# **Embedding Strength of Densified Veneer Wood for Dowel-type Fasteners**

Juergen Ehlbeck and Hartmut Werner  
University of Karlsruhe, Germany

## **1      Introduction**

The embedding strength of wood-based materials is a governing property for determining the load-carrying capacities of joints with dowel-type fasteners. The embedding strength depends on the type of fastener, the manufacturing of the joint and quality of the wood-based materials. Thus, the embedding strength is not a special material property, but a system property.

Many research work has been done to describe this property and to collect sufficient test data. The test methods used differed, however, in many cases significantly so that the results can not be compared without any reservation. It was therefore an important task of the responsible European standardization committee to produce a test standard. A proposal was presented by the CEN - TC 124 as prEN 383 "Timber Structures - Test Methods - Determination of Embedding Strength and Foundation Values for Dowel-type Fasteners".

The embedding strength of densified veneer wood (dwv) made of beech, poplar and maritime pine compressed to different densities was tested in line with the main principles of this European proposal of a harmonized test method. The tests were made under two angles between load direction and grain direction of the face ply using dowel-type fasteners with diameter of 17 mm.

## 2 Test method

In prEN 383 the embedding strength is defined as the average compressive stress at maximum load in a specimen of timber or wood-based sheet product under the action of a stiff linear fastener with the fastener's axis perpendicular to the surface of the specimen. The fastener itself is loaded perpendicular to its axis. For wood based sheet products, the thickness of the specimen shall correspond to the full thickness of the panel. The dimensions of the specimens for testing the embedding strength are shown in Fig. 1. The loading may be in compression (Fig. 1a) or tension (Fig. 1b). When performing tests under compression, the value of  $l_1$  (see prEN 383) was reduced from 7d to 3d, because there are no splitting effects in this material. The maximum load,  $F_{\max}$ , and the embedding strength derived from  $F_{\max}$  is defined as the maximum load or embedding strength before the deformation of the specimen has reached a limit of 5 mm. Fig. 2 and Fig. 3 show the test set-up.

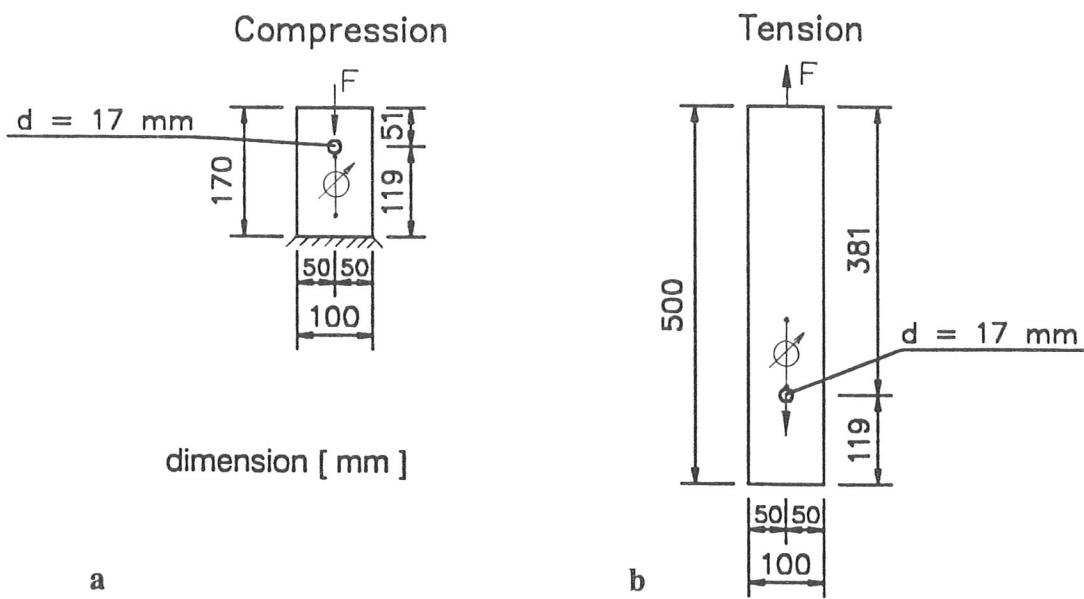

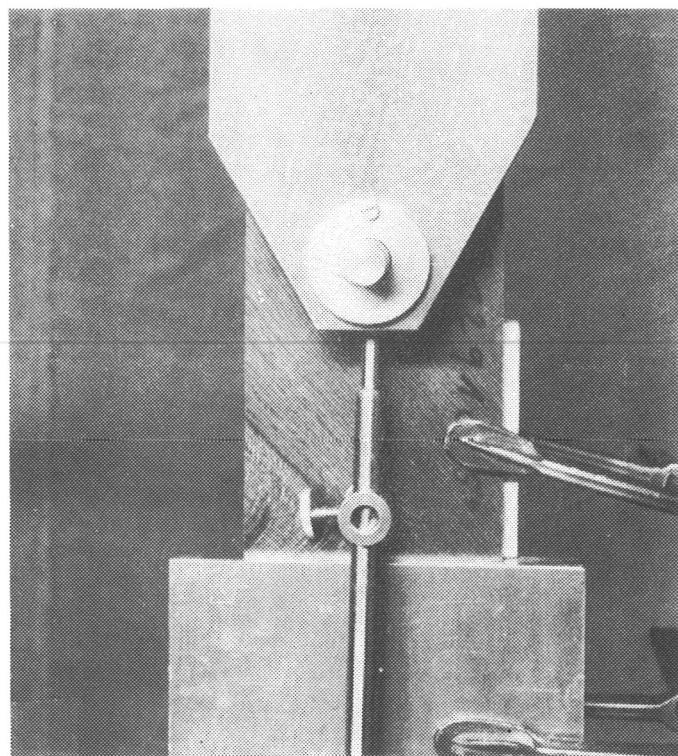

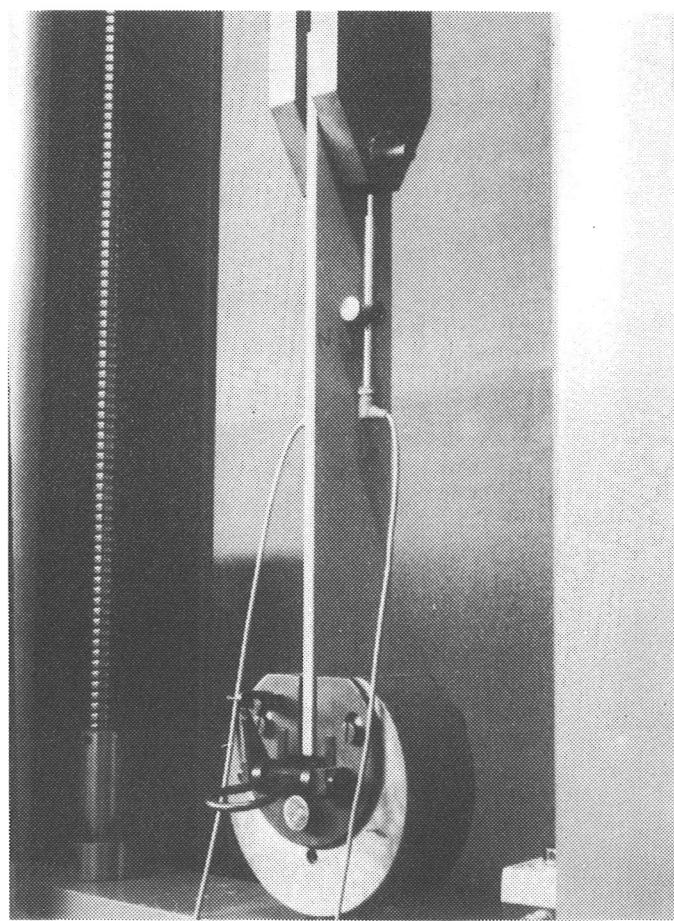

Figure 1: Test specimen

**Figure 2:** Test set-up and specimen loaded in compression

**Figure 3:** Test set-up and specimen loaded in tension

For the densified veneer wood made of beech, poplar and maritime pine in total 216 tests were carried out under compression (C) and tension (T) load with a dowel diameter of 17 mm. The panels were loaded at an angle of  $0^\circ/90^\circ$  and  $45^\circ$  between the load direction and grain direction of the face ply. The veneers of some panels were not balanced; therefore, the load - grain angle on one side was  $0^\circ$  and on the other side  $90^\circ$ . For structural use the densified veneer wood should be balanced. Fig. 4 shows the cutting schedule of the panels and the numbering of the specimens. From one panel 18 specimens were cut. The panel thickness and the density of all specimen were determined. The panels with the following numbers were tested:

dvw made of beech	B2, B5, B12 and B13
dvw made of poplar	P1, P3, P5 and P7
dvw made of maritime pine	M1, M2, M7 and M8

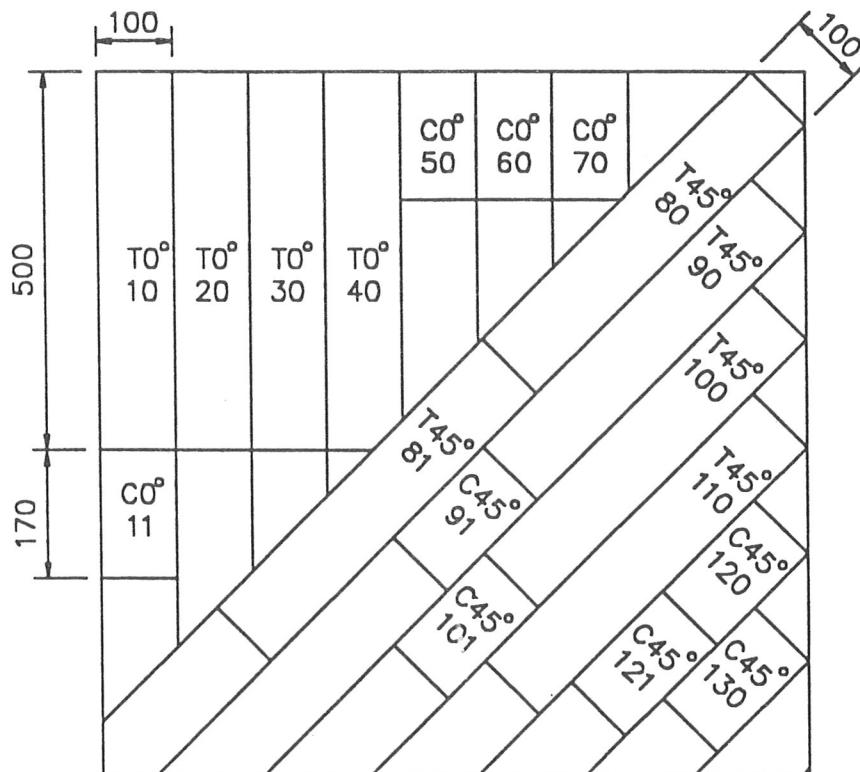

Figure 4: Cutting schedule of the panels

### 3 Test results

The load-deformation curves of all test are given in Annex 1 - 24. These curves indicate an elastic behaviour up to a certain proportional limit followed by a plastic deformation. After buckling of the outer veneers the load decreases. The results of all embedding tests are given in Annex 25 - 36.

From the load-deformaton curves the deformation and foundation values are evaluated as follows:

initial deformation	$w_i = w_{04}$
modified initial deformation	$w_{i,mod} = \frac{4}{3} \cdot (w_{04} - w_{01})$
elastic deformation	$w_e = \frac{2}{3} \cdot (w_{14} + w_{24} - w_{11} - w_{21})$
deformation at $0,6 \cdot F_{max}$	$w_{0,6}$
deformation at $0,8 \cdot F_{max}$	$w_{0,8}$
initial foundation modulus	$K_i = \frac{0,4 \cdot f_{h,est}}{w_i}$
foundation modulus	$K_s = \frac{0,4 \cdot f_{h,est}}{w_{i,mod}}$
elastic foundation modulus	$K_e = \frac{0,4 \cdot f_{h,est}}{w_e}$

The deformation values  $w_{01}$ ,  $w_{11}$ ,  $w_{04}$ ,  $w_{14}$  und  $w_{24}$  are those measured at the appertaining loading points as given in prEN 383 and  $f_{h,est}$  is the estimated embedding strength calculated with the following formula:

$$f_{h,est} = \frac{F_{max,est}}{d \cdot t}$$

The deformation and foundation values are listed in Annex 37 - 48.

The test results are summarized in Table 1 - 3. In these tables are given the panel thickness, the mean values and the coefficients of variation of the densities of the specimens as well as the mean values of the embedding strengths and their coefficients of variation.

## 4 Conclusions

From the test data the following may be argued:

- *Signification of tension and compression tests*

Due to the fact that both tension and compression tests are considered in prEN 383 it was important to perform tests with both kinds of loading. The embedding strength of dw under compression loading and under tension loading turned out to be approximately the same. The ratio  $f_{h,tension}/f_{h,comp.}$  ranges between 0,88 and 1,13 (mean value 0,98).

- *Influence of angle between load and grain direction of the face ply*

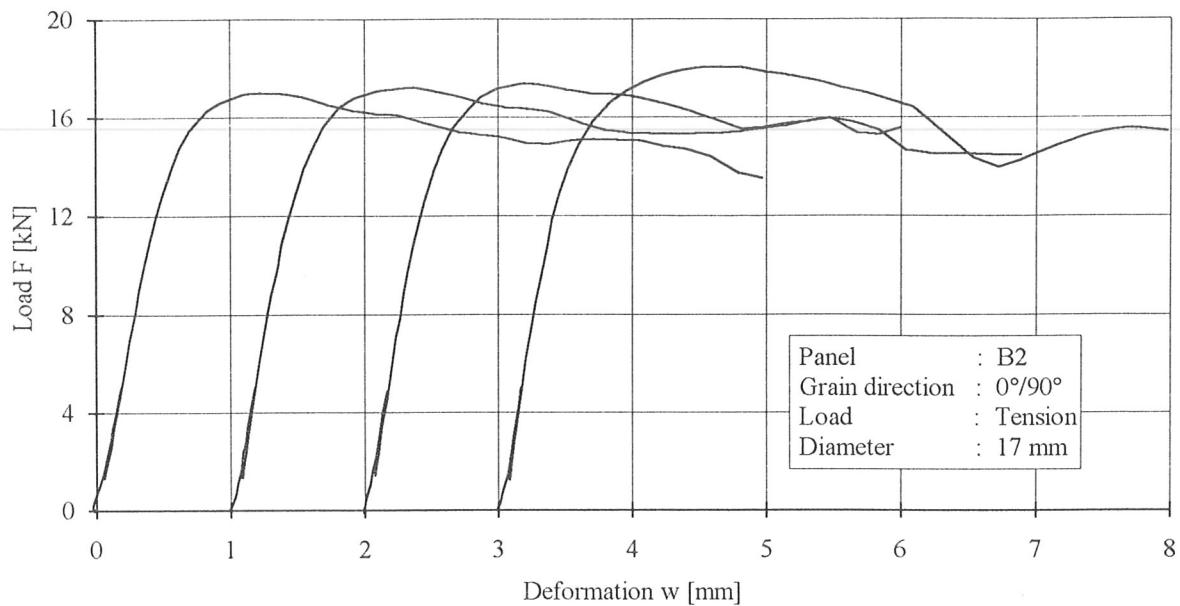

The embedding strength under an angle of 45° between load direction and grain direction of the face ply is about 5 % higher than under an angle of 0°/90°. This effect should, however, not be taken into account for structural use of densified veneer wood.

- *Influence of density*

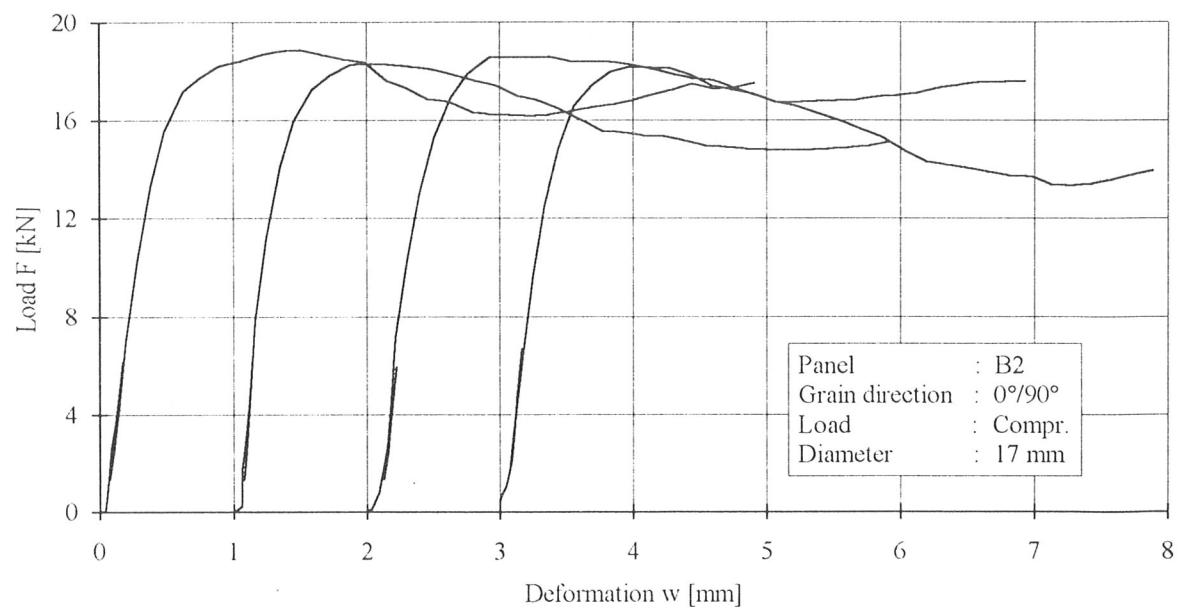

The embedding strength may be assumed to increase linearly with increasing density of the dw independent of the wood species. **Table 4** shows the mean values and the coefficient of variation of the ratios of  $f_h/\rho$  for the different dw.

**Table 4:** Ratio  $f_h/\rho$  of the embedding tests with densified veneer wood for dowel-type fasteners with  $d = 17 \text{ mm}$
