Three-dimensional effects on the local and global structure of thermo- diffusive instabilities in premixed hydrogen flames

T. Zirwes, F. Zhang, T.L. Kaiser, S. Eckart,
K. Oberleithner, O.T. Stein, H. Bockhorn

31. Deutscher Flammentag
Berlin, 27.-28. September 2023

Thermo-diffusive effects in 2D Plane-Jet Flames

$\phi = 4.0$

$\phi = 2.5$

$\phi = 1.0$

$\phi = 0.8$

$\phi = 0.5$

$\phi = 0.4$

High negative curvature

- Hydrogen/air at different ϕ
- Negative flame stretch at flame tip

Example of thermo-diffusive instabilities

- H_2/air , $\phi = 0.4$, atmospheric conditions, initial perturbation $6\delta_{th}$
- 2D, 100 Mio. cells, 12 cm x 36 cm

 Inlet: $u = s_L$

Example of thermo-diffusive instabilities

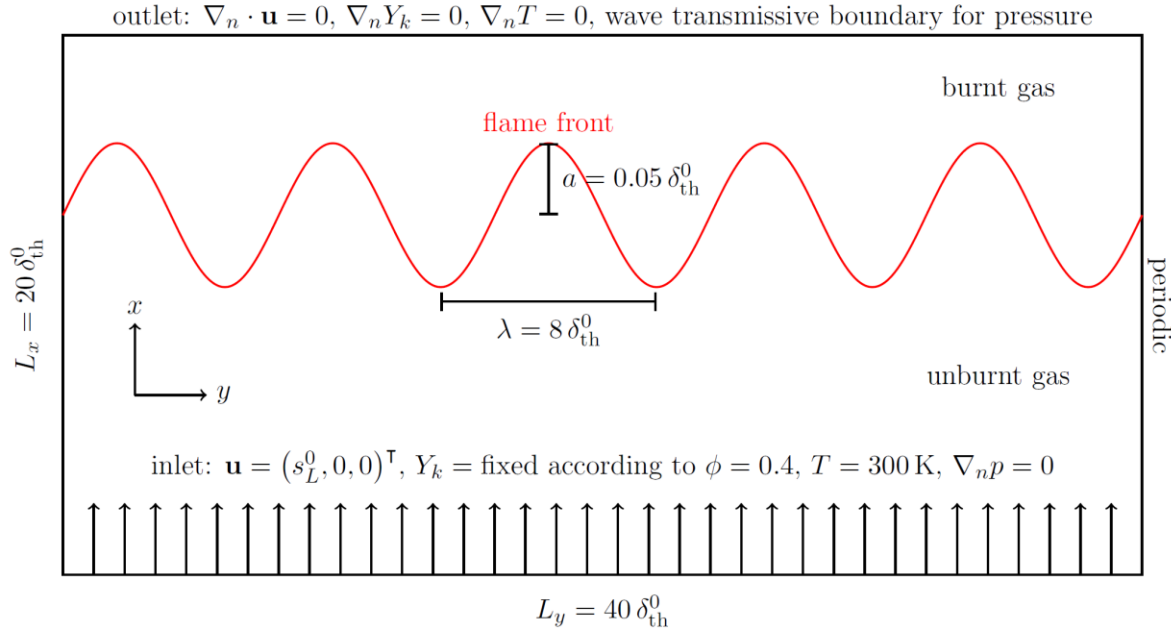

In-house OpenFOAM solver for reacting flows with preferential diffusion

- OpenFOAM has no models for detailed transport
- Reactive flow solver EBI dnsFoam uses Cantera for transport coefficients

Formation of cellular structures

Computational Setup

- H_2/air , $\phi = 0.4$
- Mixture-averaged diffusion vs. multi-component diffusion with Soret effect
- 2D vs. 3D

- $\vec{J}_{k,\text{Mix-avg}} = -\rho D_{m,k} \nabla Y_k$
- $\vec{J}_{k,\text{Multi-comp}} = \rho Y_k \frac{1}{X_k M} \sum_{i \neq k} M_i D_{k,i} \nabla X_i - D_k^T \frac{1}{T} \nabla T$

Cell formation in 2D

$t = 15.2 \text{ ms}$

- H_2 -air, $\phi = 0.4$, atmospheric conditions

inlet H_2/air

- Initial perturbation:
 $\lambda = 8\delta_{th}$, $a = 0.05\delta_{th}$

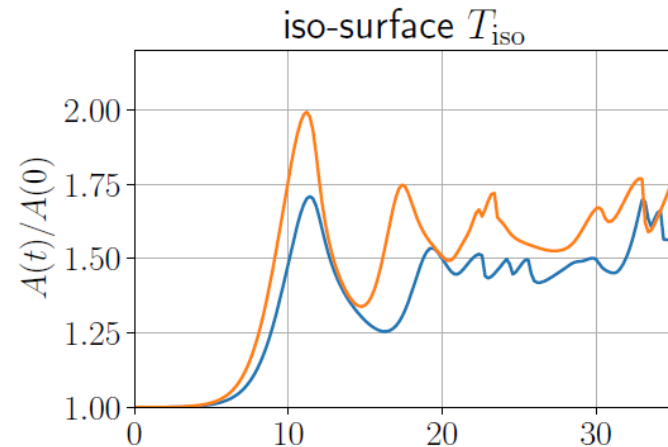

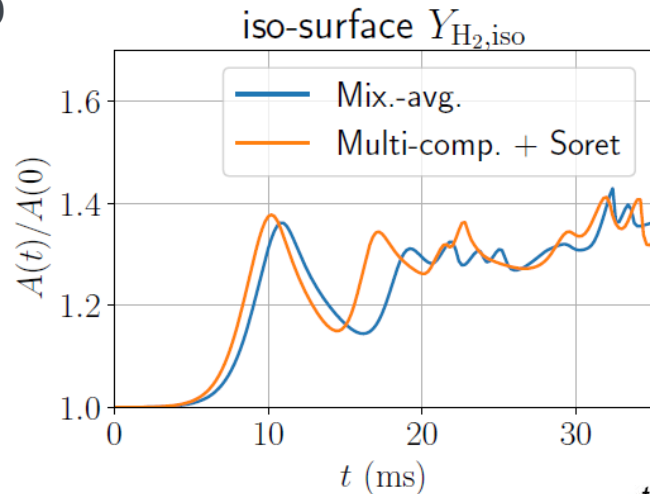

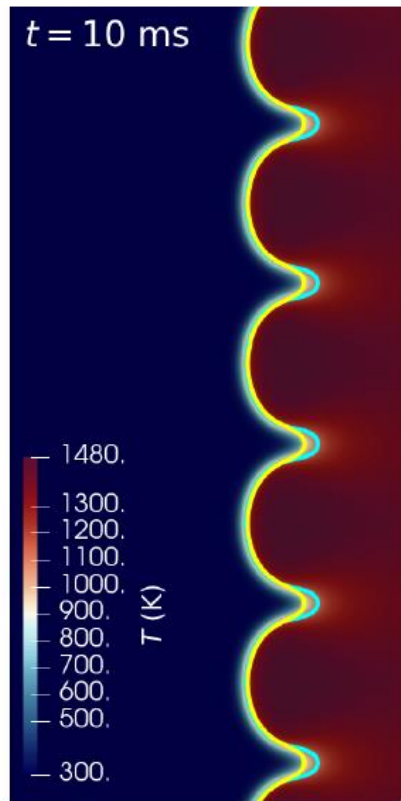

Mix.-avg.

- Breakdown into secondary structures earlier with Multi-comp. diffusion

Multi-component + Soret

Cell formation in 2D

- Primary structures form at a similar rate
- Collapse into secondary structures faster with Multi-comp. + Soret

2D vs. 3D

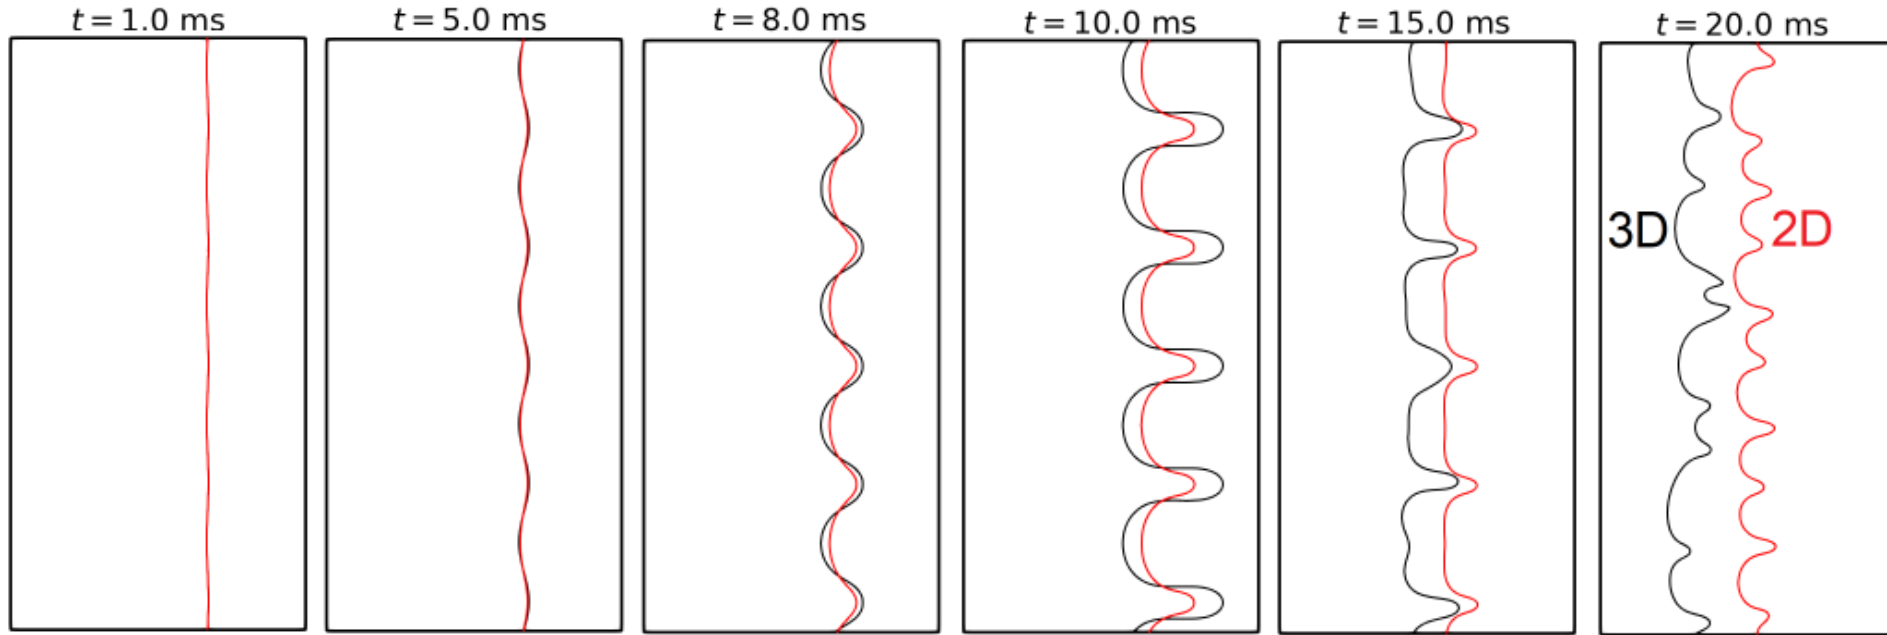

Cell formation in 3D

$t = 18.0 \text{ ms}$

- Same morphology as 2D:
 - Development of primary cells
 - Collapse into secondary structures
 - mixture-averaged diffusion model

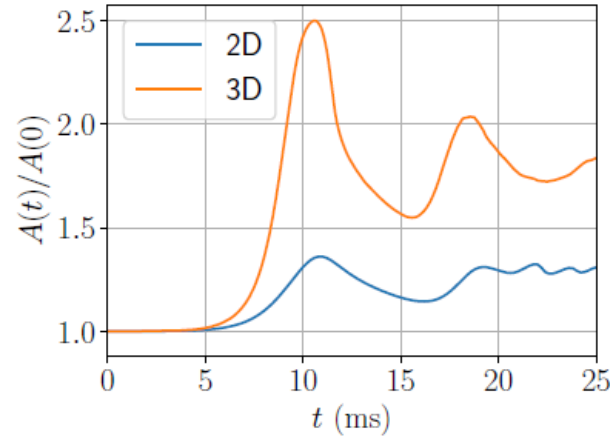

Cell formation in 3D

- Temperature iso-surfaces at 1100 K

Cell formation in 3D

- Area grows faster in 3D

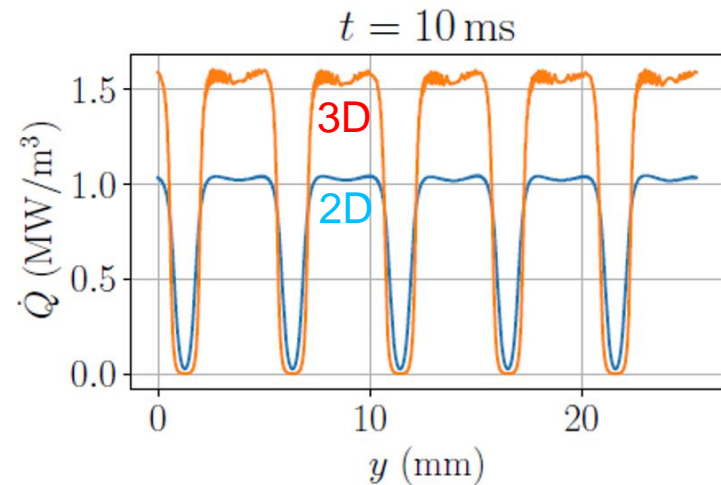

- More extreme curvatures in 3D

Cell formation in 3D

$t = 20 \text{ ms}$

Conclusions

- Numerical investigation of preferential diffusion effects with resolved simulations
- Cell formation of lean hydrogen flames depends on diffusion model
 - Multi-component diffusion and Soret diffusion do not significantly affect linear stability regime
 - But acceleration of non-linear secondary cell formation
- 3D simulations compared to 2D simulations exhibit:
 - larger curvature ranges
 - locally more strongly enhanced heat release rates
 - faster propagation and relative surface growth
 - Influence of 3D vs. 2D larger than influence of diffusion model
