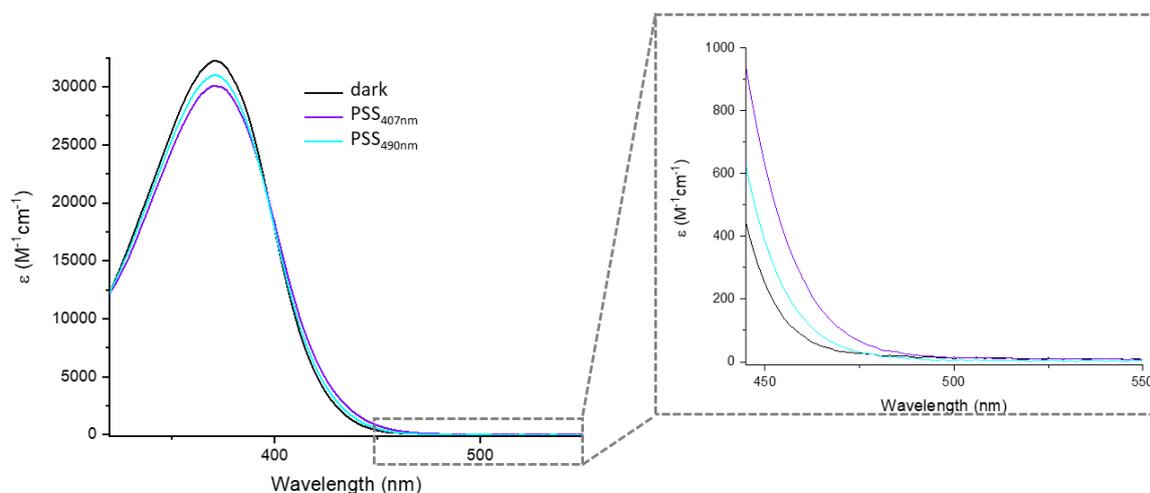

Figure 155: Compound **6** was dissolved in a saturated solution of sodium ascorbate in DMSO (80 μM). Absorption spectra ($d = 2$ mm) were first measured in the dark. The samples were then first irradiated with 407 nm (2 min), then with 490 nm (15 min) and an absorption spectrum was measured after each irradiation step.

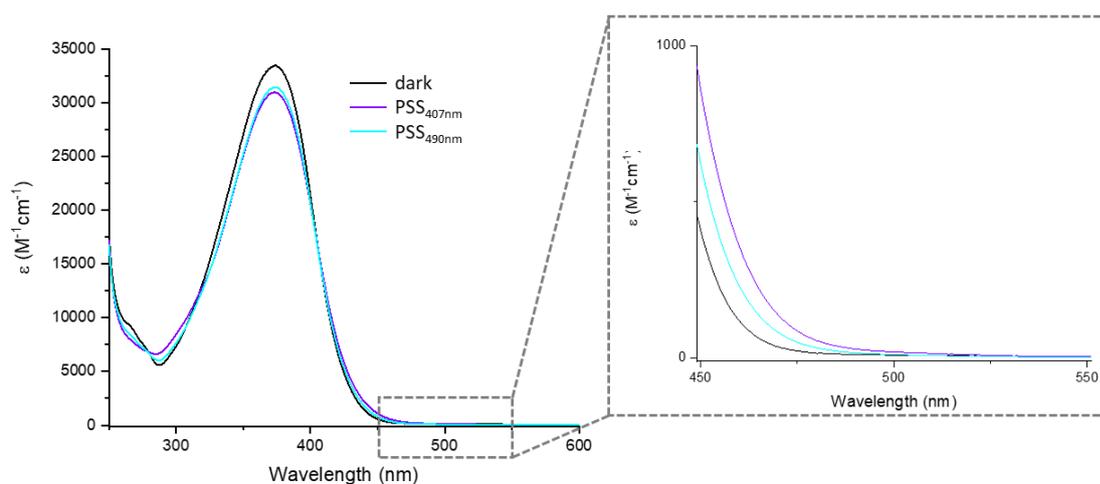

Figure 156: Absorption spectra ($d=2$ mm) of a solution of 2.0 mM (cutout) and 400 μM (full spectrum) compound **6** with 10 mM glutathione and 5.0 mM tris(2-carboxyethyl)phosphine in 25% PBS in DMSO (v/v) were first measured in the dark. The samples were then first irradiated with 407 nm (2 min), then with 490 nm (15 min) and an absorption spectrum was measured after each irradiation step.

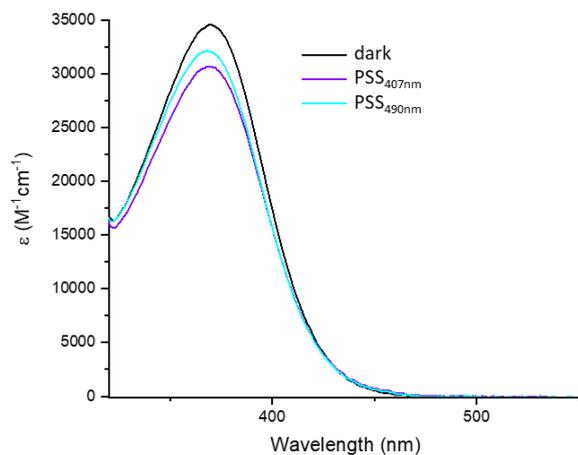

Figure 157: Compound **8** was dissolved in a saturated solution of sodium ascorbate in DMSO (80 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (2 min), then with 490 nm (15 min) and an absorption spectrum was measured after each irradiation step.

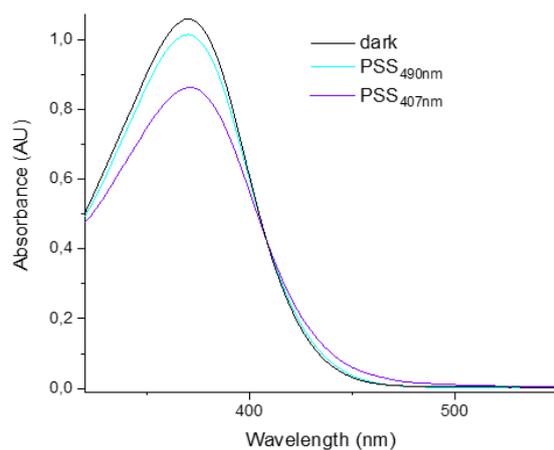

Figure 158: Compound **9** was dissolved in a saturated solution of sodium ascorbate in DMSO (160 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 490 nm (15 min), then with 407 nm (1 min) and an absorption spectrum was measured after each irradiation step.

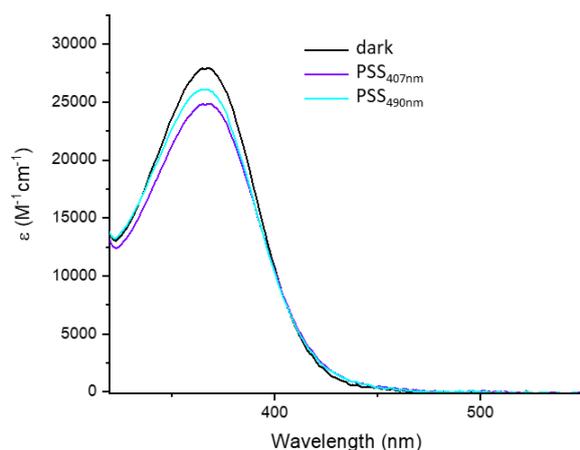

Figure 159: Compound **10** was dissolved in a saturated solution of sodium ascorbate in DMSO (80 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (2 min), then with 490 nm (15 min) and an absorption spectrum was measured after each irradiation step.

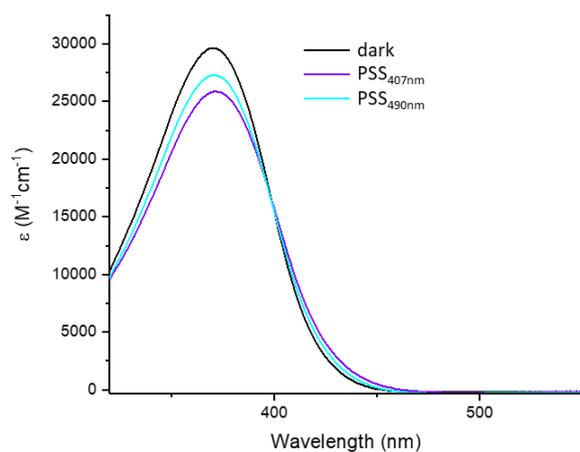

Figure 160: Compound **14** was dissolved in a saturated solution of sodium ascorbate in DMSO (80 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (2 min), then with 490 nm (15 min) and an absorption spectrum was measured after each irradiation step.

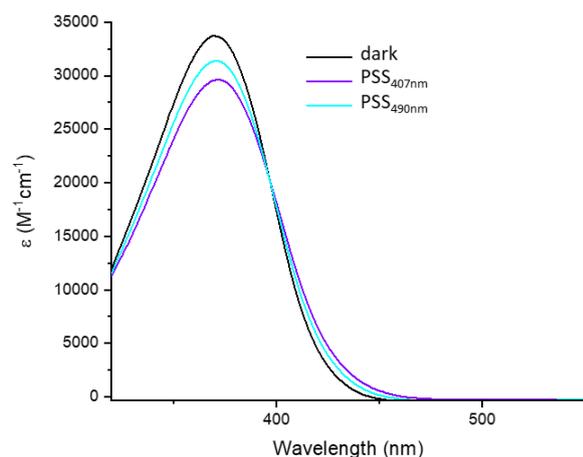

Figure 161: Compound **15** was dissolved in a saturated solution of sodium ascorbate in DMSO (80 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (2 min), then with 490 nm (15 min) and an absorption spectrum was measured after each irradiation step.

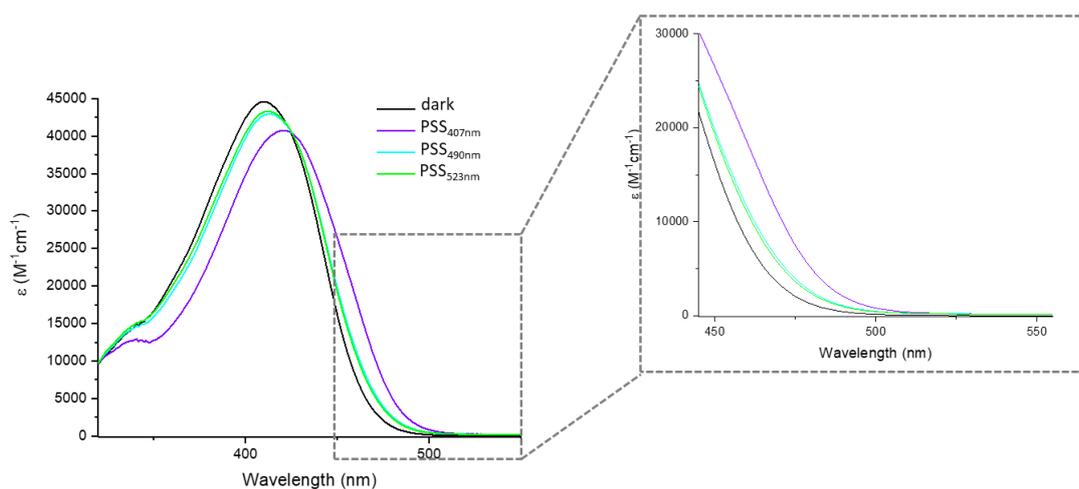

Figure 162: Compound **16** was dissolved in a saturated solution of sodium ascorbate in DMSO (80 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (2 min), then with 490 nm (15 min) and with 523 nm (5 min) and an absorption spectrum was measured after each irradiation step.

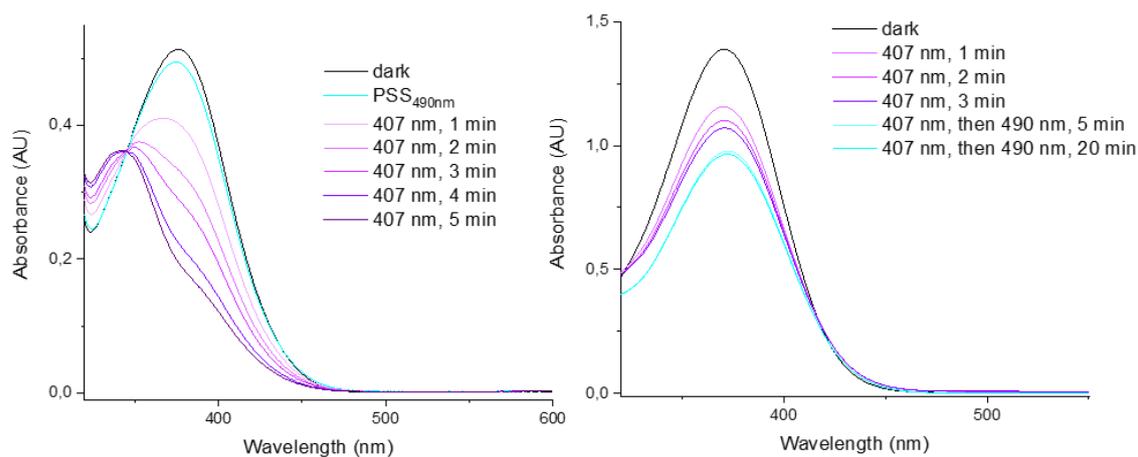

Figure 163: Left: Compound **19** was dissolved in 25% PBS in a saturated solution of sodium ascorbate in DMSO (80 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 490 nm (5 min), then with 407 nm and an absorption spectrum was measured after each irradiation step. Right: Compound **19** was dissolved in a saturated solution of sodium ascorbate in DMSO (160 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm, then with 490 nm (15 min) and an absorption spectrum was measured after each irradiation step.

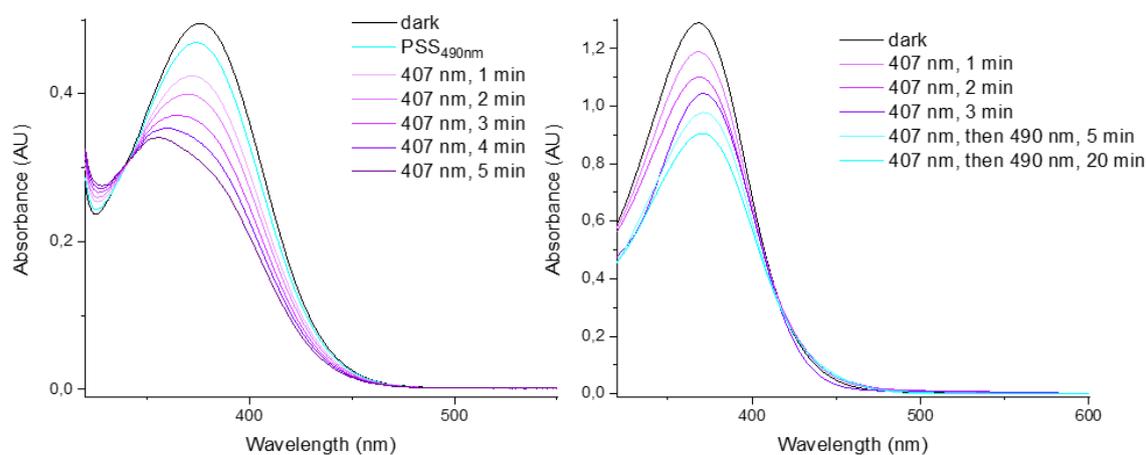

Figure 164: Left: Compound **20** was dissolved in 25% PBS in a saturated solution of sodium ascorbate in DMSO (80 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 490 nm (5 min), then with 407 nm and an absorption spectrum was measured after each irradiation step. Right: Compound **20** was dissolved in a saturated solution of sodium ascorbate in DMSO (160 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm, then with 490 nm (15 min) and an absorption spectrum was measured after each irradiation step.

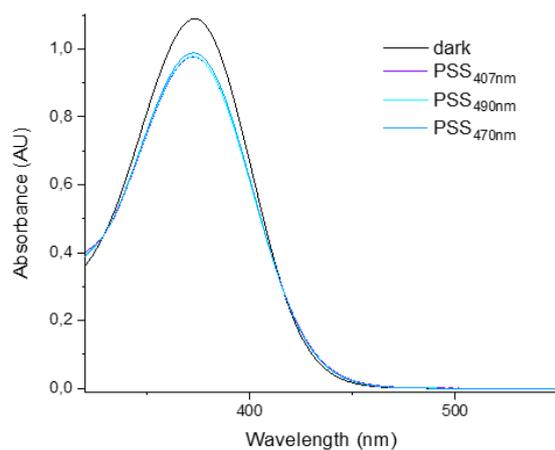

Figure 165: Compound **21** was dissolved in a saturated solution of sodium ascorbate in DMSO (160 μ M). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (1 min), then with 490 nm (15 min) and 470 nm (5 min) and an absorption spectrum was measured after each irradiation step.

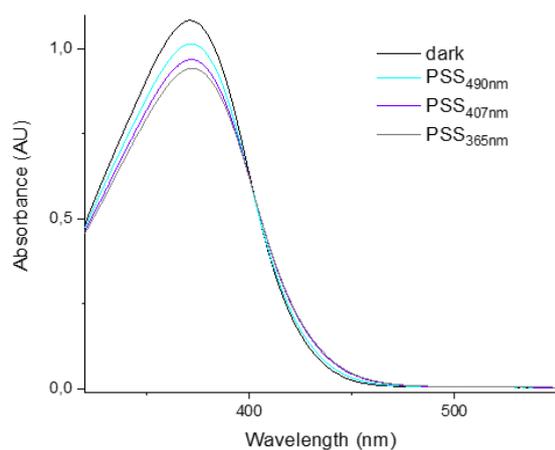

Figure 166: Compound **22** was dissolved in a saturated solution of sodium ascorbate in DMSO (160 μ M). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (1 min), then with 490 nm (13 min) and 365 nm (1 min) and an absorption spectrum was measured after each irradiation step.

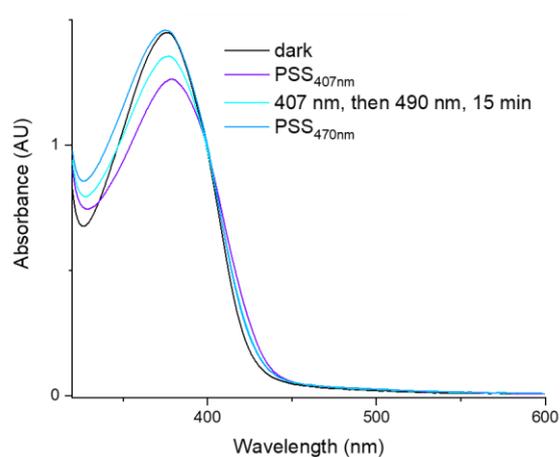

Figure 167: Compound **23** was dissolved in a saturated solution of sodium ascorbate in DMSO (48 μ M) and purged with argon. An absorption spectrum ($d = 10$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (1 min), then with 490 nm (15 min) and 470 nm (20 min) and an absorption spectrum was measured after each irradiation step.

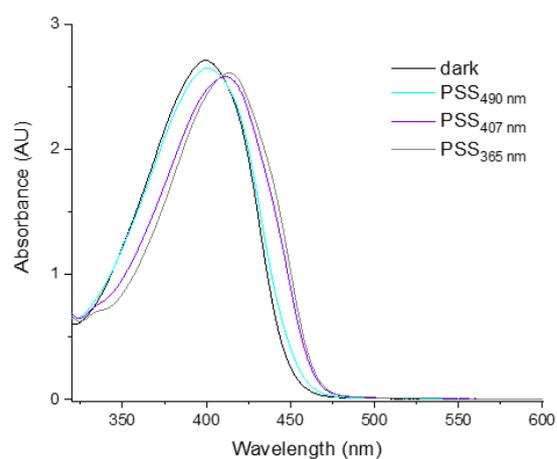

Figure 168: Compound **25** was dissolved in a saturated solution of sodium ascorbate in DMSO (81 μ M) and purged with argon. An absorption spectrum ($d = 10$ mm) was first measured in the dark. The sample was then first irradiated with 490 nm (15 min), then with 407 nm (2 min) and 365 nm (2 min) and an absorption spectrum was measured after each irradiation step.

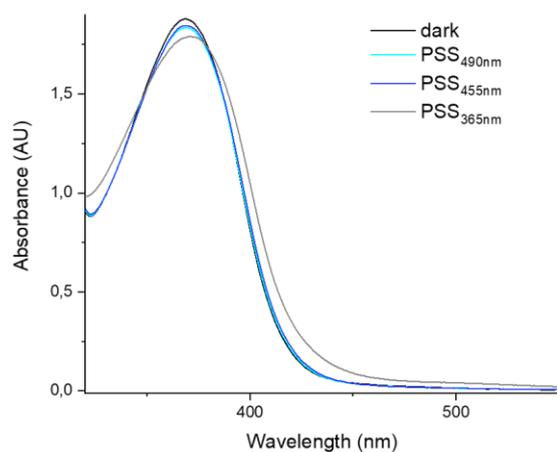

Figure 169: Compound **26** was dissolved in a saturated solution of sodium ascorbate in DMSO (48 μM) and purged with argon. An absorption spectrum ($d = 10$ mm) was first measured in the dark. The sample was then first irradiated with 490 nm (15 min), then with 455 nm (15 min) and 365 nm (2 min) and an absorption spectrum was measured after each irradiation step.

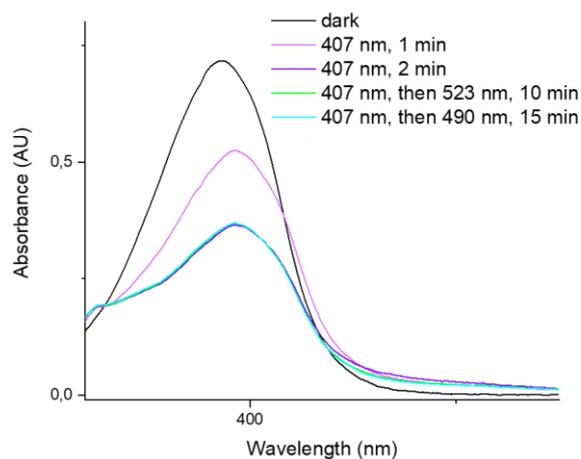

Figure 170: Compound **27** was dissolved in a saturated solution of sodium ascorbate in DMSO (160 μM). An absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then first irradiated with 407 nm (2 min), then with 523 nm and an absorption spectrum was measured after each irradiation step.

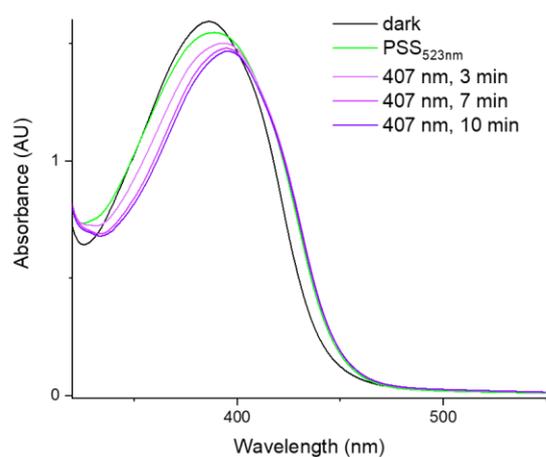

Figure 171: Compound **28** was dissolved in a saturated solution of sodium ascorbate in DMSO (48 μ M) and purged with argon. An absorption spectrum ($d = 10$ mm) was first measured in the dark. The sample was then first irradiated with 523 nm (20 min), then with 407 nm and an absorption spectrum was measured after each irradiation step.

5.4.7 Emission Spectra

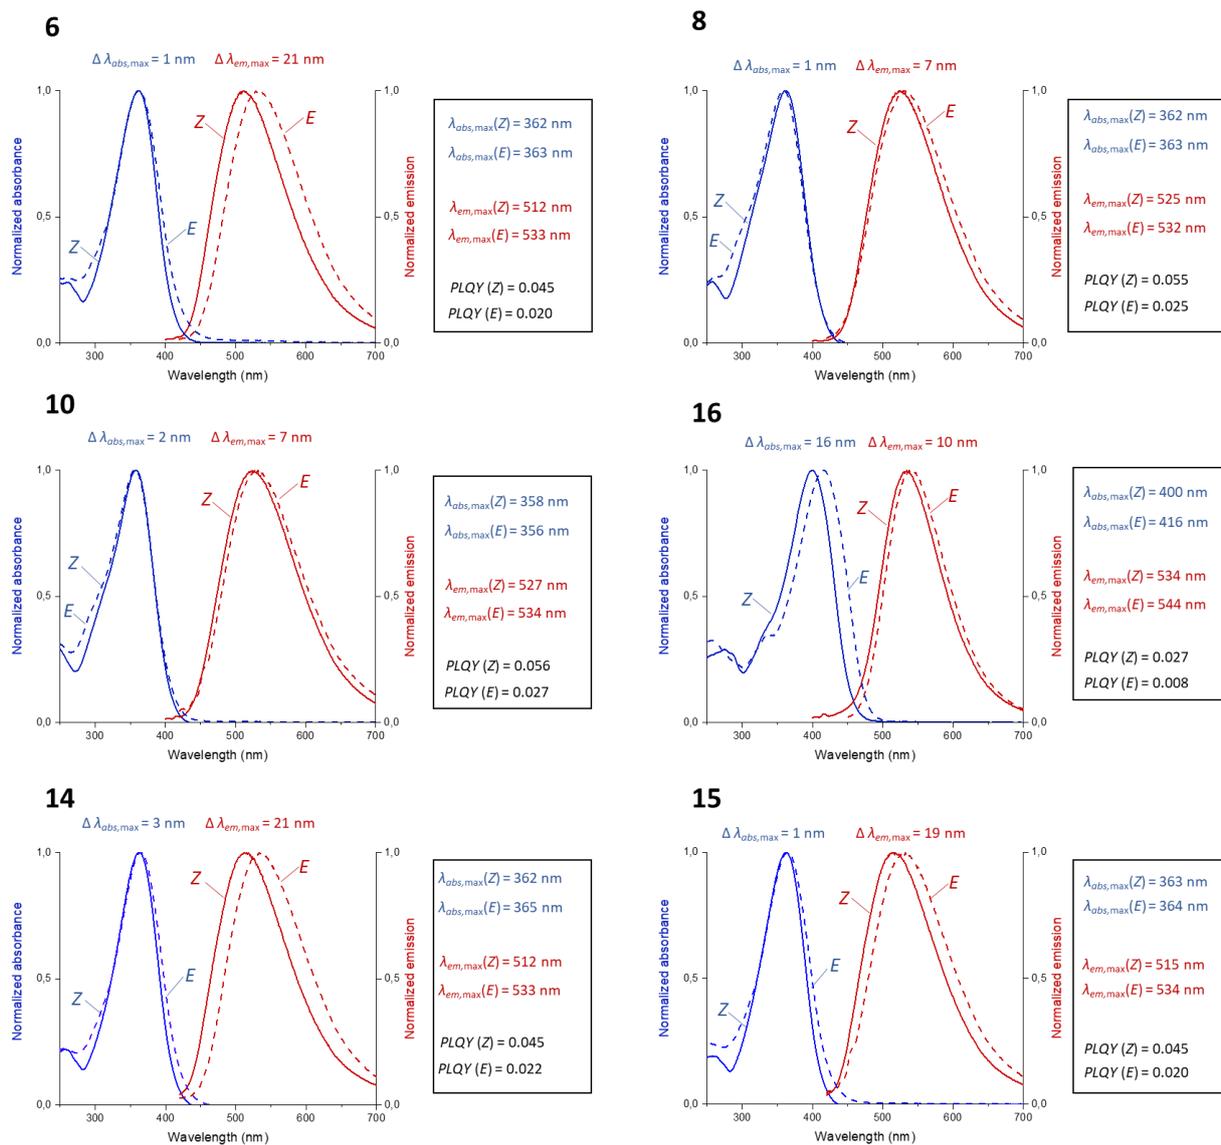

Figure 172: Normalized absorption (blue) and emission (red) spectra of 80 μM solutions of the respective Z-isomers (solid line) and E-isomers (dashed line) of **6**, **8**, and **14-16** in MeCN.

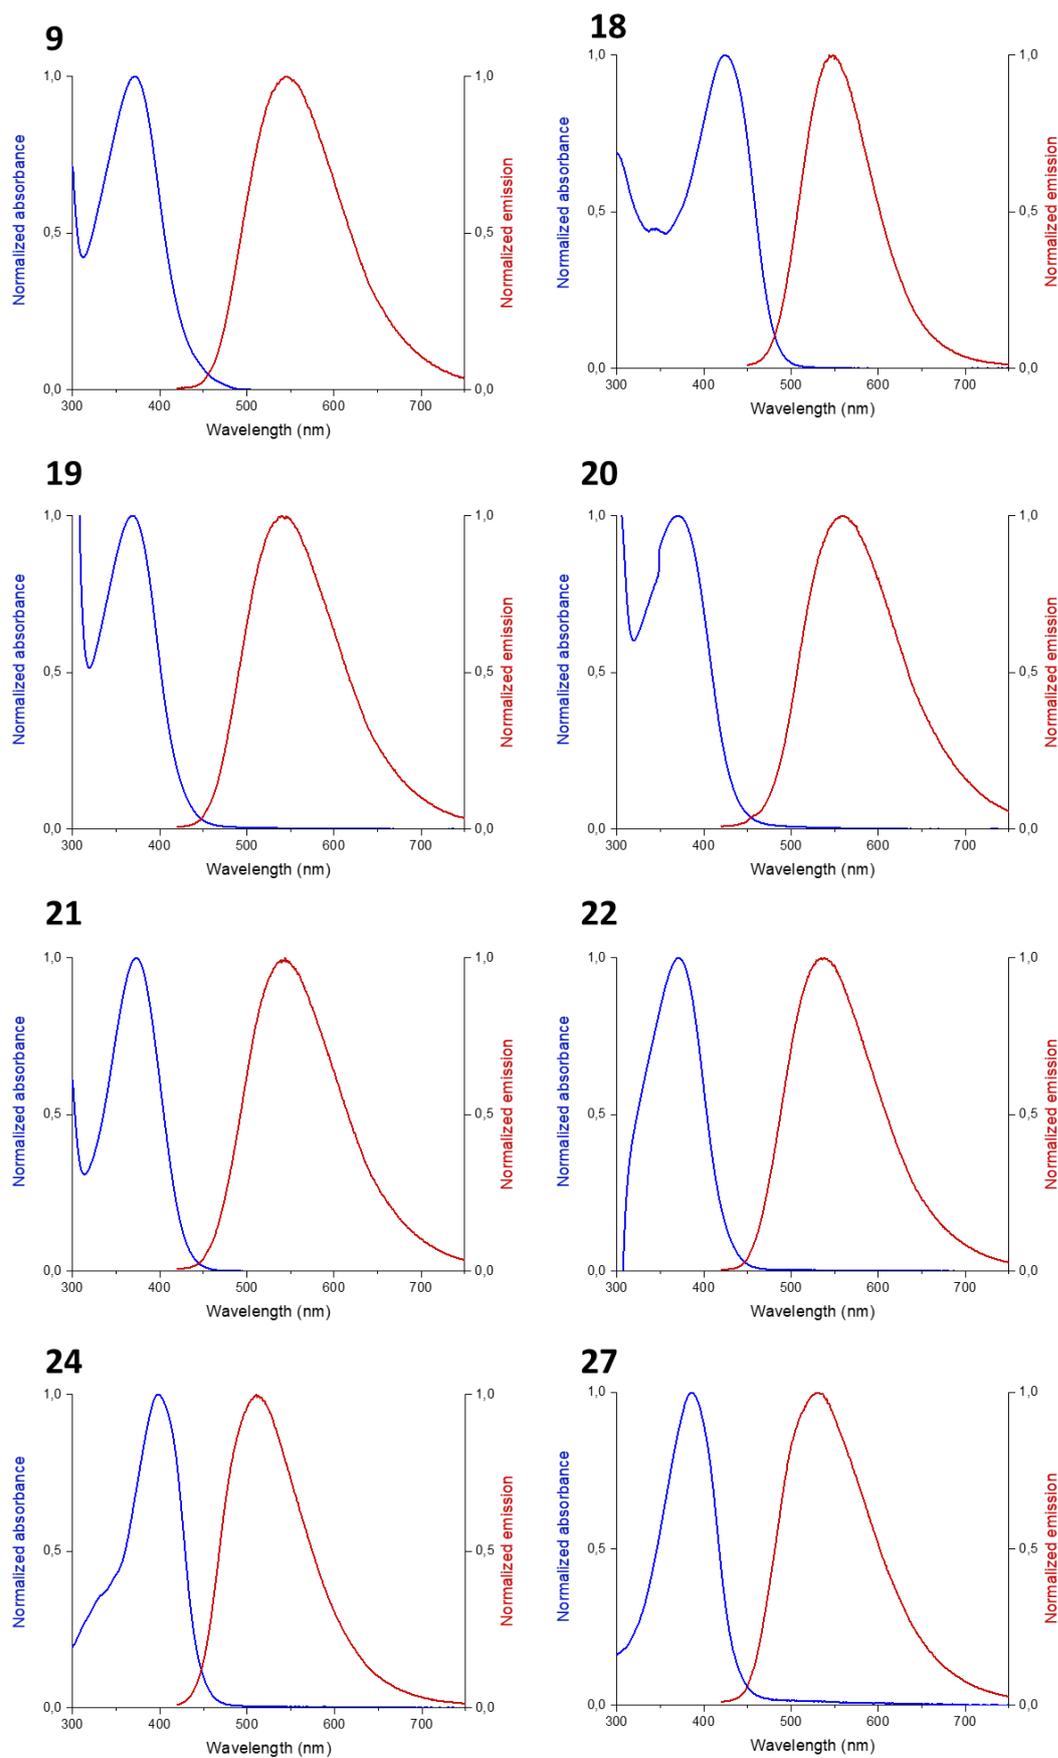

Figure 173: Normalized absorption (blue) and fluorescence (red) spectra of solutions of the respective Z-isomers of 9, 18-22, 24 and 27 in DMSO.

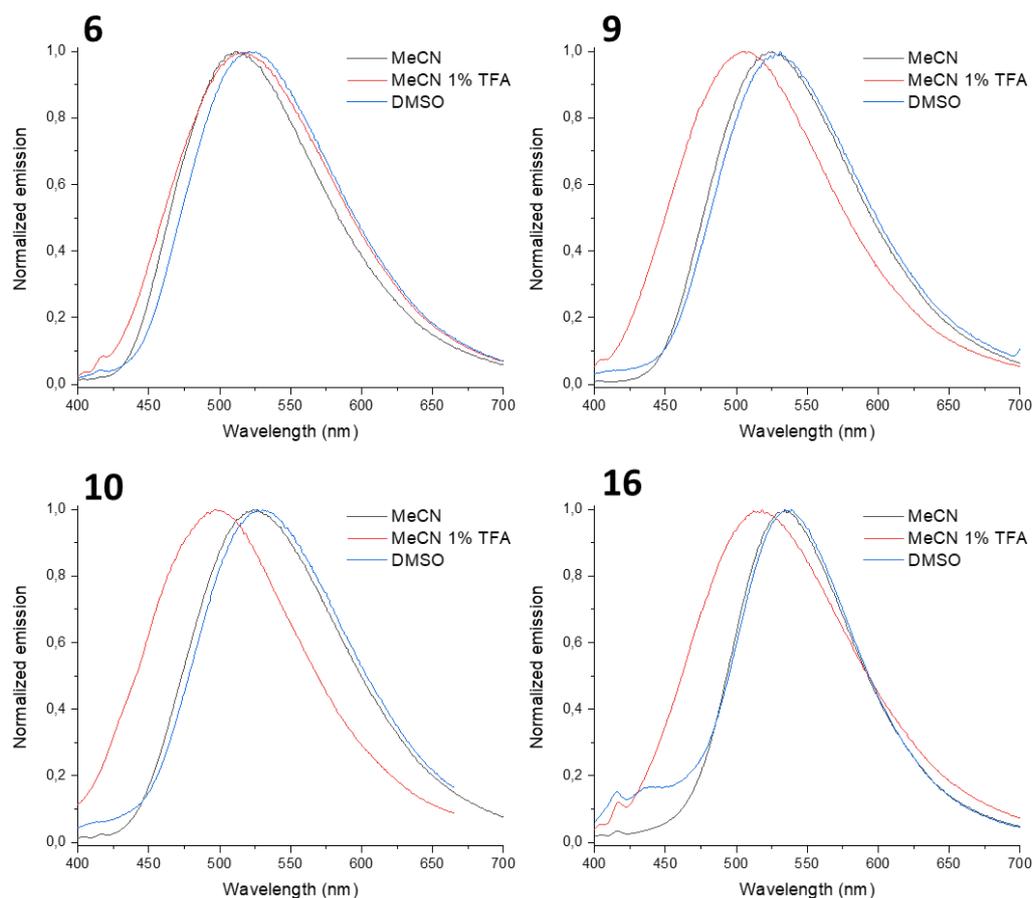

Figure 174: Normalized fluorescence spectra of compounds **Z-6**, **Z-9**, **Z-10** and **Z-16** in different solvents (80 μM) and in mixtures of 1% (v/v) TFA in MeCN, respectively. The spectra are assigned to the respective solvents *via* color code.

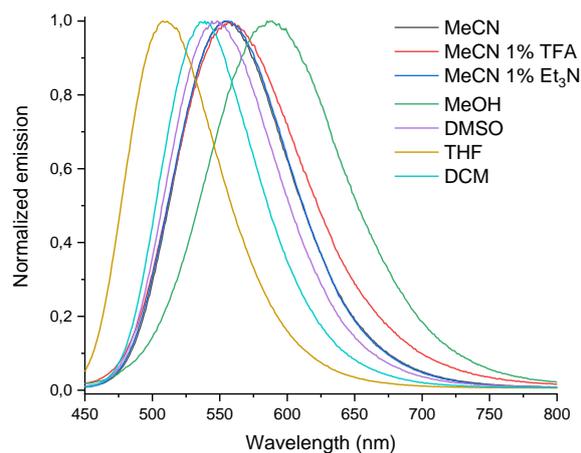

Figure 175: Normalized fluorescence spectra of compound **Z-18** in different solvents (80 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et_3N in MeCN, respectively. The spectra are assigned to the respective solvents *via* color code.

5.4.8 Composition of Photostationary States (PSSs)

The PSS composition was determined by measuring ^1H NMR spectra of the respective compounds after irradiation. The PSS values in the NMR tubes (0.5 mL of the 30-60 mM solutions in $\text{DMSO-}d_6$) have been achieved within 1 h (365, 407, 523 nm), 2 h (430, 450, 470 nm) or 4 h (380, 490 nm). Signal pairs were determined for each compound: two signals assigned to the same proton for the respective photoisomers were integrated and the % of *E*-isomer = $I_E/(I_E+I_Z)*100\%$ was determined. The final *E/Z* ratios result from the average value determined from three signal pairs.

Table 6: PSS composition in $\text{DMSO-}d_6$ determined by measuring ^1H NMR spectra of the respective compounds after irradiation. *It was not verified that the PSS had already been reached.

Compound	365 nm (% of <i>E</i> - isomer)	380 nm (% of <i>E</i> - isomer)	407 nm (% of <i>E</i> - isomer)	430 nm (% of <i>E</i> - isomer)	450 nm (% of <i>E</i> - isomer)	470 nm (% of <i>E</i> - isomer)	490 nm (% of <i>E</i> - isomer)	523 nm (% of <i>E</i> - isomer)

5.4.9 Thermal Relaxation of *E*-Isomers

Figure 189: The thermal relaxation of the respective *E*-isomers of **6**, **8**, **10**, and **14-16** was monitored *via* analytical HPLC. The integrals of the signals assigned to the respective *E*-isomer were determined at 330 nm: I_0 = initial integral, I = integral at given time point. (a) Thermal relaxation in DMSO at 150 °C. (b) Thermal relaxation in MeCN at 60 °C. (c) Thermal relaxation in MeCN at 60 °C in absence and presence of TFA.

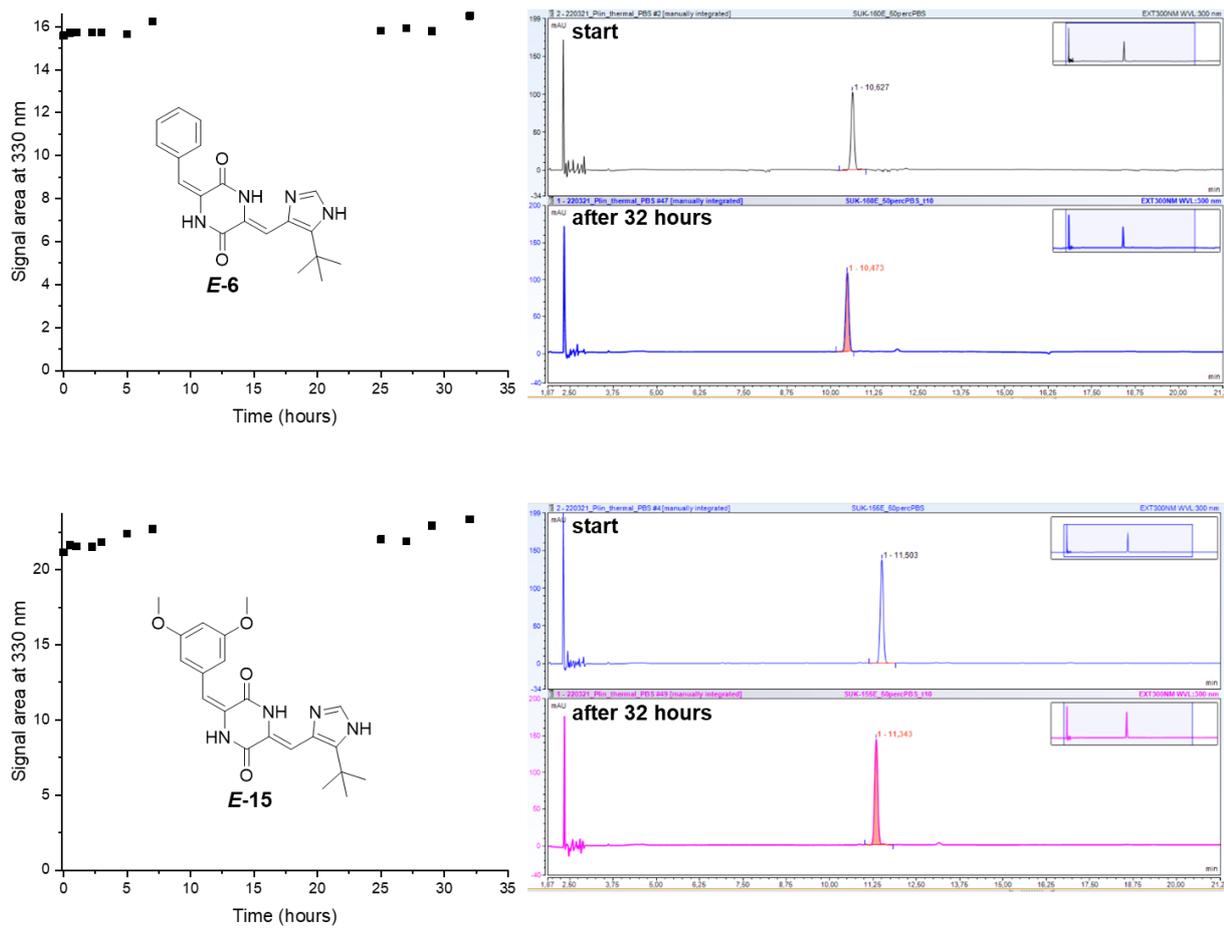

Figure 190: Solutions of compounds *E-6* (top) and *E-15* (bottom) in PBS/DMSO (1:1) with a concentration of 33 μ M were incubated at 37 °C for 32 hours. Samples were taken after certain time intervals and analyzed *via* analytical HPLC at 330 nm.

5.4.10 Switching Stability

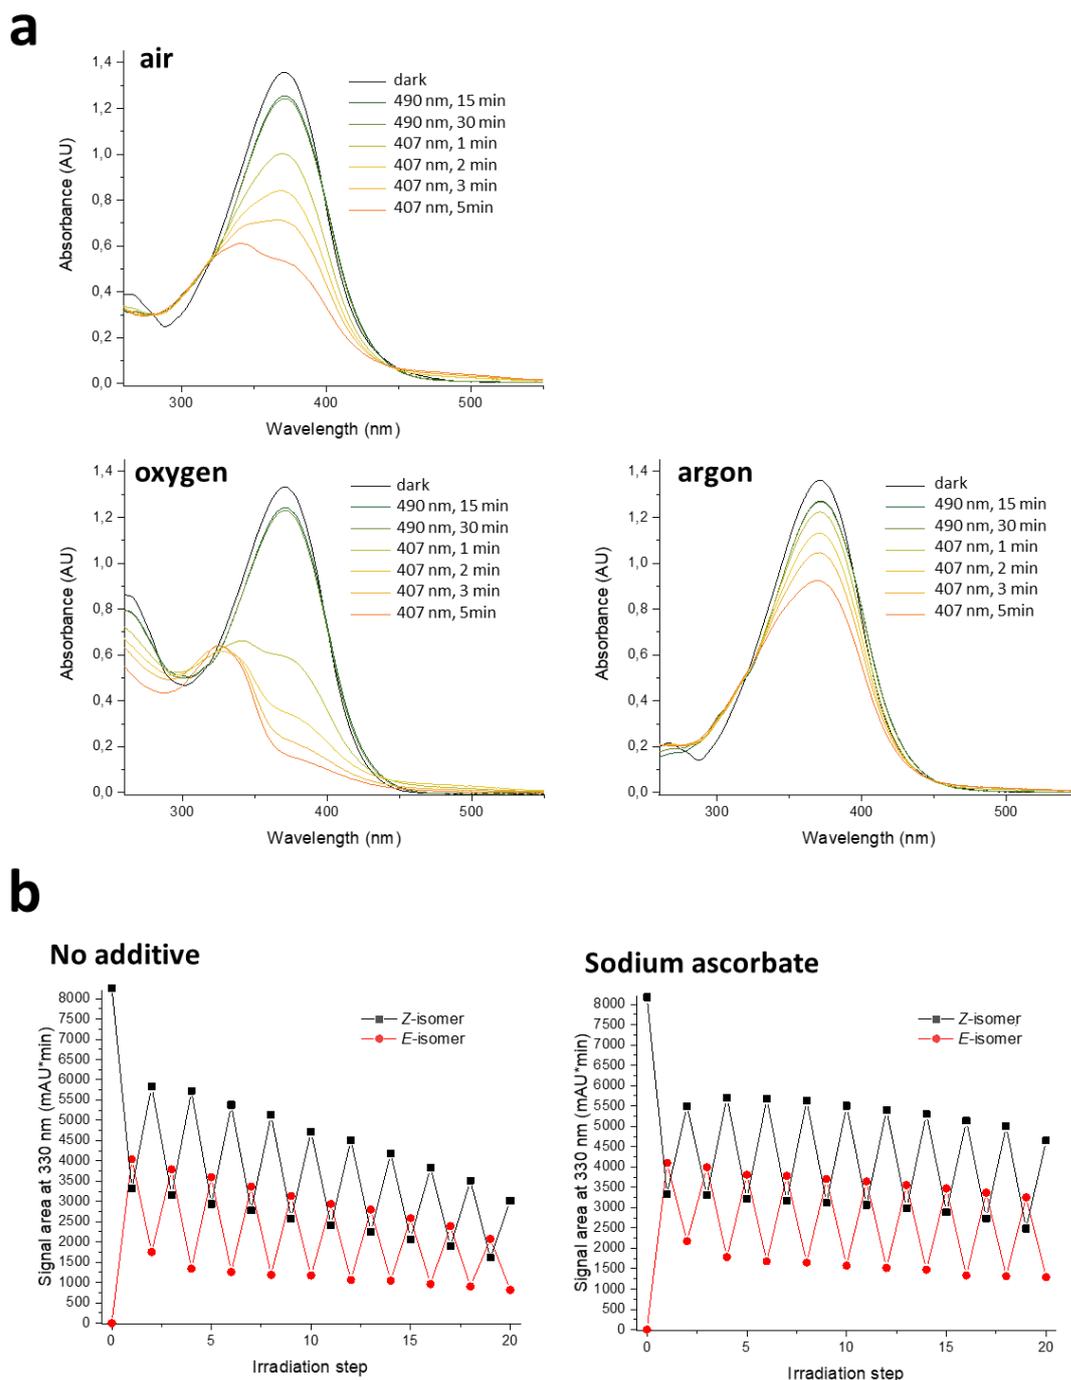

Figure 191: (a) A 40 μM solution of **6** in DMSO was prepared and split up into three samples. One sample was kept under ambient atmosphere (top), the other samples were purged for 5 min with oxygen (bottom left) or argon (bottom right), respectively. Absorption spectra were first recorded in the dark and then after each irradiation step. Afterwards, the samples were first irradiated twice for 15 min with 490 nm and subsequently five times for 1 min with 407 nm. (b) Solutions of pure Z-**6** (1.0 mM) in DMSO (left) and in a saturated solution of sodium ascorbate in DMSO (right) were analyzed *via* analytical HPLC. The samples were irradiated with 407 nm for 2 min and with 490 nm for 35 min, respectively. The irradiation cycles were repeated ten times and after every irradiation step the solutions were analyzed *via* analytical HPLC.

5.4.11 Stability in Presence of Glutathione

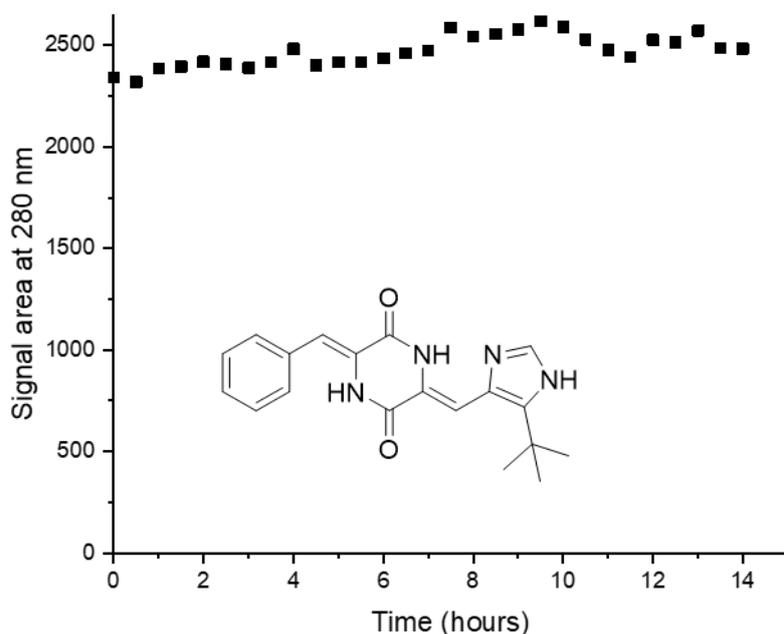

Figure 192: A 1.0 mM solution of **6** with 10.0 mM glutathione and 5.0 mM tris(2-carboxyethyl)phosphine in 25% PBS in DMSO (v/v) was monitored for 14 hours *via* analytical HPLC. The area of the signal assigned to **6** at 280 nm was determined after each HPLC run.

5.4.12 Viability Assays

Isolated Photoisomers

Table 7: The IC_{50} values were determined *via* viability assays with HT-29 cells after treatment with the respective photoisomers of **6-17**, and **19-22** for 48 hours. Data were processed using GraphPad Prism.

Compound	IC_{50} : <i>Z</i> -isomer (nM) [95% profile likelihood]	IC_{50} : <i>E</i> -isomer (nM) [95% profile likelihood]	IC_{50} ratio
6	0.30 [0.26 to 0.35]	92 [80 to 100]	306
7	5420 [n.d.]	6250 [n.d.]	1.15
8	0.27 [0.18 to 0.40]	420 [347 to 510]	1555
9	5.47 [3.83 to 7.83]	75.4 [55.6 to 102]	13.8
10	38 [31 to 46]	1046 [650 to 1548]	27.5

11	273 [253 to 301]	1720 [1648 to 1786]	6.30
12	14400 [n.d.]	8600 [n.d.]	6.14
13	4130000 [106800 to 4216000000]	129100 [35220 to 3576000]	32.0
14	0.09 [0.05 to 0.15]	471 [352 to 636]	5233
15	0.21 [0.16 to 0.28]	618 [487 to 788]	2942
16	8614 [8073 to 9189]	-	-
17	5730 [n.d.]	n.d.	> 17
19	80.3 [48.8 to 132]	-	-
20	26.7 [19.0 to 37.4]	808 [592 to 1099]	30.3
21	4.96 [3.46 to 7.11]	70.4 [51.8 to 95.5]	14.2
22	0.68 [0.47 to 1.01]	73.4 [54.6 to 98.7]	108

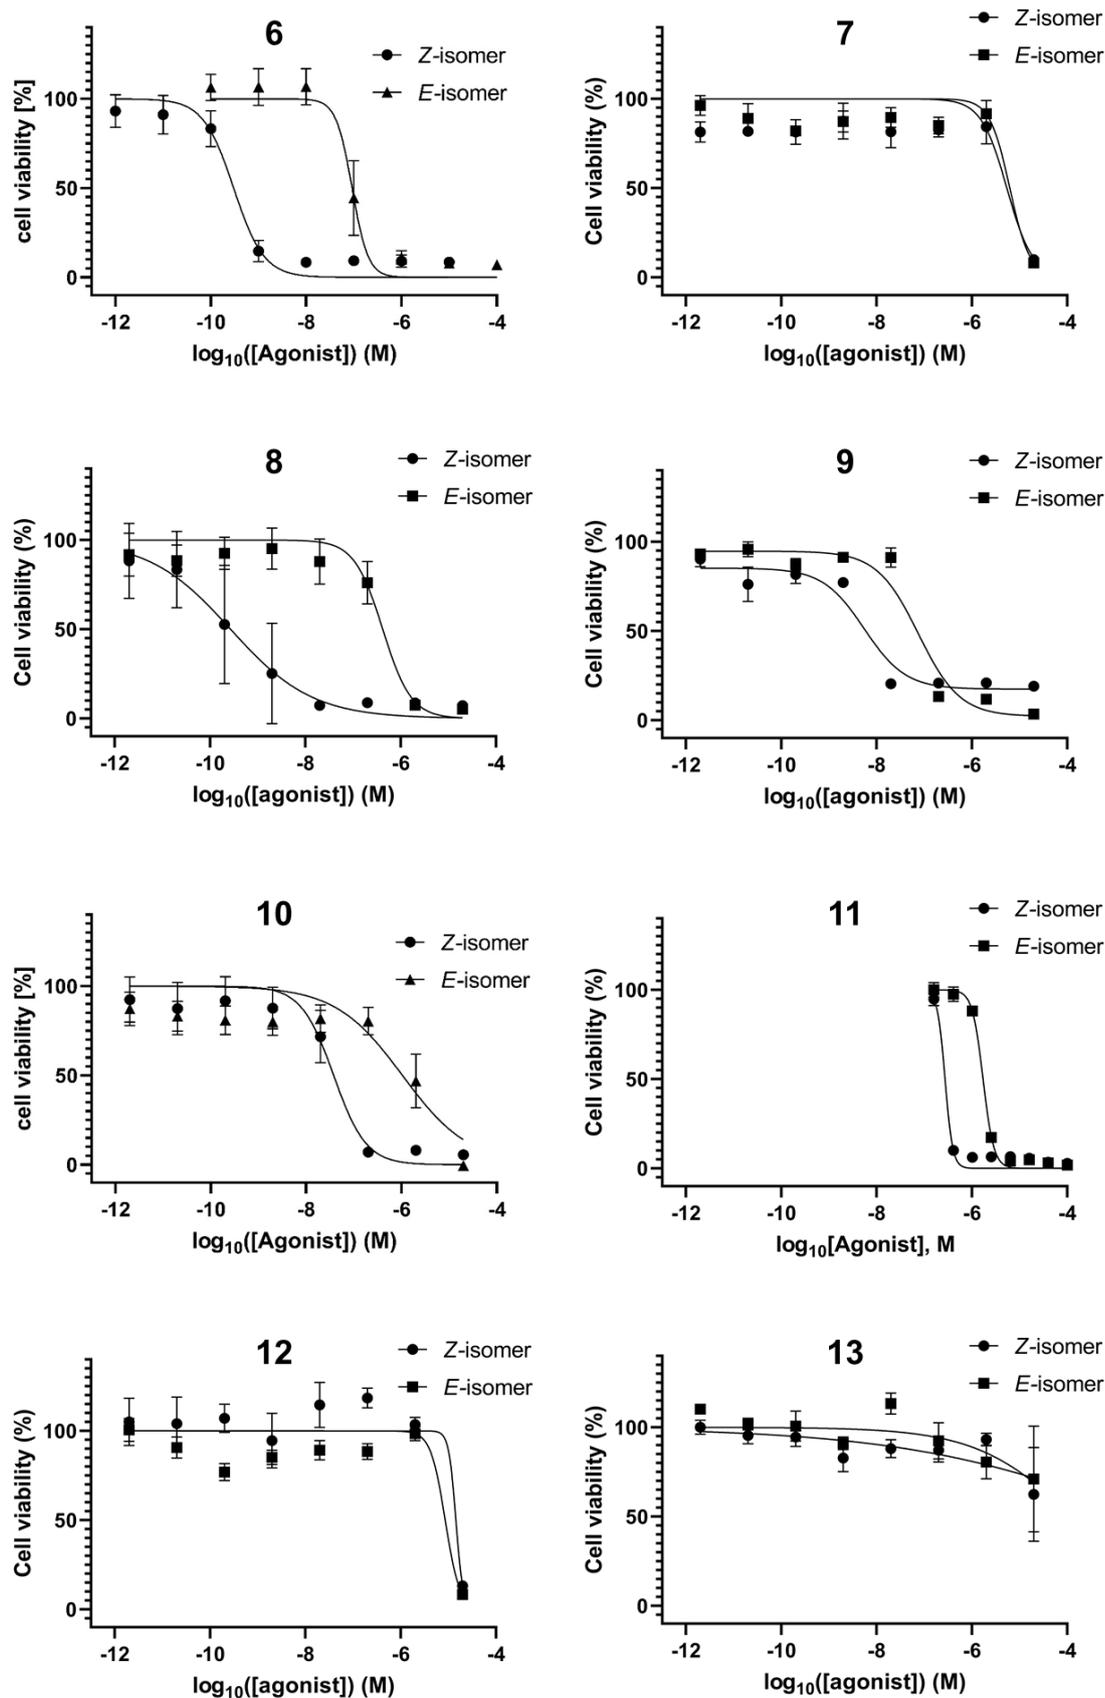

Figure 193: Viability of HT-29 cells after treatment with the HPLC-purified Z- and E-isomers of 6-13 for 48 hours. Data were plotted against the log of agonist concentration ($\log_{10}([\text{agonist}] \text{ (M)})$) with mean and SD values in GraphPad Prism.

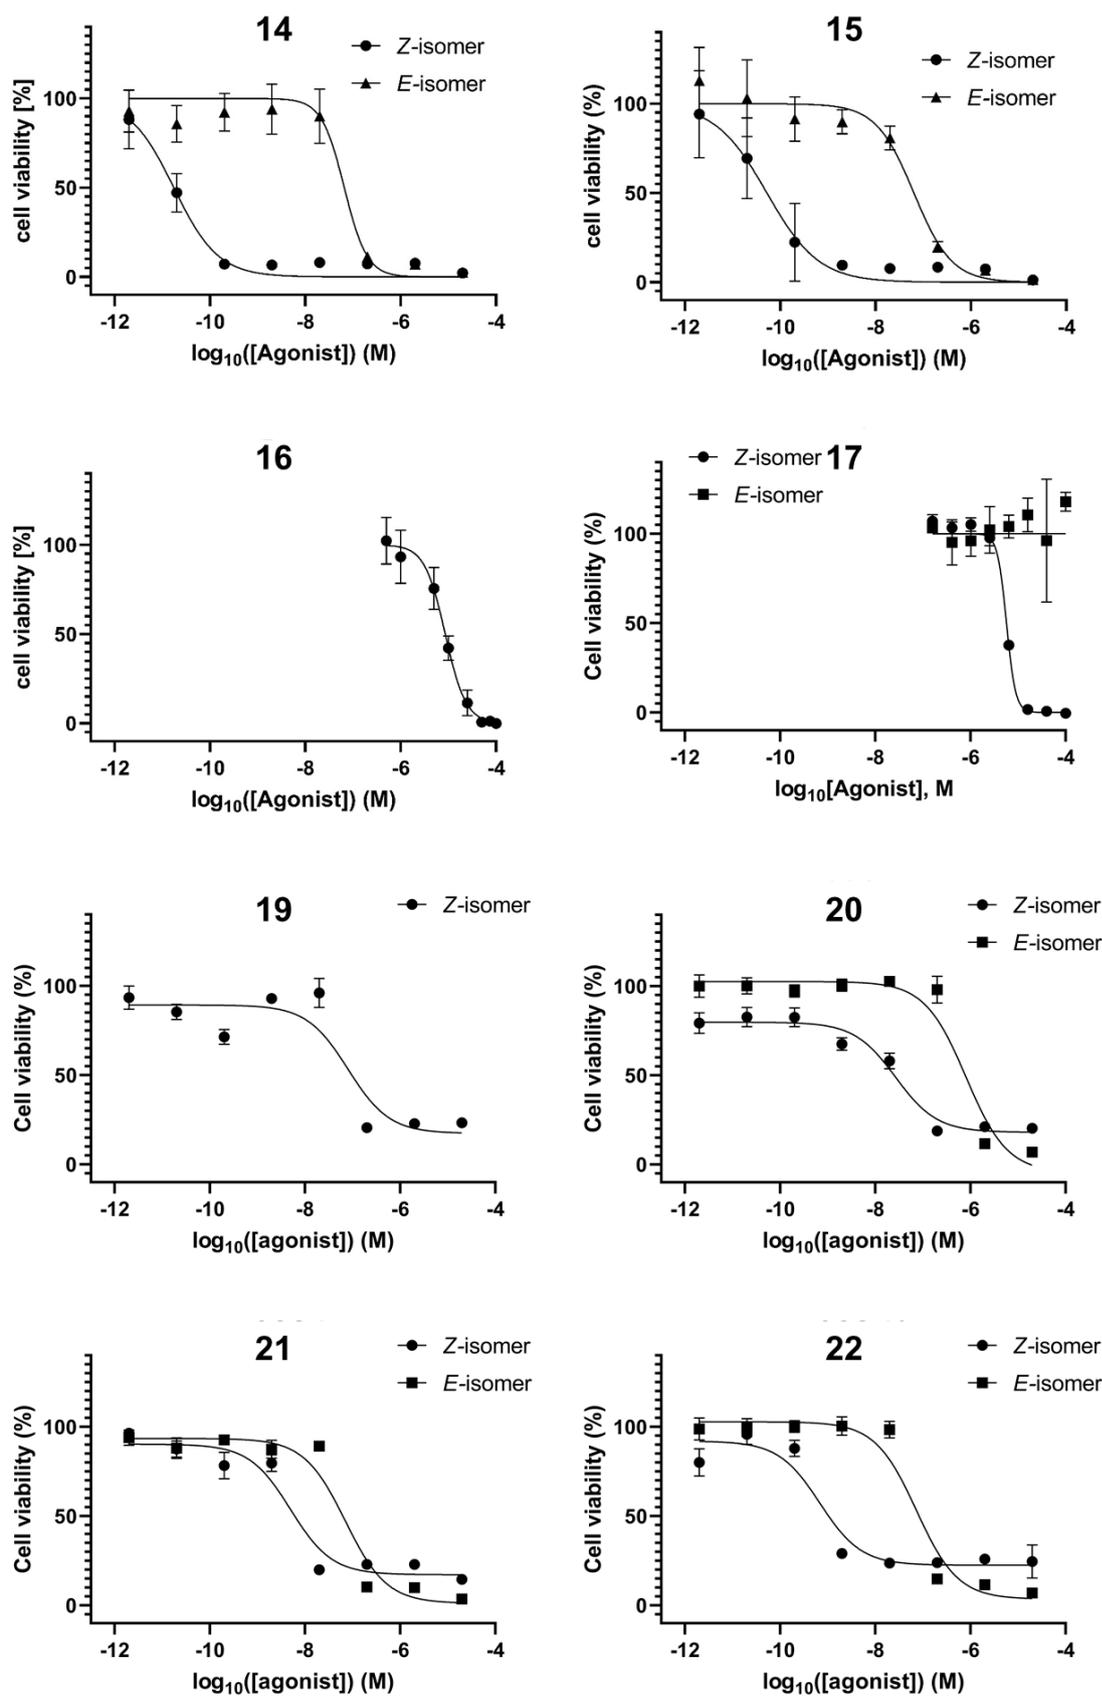

Figure 194: Viability of HT-29 cells after treatment with the HPLC-purified Z- and E-isomers of 14-17 and 19-22 for 48 hours. For compounds 16 and 19 the E-isomers were not tested. Data were plotted against the log of agonist concentration ($\log_{10}([\text{agonist}] \text{ (M)})$) with mean and SD values in GraphPad Prism.

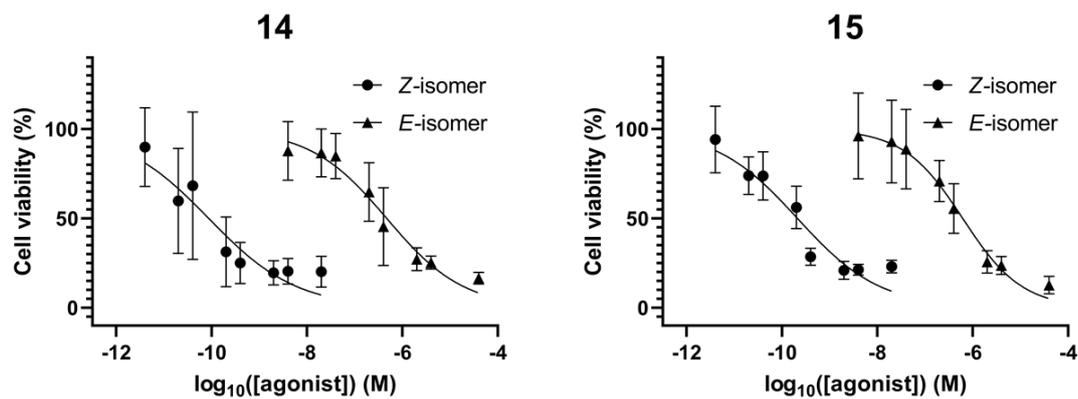

Figure 195: Viability of HT-29 cells after treatment with the respective photoisomers of **14** and **15** with concentrations in close range of the respective IC_{50} values.

Irradiated Samples

Table 8: The IC₅₀ values were determined *via* viability assays with HT-29 cells after treatment with the respective mixtures of photoisomers of 1-6 for 48 hours. Before the addition to the cells DMSO solutions were irradiated with 490 nm irradiation (cyan light), 407 nm (violet light) or 365 nm (UV-light), respectively. Data were processed using GraphPad Prism.

Compound	IC ₅₀ : PSS 490 nm (nM) [95% profile likelihood]	IC ₅₀ : PSS 407 nm (nM) [95% profile likelihood]	IC ₅₀ : PSS 365 nm (nM) [95% profile likelihood]
6	4.45 [2.71 to 7.0]	12.2 [8.79 to 16.9]	44.9 [25.5 to 73.3]
8	29 [22 to 40]	-	-
15	0.34 [0.24 to 0.49]	39.5 [29.9 to 52.1]	-

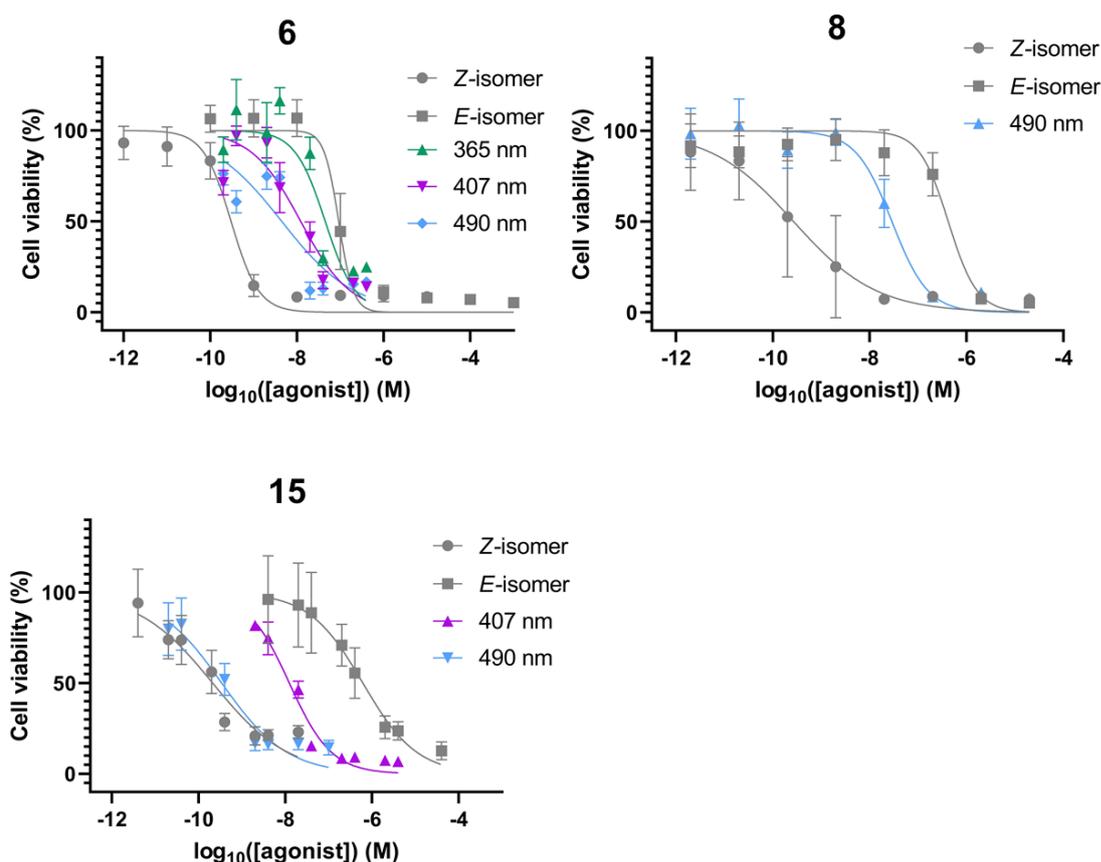

Figure 196: Viability of HT-29 cells after treatment with the mixture of the *E*- and *Z*-isomers generated upon equilibration under 490 nm irradiation (cyan light), 407 nm (violet light) or 365 nm (UV-light), respectively. Data were plotted against the log of agonist concentration ($\log_{10}([\text{agonist}])$ (M)) with mean and SD values in GraphPad Prism. Number of independent experiments (six technical replicates per test): Non-irradiated $N \geq 2$. Irradiated $N = 1$.

Samples Exposed to Daylight

Table 9: The IC₅₀ values determined *via* viability assays with HT-29 cells after treatment with the isolated photoisomers of **6**, **14** and **15** for 48 hours, as well as the results of the same procedure for samples of HPLC-purified *Z*-isomers exhibited on daylight for one day before the assay (where the content of *E*-isomer has been determined by analytical HPLC). However, incubation for further two days at daylight almost doubled the amount of *E*-isomer (IC₅₀ values were not determined for these samples). These data are compared with the values reported in literature (with the unknown final *Z/E*-isomer ratio).¹⁰⁰ Data were processed using GraphPad Prism.

Compound	IC₅₀: <i>Z</i>-isomer (nM) [95% profile likelihood]	IC₅₀: <i>E</i>-isomer (nM) [95% profile likelihood]	IC₅₀: 1 day daylight (nM) [95% profile likelihood]	IC₅₀: 3 days daylight (nM) [95% profile likelihood]	IC₅₀: literature report¹⁰⁰ (nM)
6	0.30 [0.26 to 0.35]	92 [80 to 100]	1.08 [0.66 to 1.8] (15% <i>E</i> - 6)	n.d. (32% <i>E</i> - 6)	14.9 ± 3.8
14	0.09 [0.05 to 0.15]	471 [352 to 636]	1.46 [0.96 to 2.26] (21% <i>E</i> - 14)	n.d. (34% <i>E</i> - 14)	26.1 ± 8.5
15	0.21 [0.16 to 0.28]	618 [487 to 788]	0.63 [0.43 to 0.94] (16% <i>E</i> - 15)	n.d. (30% <i>E</i> - 15)	45.4 ± 12

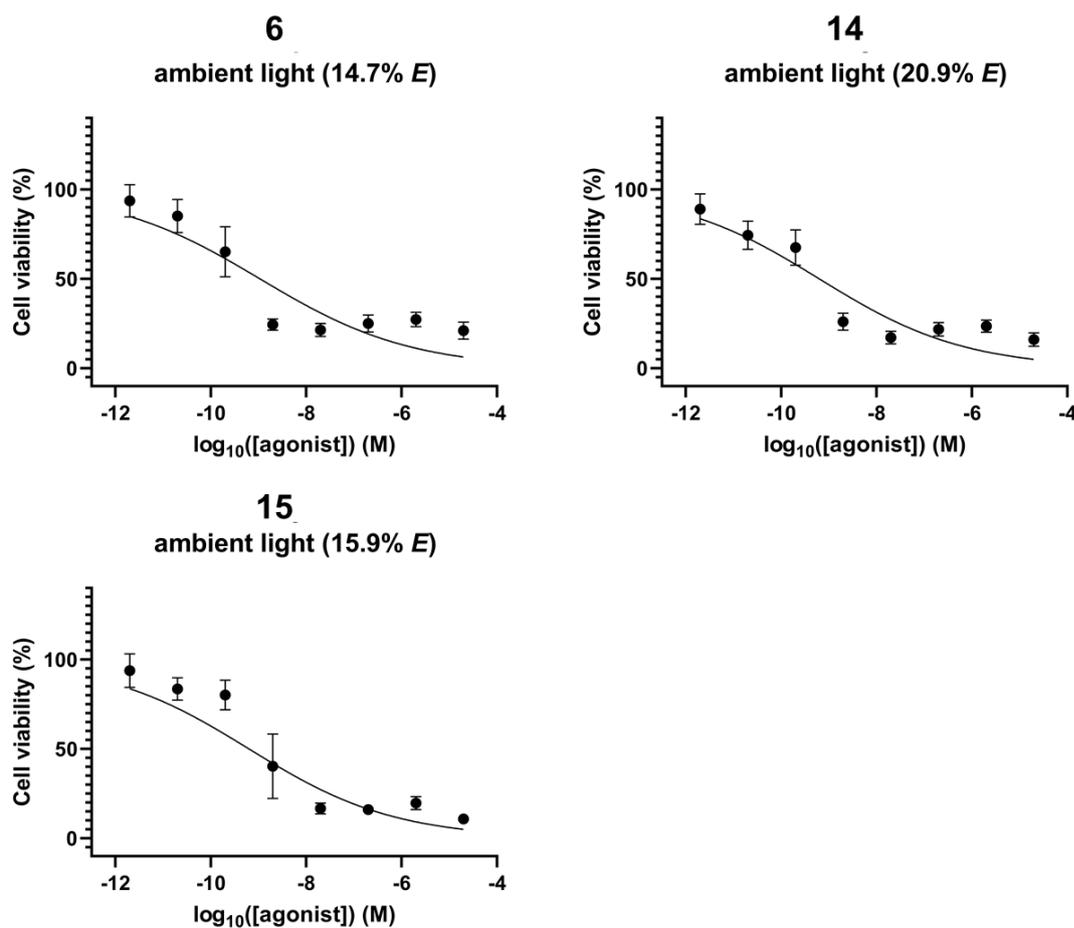

Figure 197: Viability of HT-29 cells after treatment with the mixtures of the respective photoisomers of **6**, **14** and **15** for 48 hours. The mixtures were obtained after incubation of DMSO solutions under ambient light for 24 hours. Data were plotted against the log of agonist concentration ($\log_{10}([\text{agonist}] \text{ (M)})$) with mean and SD values in GraphPad Prism. Number of independent experiments (six technical replicates per test): $N \geq 2$.

5.4.13 Immunofluorescence Assays

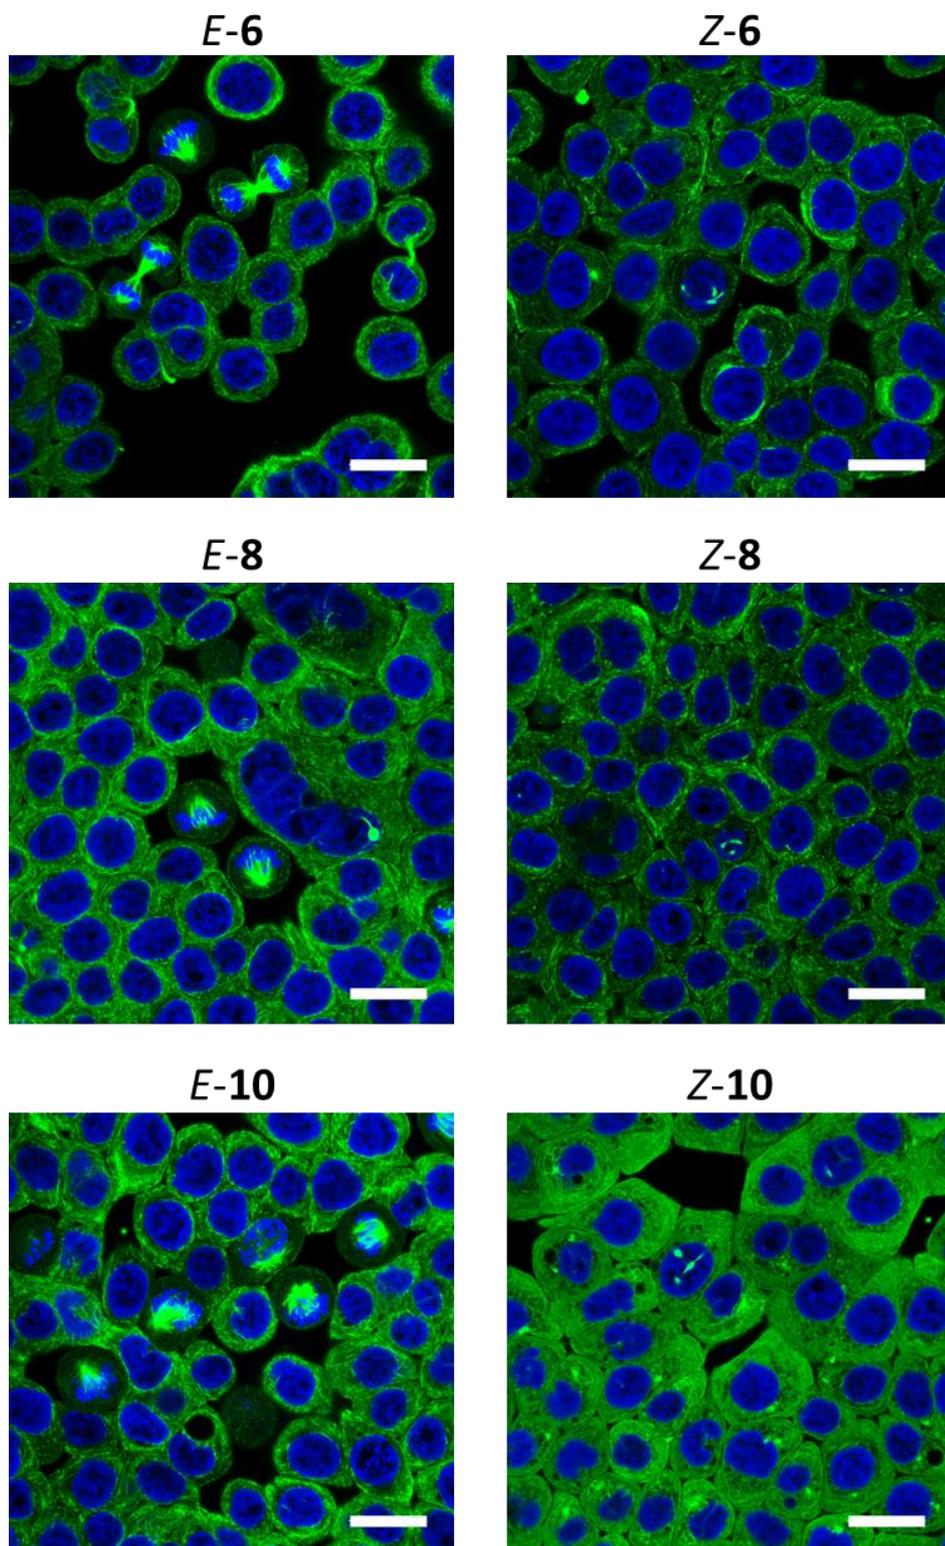

Figure 198: Immunofluorescence imaging of microtubule network structure with compounds **6**, **8** and **10**. Confocal microscopy assessment of cellular microtubule networks after treatment with the respective photoisomers of **6** (2 nM), **8** (20 nM) and **10** (200 nM). (HT-29 cells, 6 h treatment, green: α -tubulin stain for microtubule polymer network, blue: DAPI nuclear counterstain, all scale bars 20 μ m). The results were processed and visualized with Leica Application Suite X 3.5.7.23225 from Leica Microsystems CMS GmbH.

5.4.14 Crystal Structure Determinations

Crystal structures in this section were measured and solved by Dr. Martin Nieger at the University of Helsinki (Finland).

The crystals of **Z-14** and **Z-15** were provided by my colleague Anna-Lena Leistner and **Z-12** and **Z-13** by Angelika Seliwjorstow while working on her bachelor thesis under my supervision.

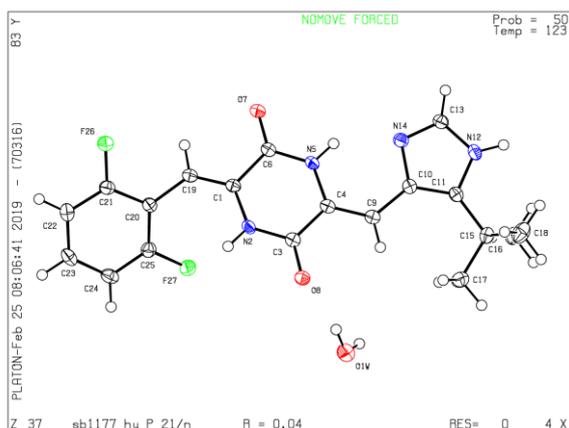

The absolute of **Z-10** (SB1192_HY) was determined by refinement of Parsons' χ -parameter¹⁴⁹. For **Z-16** (SB1373_HY) and **Z-15** (SB1336_HY) an extinction correction was applied. In **Z-14** (SB1342_HY), the 3-methoxybenzylidene moiety is disordered.

Table 10: Overview of the numbering and sample code of crystal structures solved by Dr. Martin Nieger.

Entry	Compound Number	Code Assigned by Dr. Martin Nieger	CCDC Number
1	Z-8	SB1177_HY	2076713
2	Z-10	SB1192_HY	2076714
3	E-10	SB1354_HY	2076715
4	Z-12	SB1270_HY	-
5	Z-13	SB1271_HY	-
6	Z-14	SB1342_HY	2076717
7	Z-15	SB1336_HY	2076718
8	Z-16	SB1373_HY	2076716

5.5 Synthesis and Characterization of Hemiperazines

5.5.1 Synthesis of Hemiperazines

Compound **33** was also synthesized by my colleague Peter Gödtel, who provided me with some of the corresponding NMR, IR and mass spectra. Usually, 200 – 500 mg of the starting material 1,4-diacetylpiperazine-2,5-dione **2** were applied.

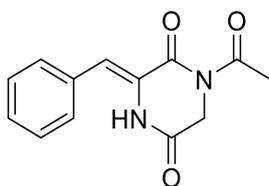

General procedure A

The aldehyde (1.00 equiv.) was dissolved in dry DMF (2.0 mL/1 mmol aldehyde) under argon atmosphere. 1,4-Diacetylpiperazine-2,5-dione (1.50 equiv.) and Cs₂CO₃ (1.50 equiv.) were added and the reaction mixture was stirred at room temperature until the complete consumption of the aldehyde was detected. The reaction mixture was then poured on ice water and the precipitate was filtered off and dried under reduced pressure.

General procedure B

The aldehyde (1.00 equiv.) and 1,4-diacetylpiperazine-2,5-dione (1.50 equiv.) were dissolved in dry THF (6.0 mL/1 mmol aldehyde) under argon atmosphere and cooled down to 0 °C. KO^tBu (1.10 equiv.) was added carefully and subsequently the reaction mixture was allowed to warm up to room temperature and stirred until the complete consumption of the aldehyde was detected. The reaction was quenched by the slow addition of ice water, THF was removed under reduced pressure and the precipitate was filtered off and dried under reduced pressure. The aqueous phase was additionally extracted with ethyl acetate. The organic phase was concentrated *in vacuo* and before purification combined with the precipitate collected before.

(Z)-1-Acetyl-3-benzylidenepiperazine-2,5-dione (**29**)

General procedure A.

The crude residue was purified *via* column chromatography (CH₂Cl₂:ethyl acetate; 10:1). (*Z*)-1-Acetyl-3-benzylidenepiperazine-2,5-dione (**29**) was isolated as a colorless solid in 57% yield (210 mg, 860 μmol).

To isolate the *E*-isomer, a solution of compound **29** in ethyl acetate was irradiated at 365 nm for 1 hour. The two photoisomers were then separated *via* column chromatography (CH₂Cl₂:ethyl acetate; 9:1).

Z-isomer

¹H NMR (400 MHz, CDCl₃): δ = 7.96 (s, 1H, NH), 7.51 – 7.42 (m, 2H, H_{arom}), 7.39 (ddt, *J* = 6.1, 3.0, 1.9 Hz, 3H, H_{arom}), 7.18 (s, 1H, Ph-CH), 4.51 (s, 2H, CH₂), 2.66 (s, 3H, CH₃) ppm.

(Z)-1-Acetyl-3-(4-methoxybenzylidene)piperazine-2,5-dione (**30**)

General procedure A.

The crude residue was purified *via* column chromatography (cyclohexane:ethyl acetate; 2:1 -> 3:2). The target compound was isolated as a pale-yellow solid in 55% yield.

To isolate the *E*-isomer a solution of compound **30** in ethyl acetate was irradiated at 365 nm for 1 hour. The two photoisomers were then separated *via* column chromatography (cyclohexane:ethyl acetate; 2:1 -> 3:2).

Z-isomer

5.5.4 Absorption Spectra of Irradiated Samples

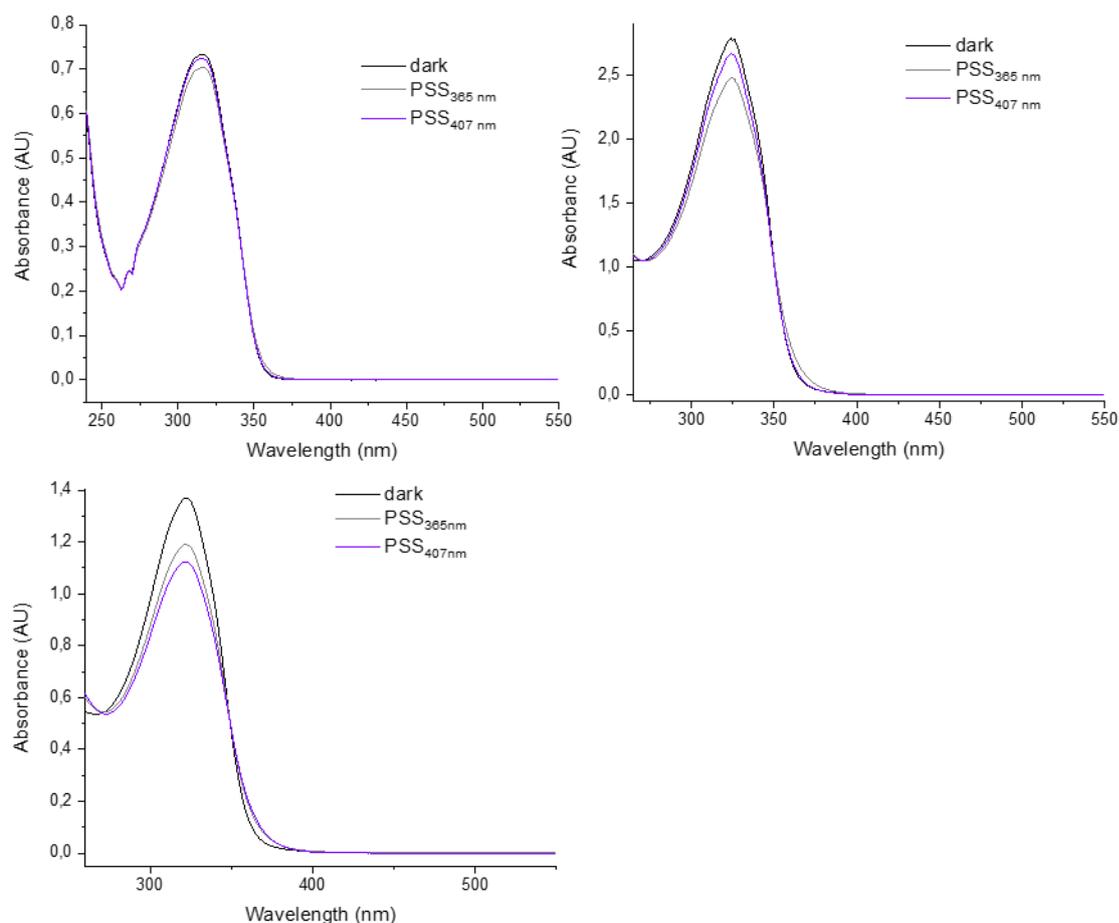

Figure 242: Compound **29** was dissolved in CH₂Cl₂ (80 μM, top left), DMSO (160 μM, top right) and 25% PBS in DMSO (v/v) (80 μM, bottom left), respectively. Absorption spectra (d=10 mm) were first measured in the dark. The samples were then irradiated with 365 nm and with 407 nm. An absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

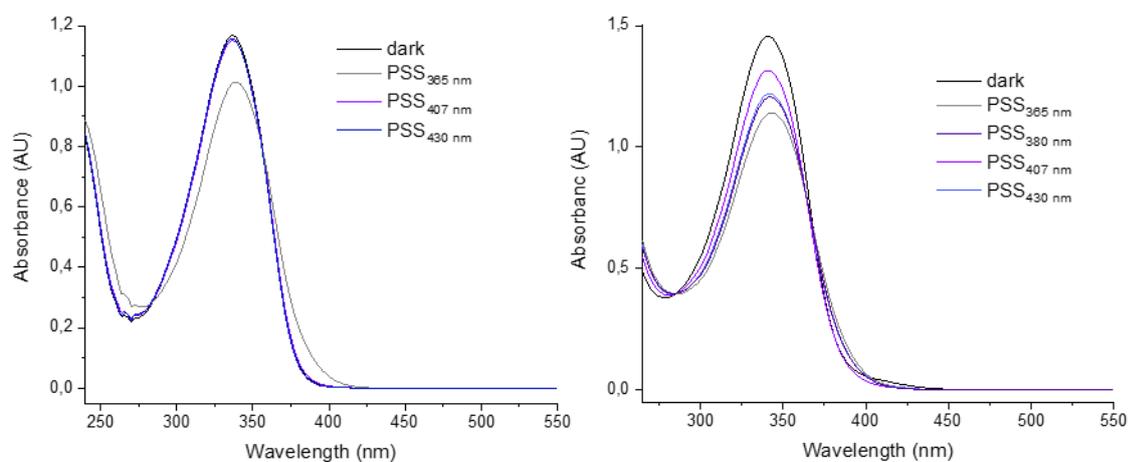

Figure 243: Compound **30** was dissolved in CH₂Cl₂ (80 μM, left) and DMSO (80 μM, right), respectively. Absorption spectra (d=10 mm) were first measured in the dark. The samples were then

irradiated with 365 nm, 407 nm and 430 nm. An absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

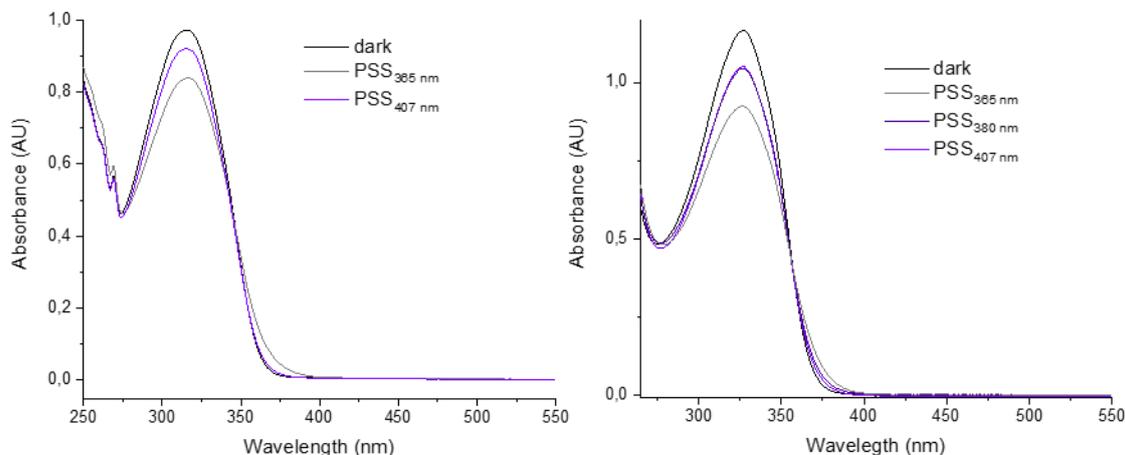

Figure 244: Compound **31** was dissolved in CH₂Cl₂ (80 μM, left) and DMSO (80 μM, right), respectively. Absorption spectra (d=10 mm) were first measured in the dark. The samples were then irradiated with 365 nm, 380 nm and 407 nm. An absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

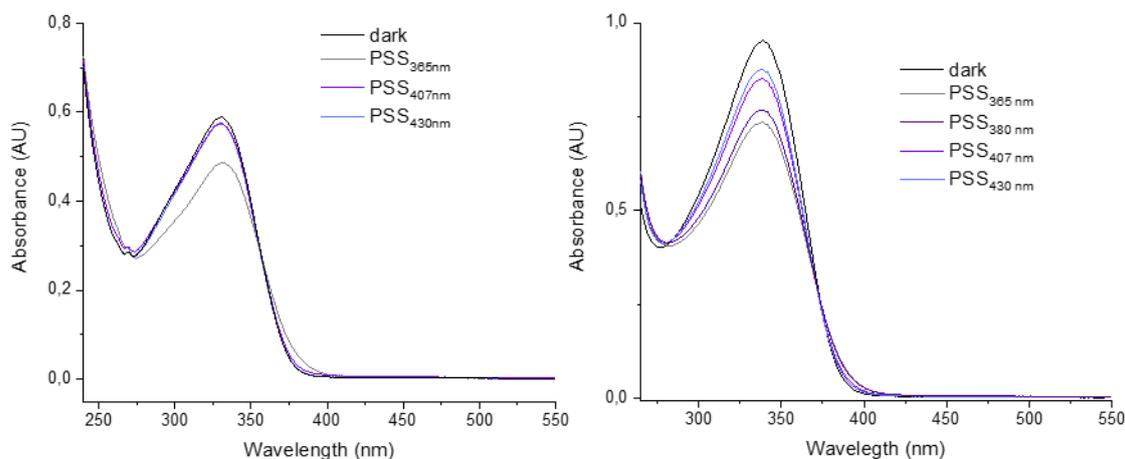

Figure 245: Compound **32** was dissolved in CH₂Cl₂ (80 μM, left) and DMSO (80 μM, right), respectively. Absorption spectra (d=10 mm) were first measured in the dark. The samples were then irradiated with 365 nm, 380 nm, 407 nm and 430 nm. An absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

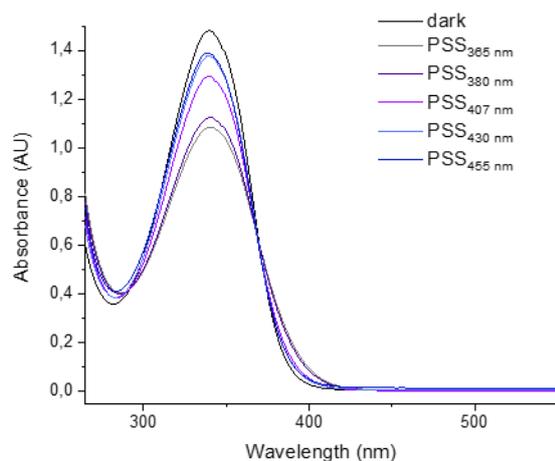

Figure 246: Compound **33** was dissolved in DMSO (80 μ M) and an absorption spectrum ($d=10$ mm) was first measured in the dark. The sample was then irradiated with 365 nm, 380 nm, 407 nm, 430 nm and 455 nm. An absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

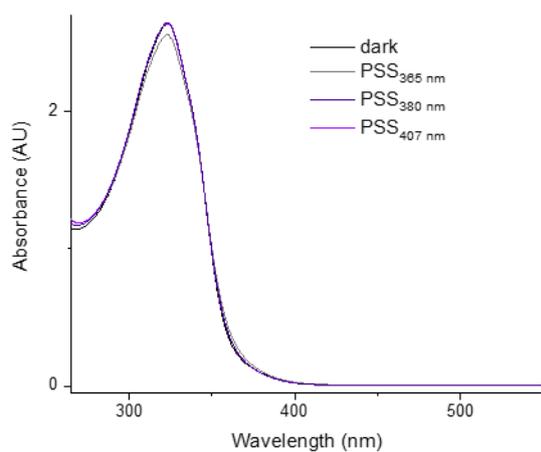

Figure 247: Compound **34** was dissolved in DMSO (80 μ M) and an absorption spectrum ($d=10$ mm) was first measured in the dark. The sample was then irradiated with 365 nm, 380 nm and 407 nm. An absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

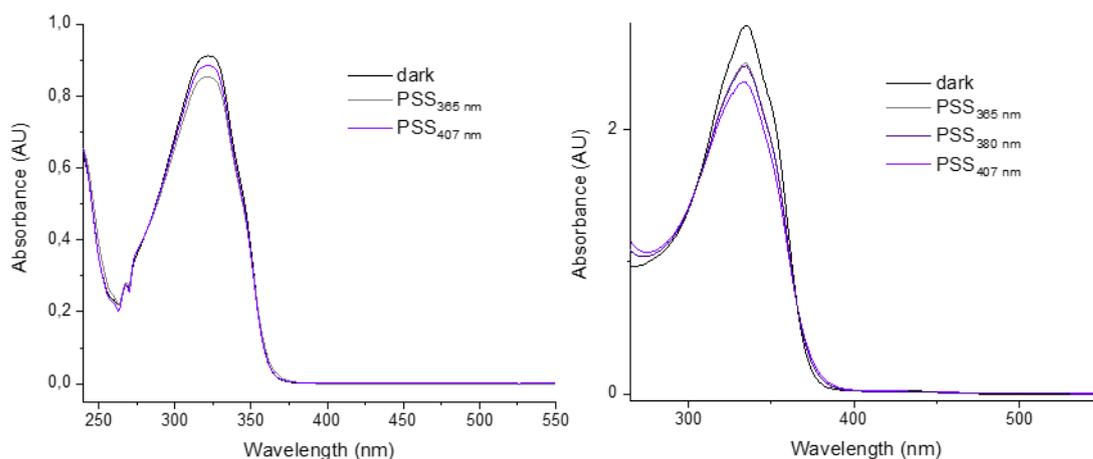

Figure 248: Compound **35** was dissolved in CH_2Cl_2 (80 μM , left) and DMSO (160 μM , right), respectively. Absorption spectra ($d=10$ mm) were first measured in the dark. The samples were then irradiated with 365 nm, 380 nm and 407 nm. An absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

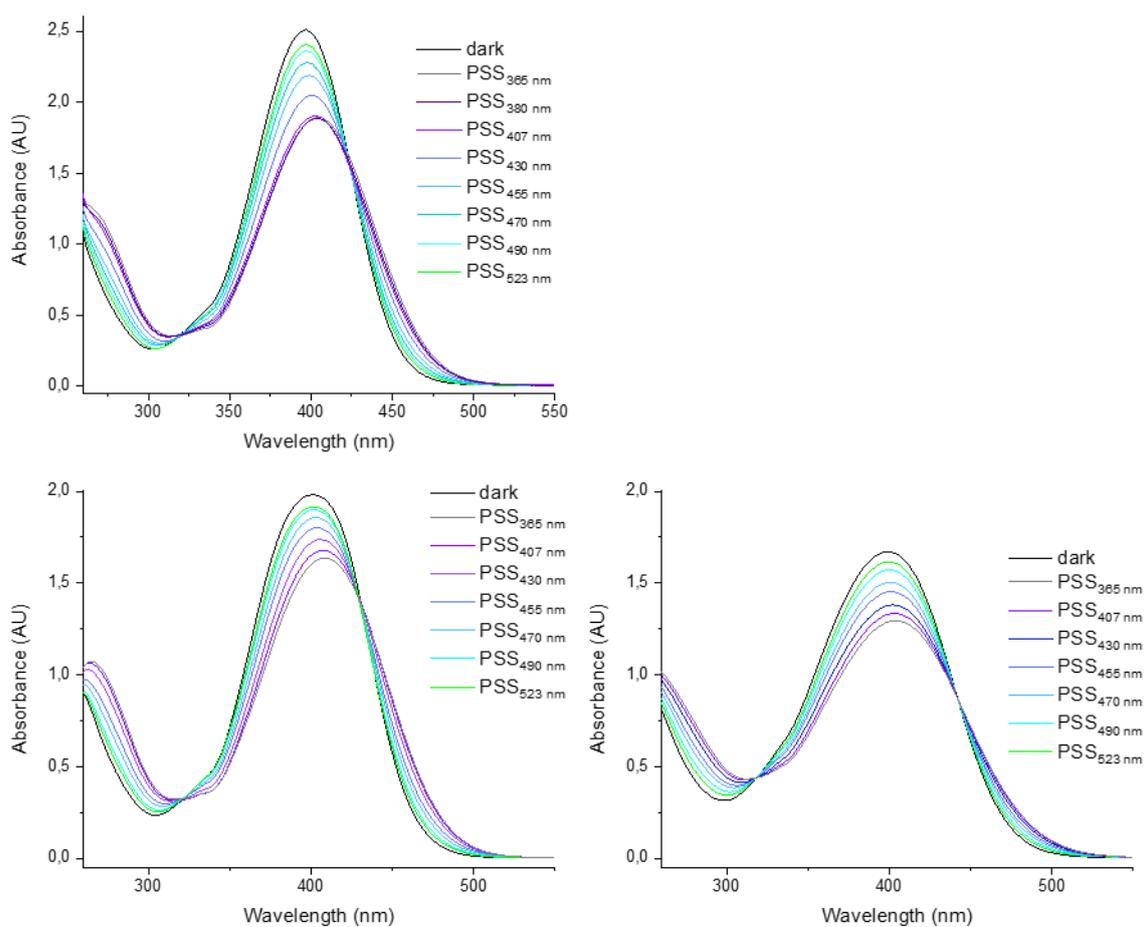

Figure 249: Compound **36** was dissolved in DMSO (80 μM , top left), 25% PBS in DMSO (v/v) (80 μM , bottom left) and 75% PBS in DMSO (v/v) (80 μM , bottom right), respectively. Absorption spectra ($d=10$ mm) were first measured in the dark. The samples were then irradiated with 365 nm,

380 nm, 407 nm, 430 nm, 455 nm, 470 nm, 490 nm and with 523 nm. An absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

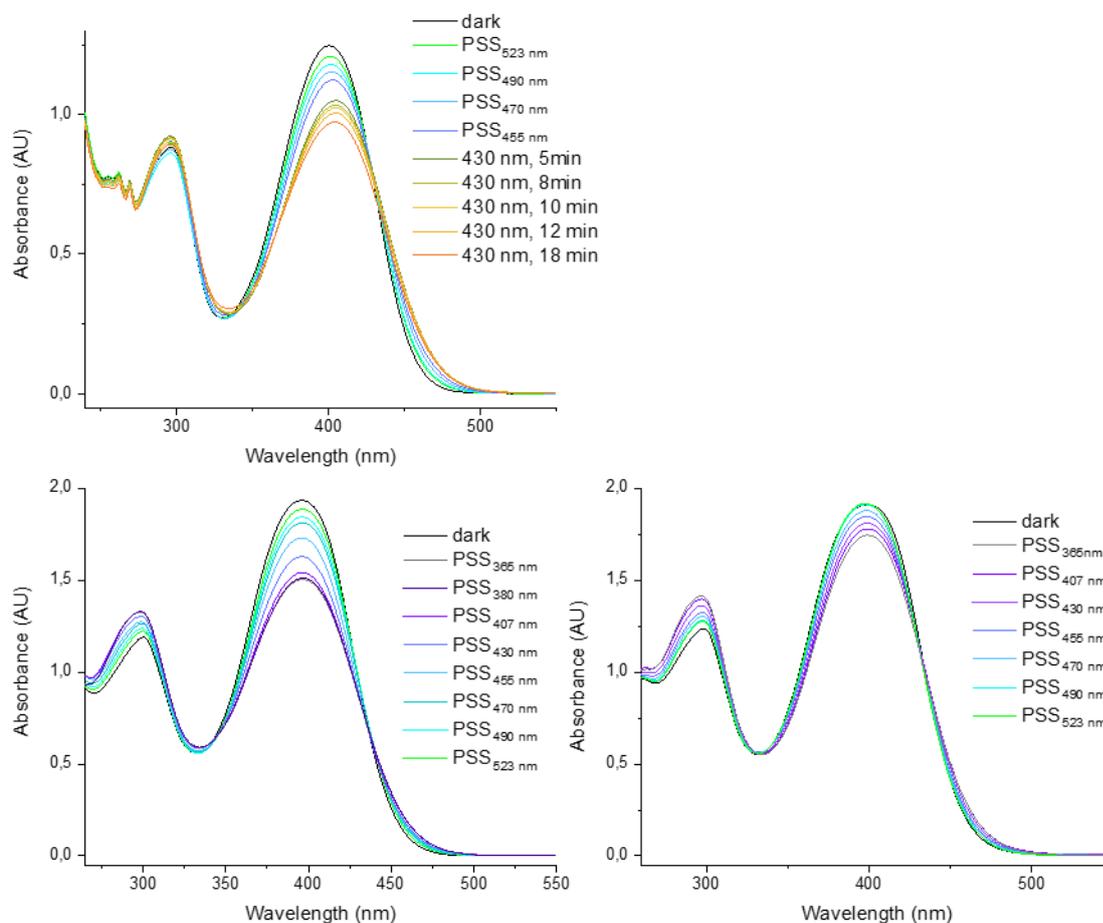

Figure 250: Compound **37** was dissolved in CH_2Cl_2 (80 μM , top left), DMSO (80 μM , bottom left) and 25% PBS in DMSO (v/v) (80 μM , bottom right), respectively. Absorption spectra ($d=10$ mm) were first measured in the dark. The samples were then irradiated with 365 nm, 380 nm, 407 nm, 430 nm, 455 nm, 470 nm, 490 nm and with 523 nm. An absorption spectrum was measured after each irradiation step until the PSS was reached, respectively. In case of the sample in CH_2Cl_2 degradation was observed upon irradiation with wavelengths < 455 nm.

5.5.5 Emission Spectra

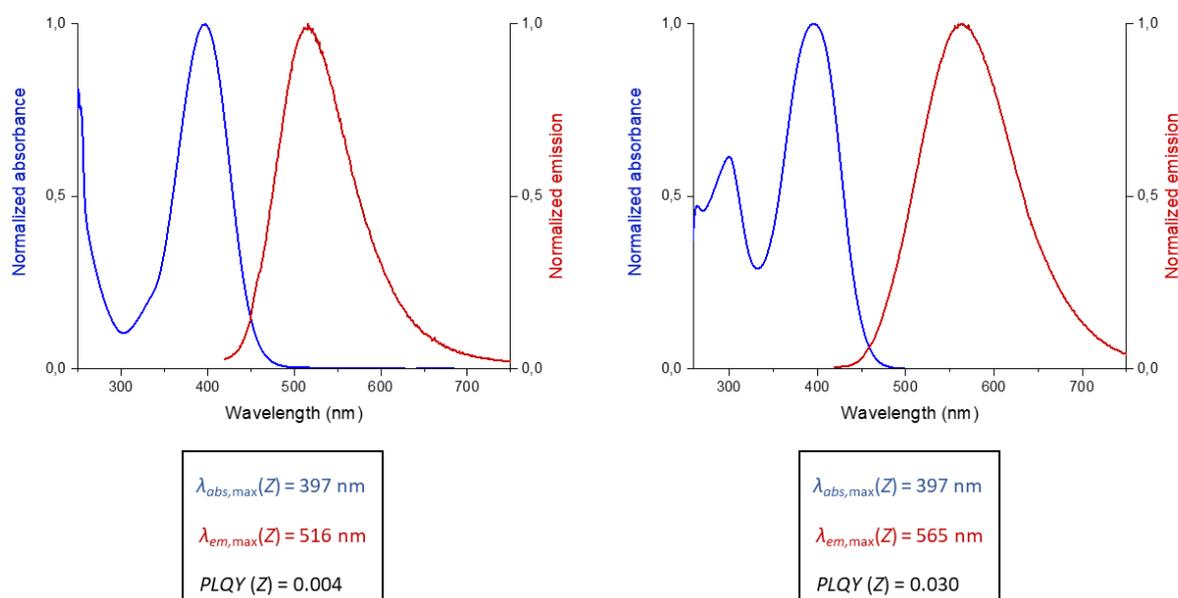

Figure 251: Normalized absorption (blue) and emission (red) spectra of 80 μM solutions of the respective Z-isomers of **36** (left) and **37** (right) in DMSO.

5.5.6 Composition of the Photostationary States (PSSs)

The PSS composition was determined by measuring ^1H NMR spectra of the respective compounds after irradiation. The PSS values in the NMR tubes (0.5 mL of the 30-60 mM solutions in DMSO- d_6 or CD_2Cl_2) have been achieved within 1 h (365, 407, 523 nm) or 2 h (430 nm). Signal pairs were determined for each compound: two signals assigned to the same proton for the respective photoisomers were integrated and the % of E-isomer = $I_E/(I_E+I_Z)*100\%$ was determined. The final E/Z ratios result from the average value determined from three signal pairs.

Table 11: PSS composition in DMSO- d_6 or CD_2Cl_2 determined by measuring ^1H NMR spectra of the respective compounds after irradiation.

Compound	365 nm (% of E-isomer)	407 nm (% of E-isomer)	430 nm (% of E-isomer)	450 nm (% of E-isomer)	470 nm (% of E-isomer)	490 nm (% of E-isomer)	523 nm (% of E-isomer)
29 (DMSO- d_6)	19	6	-	-	-	-	-
29 (CD_2Cl_2)	10	2	-	-	-	-	-
30 (CD_2Cl_2)	29	3	<1	-	-	-	-

5.5.7 Photoisomerization Quantum Yield

The measurements to determine the photoisomerization quantum yields were performed by Peter Gödtel.

A 2.5 mM solution of **37** in DMSO was irradiated with 398 nm (Edison Opto, EDEV-SLC1-03) and 520 nm (OSRAM Opto Semiconductors Inc., LTCP7P-KXKZ) in succession. Several samples were taken from the solution during irradiation and the isomer-ratio was analyzed *via* HPLC. After reaching the PSS at 398 nm (55.9% *E*-isomer), the same solution was irradiated with 520 nm for a maximum of 115 min. The LEDs were driven at 4.0 V and 100 mA (398 nm) as well as 3.7 V and 59 mA (520 nm), to ensure the same irradiation intensity at the sample of 3.095 mW/cm^2 for both wavelengths of light.

Since continuous irradiation well after the PSS is reached will eventually lead to a measured reaction quantum yield of $\Phi_{t \rightarrow \infty} = 0$, only samples were taken into account, which still lie in the linear regime of the reaction progress.¹⁵⁰ This ensures that F_{max} can be determined accurately, which more closely represents the switching efficiency of each individual molecule, rather than the efficiency of reaching the PSS of the whole mixture.

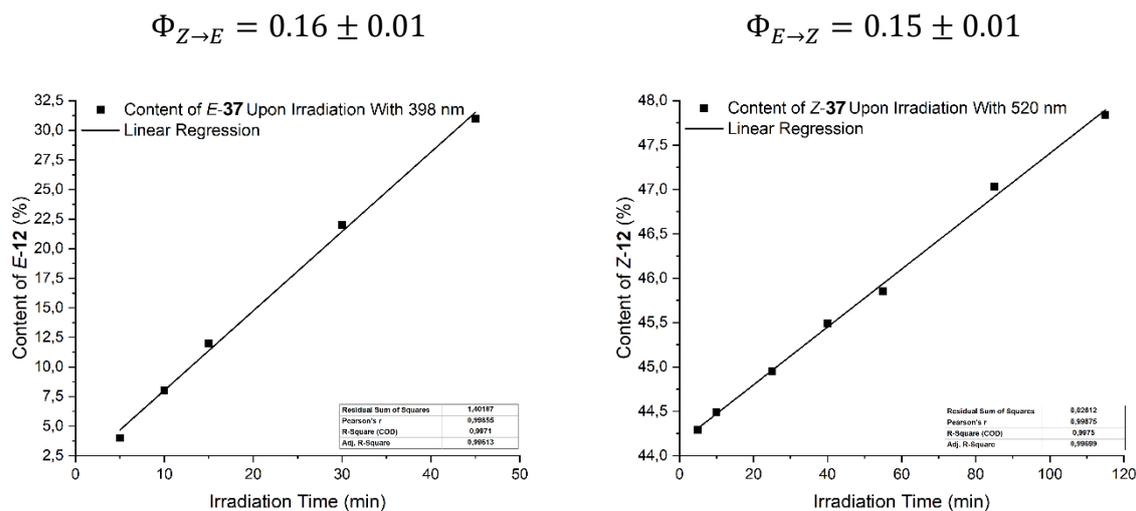

Figure 260: Content of *E*-37 upon irradiation with 398 nm over time (left) and content of *Z*-37 upon irradiation with 520 nm over time (right) in the isomer mixture, determined *via* HPLC.

5.5.8 Thermal Relaxation of *E*-Isomers

Table 12: The thermal relaxation of the respective *E*-isomers of **29-32**, **35**, and **37** in MeCN at 60 °C after one week was monitored *via* analytical HPLC.

Compound	29	30	31	32	35	37
Decrease of <i>E</i> -isomer after 7 days	4.0%	0.8%	2.2%	1.3%	0.8%	12.1%

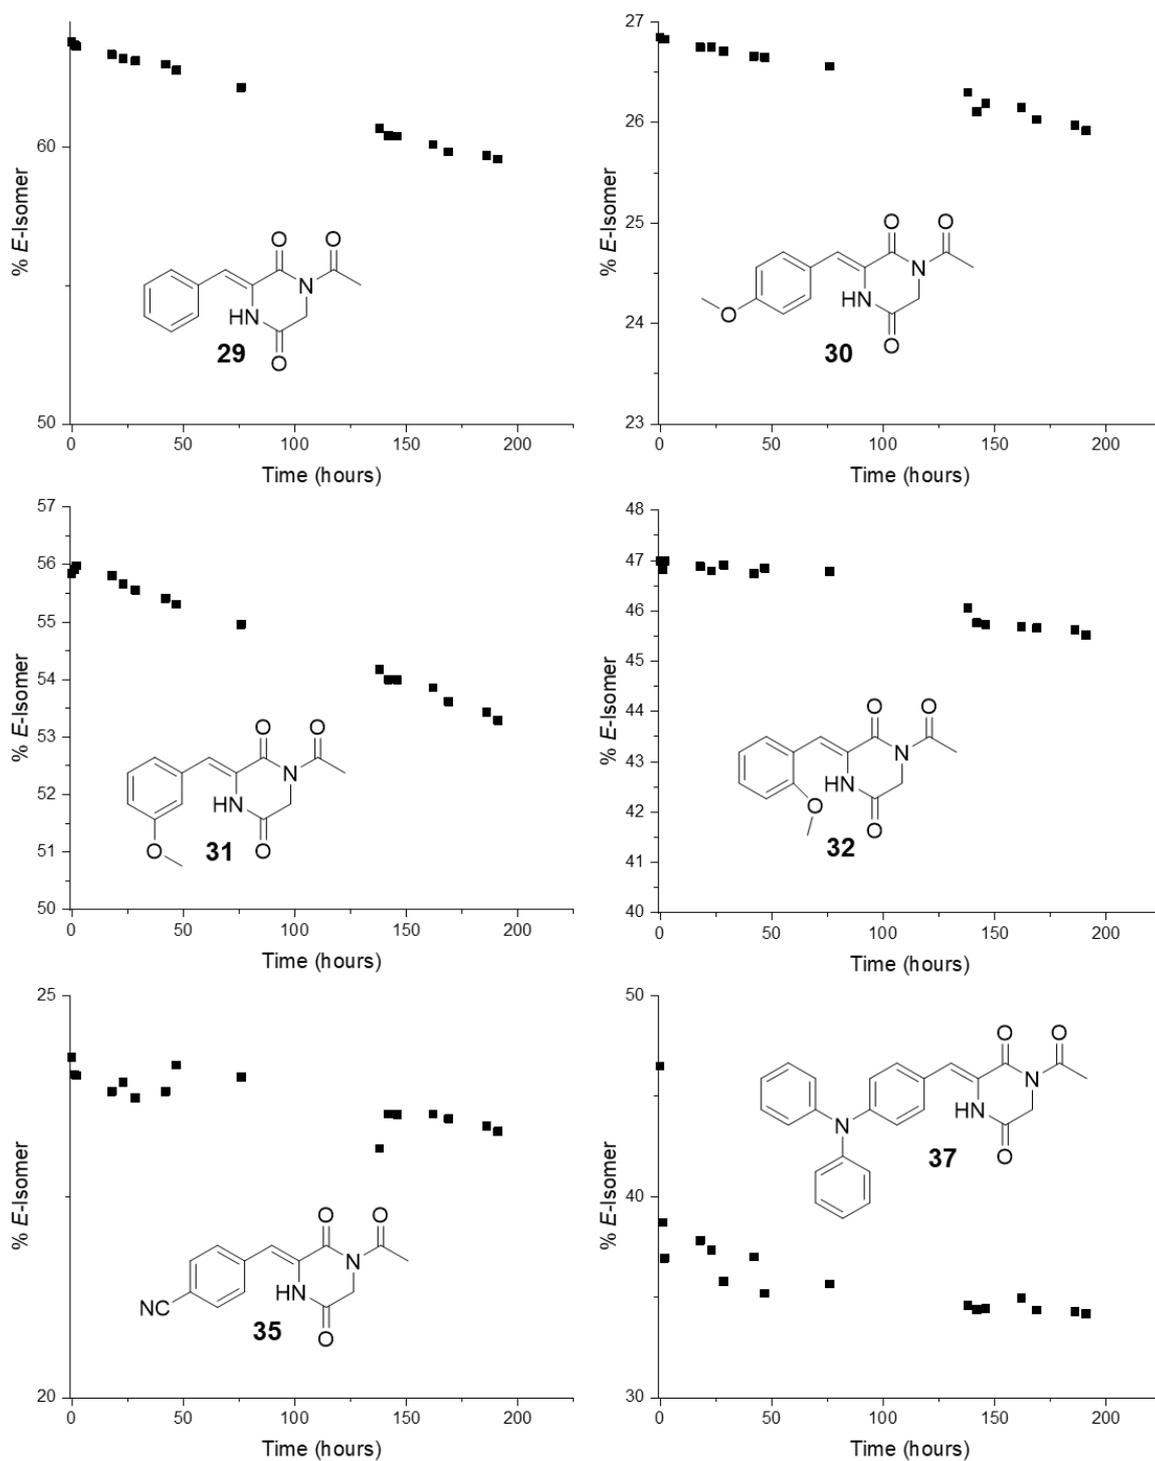

Figure 261: Thermal relaxation of the *E*-isomers in MeCN at 60 °C was monitored *via* analytical HPLC. The percentage of *E*-isomer was determined with the integrals of the signals assigned to the respective isomer.

5.5.9 Switching Stability

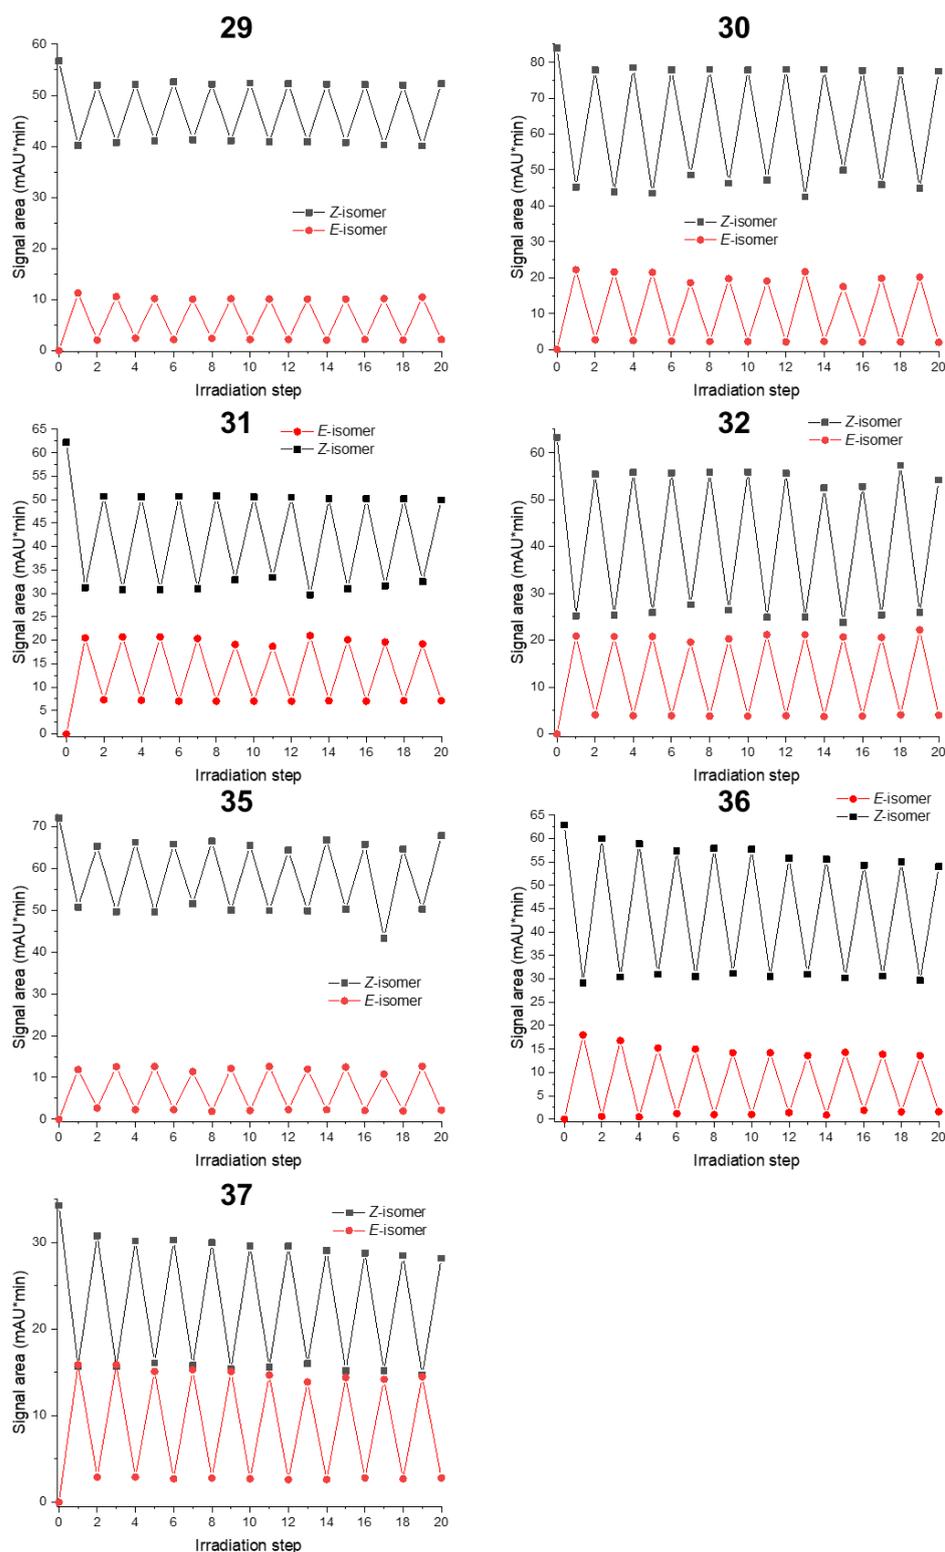

Figure 262: Solutions of pure Z-isomers in DMSO (1.0 mM) were alternately irradiated with two wavelengths and after every irradiation step the solutions were analyzed *via* analytical HPLC. **29:** 365 nm for 2 min and with 407 nm for 10 min; **30:** 365 nm for 2 min and with 430 nm for 20 min; **31:** 365 nm for 2 min and with 407 nm for 5 min; **32, 35:** 365 nm for 4 min and with 430 nm for 45 min; **36:** 407 nm for 4 min and with 523 nm for 10 min; **37:** 407 nm for 5 min and with 523 nm for 35 min.

Molecular Orbitals

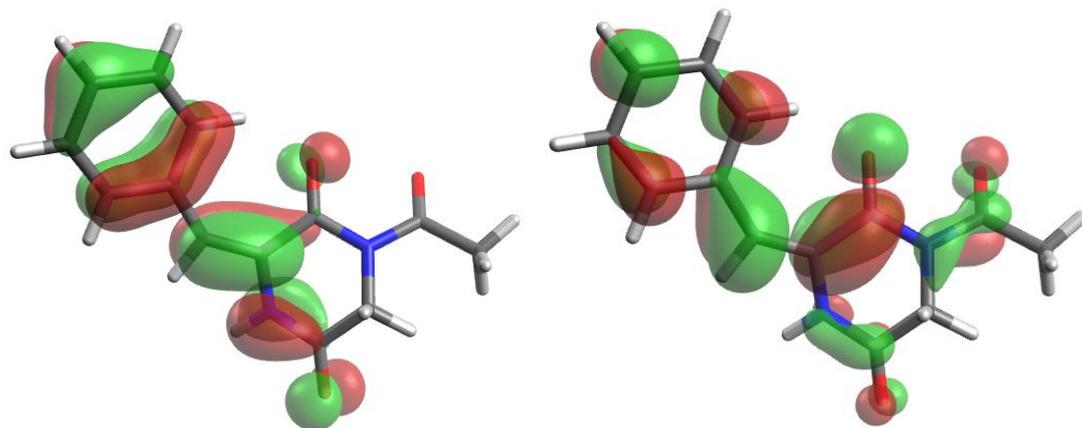

The orbital energies and the 3D representations (left: HOMO, right: LUMO) of the electron probability distributions were extracted with Avogadro 1.2.0.

Table 13: HOMO-1 (H-1), HOMO (H), LUMO (L) and LUMO+1 Kohn-Sham orbital energies (in eV) of the *E*-isomers and *Z*-isomers of the compounds **29-38** calculated on the TD-B3LYP-GD3BJ/6-311G(d,p) level of theory.

Excitation Energies

The five lowest transitions computed in the TD calculations (10 states in total) are reported. For each excited state the energy (in eV), the associated wavelength (in nm) and the oscillator strength of the transition is given. The numbers of the orbitals involved in the transition (with general formula occupied \rightarrow unoccupied) and the associated (largest) coefficient in the CI expansion is presented.

Calculated Absorption Spectra

The absorption spectra were simulated based on TD calculations (10 states in total) with Gaussview assuming a gaussian band shape (characterized by a standard deviation $s = 0.2$ eV) and the extracted data was plotted using OriginPro 2020 9.7.188 with the peaks, furnished by the calculation.

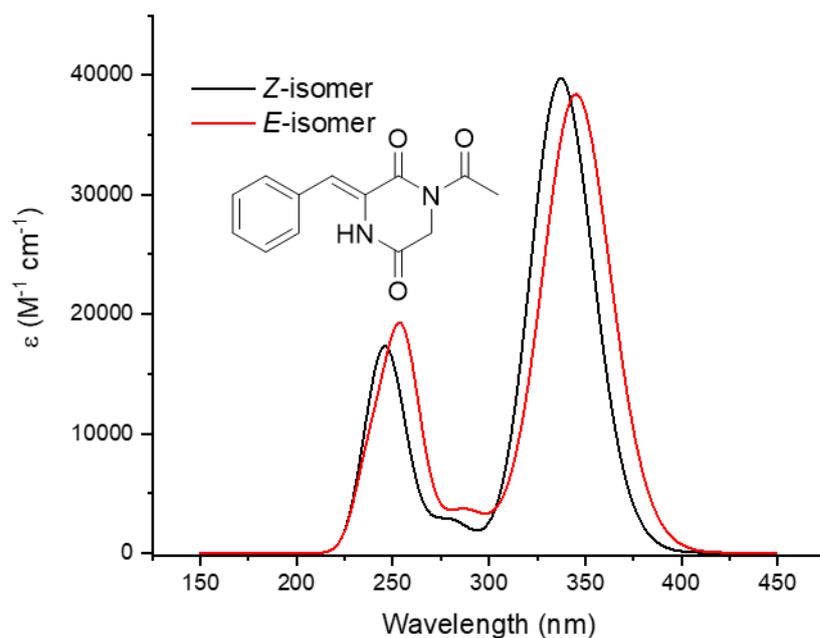

Figure 263: Simulated absorption spectrum of *E*-29 and *Z*-29 based on TD calculations (10 states in total).

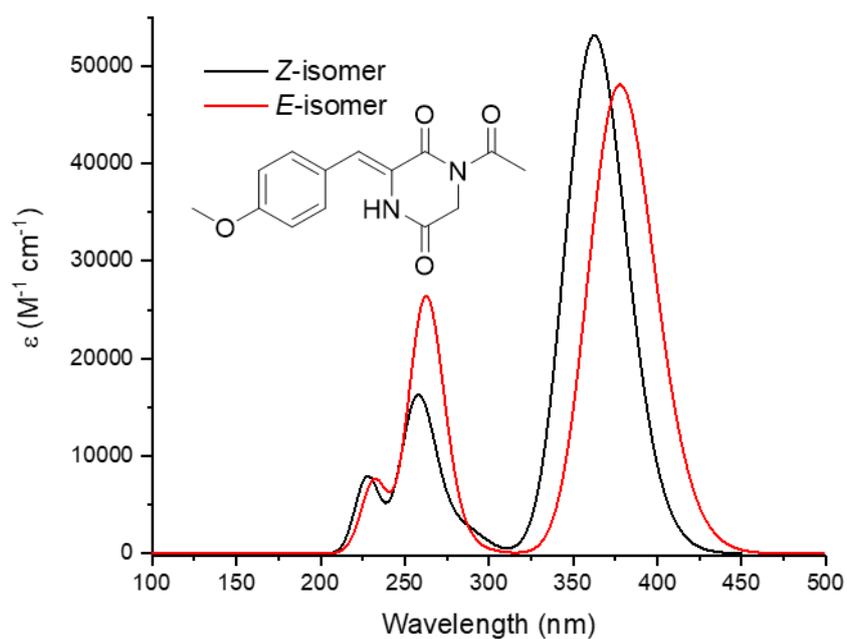

Figure 264: Simulated absorption spectrum of *E*-30 and *Z*-30 based on TD calculations (10 states in total).

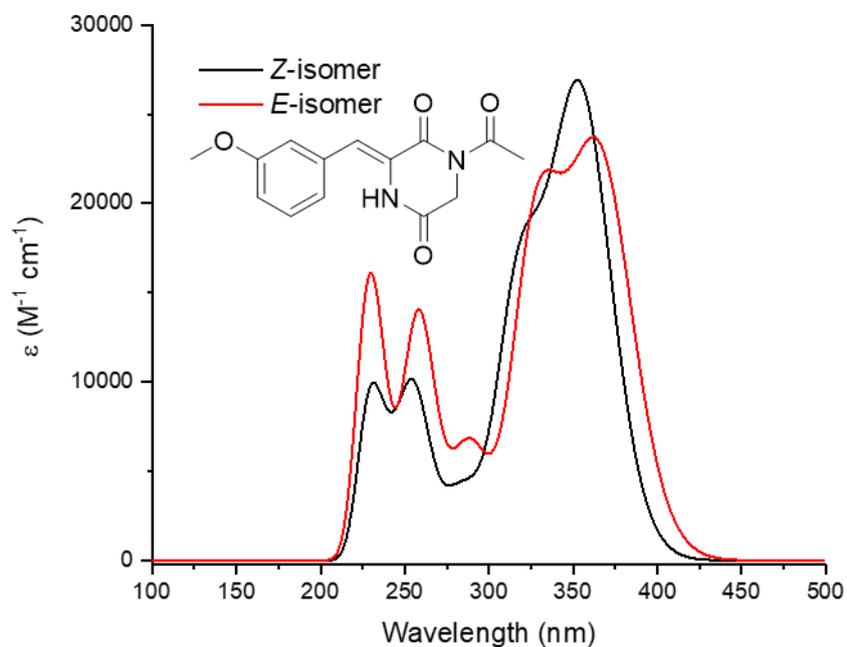

Figure 265: Simulated absorption spectrum of *E*-31 and *Z*-31 based on TD calculations (10 states in total).

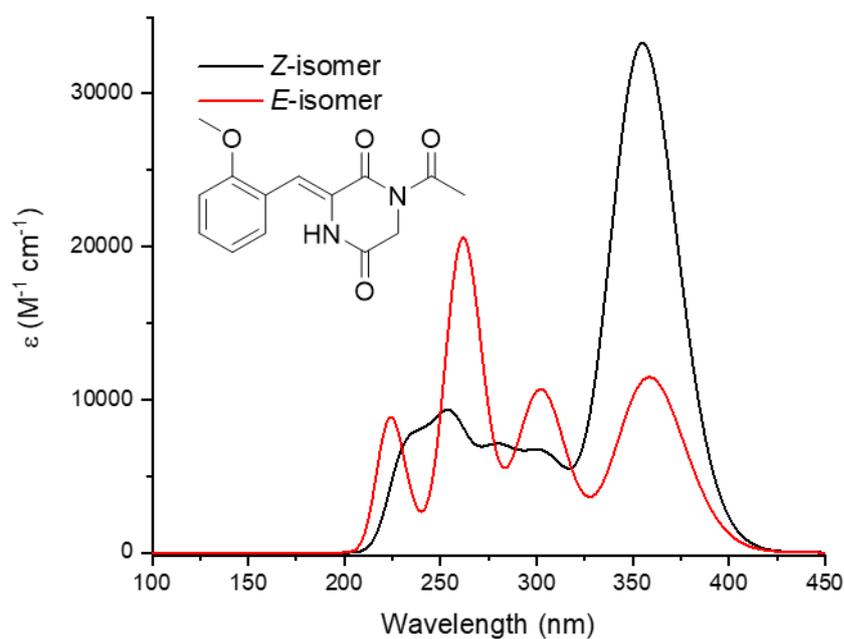

Figure 266: Simulated absorption spectrum of *E*-32 and *Z*-32 based on TD calculations (10 states in total).

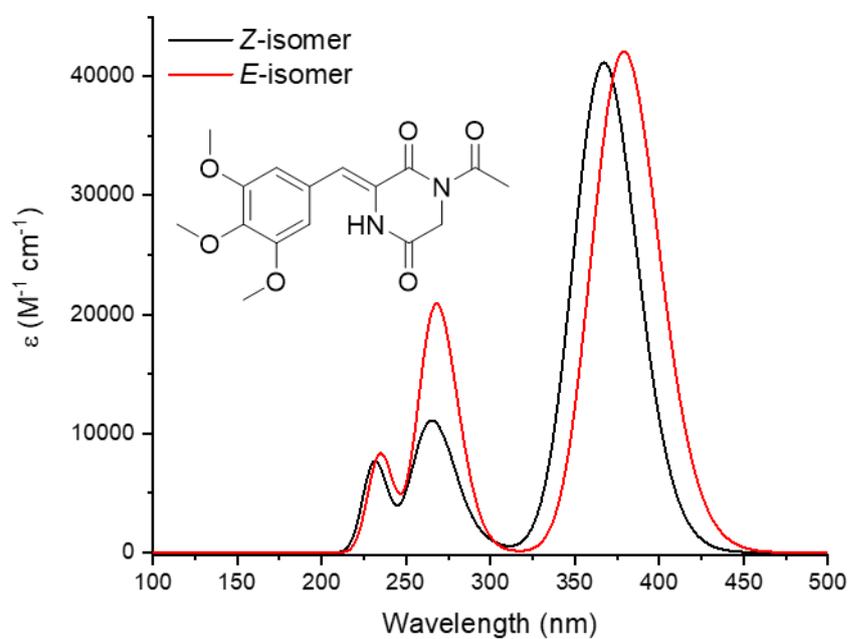

Figure 267: Simulated absorption spectrum of *E*-33 and *Z*-33 based on TD calculations (10 states in total).

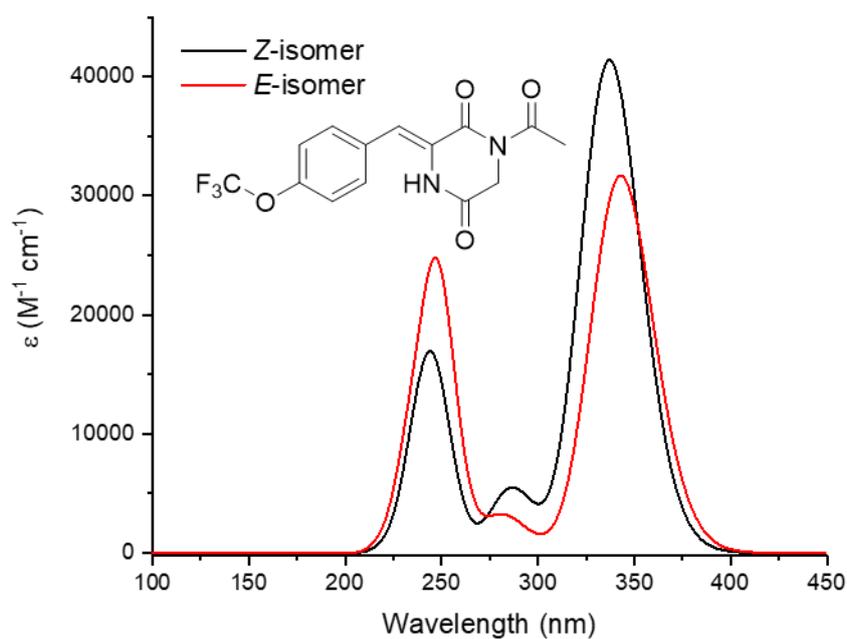

Figure 268: Simulated absorption spectrum of *E*-34 and *Z*-34 based on TD calculations (10 states in total).

5.6 Synthesis and Characterization of 'Locked' Plinabulin 40 and Derivatives

5.6.1 Precursor Synthesis

Methyl 2-(1*H*-indole-2-carboxylamino)acetate (**43**)

To a solution of 1*H*-indole-2-carboxylic acid (10.0 g, 62.1 mmol, 1.00 equiv.) and the methyl 2-aminoacetate hydrochloride (9.35 g, 74.5 mmol, 1.20 equiv.) in 620 mL CH₂Cl₂, EDC·HCl (14.3 g, 74.5 mmol, 1.20 equiv.) and DMAP (12.1 g, 99.3 mmol, 1.60 equiv.) were added at 0 °C. After stirring for 4 h at 0 °C, the solution was allowed to warm to ambient temperature and stirred for additional 20 h. The precipitate was filtered off and the mother liquor was washed with water (300 mL) and 10% HCl solution (300 mL) and evaporated *in vacuo*. The residual solid was combined with the precipitate from the first filtration step and purified by recrystallization from methanol to yield 9.05 g (40.9 mmol, 66% yield) of methyl 2-(1*H*-indole-2-carboxylamino)acetate (**43**) as a colorless solid.

¹H NMR (400 MHz, DMSO-*d*₆): δ = 11.62 (s, 1H), 8.95 (t, *J* = 6.0 Hz, 1H), 7.63 (d, *J* = 7.9, 1.1 Hz, 1H), 7.44 (d, *J* = 8.3, 1.0 Hz, 1H), 7.19 (ddd, *J* = 8.2, 7.0, 1.2 Hz, 1H), 7.16 (dd, *J* = 2.2, 0.9 Hz, 1H), 7.04 (t, *J* = 1.0 Hz, 1H), 4.06 (d, *J* = 5.9 Hz, 2H), 3.67 (s, 3H) ppm.

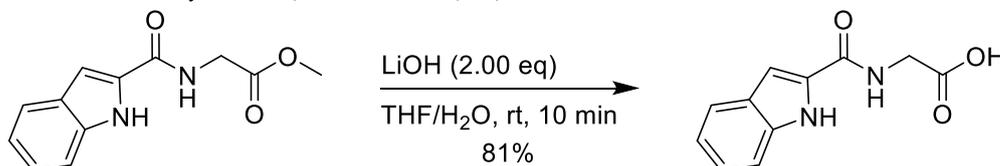

¹³C NMR (101 MHz, DMSO-*d*₆): δ = 170.5, 161.5, 136.5, 131.0, 127.0, 123.5, 121.6, 119.8, 112.3, 103.0, 51.7, 40.8 ppm.

2-(1*H*-Indole-2-carboxylamino)acetic acid (**44**)

To a solution of methyl 2-(1*H*-indole-2-carboxylamino)acetate (**43**) (8.50 g, 36.6 mmol, 1.00 equiv.) in THF (170 mL) LiOH (1.75 g, 73.2 mmol, 2.00 equiv.) in water (170 mL) was added and the reaction mixture was stirred at room temperature for 10 min. The reaction was quenched by adding aq. solution of HCl (2 M, 50 mL). Subsequently, THF was removed *in vacuo* and the precipitate was filtered off and dried. 2-(1*H*-Indole-2-carboxylamino)acetic acid (6.50 g, 29.8 mmol, 81% yield) was obtained as a yellow solid and used for the next reaction step without further purification.

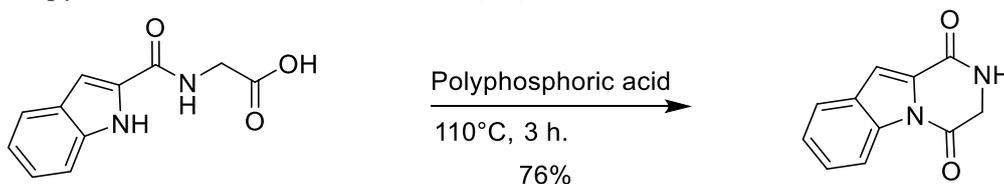

¹H NMR (400 MHz, DMSO-*d*₆): δ = 12.64 (s, 1H), 11.60 (s, 1H), 8.83 (t, *J* = 6.0 Hz, 1H), 7.63 (d, *J* = 8.0 Hz, 1H), 7.44 (d, *J* = 8.2 Hz, 1H), 7.19 (t, *J* = 7.6 Hz, 1H), 7.15 (d, *J* = 2.1 Hz, 1H), 7.04 (t, *J* = 7.5 Hz, 1H), 3.97 (d, *J* = 5.9 Hz, 2H) ppm.

HRMS (EI): m/z calcd. for $\text{C}_{11}\text{H}_8\text{N}_2\text{O}_2$ [M+H], 200.0580; found, 200.0580.

*2-Acetyl-2,3-dihydropyrazino[1,2-*a*]indole-1,4-dione (39)*

2,3-Dihydropyrazino[1,2-*a*]indole-1,4-dione (**45**) (2.00 g, 9.99 mmol, 1.00 equiv.) was dissolved in acetic anhydride (229 g, 212 mL, 2.24 mol, 224 equiv.) and stirred under reflux at 140 °C for 22 hours. The solvent was removed under reduced pressure and the product was washed with diethyl ether and filtered off to yield 2.30 g (9.50 mmol, 95%) of 2-acetyl-2,3-dihydropyrazino[1,2-*a*]indole-1,4-dione (**39**) as a beige solid.

^1H NMR (400 MHz, DMSO- d_6): $\delta = 8.35$ (d, $J = 8.3$ Hz, 1H), 7.87 (dt, $J = 7.9, 1.0$ Hz, 1H), 7.70 (s, 1H), 7.60 (ddd, $J = 8.4, 7.2, 1.3$ Hz, 1H), 7.46 (td, $J = 7.6, 7.2, 1.1$ Hz, 1H), 4.69 (s, 3H), 2.58 (s, 3H) ppm.

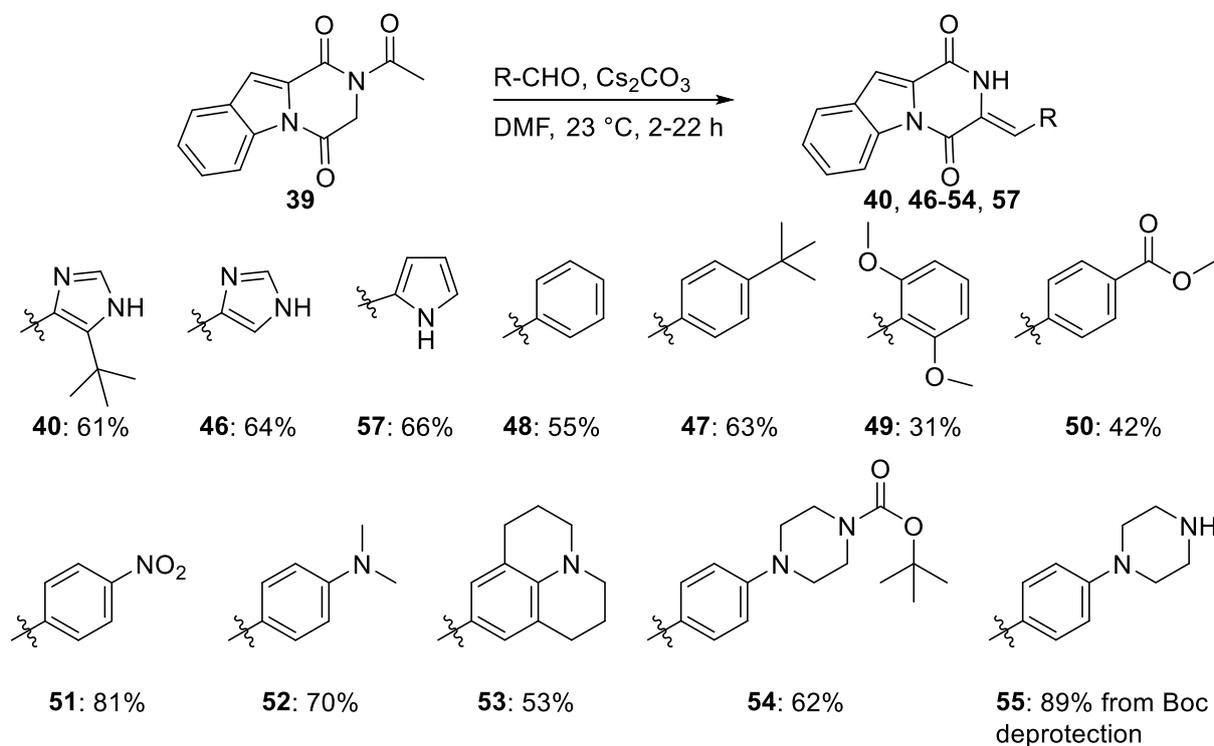

^{13}C NMR (101 MHz, DMSO- d_6): $\delta = 171.7, 162.1, 156.9, 134.2, 129.2, 128.7, 128.4, 125.2, 123.1, 115.7, 115.6, 48.9, 27.2$ ppm.

IR (ATR): $\nu = 1720$ (vs), 1696 (vs), 1679 (vs), 1606 (w), 1557 (s), 1436 (s), 1404 (vs), 1370 (s), 1360 (vs), 1336 (vs), 1266 (vs), 1234 (s), 1210 (vs), 1160 (s), 1139 (s), 1115 (m), 1099 (s), 1069 (m), 1044 (m), 1010 (m), 979 (m), 967 (s), 948 (m), 878 (m), 853 (s), 839 (m), 800 (w), 755 (vs), 739 (vs), 694 (m), 670 (m), 642 (w), 618 (m), 602 (m), 585 (m), 575 (m), 550 (m), 537 (s), 499 (w), 484 (w), 448 (w), 432 (s), 407 (w), 388 (w), 375 (m) cm^{-1} .

HRMS (EI): m/z calcd. for $\text{C}_{13}\text{H}_{10}\text{N}_2\text{O}_3$ [M+H], 242.0686; found, 242.0687.

UV/Vis (MeCN): $\lambda_{\text{max}} = 211, 235, 299$ nm.

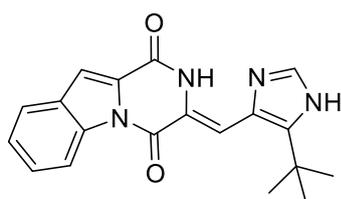

5.6.2 Synthesis of 'Locked' Derivatives

The respective aldehydes (1.00 equiv.) were dissolved in dry DMF (2.0 mL/1 mmol aldehyde) under argon atmosphere. Diketopiperazine **39** (1.00 equiv.) and Cs_2CO_3 (2.00 equiv.) were added and the mixture was stirred for 2–22 hours under argon atmosphere at room temperature. The reaction mixture was poured on an ice water/brine mix (30 mL) and the precipitate was filtered off and dried. Usually, 200 – 250 mg of the starting material diketopiperazine **39** were applied.

Compounds **48**, **50–52** were synthesized under my supervision by Rabia Elbuga-Ilica during an internship and compound **53** was synthesized by my colleague Peter Gödtel, who provided me with the corresponding NMR, IR and mass spectra.

(Z)-3-((5-(*tert*-Butyl)-1*H*-imidazol-4-yl)methylene)-2,3-dihydropyrazino[1,2-*a*]indole-1,4-dione (**40**)

The crude product was purified *via* HPLC (gradient of 40–80% MeCN in H_2O within 40 min, 0.1% TFA (v/v) in the solvents) and washed with sat. aq. solution of NaHCO_3 . *(Z)*-3-((5-(*tert*-Butyl)-

(1*H*-imidazol-4-yl)methylene)-2,3-dihydropyrazino[1,2-*a*]indole-1,4-dione (**40**) (210 mg, 628 μ mol, 61% yield) was obtained as a yellow solid.

¹H NMR (400 MHz, DMSO-*d*₆): δ = 12.49 (s, 1H), 12.40 (s, 1H), 8.51 (dd, J = 8.3, 0.9 Hz, 1H), 7.94 (d, J = 0.8 Hz, 1H), 7.85 (dt, J = 7.9, 1.1 Hz, 1H), 7.56 (ddd, J = 8.4, 7.3, 1.3 Hz, 1H), 7.51 (d, J = 0.9 Hz, 1H), 7.43 (ddd, J = 8.1, 7.1, 1.1 Hz, 1H), 7.27 (d, J = 0.8 Hz, 1H), 1.44 (s, 9H) ppm.

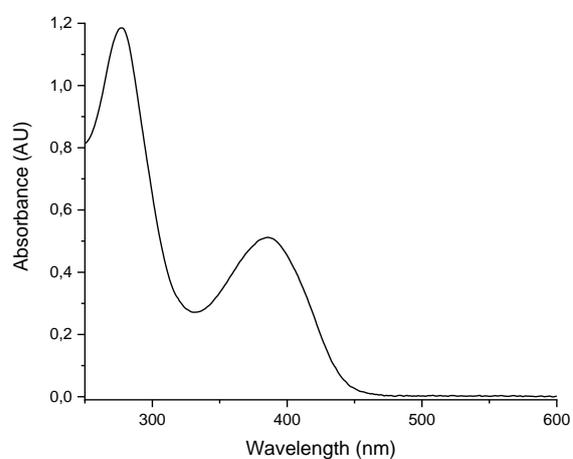

Figure 308: Absorption spectrum of compound Z-51 (160 μ M) in DMSO (d = 2 mm).

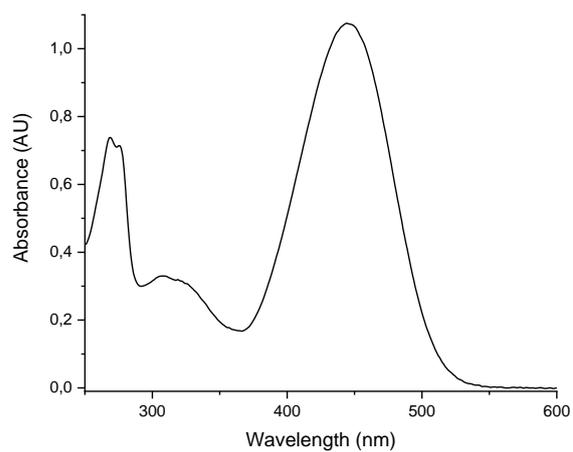

Figure 309: Absorption spectrum of compound Z-52 (160 μ M) in DMSO (d = 2 mm).

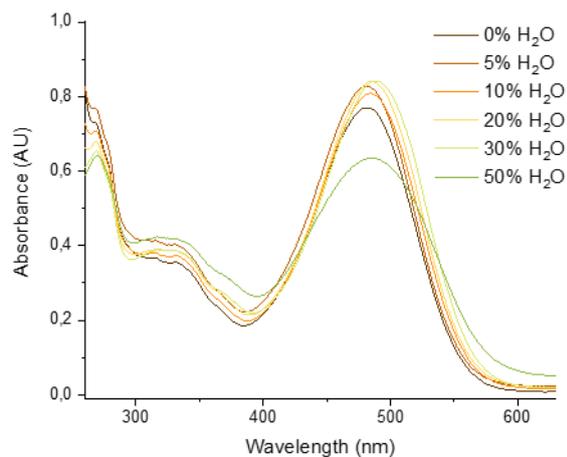

Figure 310: Absorption spectrum of compound Z-53 (160 μM) in DMSO and different mixtures of water and DMSO (d = 2 mm).

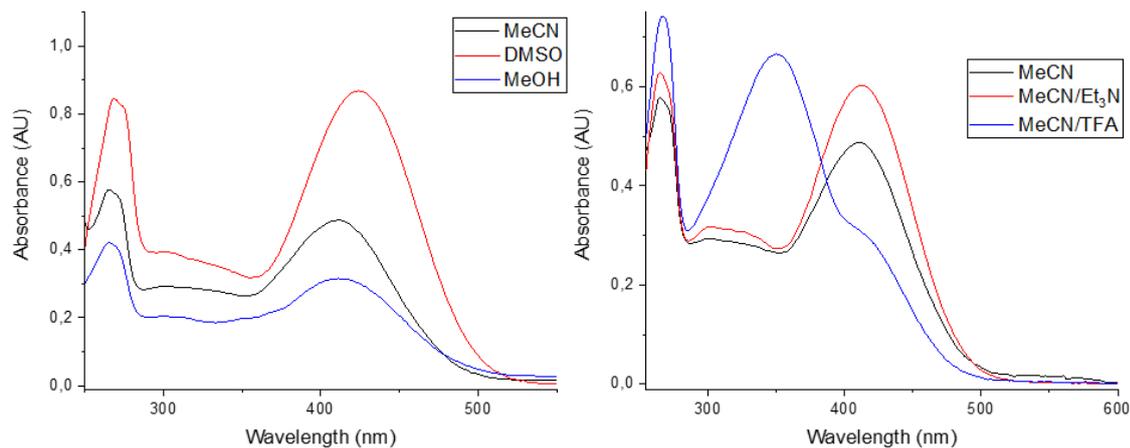

Figure 311: Compound Z-54 was dissolved in different solvents (160 μM) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark (d = 2 mm). The spectra are assigned to the respective solvents *via* color code.

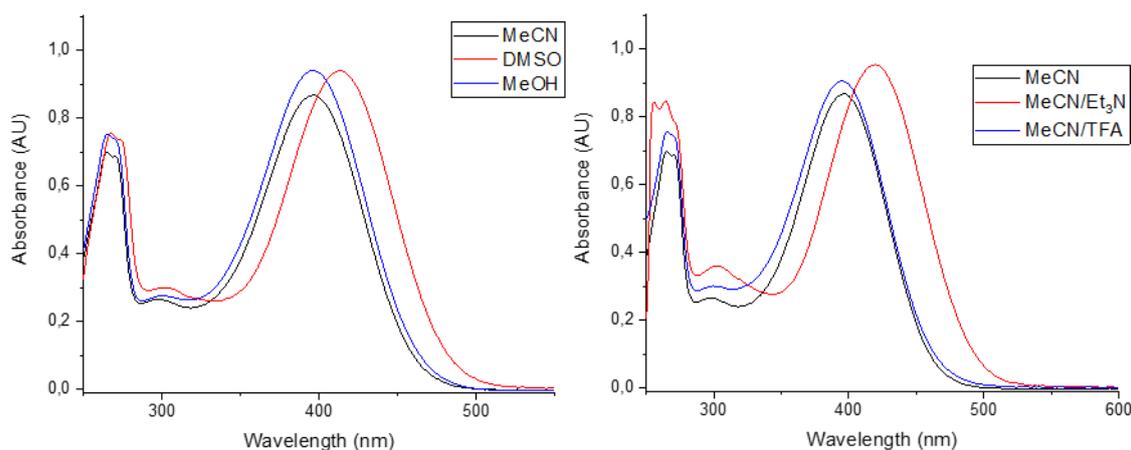

Figure 312: The TFA salt of compound **Z-55** was dissolved in different solvents (160 μ M) and in mixtures of 1% (v/v) TFA in MeCN and 1% (v/v) Et₃N in MeCN, respectively. Absorption spectra were measured in the dark ($d = 2$ mm). The spectra are assigned to the respective solvents *via* color code.

5.6.5 Absorption Spectra of Irradiated Samples

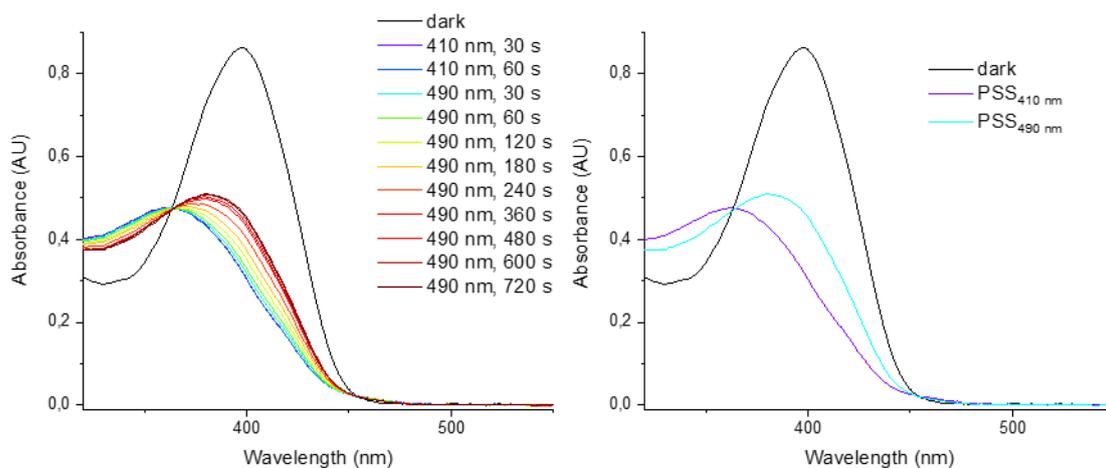

Figure 313: Compound **40** in saturated solution of ascorbic acid in DMSO (200 μ M) was irradiated and an absorption spectrum ($d = 2$ mm) was measured after each irradiation step until the PSS was reached, respectively.

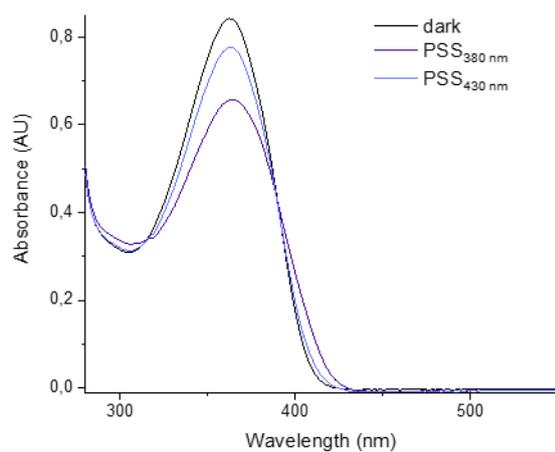

Figure 314: Compound **48** was dissolved in DMSO (160 μM) and an absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then irradiated and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

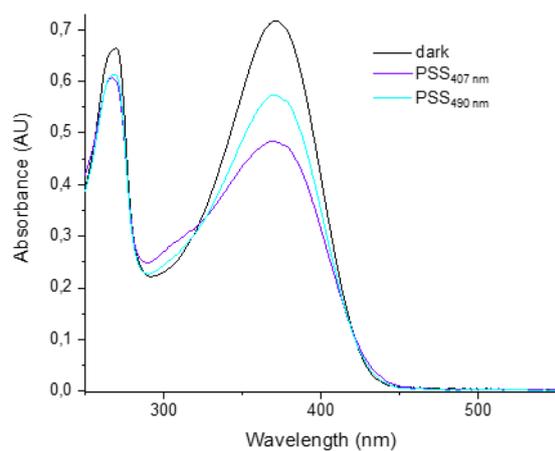

Figure 315: Compound **49** was dissolved in DMSO (160 μM) and an absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then irradiated and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

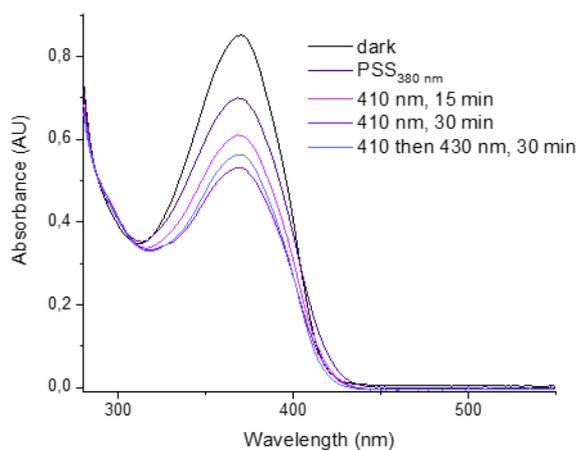

Figure 316: Compound **50** was dissolved in DMSO (160 μM) and an absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then irradiated and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively. Upon irradiation with 410 nm no PSS was reached.

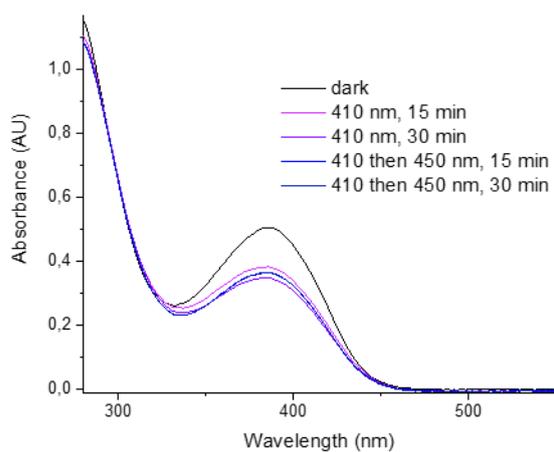

Figure 317: Compound **51** was dissolved in DMSO (160 μM) and an absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then irradiated and an absorption spectrum was measured after each irradiation step. No PSS was reached.

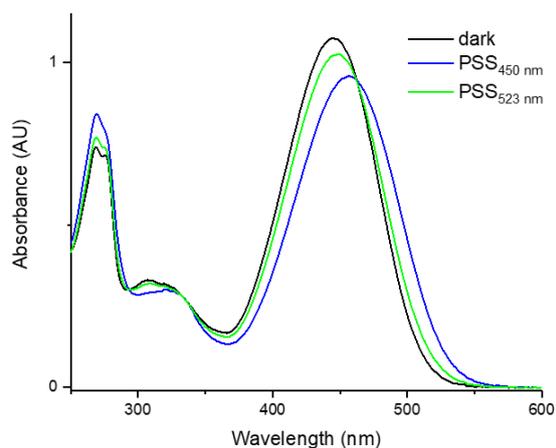

Figure 318: Compound **52** was dissolved in DMSO (160 μ M) and an absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then irradiated and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

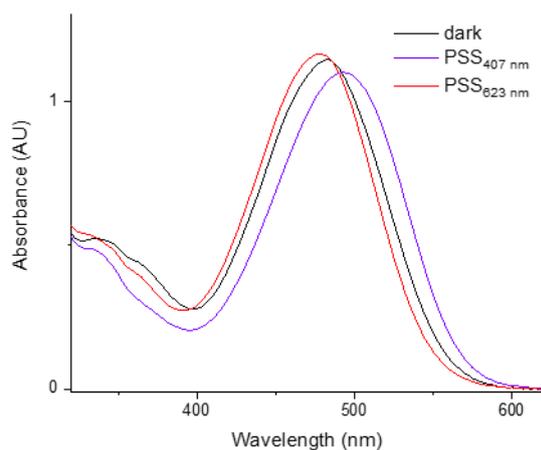

Figure 319: Compound **53** was dissolved in DMSO (80 μ M) and an absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then irradiated and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

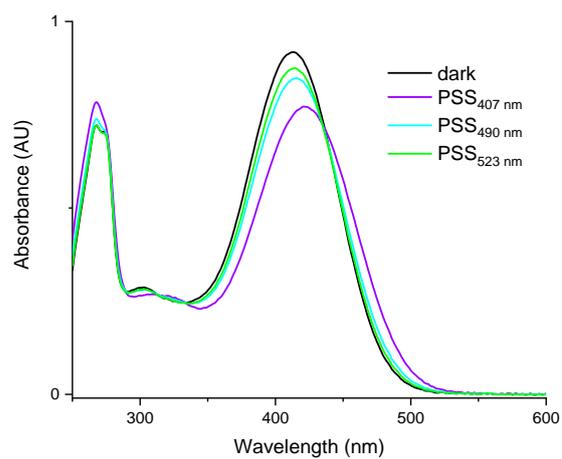

Figure 320: The TFA salt of compound **55** was dissolved in DMSO (160 μ M) and an absorption spectrum ($d = 2$ mm) was first measured in the dark. The sample was then irradiated and an absorption spectrum was measured after each irradiation step until the PSS was reached, respectively.

5.6.6 Emission Spectra

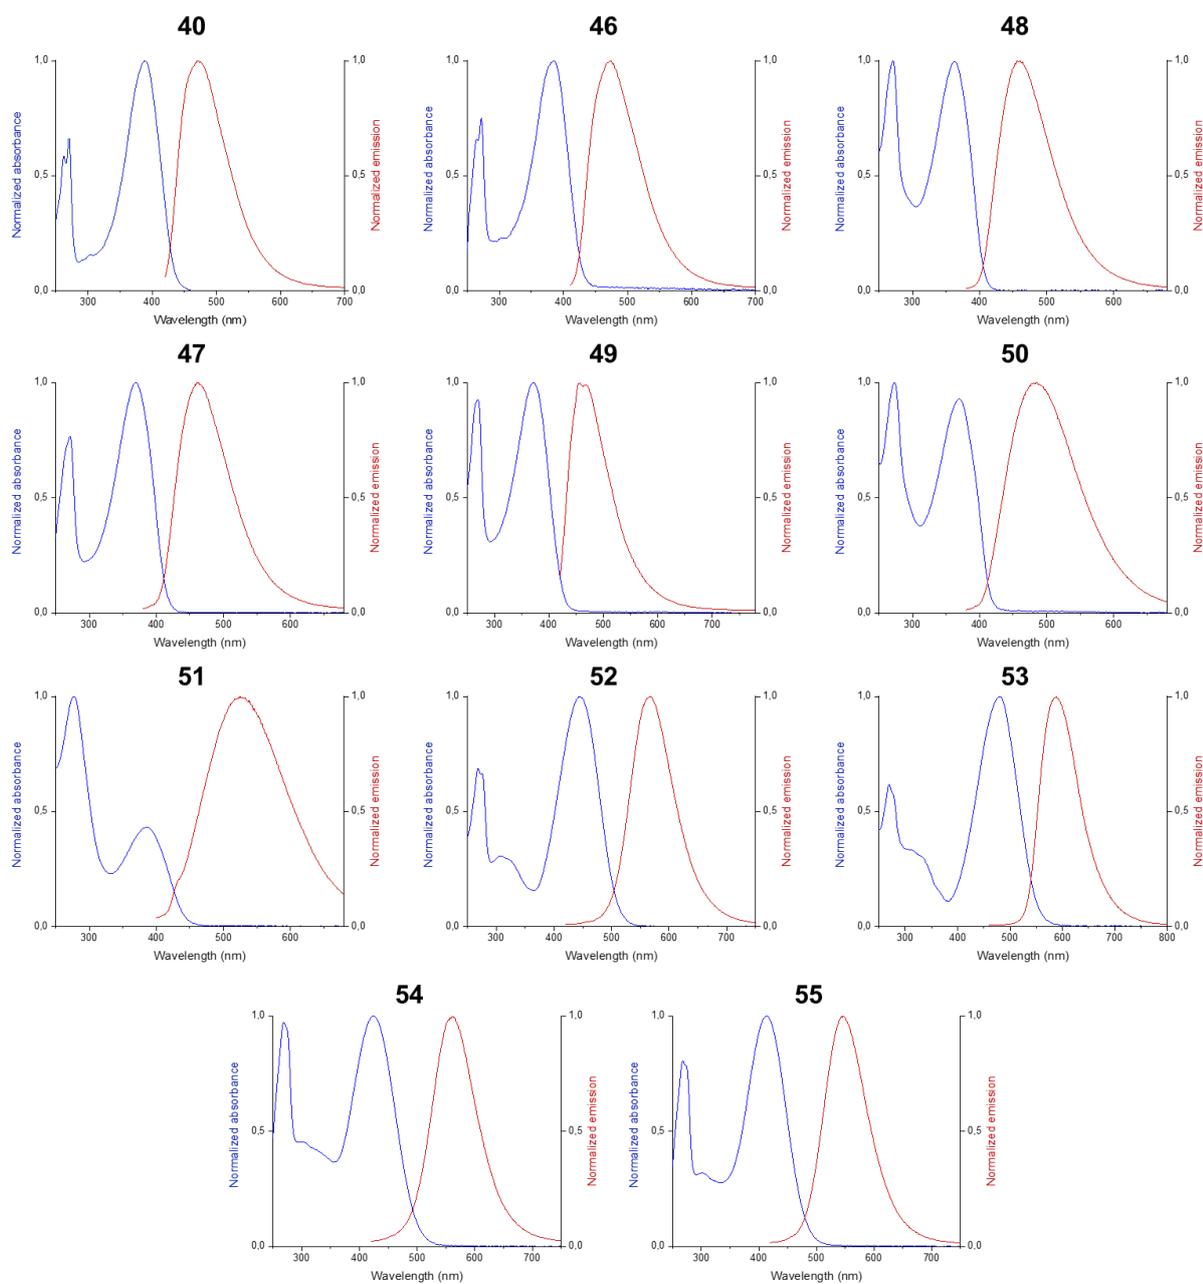

Figure 321: Normalized absorption (blue) and emission (red) spectra of solutions of the respective Z-isomers of **40** in MeCN and **46-55** in DMSO.

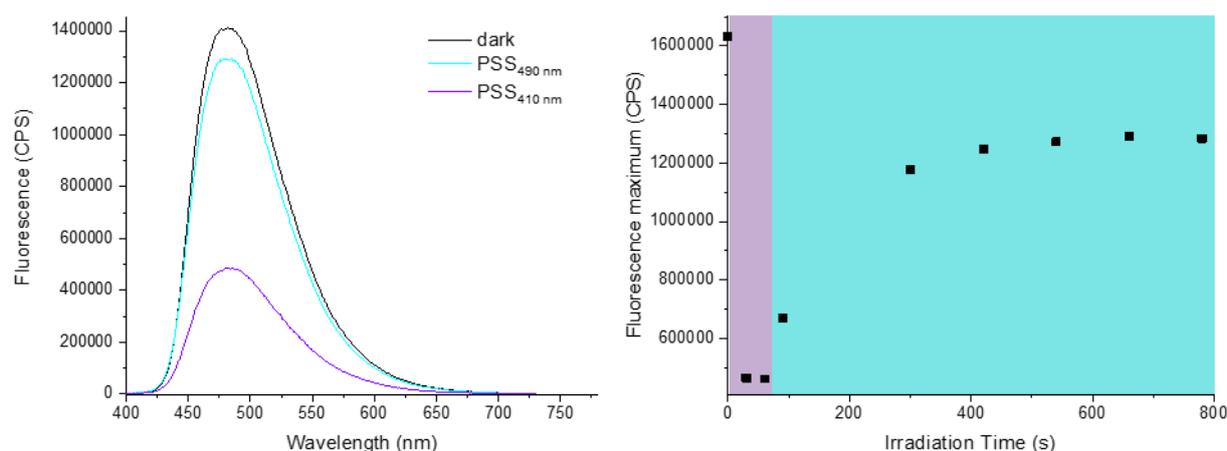

Figure 322: Left: Fluorescence spectra of compound **40** (200 μM) in saturated solution of ascorbic acid in DMSO before and after irradiation (excitation at 380 nm). The spectra are assigned to the respective mixture *via* color code. Right: Compound **40** (200 μM) in saturated solution of ascorbic acid was analyzed *via* fluorescence spectroscopy before and after irradiation with first 410 nm and subsequently 490 nm (indicated by the color of the background). The maximal fluorescence was plotted against the irradiation time.

5.6.7 Composition of the Photostationary States (PSSs)

Compound 40: Via analytical HPLC

The PSS composition was determined by analyzing 1 mM solutions of compound **40** in DMSO after irradiation *via* analytical HPLC. The PSS values have been achieved within 10 min (365, 410, 450 nm) or 20 min (490 nm). Triplicates were obtained by including two samples that were irradiated further after the PSS was reached. The signals assigned to the Z-isomer were integrated and divided by the signal area determined before irradiation:

$$\% \text{ Z-isomer} = I_{\text{after irradiation}} / I_{\text{dark}} * 100\% \quad (\% \text{ E-isomer} = 100\% - \% \text{ of Z-isomer}).$$

Table 15: PSS composition in DMSO determined by analytical HPLC measurements performed with samples of **40** before and after irradiation.

365 nm (% of E-isomer)	410 nm (% of E-isomer)	450 nm (% of E-isomer)	470 nm (% of E-isomer)	490 nm (% of E-isomer)
75	93	85	70	67

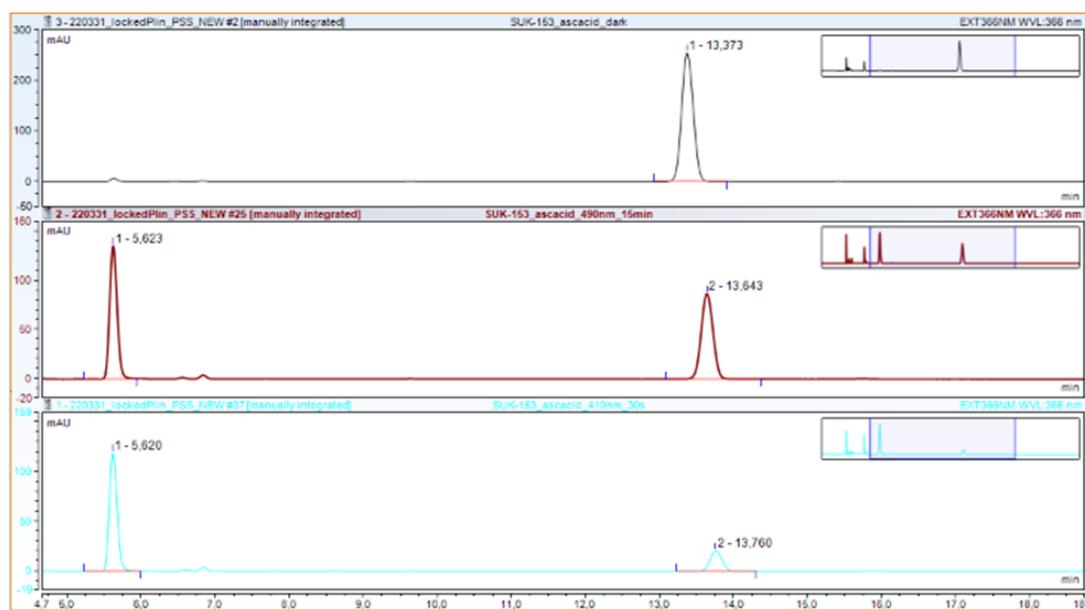

Figure 323: HPLC trace of 1 mM solutions of **40** in DMSO before irradiation (top) and after reaching the PSS upon irradiation with 490 nm (middle) and 410 nm (bottom).

Compound 52: Via NMR spectroscopy

The PSS composition was determined by measuring ^1H NMR spectra of **52** before and after irradiation. The PSS values in the NMR tube (0.5 mL of the 30-60 mM solution in $\text{DMSO-}d_6$) have been achieved within 1 h (523 nm) or 2 h (430, 470 nm). Signal pairs were determined for each compound: two signals assigned to the same proton for the respective photoisomers were integrated and the % of *E*-isomer = $I_E/(I_E+I_Z)*100\%$ was determined. The final *E/Z* ratios result from the average value determined from three signal pairs.

Table 16: PSS composition in $\text{DMSO-}d_6$ determined by measuring ^1H NMR spectra of the respective compounds after irradiation.

Compound	430 nm (% of <i>E</i> -isomer)	470 nm (% of <i>E</i> -isomer)	523 nm (% of <i>E</i> -isomer)
52	64	51	17

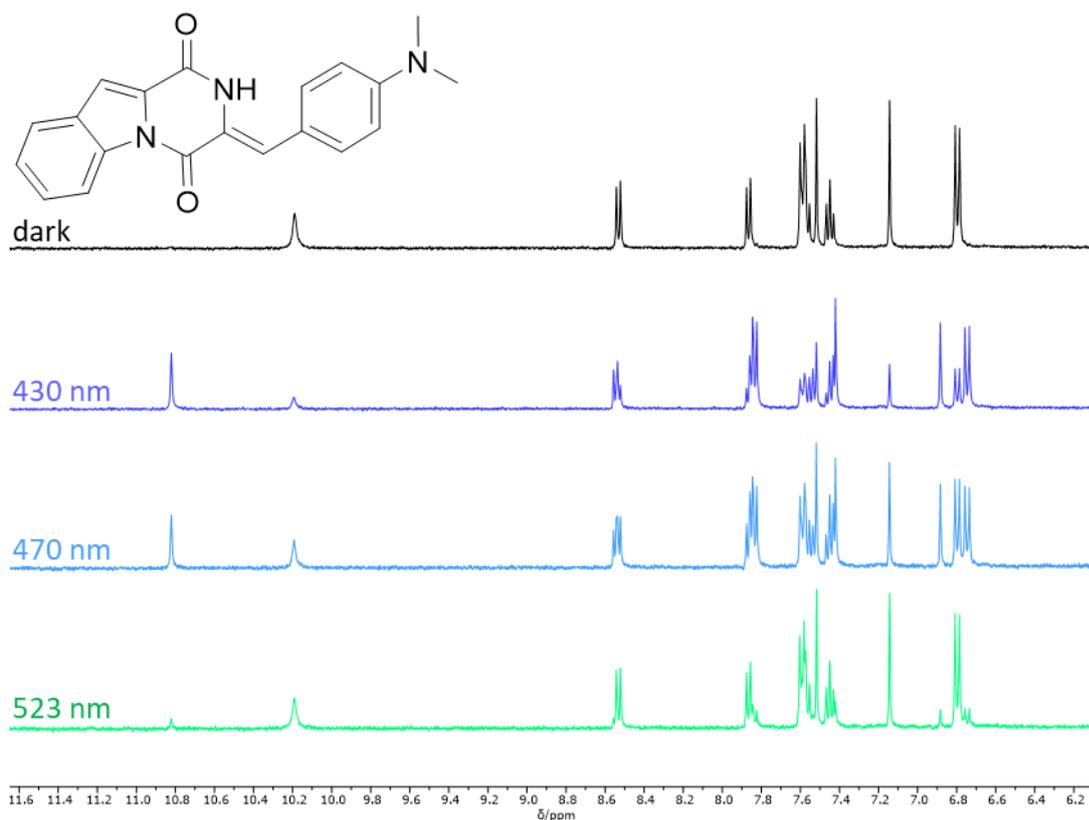

Figure 324: Sections of ^1H NMR spectra (400 MHz, $\text{DMSO}-d_6$) of compound **52** in the dark (top) and after reaching the PSS upon irradiation with 430 nm, 470 nm and 523 nm.

5.6.8 Thermal Relaxation of *E*-Isomers

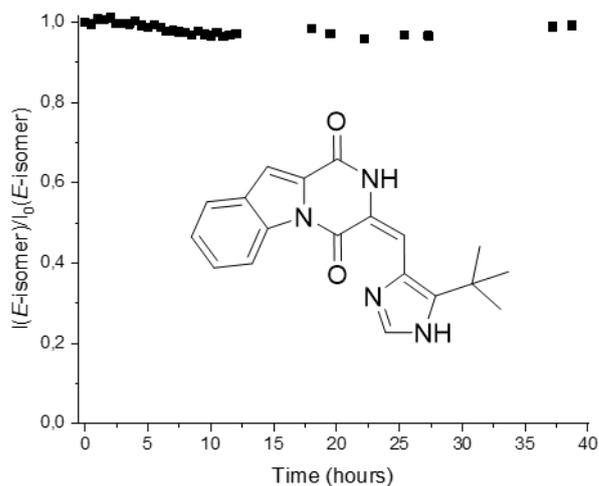

Figure 325: The thermal relaxation of *E*-40 in DMSO (1:1) at 25°C was monitored *via* analytical HPLC. The integrals of the signals assigned to the respective *E*-isomer were determined at 330 nm: I_0 = initial integral, I = integral at given time point.

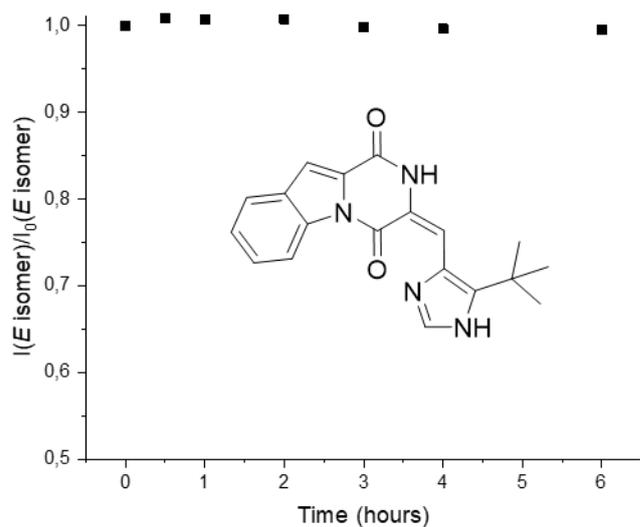

Figure 326: The thermal relaxation of *E*-40 in H₂O/DMSO (1:1) at 37 °C was monitored *via* analytical HPLC. The integrals of the signals assigned to the respective *E*-isomer were determined at 330 nm: I_0 = initial integral, I = integral at given time point.

5.6.9 Switching Stability

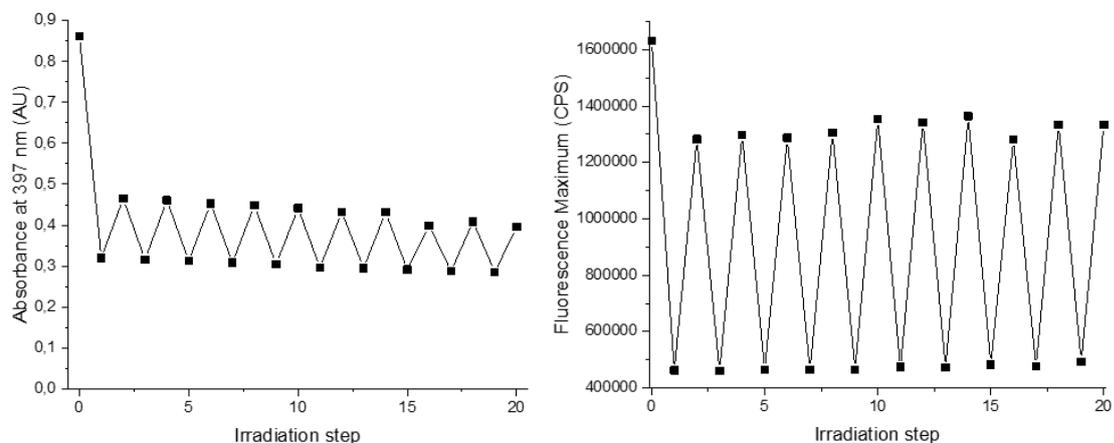

Figure 327: A solution of pure *Z*-40 in a saturated solution of ascorbic acid in DMSO (200 μ M) was irradiated with 410 nm for 30 s and with 490 nm for 12 min, respectively. The irradiation cycle was repeated ten times and after every irradiation step the solution was analyzed *via* absorbance (left) and fluorescence (right) spectroscopy.

5.6.10 Cell Penetration Assays

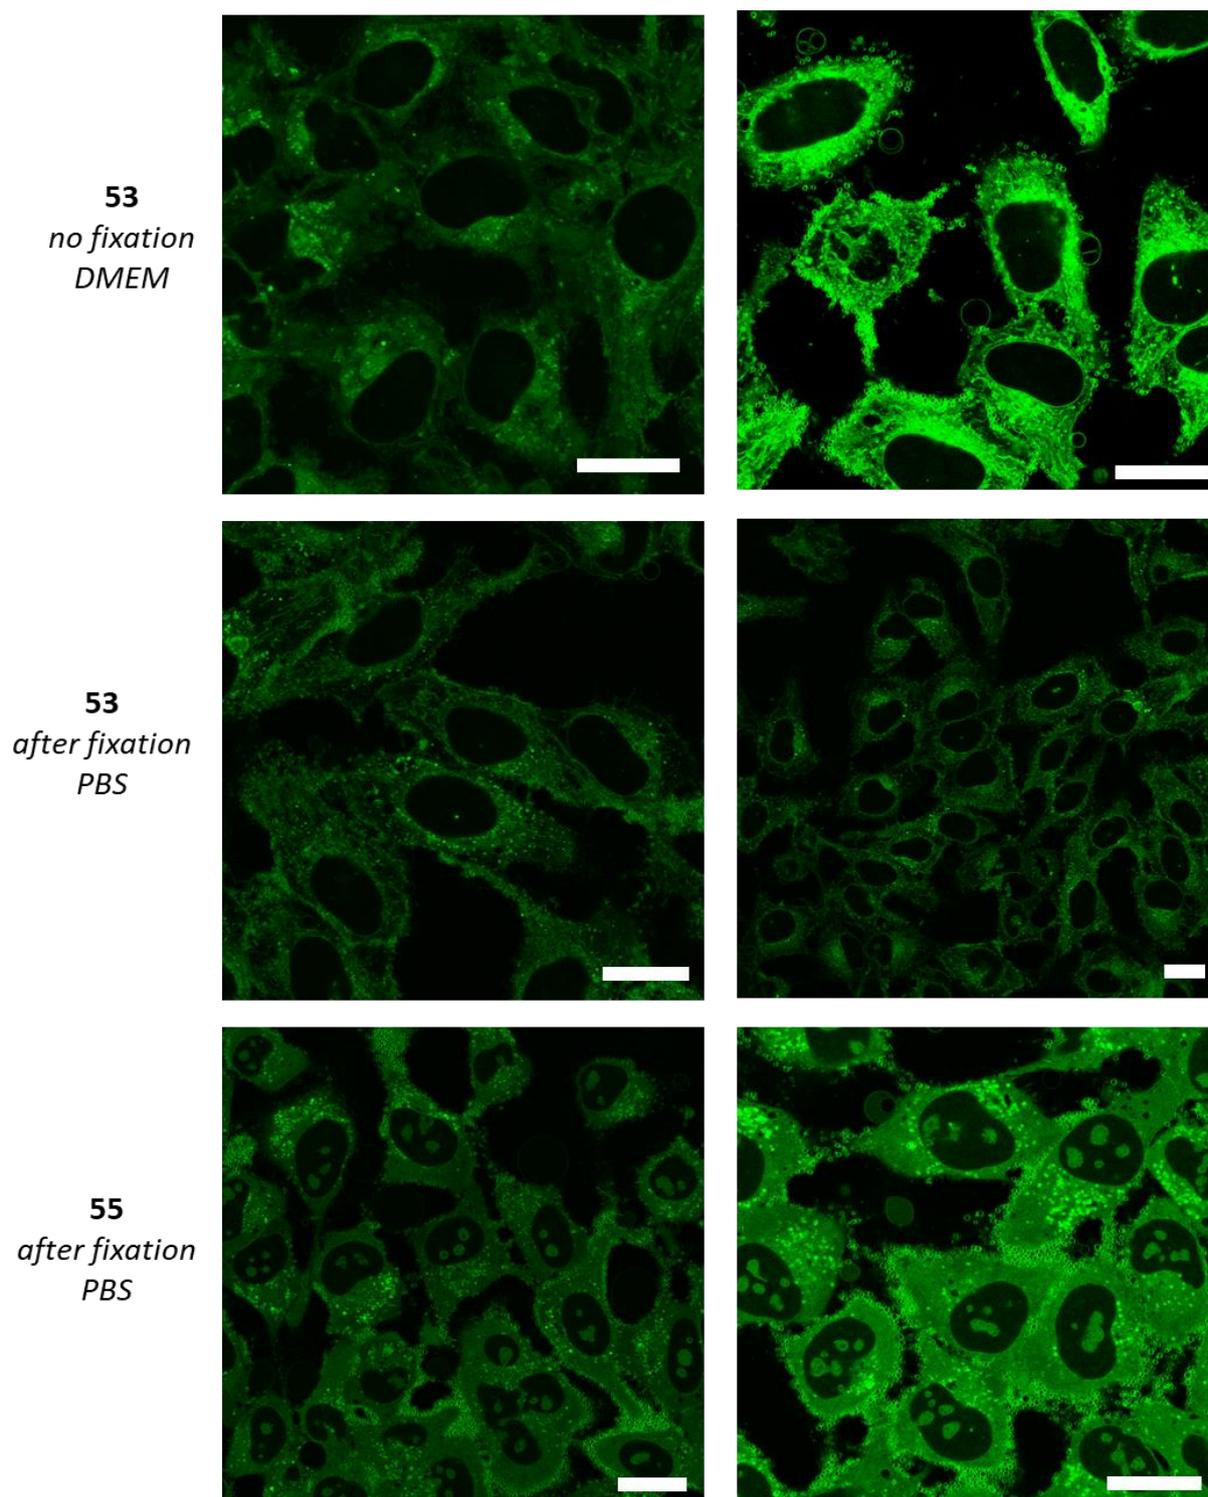

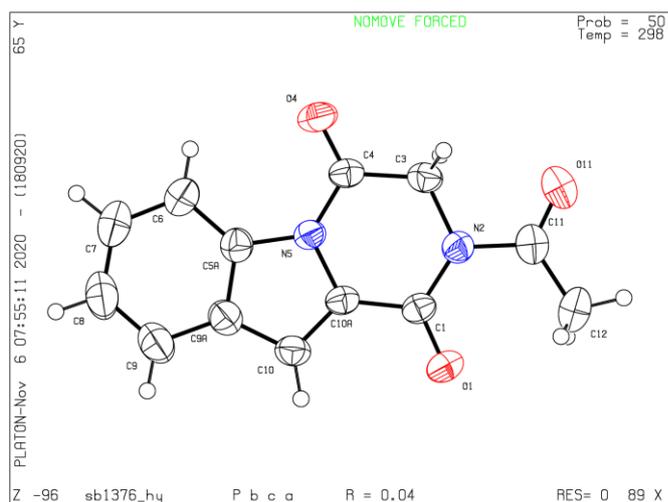

Figure 328: Imaging of compounds **53** and **55** in HeLa cells *via* confocal microscopy after 15 h treatment with the respective compounds (8.0 μ M) (scale bars 20 μ m). The results were processed and visualized with LEICA Application Suite X 3.7.4.23463 from LEICA Microsystems CMS GmbH.

5.6.11 Crystal Structure Determinations

Crystal structures in this section were measured and solved by Dr. Martin Nieger at the University of Helsinki (Finland).

Table 17: Overview of the numbering and sample code of crystal structures solved by Dr. Martin Nieger.

SB1376_HY

SUK-152

2-Acetyl-2,3-dihydropyrazino[1,2-a]indole-1,4-dione – SB1376_HY

Crystal data

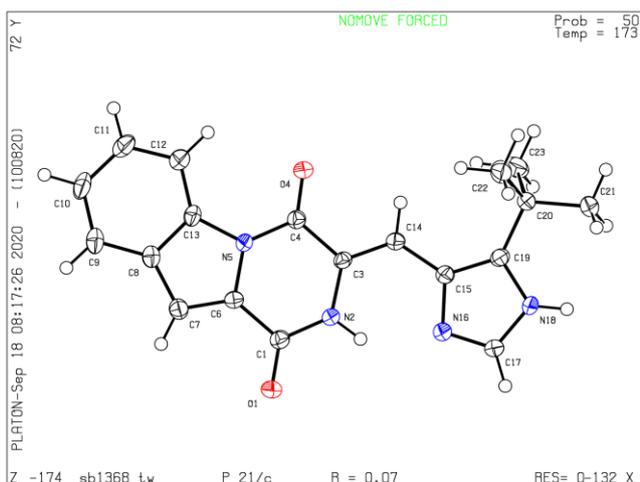

$C_{13}H_{10}N_2O_3$	$D_x = 1.423 \text{ Mg m}^{-3}$
$M_r = 242.23$	Cu $K\alpha$ radiation, $\lambda = 1.54178 \text{ \AA}$
Orthorhombic, <i>Pbca</i> (no.61)	Cell parameters from 9904 reflections
$a = 15.4147 (2) \text{ \AA}$	$\theta = 3.7\text{--}72.1^\circ$
$b = 6.1889 (1) \text{ \AA}$	$\mu = 0.86 \text{ mm}^{-1}$
$c = 23.7010 (3) \text{ \AA}$	$T = 298 \text{ K}$
$V = 2261.08 (5) \text{ \AA}^3$	Plates, colourless
$Z = 8$	$0.18 \times 0.12 \times 0.02 \text{ mm}$
$F(000) = 1008$	

Data collection

Bruker D8 VENTURE diffractometer with PhotonII CPAD detector	1986 reflections with $I > 2\sigma(I)$
Radiation source: INCOATEC microfocuss sealed tube	$R_{\text{int}} = 0.039$
rotation in ϕ and ω , 1° , shutterless scans	$\theta_{\text{max}} = 72.1^\circ$, $\theta_{\text{min}} = 4.7^\circ$
Absorption correction: multi-scan SADABS (Sheldrick, 2014)	$h = -19 \rightarrow 19$
$T_{\text{min}} = 0.849$, $T_{\text{max}} = 0.971$	$k = -7 \rightarrow 7$
36062 measured reflections	$l = -29 \rightarrow 29$
2223 independent reflections	

Refinement

Refinement on F^2	Primary atom site location: dual
Least-squares matrix: full	Secondary atom site location: difference Fourier map
$R[F^2 > 2\sigma(F^2)] = 0.038$	Hydrogen site location: inferred from neighbouring sites
$wR(F^2) = 0.103$	H-atom parameters constrained
$S = 1.05$	$w = 1/[\sigma^2(F_o^2) + (0.0459P)^2 + 0.6582P]$ where $P = (F_o^2 + 2F_c^2)/3$
2223 reflections	$(\Delta/\sigma)_{\text{max}} < 0.001$
164 parameters	$\Delta_{\text{max}} = 0.15 \text{ e \AA}^{-3}$
0 restraints	$\Delta_{\text{min}} = -0.17 \text{ e \AA}^{-3}$

SB1368_HY

SUK-153

non-merohedral twin

(Z)-3-((5-(*tert*-Butyl)-1*H*-imidazol-4-yl)methylene)-2,3-dihydropyrazino[1,2-*a*]indole-1,4-dione – SB1368_HY

Crystal data

$C_{19}H_{18}N_4O_2$	$F(000) = 704$
$M_r = 334.37$	$D_x = 1.392 \text{ Mg m}^{-3}$
Monoclinic, $P2_1/c$ (<i>no.14</i>)	Cu $K\alpha$ radiation, $\lambda = 1.54178 \text{ \AA}$
$a = 7.1588$ (3) \AA	Cell parameters from 7631 reflections
$b = 15.0290$ (6) \AA	$\theta = 4.1\text{--}72.3^\circ$
$c = 14.9109$ (6) \AA	$\mu = 0.76 \text{ mm}^{-1}$
$\beta = 95.951$ (2) $^\circ$	$T = 173 \text{ K}$
$V = 1595.61$ (11) \AA^3	Plates, yellow
$Z = 4$	$0.18 \times 0.04 \times 0.02 \text{ mm}$

Data collection

Bruker D8 VENTURE diffractometer with PhotonII CPAD detector	3119 independent reflections
Radiation source: INCOATEC microfocus sealed tube	2743 reflections with $I > 2\sigma(I)$
rotation in ϕ and ω , 1° , shutterless scans	$\theta_{\max} = 72.3^\circ$, $\theta_{\min} = 4.2^\circ$
Absorption correction: multi-scan <i>SADABS</i> (Sheldrick, 2014)	$h = -8 \rightarrow 8$
$T_{\min} = 0.784$, $T_{\max} = 0.971$	$k = -18 \rightarrow 18$
3119 measured reflections	$l = -2 \rightarrow 18$

Refinement

Refinement on F^2	Primary atom site location: dual
Least-squares matrix: full	Secondary atom site location: difference Fourier map
$R[F^2 > 2\sigma(F^2)] = 0.068$	Hydrogen site location: difference Fourier map
$wR(F^2) = 0.163$	H atoms treated by a mixture of independent and constrained refinement
$S = 1.18$	$w = \frac{1}{[\sigma^2(F_o^2) + (0.015P)^2 + 3.480P]}$ where $P = (F_o^2 + 2F_c^2)/3$
3119 reflections	$(\Delta/\sigma)_{\max} < 0.001$
233 parameters	$\Delta_{\max} = 0.28 \text{ e \AA}^{-3}$
2 restraints	$\Delta_{\min} = -0.35 \text{ e \AA}^{-3}$

6 Abbreviation Index

%	percent
°	degree (unit of angle measurement)
Å	Angström (10^{-10} m)
Ac	acetyl
ATR	attenuated total reflection (IR)
°	degree (unit of angle measurement)
Boc	<i>tert</i> -Butyloxycarbonyl
°C	degree Celsius (unit of temperature)
CA4	combretastatin A-4
cm	centimeter
conc.	concentrated
δ	chemical shift (in ppm)
d	doublet (NMR)
DCM	dichloromethane
dd	doublet of doublets (NMR)
ddd	doublet of doublets of doublets (NMR)
DFT	density functional theory
DMF	<i>N,N</i> -dimethylformamide
DMSO	dimethylsulfoxid
DMSO- <i>d</i> ₆	deuterated dimethylsulfoxide
E	energy
EA	elemental analysis
EDC	1-ethyl-3-(3-dimethylaminopropyl)carbodiimide
EI	electron ionization
ESI	electrospray ionization
<i>et al.</i>	<i>et alia</i>
eV	electronvolt
FAB	fast atom bombardment
g	grams
GDP	guanosine diphosphate
GTP	guanosine triphosphate
h	hours
HITub	hemithioindigo-based indanone-like tubulin inhibitors
HOMO	highest occupied molecular orbital
HOTub	hemithioindigo-colchicinoid tubulin binders
HPI	hemipiperazine
HPLC	high pressure liquid chromatography
HRMS	high resolution mass spectrometry (NMR)
Hz	Hertz
I	integral
IR	infrared
<i>J</i>	coupling constant (NMR)

K	kelvin
KHYS	Karlsruhe House of Young Scientists
KIT	Karlsruhe Institute of Technology
L	liter
λ	wavelength
LED	light-emitting diode
LUMO	lowest unoccupied molecular orbital
M	Molar concentration
m	mass, multiplett (NMR), medium (IR)
MAP	microtubule-associated proteins
max.	maximal
MDA	microtubule destabilizing agent
Me	methyl
MeCN	acetonitrile
mg	milligram
MHz	megahertz
μm	mikrometer
μM	micromolar concentration
μs	microsecond
min	minutes
mL	millilitre
mm	millimetre
mM	millimolar concentration
mmol	millimole
MS	mass spectrometry
MSA	microtubule stabilizing agent
m/z	mass to charge ratio
<i>n</i> BuLi	<i>n</i> -butyllithium
nm	nanometer
NMR	nuclear magnetic resonance
NOESY	nuclear overhauser effect spectroscopy
OD	Optical Density
Ph	phenyl
PHT	pyrrole hemithioindigo
PHTub	PHT-based photopharmaceuticals
ppm	parts per million, 10^{-6}
PSS	photostationary state
PST	photostatin
quant.	quantitative
R	not defined substituents
R_f	retention factor
ROS	reactive oxygen species
s	singlet (NMR), strong (IR), seconds
SBT	styrylbenzothiazole
SBTax	SBT-taxane

SBTub	SBT-based tubulin inhibitors
ST	styrylthiazole
STEpo	epothilone-based microtubule stabilisers
T	temperature
t	triplet (NMR)
<i>t</i> Bu	<i>tert</i> -butyl
td	triplet of doublets (NMR)
TD-DFT	time-dependent density functional theory
TFA	trifluoroacetic acid
THF	tetrahydrofuran
TIPS	triisopropylsilyl
TLC	thin-layer chromatography
Tol	toluene
UV	ultraviolet
ν	wavenumber [cm^{-1}]
V	volt
vis	visible
vs	very strong (IR)
vs.	versus
vw	very weak (IR)
W	watt
w	weak (IR)

8 Appendix

8.1 Curriculum Vitae

Susanne Kirchner

22.06.1991, Tübingen, Germany

+4917661307610, kirchnersusanne@web.de

Education

- 10/2018 – 07/2022 **Doctoral work**, Karlsruhe Institute of Technology (KIT), Karlsruhe
Institute of Organic Chemistry, Priv.-Doz. Dr. Zbigniew Pianowski
*„Hemipiperazines - Novel Photochromic Cyclic Dipeptides for Bioactivity
Photomodulation“*
- 09/2014 – 08/2018 **M.Sc. – Chemistry** (Ø 1.3), Heidelberg University, Heidelberg
Master Thesis, Karlsruhe Institute of Technology, Karlsruhe.
*„Photochromic 2,5-Diketopiperazines and Peptides for Photomodulation
of Biological Systems with Visible Light“*
- 09/2011 – 08/2014 **B.Sc. – Chemistry** (Ø 2.3), Heidelberg University, Heidelberg
Bachelor Thesis, Biochemistry Center Heidelberg (BZH), Heidelberg.
„Lipidanalytik Sphingosin-1-Phosphat-Lyase defizienter Zellen“
- 09/2001 – 06/2010 **General higher education entrance qualification** (Ø 1.6),
Carlo-Schmid-Gymnasium, Tübingen
Specialized courses: Chemistry & Social studies

Further experience & qualifications

- 11/2019 – 07/2022 **Qualification program**, Research Training Group GRK 2039
- 10/2019 – 11/2021 **Board member**, Faculty of Chemistry and Biosciences, KIT, Karlsruhe
- 10/2018 – 07/2022 **Supervision & teaching** at KIT,
Bachelor & Master students, interns, seminars & practical courses

8.2 Publications

8.3 Conference Contributions

- S. Kirchner, J. Karcher. Z. L. Pianowski, *Chemical Biology*, EMBL Heidelberg, Germany, 29th August – 01st September **2018**. *Novel halogenated azobenzene derivatives for photocontrol of peptide-based systems*. (Poster)
- S. Kirchner, J. Karcher. Z. L. Pianowski, *ESOC*, Vienna, Austria, 14th – 18th July **2019**. *Photochromic Peptides for light-triggered Drug Delivery and beyond*. (Poster)
- S. Kirchner, J. Karcher. Z. L. Pianowski, *POPs Satellite Meeting*, Karlsruhe, Germany, 13th September **2019**. *Photochromic Peptides for light-triggered Drug Delivery and beyond*. (Poster)
- S. Kirchner, *I, Scientist*, virtual conference, 16th – 19th September **2020**. (Attendance)
- S. Kirchner, A.-L. Leistner, J. Karcher. Z. L. Pianowski, *RICT*, virtual conference, 7th – 9th July **2021**. *Photochromic Peptides for light-triggered Drug Delivery*. (Poster)
- S. Kirchner, J. Karcher. Z. L. Pianowski, *Photopharmacology III*, virtual conference, 29th – 30th November **2021**. *Photochromic Peptides for light-triggered Drug Delivery*. (Poster)

8.4 Additional Contributions & Training

- S. Kirchner, *GRK 2039 Qualification Program*, Karlsruhe, Germany, 4th – 6th February **2020**. *Annual Retreat*. (Presentation & Poster)
- S. Kirchner, *KHYS Further Education Program for Doctoral Researchers*, Karlsruhe, Germany, 11th February **2020**. *Workshop: Good Scientific Practice*. (Attendance)
- S. Kirchner, *Knigge-Reich*, Speyer, Germany, 27th – 28th May **2020**. *Workshop: Business-Knigge-Seminar*. (Attendance)
- S. Kirchner, *GRK 2039 Qualification Program*, Karlsruhe, Germany, 8th October **2020**. *Seminar Day: Zebrafish – from Introduction as a Model System to latest Research Results*. (Attendance)
- S. Kirchner, *GRK 2039 Qualification Program*, Karlsruhe, Germany, 15th February **2021**. *Merck Virtual Site Experience*. (Attendance)
- S. Kirchner, *In-visible Berlin*, virtual workshop, Germany, 07th – 08th April **2021**. *Workshop: Unconscious Bias Training*. (Attendance)
- S. Kirchner, *Sheboss*, virtual workshop, Germany, 11th June **2021**. *Workshop: The Game of Power*. (Attendance)
- S. Kirchner, *GRK 2039 Qualification Program*, Karlsruhe, Germany, 3rd – 5th November **2021**. *Annual Retreat*. (Presentation & Poster)
- S. Kirchner, *KHYS Further Education Program for Doctoral Researchers*, Karlsruhe, Germany, 12th April **2022**. *Ethics in the Lab*. (Attendance)
- S. Kirchner, *GRK 2039 Qualification Program*, Karlsruhe, Germany, 30th May **2022**. *Seminar Day: Time resolved Spectroscopy*. (Attendance)

8.5 Acknowledgements

At this point, I would like to thank from the bottom of my heart everyone who supported me in one way or another during my doctorate and thus contributed to the success of this work.

My special thanks go to my supervisor Priv.-Doz. Dr. Zbigniew Pianowski for the opportunity to do research in his group and for the exciting and challenging PhD topic entrusted to me. Many thanks for the support and continuous mentoring as well as the freedom given to me that allowed me to gain valuable experience.

I am very grateful to Prof. Dr. Hans-Achim Wagenknecht, who agreed to be my coreferent.

Furthermore, I would like to thank Prof. Dr. Hans-Achim Wagenknecht for accepting me in the GRK 2039. The interdisciplinary exchange in the group and the numerous seminars and courses gave me the opportunity to grow professionally as well as personally.

For the financial support of this work I would like to thank the Jürgen Manchot Stiftung.

I want to thank Prof. Dr. Stefan Bräse for the infrastructural support and his constructive criticism and ideas.

A big thank you goes to Dr. Martin Nieger for the crystal structure analyses.

I also want to thank Tobias Kirschbaum for his support in the theoretical calculations and also the support by the state of Baden-Württemberg through bwHPC and the DFG through grant no INST 40/467-1 FUGG (JUSTUS cluster) is acknowledged.

I would like to thank Dr. Norbert Foitzik, Angelika Möhle, Danny Wagner, Lara Hirsch, Andreas Rapp, Pia Lang, Tanja Ohmer-Scherrer, Richard von Budberg, Karolin Kohnle and Despina Savvidou-Kourmpidou for all their efforts.

Thanks to Christiane Lampert, Janine Bolz, and Dr. Christin Bednarek for their always friendly, quick and competent support with organizational questions.

I would like to thank Angelika Seliwjorstow, Thomas Schidelko, Rabia Elbuga-Ilica, Maysun Naamnih, Heike Eckert, Florian Dobreff, Sven Schenk and Jonas Springer for their support in the lab, good ideas and motivation.

I would like to thank the whole AK Bräse team for helpfulness and constructive feedback and above all for an unforgettable time. I want to thank my awesome lab neighbors Dr. Janina Beck and Dr. Alexander Braun for lots of fun and good conversations. I am looking forward to seeing

you again soon on a regular basis. Thank you Dr. Lamiaa Elsayed Abd El-haleem - it was an enrichment to have met you and your family and I miss you. A big thanks goes to Robert(in)a Tabone for all the fun conversations and personal support.

A special thanks goes to the whole working group of Zibilab for making this a unique experience and to for the great teamwork. I thank Dr. Johannes Karcher for welcoming me into his lab and introducing me to the world of photoswitchable diketopiperazines. You allowed me to have a great start at KIT and you still support me today with incredibly helpful tips and knowledge. I want to thank Dr. Tobias Bantle and Anna-Lena Leistner for the help and for being great people. Particular thanks goes to the lab 403 for being the best lab mates one could imagine: Peter Gödtel, Angelika Seliwjorstow and Valentin Schäfer. The mutual support - professional and also personal - creates an ideal environment to master even the biggest challenges and even have a good time in the process.

Peter Gödtel, Angelika Seliwjorstow, Anna-Lena Leistner and Valentin Schäfer I thank for the thorough correction of this work. Thank you for helping me to make my thesis better even in such a limited time.

Thank you also to my dear friends Amani, Johanna and Pia, who have accompanied my life for so many years now and who have experienced and supported all the ups and downs. Thank you for your loyal friendship, and always seeing the best in me.

From the bottom of my heart, I thank my parents for their faith in me, the everlasting support and giving me the possibility to do what I want to do. Thank you for your confidence, an always open ear and unconditional trust in me.

A very special thanks goes to Jochen for everything: for his endless support and unlimited patience, for always being able to make me smile and his unconditional love. Thank you for listening, talking and making every day a little bit brighter.
