

# Cool-down studies of the low-frequency interferometer in the Einstein Telescope

L. Busch and S. Grohmann

## Helium-fed suspension tube: CFD model geometry

## System parameters and boundary conditions

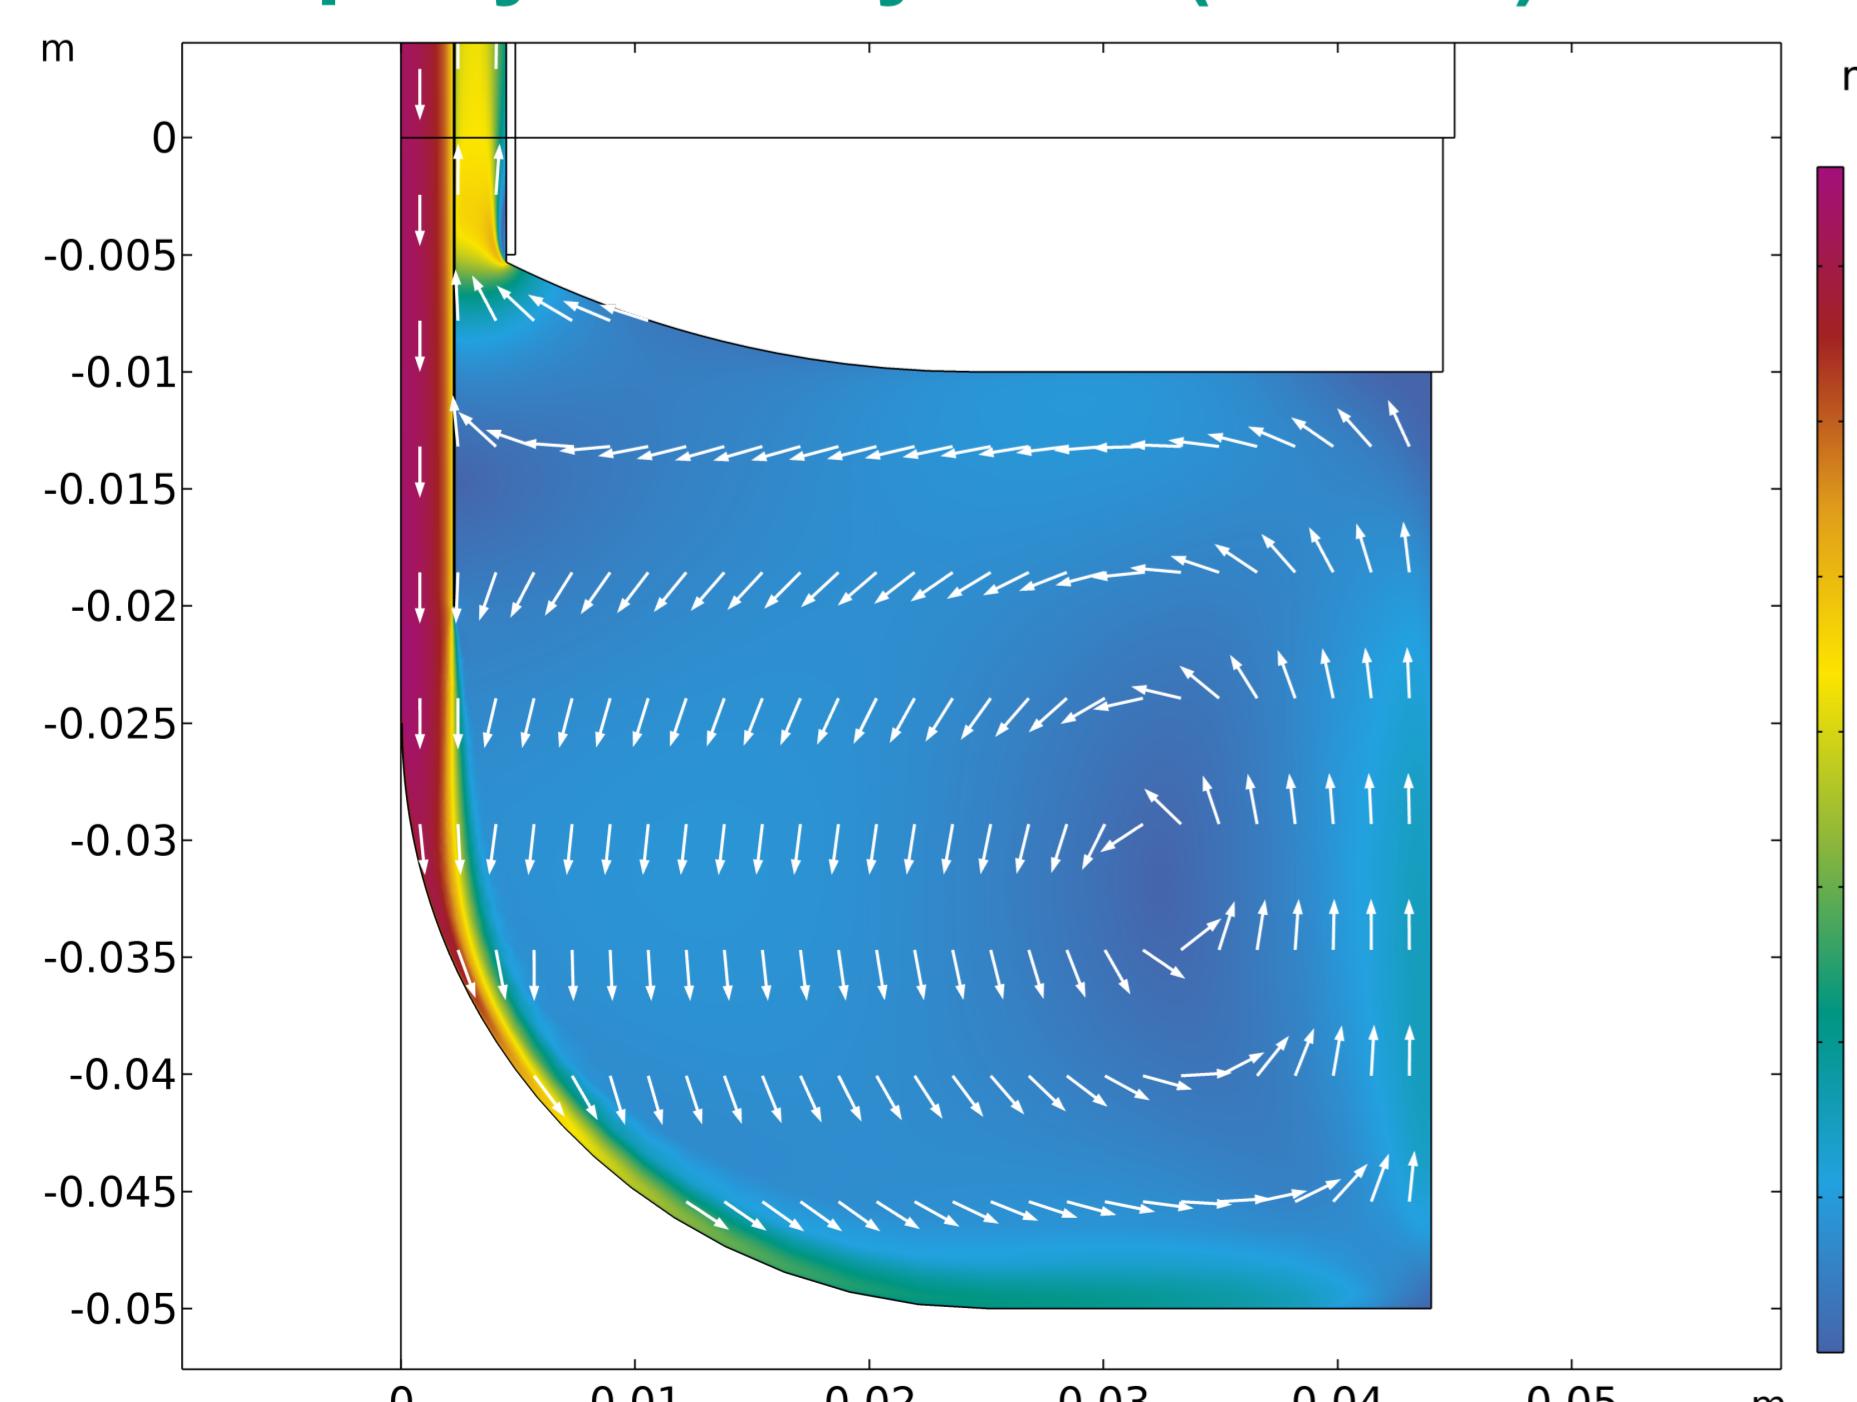

Parameter	Description	Expression / value
$\dot{m}_{\text{He}}$	Helium mass flow	up to $> 1000 \text{ mg/s}$
$T_{\text{He,in}}(t)$	Helium supply temperature	$\bar{T}_{\text{MAR}}(t) - \Delta T(t)$
$\bar{T}_{\text{MAR}}(t)$	Average marionette temperature	From transient solution data
$\Delta T(t)$	Temperature difference	50...110 K
$T_{\text{He,in,min}}$	Lowest He-I supply temperature	3.0 K
$p_{\text{He,out}}$	Absolute pressure at helium outlet	3.0...4.0 bar(a)

### Key conditions

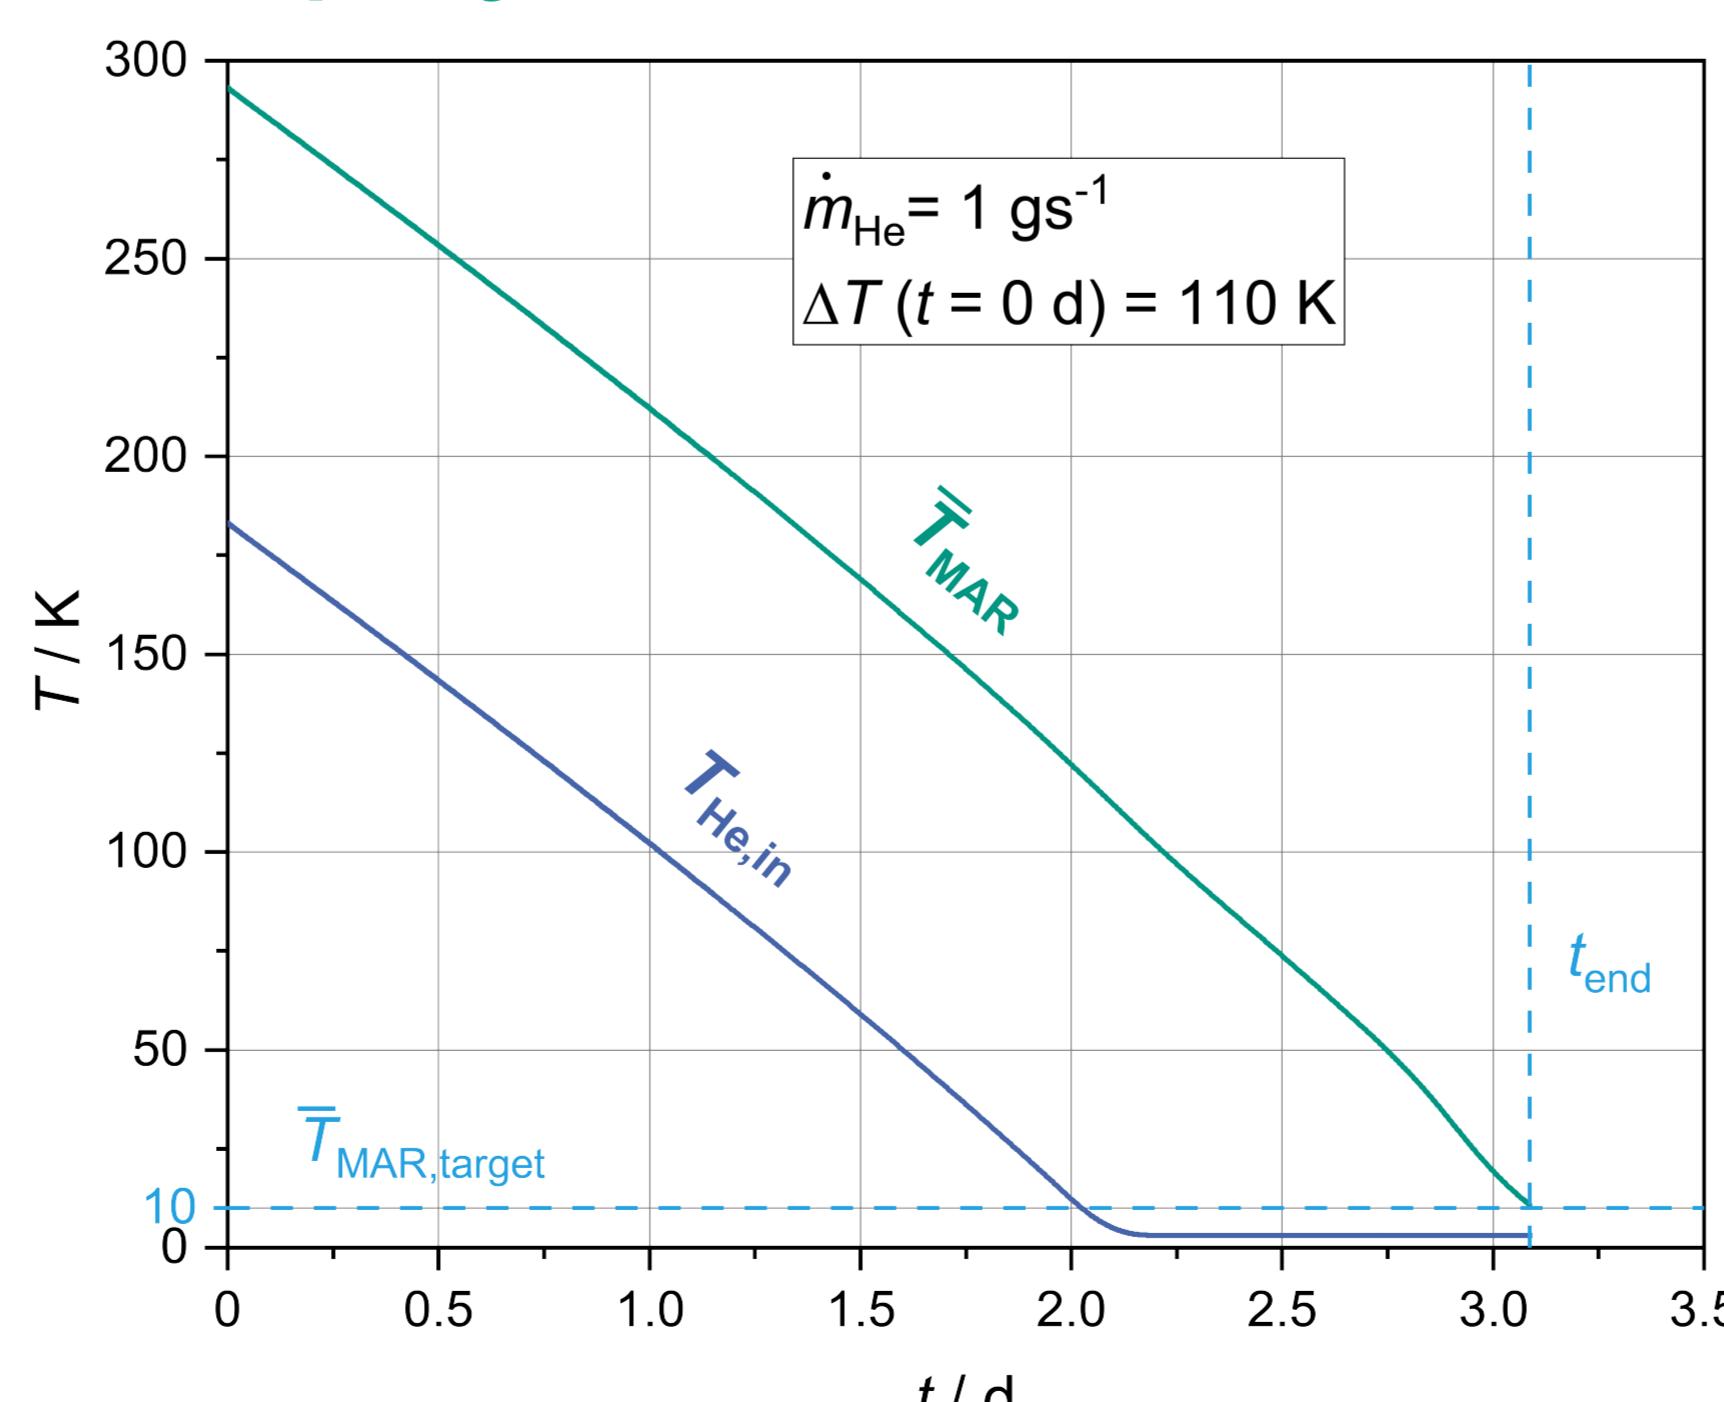

- Marionette
    - Material: stainless steel 314L
    - Mass: ca. 400 kg
  - Suspension tube
    - Material: Ti6Al4V
    - Wall thicknesses: 390  $\mu\text{m}$  (outside), 50  $\mu\text{m}$  (inside)
  - Helium
    - EOS: Peng-Robinson-Twu / Ideal Gas
    - Turbulence model: k- $\epsilon$  (compressible fluid)
- X. Koroveshi (2022)

## Current status and preliminary results

### Exemplary velocity field ( $t \approx 2 \text{ d}$ )

### Exemplary MAR cool-down curve

### Conclusions

- $t_{\text{end,MAR}} < 7 \text{ d}$  appear achievable
- Mostly turbulent flow regimes ( $\forall t$ )  $Re_{\text{max}} \approx 10^3 \dots 10^5$
- $\Delta p_{\text{global}} < 100 \text{ mbar}$

### Prospects

- Real gas behavior to be implemented
- Conduct parameter studies
