Λ(2085) 7/2+

$I(J^P) = 0(\frac{7}{2}^+)$ Status: **

OMITTED FROM SUMMARY TABLE
was Λ(2020)

In LITCHFIELD 71, need for the state rests solely on a possibly inconsistent polarization measurement at 1.784 GeV/c. HEMINGWAY 75 does not require this state. GOPAL 77 does not need it in either $N\overline{K}$ or $\Sigma\pi$. With new K^-n angular distributions included, DECLAIS 77 sees it. However, this and other new data are included in GOPAL 80 and the state is not required. BACCARI 77 weakly supports it.

$\Lambda(2100)\ 7/2^-$

$I(J^P) = 0(\frac{7}{2}^-)$ Status: ****

Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and in invariant-mass distributions around 2100 MeV used to be listed in a separate entry immediately following. It may be found in our 1986 edition Physics Letters **170B** 1 (1986).

$\Lambda(2100)$ FOOTNOTES

[1] The NAKKASYAN 75 values are from the two best solutions found. Each has the $\Lambda(2100)$ and one additional resonance (P_3 or F_5).
[2] Note that the three for BACCARI 77 entries are for three different waves.
[3] The published sign has been changed to be in accord with the baryon-first convention. The upper limit on the G_3 wave is 0.03.

$\Lambda(2325)\ 3/2^-$

$I(J^P) = 0(\frac{3}{2}^-)$ Status: *

OMITTED FROM SUMMARY TABLE

BACCARI 77 finds this state with either $J^P = 3/2^-$ or $3/2^+$ in a energy-dependent partial-wave analyses of $K^-p \to \Lambda\omega$ from 2070 to 2436 MeV. A subsequent semi-energy-independent analysis from threshold to 2436 MeV selects $3/2^-$. DEBELLEFON 78 (same group) also sees this state in an energy-dependent partial-wave analysis of $K^-p \to \overline{K}N$ data, and finds $J^P = 3/2^-$ or $3/2^+$. They again prefer $J^P = 3/2^-$, but only on the basis of model-dependent considerations.

Λ(2350) 9/2+

$I(J^P) = 0(\frac{9}{2}^+)$ Status: ***

DAUM 68 favors $J^P = 7/2^-$ or $9/2^+$. BRICMAN 70 favors $9/2^+$. LASINSKI 71 suggests three states in this region using a Pomeron + resonances model. There are now also three formation experiments from the College de France-Saclay group, DEBELLEFON 77, BACCARI 77, and DEBELLEFON 78, which find $9/2^+$ in energy-dependent partial-wave analyses of $\overline{K}N \to \Sigma\pi$, $\Lambda\omega$, and $N\overline{K}$.

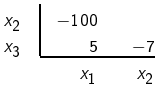
[a] See the Listings below for the pion momentum range used in this measurement.



CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 15 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 22.0$ for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[2] Uses $B(\Sigma^+ \to p\pi^0) = (51.57 \pm 0.30) \times 10^{-2}$.
[3] AAIJ 18E sees no structure in the dimuon mass distribution, contrary to PARK 05.
[4] The masses of the three dimuons of PARK 05 are within 1 MeV of one another, perhaps indicating the existence of a new state P^0 with mass 214.3 ± 0.5 MeV. In that case, the decay is $\Sigma^+ \to pP^0$, $P^0 \to \mu^+\mu^-$, with a branching fraction of $(3.1^{+2.4}_{-1.9} \pm 1.5) \times 10^{-8}$.

Σ^0

$I(J^P) = 1(\frac{1}{2}^+)$ Status: ****

COURANT 63 and ALFF 65, using $\Sigma^0 \to \Lambda e^+e^-$ decays (Dalitz decays), determined the Σ^0 parity to be positive, given that $J = 1/2$ and that certain very reasonable assumptions about form factors are true. The results of experiments involving the Primakoff effect, from which the Σ^0 mean life and $\Sigma^0 \to \Lambda$ transition magnetic moment come (see below), strongly support $J = 1/2$.

Σ^0 MASS

The fit uses Σ^+, Σ^0, Σ^-, and Λ mass and mass-difference measurements.

Σ^0 MEAN LIFE

These lifetimes are deduced from measurements of the cross sections for the Primakoff process $\Lambda \to \Sigma^0$ in nuclear Coulomb fields. An alternative expression of the same information is the Σ^0-Λ transition magnetic moment given in the following section. The relation is $(\mu_{\Sigma\Lambda}/\mu_N)^2\,\tau = 1.92951 \times 10^{-19}$ s (see DEVLIN 86).

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 16 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 8.7$ for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$+\ 5\pm23$	1092	[1] BERLEY	70B	HBC	n rescattering
14 ± 19	1385	BANGERTER	69B	HBC	K^-p 0.4 GeV/c

[1] BERLEY 70B changed from -5 to $+5°$ to agree with our sign convention.

g_A/g_V FOR $\Sigma^- \to n e^- \overline{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the "Note on Baryon Decay Parameters" in the neutron Listings. What is actually listed is $|g_1/f_1 - 0.237 g_2/f_1|$. This reduces to $g_A/g_V \equiv g_1(0)/f_1(0)$ on making the usual assumption that $g_2 = 0$. See also the note on HSUEH 88.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.340±0.017 OUR AVERAGE					
$+0.327\pm0.007\pm0.019$	50k	[1] HSUEH	88	SPEC	Σ^- 250 GeV
$+0.34\ \pm0.05$	4456	[2] BOURQUIN	83C	SPEC	SPS hyperon beam
0.385 ± 0.037	3507	[3] TANENBAUM	74	ASPK	
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$0.29\ \pm0.07$	25k	HSUEH	85	SPEC	See HSUEH 88
$0.17\ ^{+0.07}_{-0.09}$	519	DECAMP	77	ELEC	Hyperon beam

[1] The sign is, *with our conventions*, unambiguously positive. The value assumes, as usual, that $g_2 = 0$. If g_2 is included in the fit, than (with our sign convention) $g_2 = -0.56 \pm 0.37$, with a corresponding reduction of g_A/g_V to $+0.20 \pm 0.08$.

[2] BOURQUIN 83C favors the positive sign by at least 2.6 standard deviations.

[3] TANENBAUM 74 gives 0.435 ± 0.035, assuming no q^2 dependence in g_A and g_V. The listed result allows q^2 dependence, and is taken from HSUEH 88.

$f_2(0)/f_1(0)$ FOR $\Sigma^- \to n e^- \overline{\nu}_e$

The signs have been changed to be in accord with our conventions, given in the "Note on Baryon Decay Parameters" in the neutron Listings.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT

$\Sigma(1385)\ 3/2^+$

$I(J^P) = 1(\frac{3}{2}^+)$ Status: ****

Discovered by ALSTON 60. Early measurements of the mass and width for combined charge states have been omitted. They may be found in our 1984 edition Reviews of Modern Physics **56** S1 (1984).

We average only the most significant determinations. We do not average results from inclusive experiments with large backgrounds or results which are not accompanied by some discussion of experimental resolution. Nevertheless systematic differences between experiments remain. (See the ideograms in the Listings below.) These differences could arise from interference effects that change with production mechanism and/or beam momentum. They can also be accounted for in part by differences in the parametrizations employed. (See BORENSTEIN 74 for a discussion on this point.) Thus BORENSTEIN 74 uses a Breit-Wigner with energy-independent width, since a P-wave was found to give unsatisfactory fits. CAMERON 78 uses the same form. On the other hand HOLMGREN 77 obtains a good fit to their $\Lambda\pi$ spectrum with a P-wave Breit-Wigner, but includes the partial width for the $\Sigma\pi$ decay mode in the parametrization. AGUILAR-BENITEZ 81D gives masses and widths for five different Breit-Wigner shapes. The results vary considerably. Only the best-fit S-wave results are given here.

$\Sigma(1385)$ FOOTNOTES

[1] From fit to inclusive $\Lambda\pi$ spectrum.
[2] Includes data of HOLMGREN 77.
[3] The errors are statistical only. The resolution is not unfolded.
[4] The error is enlarged to $\Gamma/\sqrt{N}$. See the note on the $K^*(892)$ mass in the 1984 edition.
[5] From a fit to $\Lambda\pi^0$ with the width fixed at 34 MeV.
[6] From fit to inclusive $\Lambda\pi^0$ spectrum with the width fixed at 40 MeV.
[7] Redundant with data in the mass Listings.
[8] Results from $\Lambda\pi^+\pi^-$ and $\Lambda\pi^+\pi^-\pi^0$ combined by us.
[9] The error is enlarged to $4\Gamma/\sqrt{N}$. See the note on the $K^*(892)$ mass in the 1984 edition.
[10] Consistent with +, 0, and − widths equal.
[11] KELLER 12 gives $\Gamma(\Sigma^+\gamma)/\Gamma(\Sigma^+\pi^0) = (11.95 \pm 2.21^{+0.53}_{-1.21})\%$, using 1/2 our total $\Sigma(1385) \to \Sigma\pi$ fraction for $\Sigma^+\pi^0$. We divide the KELLER 12 value by two.
[12] We calculate this from the MOLCHANOV 04 upper limit of 9.5 keV on the $\Sigma^-\gamma$ width.
[13] We calculate this from the ARIK 77 upper limit of 24 keV on the $\Sigma^-\gamma$ width.
[14] An extrapolation of the parametrized amplitude below threshold.

$\Sigma(1580)$ $3/2^-$

$I(J^P) = 1(\frac{3}{2}^-)$ Status: *

OMITTED FROM SUMMARY TABLE

Seen in the isospin-1 $\overline{K}N$ cross section at BNL (LI 73, CARROLL 76) and in a partial-wave analysis of $K^-p \to \Lambda\pi^0$ for c.m. energies 1560–1600 MeV by LITCHFIELD 74. LITCHFIELD 74 finds $J^P = 3/2^-$. Not seen by ENGLER 78, CAMERON 78C, OLMSTED 04, nor by PRAKHOV 04.

Neither ZHANG 13A nor SARANTSEV 19 see any evidence for this state.

$\Sigma(1620)$ $1/2^-$

$I(J^P) = 1(\frac{1}{2}^-)$ Status: *

OMITTED FROM SUMMARY TABLE

The S_{11} state at 1697 MeV reported by VANHORN 75 is tentatively listed under the $\Sigma(1750)$. CARROLL 76 sees two bumps in the isospin-1 total cross section near this mass. GAO 12 sees no evidence for this resonance.

Production experiments are listed separately in the next entry.

$\Sigma(1750)$ $1/2^-$

$I(J^P) = 1(\frac{1}{2}^-)$ Status: ***

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

There is evidence for this state in many partial-wave analyses, but with wide variations in the mass, width, and couplings. The latest analyses indicated significant couplings to $N\overline{K}$ and $\Lambda\pi$, as well as to $\Sigma\eta$ whose threshold is at 1746 MeV (JONES 74).

$\Sigma(1775)\ 5/2^-$

$I(J^P) = 1(\frac{5}{2}^-)$ Status: ****

Discovered by GALTIERI 63, this resonance plays the same role as cornerstone for isospin-1 analyses in this region as the $\Lambda(1820)F_{05}$ does in the isospin-0 channel.

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

$\Sigma(1880)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] From solution 1 of BAILLON 75; not present in solution 2.
[3] Only unconstrained states from table 1 of LEA 73 are listed.
[4] The published sign has been changed to be in accord with the baryon-first convention.

$\Sigma(1910)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] The published sign has been changed to be in accord with the baryon-first convention.
[3] Upper limits on the D_1 and D_3 waves are each 0.03.

$\Sigma(2010)$ REFERENCES

SARANTSEV 19 EPJ A55 180 A.V. Sarantsev *et al.* (BONN, PNPI)

$\Sigma(2030)\ 7/2^+$

$I(J^P) = 1(\frac{7}{2}^+)$ Status: ****

Discovered by COOL 66 and by WOHL 66. For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions around 2030 MeV may be found in our 1984 edition, Reviews of Modern Physics **56** S1 (1984).

$\Sigma(2070)$ $5/2^+$

$I(J^P) = 1(\frac{5}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

This state suggested by BERTHON 70B finds support in GOPAL 80 with new $K^- p$ polarization and $K^- n$ angular distributions. The very broad state seen in KANE 72 is not required in the later (KANE 74) analysis of $\overline{K}N \to \Sigma\pi$.

$\Sigma(2250)$

$I(J^P) = 1(?^?)$ Status: **

OMITTED FROM SUMMARY TABLE

Results from partial-wave analyses are too weak to warrant separating them from the production and cross-section experiments. LASINSKI 71 in $\overline{K}N$ using a Pomeron + resonances model, and DEBELLEFON 76, DEBELLEFON 77, and DEBELLEFON 78 in energy-dependent partial-wave analyses of $\overline{K}N \to \Lambda\pi$, $\Sigma\pi$, and $N\overline{K}$, respectively, suggest two resonances around this mass.

$\Sigma(3170)$ Bumps

$I(J^P) = 1(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

Seen by AMIRZADEH 79 as a narrow 6.5-standard-deviation enhancement in the reaction $K^- p \to Y^{*+}\pi^-$ using data from independent high statistics bubble chamber experiments at 8.25 and 6.5 GeV/c. The dominant decay modes are multibody, multistrange final states and the production is via isospin-3/2 baryon exchange. Isospin 1 is favored.

Not seen in a $K^- p$ experiment in LASS at 11 GeV/c (ASTON 85B).

CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 12 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 10.2$ for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

RADIATIVE HYPERON DECAYS

Revised July 2011 by J.D. Jackson (LBNL).

The weak radiative decays of spin-1/2 hyperons, $B_i\to B_f\gamma$, yield information about matrix elements (form factors) similar to that gained from weak hadronic decays. For a polarized spin-1/2 hyperon decaying radiatively via a $\Delta Q=0$, $\Delta S=1$ transition, the angular distribution of the direction $\hat{\mathbf{p}}$ of the final spin-1/2 baryon in the hyperon rest frame is

$$\frac{dN}{d\Omega}=\frac{N}{4\pi}\left(1+\alpha_\gamma\,\mathbf{P}_i\cdot\hat{\mathbf{p}}\right). \qquad (1)$$

Here $\mathbf{P}_i$ is the polarization of the decaying hyperon, and α_γ is the asymmetry parameter. In terms of the form factors $F_1(q^2)$, $F_2(q^2)$, and $G(q^2)$ of the effective hadronic weak electromagnetic vertex,

$$F_1(q^2)\gamma_\lambda+iF_2(q^2)\sigma_{\lambda\mu}q^\mu+G(q^2)\gamma_\lambda\gamma_5\ ,$$

α_γ is

$$\alpha_\gamma=\frac{2\,\mathrm{Re}[G(0)F_M^*(0)]}{|G(0)|^2+|F_M(0)|^2}\ , \qquad (2)$$

where $F_M=(m_i-m_f)[F_2-F_1/(m_i+m_f)]$. If the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f=-\alpha_\gamma$ [1].

The angular distribution for the weak hadronic decay, $B_i\to B_f\pi$, has the same form as Eq. (1), but of course with a different asymmetry parameter, α_π. Now, however, if the decaying hyperon is unpolarized, the decay baryon has a

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

longitudinal polarization given by $P_f = +\alpha_\pi$ [2,3]. The difference of sign is because the spins of the pion and photon are different.

$\Xi^0 \to \Lambda\gamma$ *decay*—The radiative decay $\Xi^0 \to \Lambda\gamma$ of an unpolarized Ξ^0 uses the hadronic decay $\Lambda \to p\pi^-$ as the analyzer. As noted above, the longitudinal polarization of the Λ will be $P_\Lambda = -\alpha_{\Xi\Lambda\gamma}$. Let α_- be the $\Lambda \to p\pi^-$ asymmetry parameter and $\theta_{\Lambda p}$ be the angle, as seen in the Λ rest frame, between the Λ line of flight and the proton momentum. Then the hadronic version of Eq. (1) applied to the $\Lambda \to p\pi^-$ decay gives

$$\frac{dN}{d\cos\theta_{\Lambda p}} = \frac{N}{2}\left(1 - \alpha_{\Xi\Lambda\gamma}\,\alpha_-\cos\theta_{\Lambda p}\right) \qquad (3)$$

for the angular distribution of the proton in the Λ frame. Our current value, from the CERN NA48/1 experiment [4], is $\alpha_{\Xi\Lambda\gamma} = -0.704 \pm 0.019 \pm 0.064$.

$\Xi^0 \to \Sigma^0\gamma$ *decay*—The asymmetry parameter here, $\alpha_{\Xi\Sigma\gamma}$, is measured by following the decay chain $\Xi^0 \to \Sigma^0\gamma$, $\Sigma^0 \to \Lambda\gamma$, $\Lambda \to p\pi^-$. Again, for an unpolarized Ξ^0, the longitudinal polarization of the Σ^0 will be $P_\Sigma = -\alpha_{\Xi\Sigma\gamma}$. In the $\Sigma^0 \to \Lambda\gamma$ decay, a parity-conserving magnetic-dipole transition, the polarization of the Σ^0 is transferred to the Λ, as may be seen as follows. Let $\theta_{\Sigma\Lambda}$ be the angle seen in the Σ^0 rest frame between the Σ^0 line of flight and the Λ momentum. For Σ^0 helicity $+1/2$, the probability amplitudes for positive and negative spin states of the Σ^0 *along the* Λ *momentum* are $\cos(\theta_{\Sigma\Lambda}/2)$ and $\sin(\theta_{\Sigma\Lambda}/2)$. Then the amplitude for a negative helicity photon and a negative helicity Λ is $\cos(\theta_{\Sigma\Lambda}/2)$, while the amplitude for positive helicities for the photon and Λ is $\sin(\theta_{\Sigma\Lambda}/2)$. For Σ^0 helicity $-1/2$, the amplitudes are interchanged. If the Σ^0 has longitudinal polarization P_Σ, the probabilities for Λ helicities $\pm 1/2$ are therefore

$$p(\pm 1/2) = \frac{1}{2}(1 \mp P_\Sigma)\cos^2(\theta_{\Sigma\Lambda}/2) + \frac{1}{2}(1 \pm P_\Sigma)\sin^2(\theta_{\Sigma\Lambda}/2)\ , \quad (4)$$

and the longitudinal polarization of the Λ is

$$P_\Lambda = -P_\Sigma\cos\theta_{\Sigma\Lambda} = +\alpha_{\Xi\Sigma\gamma}\cos\theta_{\Sigma\Lambda}\ . \qquad (5)$$

Using Eq. (1) for the $\Lambda \to p\pi^-$ decay again, we get for the joint angular distribution of the $\Sigma^0 \to \Lambda\gamma$, $\Lambda \to p\pi^-$ chain,

$$\frac{d^2N}{d\cos\theta_{\Sigma\Lambda}\,d\cos\theta_{\Lambda p}} = \frac{N}{4}\left(1 + \alpha_{\Xi\Sigma\gamma}\cos\theta_{\Sigma\Lambda}\,\alpha_-\cos\theta_{\Lambda p}\right)\ . \qquad (6)$$

Our current average for $\alpha_{\Xi\Sigma\gamma}$ is -0.69 ± 0.06 [4,5].

References

1. R.E. Behrends, Phys. Rev. **111**, 1691 (1958); see Eq. (7) or (8).
2. In ancient times, the signs of the asymmetry term in the angular distributions of radiative and hadronic decays of polarized hyperons were sometimes opposite. For roughly 50 years, however, the overwhelming convention has been to make them the same. The aim, not always achieved, is to remove ambiguities.
3. For the definition of α_π, see the note on "Baryon Decay Parameters" in the Neutron Listings.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 1.0$ for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Ξ AND Ω RESONANCES

Revised 2025 by V. Crede (FSU), U. Thoma (U. Bonn)

Most of our present knowledge of Ξ and Ω resonances stems from the low-statistics data samples recorded in the 1960s–1980s using K^- beams and in the 1980s and 1990s using hyperon (Σ^-, Ξ^-) beams. This is because (1) they could only be produced as a part of a final state, and so the analysis is more complicated than if direct formation were possible, (2) the production cross sections are small (typically a few μb), and (3) the final states are topologically complicated and difficult to study with electronic techniques. Thus, early information about

See key on page 1227

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

Ξ resonances came entirely from bubble chamber experiments, where the numbers of events were small, and only in the 1980s did electronic experiments make any significant contributions.

Table 1. Our estimate of the status of the Ξ resonances. Only those with an overall status of *** or **** are included in the Baryon Summary Table.

Particle	J^P	Overall status	Status as seen in — $\Xi\pi$	ΛK	ΣK	$\Xi(1530)\pi$	Other channels
Ξ(1320)	1/2+	****					Decays weakly
Ξ(1530)	3/2+	****	****				
Ξ(1620)		**	**				
Ξ(1690)	1/2−	***	**	***	**		
Ξ(1820)	3/2−	****	**	****	**	**	
Ξ(1950)		***	**	**		*	
Ξ(2030)		***		**	***		
Ξ(2120)		*		*			
Ξ(2250)		**					3-body decays
Ξ(2370)		**					3-body decays
Ξ(2500)		*		*	*		3-body decays

**** Existence is certain, and properties are at least fairly well explored.
*** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, *etc.* are not well determined.
** Evidence of existence is only fair.
* Evidence of existence is poor.

In recent years, the two ground states, $\Xi(1320)^-$ and $\Xi(1530)^-$, have been observed in photoproduction by the CLAS Collaboration in the reaction $\gamma p \to K^+K^+\Xi^{(*)}_{\rm miss}$ [1]. New opportunities for studying multi-strange hyperons have also emerged from the high-energy collider experiments, amongst others, Belle, BES III, and LHCb. At these facilities, light-flavor baryon resonances are copiously produced in the decays of heavy baryons containing a charm or bottom quark, or in the decay of heavy-flavor mesons. The available high-statistics data samples provide a rich source for studying multi-strange hyperons. For example, excited Ξ baryons are produced and have been studied in the decay of the charmed Λ_c^+ into $(\Sigma^+K^-)_{\Xi(1690)}\,K^+$ by the Belle Collaboration [2] and into $(\Xi^-\pi^+)_{\Xi^*}\,K^+$ by the BaBar Collaboration [3], but also by Belle in the decay $\Xi_c^+ \to (\Xi^-\pi^+)_{\Xi^*}\,\pi^+$ [4] with high statistical quality. Clear signatures are observed for the decuplet ground state, Ξ(1530), and for the lowest-mass excitations, Ξ(1620) and Ξ(1690). The BES III Collaboration studied Ξ^* production in reactions such as $e^+e^- \to \psi(3686) \to (K^-\Lambda)_{\Xi^*}\bar{\Xi}^+$ and has observed structures associated with the Ξ(1690) and Ξ(1820) resonances [5]. Even a partial wave analysis (PWA) was performed to study the properties of these intermediate state Ξ^* hyperons. However, such studies from $c\bar{c}$ decays are still statistically limited and nothing of significance has been observed for masses beyond 1.9 GeV. Finally, the LHCb Collaboration studied Ξ^* resonances in high-energy pp collisions. The results are based on an analysis of the reaction $\Xi_b \to J/\psi\,(\Lambda K^-)_{\Xi^*}$ and the first observation of Ξ(1690) and Ξ(1820) in the decay of Ξ_b^- was announced [6]. Masses and widths have been determined with improved precision in an amplitude analysis of the $K^-\Lambda$ mass distribution. Large uncertainties in the width of excited Ξ resonances remain. The asignment of the Ξ(1530) to the ground-state decuplet is undisputed and the corresponding $J^P = 3/2^+$ quantum numbers have been experimentally confirmed by the BaBar Collaboration [3]. With few exceptions, experimental analyses and theoretical approaches suggest $J^P = 1/2^-$ and $J^P = 3/2^-$ for Ξ(1690) and Ξ(1820), respectively [7]. All other J^P assignments for Ξ resonances are speculative.

The $\Omega(2012)^- \to \Xi^0\,K^-$ $(\Xi^-\,K^0_S)$ was discovered by Belle in 2018 in the decays of the $b\bar{b}$ mesons $\Upsilon(1S), \Upsilon(2S)$, and $\Upsilon(3S)$ [8]. The ground-state Ω^- is copiously produced in the decay $\Xi_c^0 \to \Omega^-\,K^-$ and with lower statistics in $\Omega_c^0 \to \Omega^-\,\pi^+$. Such data samples were used by the BaBar Collaboration for a spin measurement of the Ω^- hyperon [9], for instance. The most recent addition to the family of Ω baryons was reported by the BES III Collaboration in 2025 in the process $e^+e^- \to \Omega(2109)^-\bar{\Omega}^+$ [10].

Ξ(1530) 3/2+

$I(J^P) = \frac{1}{2}(\frac{3}{2}^+)$ Status: ****

This is the only Ξ resonance whose properties are all reasonably well known. Assuming that the Λ_c^+ has $J^P = 1/2^+$, AUBERT 08AK, in a study of $\Lambda_c^+ \to \Xi^-\pi^+K^+$, finds conclusively that the spin of the $\Xi(1530)^0$ is 3/2. In conjunction with SCHLEIN 63B and BUTTON-SHAFER 66, this proves also that the parity is +.

We use only those determinations of the mass and width that are accompanied by some discussion of systematics and resolution.

$\Xi(1690)$

$I(J^P) = \frac{1}{2}(?^?)$ Status: ***

AUBERT 08AK, in a study of $\Lambda_c^+ \to \Xi^-\pi^+K^+$, finds some evidence that the $\Xi(1690)$ has $J^P = 1/2^-$.

DIONISI 78 sees a threshold enhancement in both the neutral and negatively charged $\Sigma\overline{K}$ mass spectra in $K^- p \to (\Sigma\overline{K})K\pi$ at 4.2 GeV/c. The data from the $\Sigma\overline{K}$ channels alone cannot distinguish between a resonance and a large scattering length. Weaker evidence at the same mass is seen in the corresponding $\Lambda\overline{K}$ channels, and a coupled-channel analysis yields results consistent with a new Ξ.

BIAGI 81 sees an enhancement at 1700 MeV in the diffractively produced ΛK^- system. A peak is also observed in the $\Lambda\overline{K}^0$ mass spectrum at 1660 MeV that is consistent with a 1720 MeV resonance decaying to $\Sigma^0\overline{K}^0$, with the γ from the Σ^0 decay not detected.

BIAGI 87 provides further confirmation of this state in diffractive dissociation of Ξ^- into ΛK^-. The significance claimed is 6.7 standard deviations.

ADAMOVICH 98 sees a peak of 1400 ± 300 events in the $\Xi^-\pi^+$ spectrum produced by 345 GeV/c Σ^--nucleus interactions.

SUMIHAMA 19 observes a peak in the $\Xi^-\pi^+$ spectrum with a significance of 4.0 standard deviations.

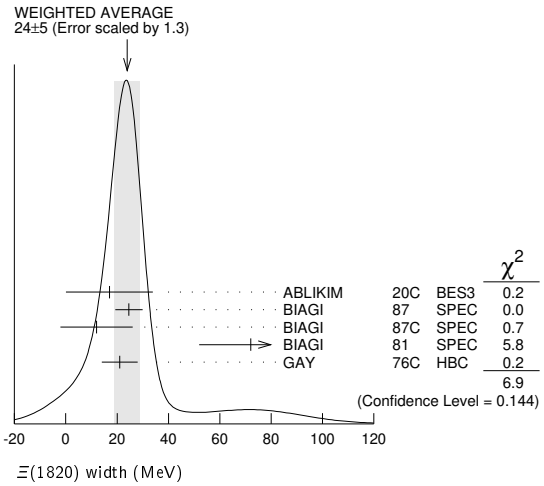
$\Xi(1820)$ $3/2^-$

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: ***

The clearest evidence is an 8-standard-deviation peak in ΛK^- seen by GAY 76C. TEODORO 78 favors $J = 3/2$, but cannot make a parity discrimination. BIAGI 87C is consistent with $J = 3/2$ and favors negative parity for this J value.



$\Xi(1820)$ MASS

We only average the measurements that appear to us to be most significant and best determined.

$\Xi(1820)$ FOOTNOTES

[1] BIAGI 87 also sees weak signals in the in the $\Xi^-\pi^+\pi^-$ channel at 1782.6 ± 1.4 MeV (Γ = 6.0 ± 1.5 MeV) and 1831.9 ± 2.8 MeV (Γ = 9.6 ± 9.9 MeV).
[2] BADIER 72 adds all channels and divides the peak into lower and higher mass regions. The data can also be fitted with a single Breit-Wigner of mass 1800 MeV and width 150 MeV.
[3] From a fit to inclusive $\Xi\pi$, $\Xi\pi\pi$, and ΛK^- spectra.
[4] From a fit to inclusive $\Xi\pi$ and $\Xi\pi\pi$ spectra only.
[5] Including $\Xi\pi\pi$.
[6] DAUBER 69 uses in part the same data as SMITH 65C.
[7] For the decay mode $\Xi^-\pi^+\pi^0$ only. This limit includes $\Xi(1530)\pi$.
[8] Or less. Upper limit for the 3-body decay.

$\Xi(1950)$

$I(J^P) = \frac{1}{2}(?^?)$ Status: ***

We list here everything reported between 1875 and 2000 MeV. The accumulated evidence for a Ξ near 1950 MeV seems strong enough to include a $\Xi(1950)$ in the main Baryon Table, but not much can be said about its properties. In fact, there may be more than one Ξ near this mass.

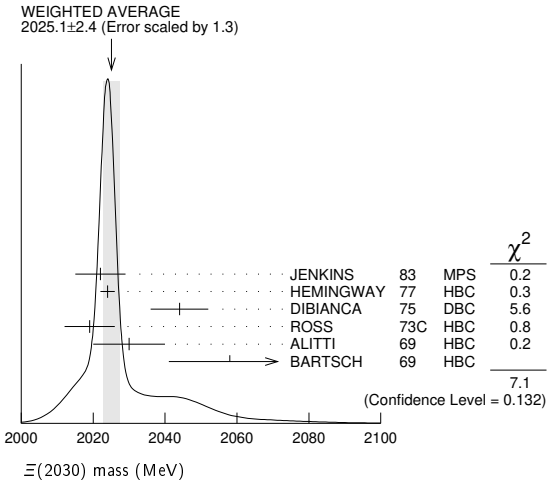
Baryon Particle Listings

Ξ(2030)

Ξ(2030)



$I(J^P) = \frac{1}{2}(\geq \frac{5}{2}^?)$ Status: ***

The evidence for this state has been much improved by HEMINGWAY 77, who see an eight standard deviation enhancement in $\Sigma\overline{K}$ and a weaker coupling to $\Lambda\overline{K}$. ALITTI 68 and HEMINGWAY 77 observe no signals in the $\Xi\pi\pi$ (or $\Xi(1530)\pi$) channel, in contrast to DIBIANCA 75. The decay $(\Lambda/\Sigma)\overline{K}\pi$ reported by BARTSCH 69 is also not confirmed by HEMINGWAY 77.

A moments analysis of the HEMINGWAY 77 data indicates at a level of three standard deviations that $J \geq 5/2$.

Ξ(2120) FOOTNOTES

[1] CHLIAPNIKOV 79 does not uniquely identify the K^+ in the $(\overline{\Lambda} K^+)$ X final state. It also reports bumps with fewer events at 2240, 2540, and 2830 MeV.

[2] GAY 76C sees a 4-standard deviation signal. However, HEMINGWAY 77, with more events from the same experiment points out that the signal is greatly reduced if a cut is made on the 4-momentum u. This suggests an anomalous production mechanism if the Ξ(2120) is real.

Ω BARYONS
($S = -3$, $I = 0$)

$\Omega^- = sss$

Ω^-

$I(J^P) = 0(\frac{3}{2}^+)$ Status: ****

The unambiguous discovery in both production and decay was by BARNES 64. The quantum numbers follow from the assignment of the particle to the baryon decuplet. DEUTSCHMANN 78 and BAUBILLIER 78 rule out $J = 1/2$ and find consistency with $J = 3/2$. AUBERT,BE 06 finds from the decay angular distributions of $\Xi_c^0 \to \Omega^- K^+$ and $\Omega_c^0 \to \Omega^- K^+$ that $J = 3/2$; this depends on the spins of the Ξ_c^0 and Ω_c^0 being $J = 1/2$, their supposed values. ABLIKIM 21E determines the Ω^- spin to be $J = 3/2$ from the decay angular distributions of the complete decay chain $\psi(3686) \to \Omega^- \overline{\Omega}^+$, with subsequent decays $\Omega^- \to K^- \Lambda$ and $\overline{\Omega}^+ \to K^+ \overline{\Lambda}$.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

Ω^- MASS

The fit assumes the Ω^- and $\overline{\Omega}^+$ masses are the same, and averages them together.

1670.6 ±1.0	1	[2] FRY	55B	EMUL	
1615	1	[4] EISENBERG	54	EMUL	

[1] DIBIANCA 75 gives a mass for each event. We quote the average.
[2] The FRY 55 and FRY 55B events were identified as Ω^- by ALVAREZ 73. The masses assume decay to ΛK^- at rest. For FRY 55B, decay from an atomic orbit could Doppler shift the K^- energy and the resulting Ω^- mass by several MeV. This shift is negligible for FRY 55 because the Ω decay is approximately perpendicular to its orbital velocity, as is known because the Λ strikes the nucleus (L.Alvarez, private communication 1973). We have calculated the error assuming that the orbital n is 4 or larger.
[3] Excluded from the average; the Ω^- lifetimes measured by the experiments differ significantly from other measurements.
[4] The EISENBERG 54 mass was calculated for decay in flight. ALVAREZ 73 has shown that the Ω interacted with an Ag nucleus to give $K^-\Xi$Ag.

$\overline{\Omega}^+$ MASS

• • • We do not use the following data for averages, fits, limits, etc. • • •					
$4.3\ ^{+3.4}_{-1.3}$	4	BOURQUIN	84	SPEC	SPS hyperon beam

[5] This KAMAEV 10 value uses 76 $\Omega^- \to \Xi^-\pi^+\pi^-$ and 24 $\overline{\Omega}^+ \to \overline{\Xi}^+\pi^-\pi^+$ decays. The Ω^- and $\overline{\Omega}^+$ branching fractions measurements are statistically equal. The errors given combine statistical and systematic contributions. The *CP* branching-fraction asymmetry, $(\Omega^- - \overline{\Omega}^+)$/sum, is $+0.12 \pm 0.20$.

OMITTED FROM SUMMARY TABLE

A peak in the $\Omega^-\pi^+\pi^-$ mass spectrum with a signal significance claimed to be at least 5.5 standard deviations. There is no reason to seriously doubt the existence of this state, but unless the evidence is overwhelming we usually wait for confirmation from a second experiment before elevating peaks to the Summary Table.

CHARMED BARYONS ($C = +1$)

$\Lambda_c^+ = udc$, $\Sigma_c^{++} = uuc$, $\Sigma_c^+ = udc$, $\Sigma_c^0 = ddc$,
$\Xi_c^+ = usc$, $\Xi_c^0 = dsc$, $\Omega_c^0 = ssc$

Λ_c^+

$I(J^P) = 0(\frac{1}{2}^+)$ Status: ****

The parity of the Λ_c^+ is defined to be positive (as are the parities of the proton, neutron, and Λ). The quark content is udc. Results of an analysis of $p K^- \pi^+$ decays (JEZABEK 92) are consistent with $J = 1/2$. ABLIKIM 21N determines the Λ_c^+ spin to be $J = 1/2$, from an angular analysis of various 2-body Λ_c^+ decays in $e^+e^- \to \Lambda_c^+ \overline{\Lambda}_c^-$.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in earlier editions.

Λ_c^+ MASS

Our value in 2004, 2284.9 ± 0.6 MeV, was the average of the measurements now filed below as "not used." The BABAR measurement is so much better that we use it alone. Note that it is about 2.6 (old) standard deviations above the 2004 value.

The fit also includes Σ_c–Λ_c^+ and Λ_c^{*+}–Λ_c^+ mass-difference measurements, but this doesn't affect the Λ_c^+ mass. The new (in 2006) Λ_c^+ mass simply pushes all those other masses higher.

[1] AUBERT,B 05S uses low-Q $\Lambda K_S^0 K^+$ and $\Sigma^0 K_S^0 K^+$ decays to minimize systematic errors. The error above includes systematic as well as statistical errors. Many cross checks and adjustments to properties of the BABAR detector, as well as the large number of clean events, make this by far the best measurement of the Λ_c^+ mass.

Λ_c^+ MEAN LIFE

Measurements with an error $\geq 100 \times 10^{-15}$ s or with fewer than 20 events have been omitted from the Listings.

[1] AAIJ 19AG reports $[\Lambda_c^+$ MEAN LIFE$]$ / $[D^\pm$ MEAN LIFE$] = 0.1956 \pm 0.0010 \pm 0.0013$ which we multiply by our best (shown rounded) value $D^\pm$ MEAN LIFE $= (1.033 \pm 0.005) \times 10^{-12}$ s. Our first error is their experiment's error and our second error is the systematic error from using our best (shown rounded) value.

Λ_c^+ DECAY MODES

Branching fractions marked with a footnote, e.g. [a], have been corrected for decay modes not observed in the experiments. For example, the sub-mode fraction $\Lambda_c^+ \to p\overline{K}^*(892)^0$ seen in $\Lambda_c^+ \to p K^- \pi^+$ has been multiplied up to include $\overline{K}^*(892)^0 \to \overline{K}^0 \pi^0$ decays.

	Mode		Fraction (Γ_i/Γ)	Scale factor / Confidence level

[a] This branching fraction includes all the decay modes of the final-state resonance.

[b] Here γ_D stands for a dark photon.

FIT INFORMATION

An overall fit to 56 branching ratios uses 87 measurements to determine 26 parameters. The overall fit has a $\chi^2 = 61.2$ for 61 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$.

4.38±0.79±0.21	75	[1] ABLIKIM	23BY	BES3	e^+e^- at 4.600–4.699 GeV

[1] We do not include this measurement in our average because it is highly correlated to the relative branching fractions $B(\Lambda_c \to \Sigma^+K^+K^-)$ / $B(\Lambda_c \to \Sigma^+\pi^+\pi^-)$ and $B(\Lambda_c \to \Sigma^+\phi)$ / $B(\Lambda_c \to \Sigma^+\pi^+\pi^-)$ measured in the same analysis (which we do use). Although the measurements are done on the same data, ABLIKIM 23BY do not obtain exactly $B(\Lambda_c \to \Sigma^+\phi)\cdot B(\phi \to K^+K^-)$ / $B(\Lambda_c \to \Sigma^+\pi^+\pi^-) + B(\Lambda_c^+ \to \Sigma^+K^+K^-(\text{non-}\phi))$ / $B(\Lambda_c \to \Sigma^+\pi^+\pi^-) = B(\Lambda_c \to \Sigma^+K^+K^-)$ / $B(\Lambda_c \to \Sigma^+\pi^+\pi^-)$.

[1] AAIJ 24AH also reports the measurements of the decay parameters β and γ, the phase difference Δ, the CP asymmetry R_β and the CP average R'_β for $\Lambda_c\rightarrow\ \Lambda\pi$ and its charge-conjugated decay.

[2] LI 23C obtained the value by a fit for the product $\alpha\times\alpha_\Lambda^{avg}$, and dividing by the value $\alpha_\Lambda^{avg}=0.7542\pm0.0026$ reported in ABLIKIM 22AG.

[3] BISHAI 95 actually gives $\alpha=-0.94^{+0.21+0.12}_{-0.06-0.06}$, chopping the errors at the physical limit -1.0. However, for $\alpha\approx\ -1.0$, some experiments should *get* unphysical values ($\alpha<-1.0$), and for averaging with other measurements such values (or errors that extend below -1.0) should *not* be chopped.

[1] ABLIKIM 23AT measures α of $\Lambda_c^+\rightarrow\ \Lambda\mu^+\nu_\mu$ decay over eight q^2 bins from zero to the kinematic endpoint. The value provided here is $\langle\alpha\rangle$, averaged over q^2. The analysis uses form factors extracted from a simultaneous fit to electron and muon mode data.

[2] HINSON 05 measures the form-factor ratio $R\equiv f_2/f_1$ for $\Lambda_c^+\rightarrow\ \Lambda e^+\nu_e$ events to be $-0.31\pm0.05\pm0.04$ and the pole mass to be $2.21\pm0.08\pm0.14$ GeV/c^2, and from these calculates α, averaged over q^2, where $\langle q^2\rangle=0.67\,(\mathrm{GeV/c})^2$.

[3] ALBRECHT 94B uses Λe^+ and $\Lambda\mu^+$ events in the mass range $1.85<M(\Lambda\ell^+)<2.20$ GeV.

[4] CRAWFORD 95 measures the form-factor ratio $R\equiv f_2/f_1$ for $\Lambda_c^+\rightarrow\ \Lambda e^+\nu_e$ events to be $-0.25\pm0.14\pm0.08$ and from this calculates α, averaged over q^2, to be the above.

[5] BERGFELD 94 uses Λe^+ events.

[1] AAIJ 23Z uses an amplitude analysis of 400k $\Lambda_c \to pK^-\pi^+$ decays, the last uncertainty is due to the amplitude model. Sign determined per authors; see also AAIJ 23AJ.

α FOR $\Lambda_c^+ \to \Lambda(1690)\pi^+$

The polarization is defined with respect to the daughter baryon momentum in the parent rest frame. See "Baryon Decay Parameters" review.

$\Lambda_c(2595)^+$

$I(J^P) = 0(\frac{1}{2}^-)$ Status: ***

The $\Lambda_c^+\pi^+\pi^-$ mode is largely, and perhaps entirely, $\Sigma_c\pi$, which is just at threshold; since the Σ_c has $J^P = 1/2^+$, the J^P here is almost certainly $1/2^-$. This result is in accord with the theoretical expectation that this is the charm counterpart of the strange $\Lambda(1405)$.

$\Lambda_c(2595)^+$ MASS

The mass is obtained from the $\Lambda_c(2595)^+$–Λ_c^+ mass-difference measurements below.

305.79±0.14±0.20	3.5k	AALTONEN	11H	CDF	$p\overline{p}$ at 1.96 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
305.6 ±0.3		[1] BLECHMAN	03		Threshold shift
309.7 ±0.9 ±0.4	19	ALBRECHT	97	ARG	$e^+e^- \approx$ 10 GeV
309.2 ±0.7 ±0.3	14 ± 4.5	FRABETTI	96	E687	γBe, $\overline{E}_\gamma \approx$ 220 GeV
307.5 ±0.4 ±1.0	112 ± 17	EDWARDS	95	CLE2	$e^+e^- \approx$ 10.5 GeV

[1] BLECHMAN 03 finds that a more sophisticated treatment than a simple Breit-Wigner for the proximity of the threshold of the dominant decay, $\Sigma_c(2455)\pi$, lowers the $\Lambda_c(2595)^+ - \Lambda_c^+$ mass difference by 2 or 3 MeV. The analysis of AALTONEN 11H bears this out.

$\Lambda_c(2595)^+$ WIDTH

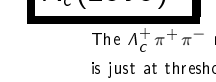
VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
2.59±0.30±0.47	3.5k	[1] AALTONEN	11H	CDF	$p\overline{p}$ at 1.96 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$2.9\ ^{+2.9}_{-2.1}\ ^{+1.8}_{-1.4}$	19	ALBRECHT	97	ARG	$e^+e^- \approx$ 10 GeV
$3.9\ ^{+1.4}_{-1.2}\ ^{+2.0}_{-1.0}$	112 ± 17	EDWARDS	95	CLE2	$e^+e^- \approx$ 10.5 GeV

[1] AALTONEN 11H treats the three charged modes $\Lambda_c(2595)^+ \to \Sigma_c(2455)^{++}\pi^-$, $\Sigma_c(2455)^+\pi^0$, $\Sigma_c(2455)^0\pi^+$ separately in terms of a common coupling constant h_2 and obtains $h_2^2 = 0.36 \pm 0.08$. From this the width is determined.

$\Lambda_c(2595)^+$ DECAY MODES

$\Lambda_c^+\pi\pi$ and its submode $\Sigma_c(2455)\pi$ — the latter just barely — are the only strong decays allowed for an excited Λ_c^+ having this mass; and the submode seems to dominate.

	Mode		Fraction (Γ_i/Γ)		Confidence level
Γ_1	$\Lambda_c^+\pi^+\pi^-$	[a]	(40±14)	%	
Γ_2	$\Sigma_c(2455)^{++}\pi^-$		(15± 6)	%	
Γ_3	$\Sigma_c(2455)^0\pi^+$		(15± 6)	%	
Γ_4	$\Lambda_c^+\pi^+\pi^-$ 3-body				
Γ_5	$\Lambda_c^+\pi^0\pi^0$	[a]	(60±14)	%	
Γ_6	$\Lambda_c^+\pi^0$	[b]	< 140	%	90%
Γ_7	$\Lambda_c^+\gamma$		< 40	%	90%



[a] See AALTONEN 11H, Fig. 8, for the calculated ratio of $\Lambda_c^+\pi^0\pi^0$ and $\Lambda_c^+\pi^+\pi^-$ partial widths as a function of the $\Lambda_c(2595)^+ - \Lambda_c^+$ mass difference. At our value of the mass difference, the predicted ratio is about 4. Using the measured value of $\Lambda_c^+\pi^0\pi^0$ branching fraction and assuming the $\Lambda_c\pi\pi$ branching fractions sum to unity, we derive the $\Lambda_c\pi^+\pi^-$ branching fraction. The derived ratio of the $\Lambda_c\pi^0\pi^0$ to $\Lambda_c\pi^+\pi^-$ partial widths is correspondingly 1.5 ± 0.2.

[b] A test that the isospin is indeed 0, so that the particle is indeed a Λ_c^+.

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 1 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 0.0$ for 0 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\Lambda_c(2940)^+$

$I(J^P) = 0(\frac{3}{2}^-)$ Status: ***

A narrow peak seen in pD^0 and in $\Lambda_c^+\pi^+\pi^-$. It is not seen in pD^+, and therefore it is a Λ_c^+ and not a Σ_c. $J^P = 3/2^-$ is favored, but not certain.

$\Sigma_c(2455)$

$I(J^P) = 1(\frac{1}{2}^+)$ Status: ****

The angular distribution of $B^- \to \Sigma_c(2455)^0\overline{p}$ favors $J = 1/2$ (as the quark model predicts). $J = 3/2$ is excluded by more than four standard deviations; see AUBERT 08BN.

$\Sigma_c(2800)$

$I(J^P) = 1(?^?)$ Status: ***

Seen in the $\Lambda_c^+\pi^+$, $\Lambda_c^+\pi^0$, and $\Lambda_c^+\pi^-$ mass spectra.

$\Sigma_c(2800)$ MASSES

The charged ++ and + masses are obtained from the mass-difference measurements that follow. The neutral mass is dominated by the mass-difference measurement, but is pulled up somewhat by the less well-determined but considerably higher direct-mass measurement. It is possible, in fact, that AUBERT 08BN is seeing a different Σ_c.

2460 ±25	82	BIAGI	83	SPEC	Σ^-Be 135 GeV

[1] AAIJ 14Z systematic error includes in quadrature the 0.14 MeV uncertainty from the m(Λ_c^+) mass value.

[2] The systematic error was (wrongly) given the other way round in LESIAK 05; see the erratum.

[3] Although COTEUS 87 claims to agree well with BIAGI 83 on the mass and width, there appears to be a discrepancy between the two experiments. BIAGI 83 sees a single peak (stated significance about 6 standard deviations) in the $\Lambda K^-\pi^+\pi^+$ mass spectrum. COTEUS 87 sees *two* peaks in the same spectrum, one at the Ξ_c^+ mass, the other 75 MeV lower. The latter is attributed to $\Xi_c^+ \to \Sigma^0 K^-\pi^+\pi^+ \to (\Lambda\gamma)K^-\pi^+\pi^+$, with the γ unseen. The *combined* significance of the double peak is stated to be 5.5 standard deviations. But the absence of any trace of a lower peak in BIAGI 83 seems to us to throw into question the interpretation of the lower peak of COTEUS 87.

[1] AAIJ 19AG reports [Ξ_c^+ MEAN LIFE] / [$D^\pm$ MEAN LIFE] = 0.4392 ± 0.0034 ± 0.0028 which we multiply by our best (shown rounded) value $D^\pm$ MEAN LIFE = (1.033 ± 0.005) × 10^{-12} s. Our first error is their experiment's error and our second error is the systematic error from using our best (shown rounded) value.

Ξ_c^+ DECAY MODES

Branching fractions marked with a footnote, e.g. [a], have been corrected for decay modes not observed in the experiments. For example, the submode fraction $\Xi_c^+ \to \Sigma^+\overline{K}^*(892)^0$ seen in $\Xi_c^+ \to \Sigma^+K^-\pi^+$ has been multiplied up to include $\overline{K}^*(892)^0 \to \overline{K}^0\pi^0$ decays.

[1] Uses $B^- \to D^0\pi^-$, $D^0 \to K^-K^+\pi^-\pi^+$ as a normalization mode to minimize the uncertainties associated with the decay time acceptance. The third uncertainty is due to the uncertainty of the D^0 lifetime, which is taken to be 410.3 ± 1.0 fs.
[2] Measured in Ξ_c^0 produced promptly in pp collisions, using $D^0 \to K^+K^-\pi^+\pi^-$ as normalisation mode. AAIJ 22Y reports this lifetime value as $(148.0 \pm 2.3 \pm 2.2 \pm 0.2) \times 10^{-15}$ s where the last uncertainty is due to the uncertainty on the D^0 lifetime value from PDG 20 average, $\tau_{D^0} = (410.1 \pm 1.5)$ fs.
[3] AAIJ 19AG reports [Ξ_c^0 MEAN LIFE] / [$D^\pm$ MEAN LIFE] = 0.1485 ± 0.0017 ± 0.0016 which we multiply by our best (shown rounded) value $D^\pm$ MEAN LIFE = (1.033 ± 0.005) × 10^{-12} s. Our first error is their experiment's error and our second error is the systematic error from using our best (shown rounded) value.
[4] Measured in Ξ_c^0 produced in semileptonic Ξ_b^- decays.

FIT INFORMATION

An overall fit to 7 branching ratios uses 8 measurements to determine 4 parameters. The overall fit has a $\chi^2 = 1.4$ for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$.

5.5±1.1 OUR FIT					
5.5±0.2±1.8	6.3k	[1] AAIJ	20AH	LHCB	pp at 13 TeV

[1] AAIJ 20AH extracts $B(\Xi_c^0 \to \Lambda_c^+ \pi^-)$ using two different normalization modes: $\Lambda_c^+ \to p K^- \pi^+$ and $\Xi_c^+ \to p K^- \pi^+$. The mean value of both results, taking their correlations into account, is presented as the final result. The measurement assumes production fraction ratios $f_{\Xi_c^0}/f_{\Lambda_c^+} = (9.7 \pm 0.9 \pm 3.1) \times 10^{-2}$ (from AAIJ 19AB plus heavy quark symmetry arguments) as well as $f_{\Xi_c^0}/f_{\Xi_c^+} = 1.00 \pm 0.01$. It further uses the inputs $B(\Lambda_c^+ \to p K^- \pi^+) = (6.23 \pm 0.33) \times 10^{-2}$ and $B(\Xi_c^+ \to p K^- \pi^+) = (4.5 \pm 2.1 \pm 0.7) \times 10^{-3}$ (from LI 19C). Its correlation with $B(\Xi_c^+ \to p K^- \pi^+)$, as measured in AAIJ 20AH, is 0.414.

$1.67\pm0.29^{+0.15}_{-0.09}\pm0.25$	778	[1] MOON	21	BELL	e^+e^- at Υ(nS)

[1] Measurement of the ratio of $\Xi_c(2970)^+ \to \Xi_c(2645)^0\pi^+$ versus $\Xi_c(2970)^+ \to \Xi_c'^0\pi^+$. The last uncertainty is from possible isospin-symmetry-breaking effects. MOON 21 determines from an angular analysis of the $\Xi_c^+\pi^+\pi^-$ final state that the spin of the $\Xi_c(2970)^+$ is strongly compatible with $J = 1/2$, assuming domination by the lowest partial wave in $\Xi_c(2970)^+ \to \Xi_c(2645)^0\pi^+$. When further combined with the size of this ratio, MOON 21 determines from heavy quark symmetry that the spin-parity of the $\Xi_c(2970)^+$ is favored to be $J^P = 1/2^+$, with light degrees of freedom in the 0^+ state.

86 $^{+27}_{-20}$ ±28	25	FRABETTI	95D	E687	$\Sigma^+ K^- K^- \pi^+$

[1] Uses $B^- \to D^0 \pi^-$, $D^0 \to K^- K^+ \pi^- \pi^+$ as a normalization mode to minimize the uncertainties associated with the decay time acceptance. The third uncertainty is due to the uncertainty of the D^0 lifetime, which is taken to be 410.3 ± 1.0 fs.
[2] Recent measurements by AAIJ 18J, AAIJ 22Y, and ABUDINEN 23 obtain consistent results that are nearly four times larger than the average result of previous experiments, $(69 \pm 12) \times 10^{-15}$ s. We go with the more recent results, mostly obtained with much larger data samples, and also note the positive correlation between the measured value and the inverse of the estimated statistical uncertainty in lifetime measurements.
[3] AAIJ 22Y reports this measurement as $(276.5 \pm 13.4 \pm 4.4 \pm 0.7) \times 10^{-15}$ s. The last uncertainty is due to the uncertainty on the D^0 lifetime $\tau_{D^0} = (410.1 \pm 1.5)$ fs from PDG 20. Measured in Ω_c produced promptly in pp collisions, using $D^0 \to K^+ K^- \pi^+ \pi^-$ as normalisation mode.
[4] Measured using Ω_c produced in semileptonic Ω_b decays.

Ω_c^0 DECAY MODES

No absolute branching fractions have been measured. The following are branching *ratios* relative to $\Omega^- \pi^+$.

	Mode	Fraction (Γ_i/Γ)	Confidence level
	Cabibbo-favored ($S = -3$) decays — relative to $\Omega^- \pi^+$		
Γ_1	$\Omega^- \pi^+$	**DEFINED AS 1**	
Γ_2	$\Omega^- \pi^+ \pi^0$	1.80 ±0.33	
Γ_3	$\Omega^- \rho^+$	>1.3	90%
Γ_4	$\Omega^- \pi^- 2\pi^+$	0.31 ±0.05	
Γ_5	$\Omega^- e^+ \nu_e$	1.98 ±0.29	
Γ_6	$\Omega^- \mu^+ \nu_\mu$	1.94 ±0.21

DOUBLY CHARMED BARYONS ($C = +2$)

$\Xi_{cc}^{++} = ucc$, $\Xi_{cc}^{+} = dcc$, $\Omega_{cc}^{+} = scc$

Ξ_{cc}^{+}

$I(J^P) = ?(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

Nominally the isospin partner of the Ξ_{cc}^{++} (ccu). While the SELEX experiment (MATTSON 02, OCHERASHVILI 05) claimed an observation of this state, subsequent searches by BABAR (AUBERT,B 06D), Belle (CHISTOV 06, KATO 14), and LHCb (AAIJ 13CD, AAIJ 20AX) did not find any significant signal or evidence for the Ξ_{cc}^{+}. However, AAIJ 21AE reports that its search for $\Xi_{cc}^{+} \to \Xi_c^{+}\pi^+\pi^-$, when combined with a prior search for $\Xi_{cc}^{+} \to \Lambda_c^{+}K^-\pi^+$ decays in AAIJ 20AX, yields a signal at 2.9 σ global significance (4.0 σ local).

Ξ_{cc}^{+} MASS

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
3518.9±0.9 OUR AVERAGE					
3518 ±3	6	[1] OCHERASHVI..05		SELX	Σ^- nucleus ≈ 600 GeV
3519 ±1	16	[2] MATTSON	02	SELX	Σ^- nucleus ≈ 600 GeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
3623.0±1.4	368 ± 193	[3] AAIJ	21AE	LHCB	pp at 7, 8, 13 TeV

[1] OCHERASHVILI 05 claims "an excess of 5.62 events over ... 1.38 ± 0.13 events" for a significance of 4.8 σ in pD^+K^- events.
[2] MATTSON 02 claims "an excess of 15.9 events over an expected background of 6.1 ± 0.5 events, a statistical significance of 6.3 σ" in the $\Lambda_c^+K^-\pi^+$ invariant-mass spectrum. The probability that the peak is a fluctuation increases from 1.0×10^{-6} to 1.1×10^{-4} when the number of bins searched is considered.
[3] Uncertainties are statistical only. Because of undetermined systematic uncertainties in the extraction of this result it cannot be considered a mass measurement. AAIJ 21AE performs a combined fit to its $\Xi_{cc}^{+} \to \Xi_c^{+}\pi^+\pi^-$ data and the $\Xi_{cc}^{+} \to \Lambda_c^{+}K^-\pi^+$ data from AAIJ 20AX, finding a global significance of 2.9 σ (4.0 σ local).

BOTTOM BARYONS
($B = -1$)

$\Lambda_b^0 = udb$, $\Sigma_b^0 = udb$, $\Sigma_b^+ = uub$, $\Sigma_b^- = ddb$
$\Xi_b^0 = usb$, $\Xi_b^- = dsb$, $\Omega_b^- = ssb$

Λ_b^0

$I(J^P) = 0(\frac{1}{2}^+)$ Status: ***

In the quark model, a Λ_b^0 is an isospin-0 udb state. The lowest Λ_b^0 ought to have $J^P = 1/2^+$. None of I, J, or P have actually been measured.

Λ_b^0 MASS

$m_{\Lambda_b^0}$

[1] Uses $\Lambda_b^0 \to \Lambda_c^+ D_s^-$ decays.
[2] Uses $\Lambda_b^0 \to \chi_{c1} p K^-$, $\Lambda_b^0 \to \chi_{c2} p K^-$, $\Lambda_b^0 \to J/\psi\Lambda$, $\Lambda_b^0 \to p\psi(2S) K^-$, $\Lambda_b^0 \to pJ/\psi\pi^+\pi^- K^-$, and $\Lambda_b^0 \to pJ/\psi K^-$ decays.
[3] Uses exclusively reconstructed final states $\Lambda_b^0 \to \Lambda_c^+ D_s^-$, $\Lambda_c^+ D^-$ and $\overline{B}^0 \to D^+ D_s^-$ decays. The uncertainty includes both statistical and systematic contributions.
[4] Uses $\Lambda_b^0 \to J/\psi\Lambda$ fully reconstructed decays.
[5] ABE 97B observed 38 events with a background of 18 ± 1.6 events in the mass range 5.60–5.65 GeV/c^2, a significance of > 3.4 standard deviations.
[6] Uses 4 fully reconstructed Λ_b events.
[7] Uses $\Lambda_b^0 \to p\psi(2S) K^-$, $\Lambda_b^0 \to pJ/\psi\pi^+\pi^- K^-$, and $\Lambda_b^0 \to pJ/\psi K^-$ decays.
[8] Uses exclusively reconstructed final states containing a $J/\psi \to \mu^+\mu^-$ decays.
[9] ABE 93B states that, based on the signal claimed by ALBAJAR 91E, CDF should have found 30 ± 23 $\Lambda_b^0 \to J/\psi(1S)\Lambda$ events. Instead, CDF found not more than 2 events.
[10] ALBAJAR 91E claims 16 ± 5 events above a background of 9 ± 1 events, a significance of about 5 standard deviations.

[1] Measured using $\Lambda_b^0 \to J/\psi\Lambda$ and $B^0 \to J/\psi K^*(892)^0$ decays.
[2] Used $\Lambda_b^0 \to J/\psi p K^-$ and $B^0 \to J/\psi K^*(892)^0$ decays.
[3] Measured with $\Lambda_b^0 \to J/\psi(\mu^+\mu^-)\,\Lambda^0(p\pi^-)$ decays.
[4] Uses fully reconstructed $\Lambda_b \to J/\psi\Lambda$ decays.
[5] Uses $B^0 \to J/\psi K_S^0$ decays for denominator.
[6] Measures $1/\tau_{\Lambda_b^0} - 1/\tau_{B^0}$ and uses $\tau_{B^0} = 1.519 \pm 0.007$ ps to extract lifetime ratio.
[7] Measured mean life ratio using fully reconstructed decays.

Λ_b^0 DECAY MODES

The branching fractions B(b-baryon $\to \Lambda\ell^-\overline{\nu}_\ell$anything) and B($\Lambda_b^0 \to \Lambda_c^+\ell^-\overline{\nu}_\ell$anything) are not pure measurements because the underlying measured products of these with B($b \to b$-baryon) were used to determine B($b \to b$-baryon), as described in the note "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, *e.g.*, $\Lambda_b \to \overline{\Lambda}_c$anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

FIT INFORMATION

An overall fit to 14 branching ratios uses 18 measurements to determine 9 parameters. The overall fit has a $\chi^2 = 11.7$ for 9 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$.

The values and averages in this section serve only to show what values result if one assumes our $\mathrm{B}(b \to b\text{-baryon})$. They cannot be thought of as measurements since the underlying product branching fractions were also used to determine $\mathrm{B}(b \to b\text{-baryon})$ as described in the note on "Production and Decay of b-Flavored Hadrons."

2.56±0.10±0.15	[1] AAIJ	23K	LHCB	pp at 13 TeV

[1] AAIJ 23K reports this measurement as $(2.56 \pm 0.10 \pm 0.05 \pm 0.14)\times10^{-3}$ where the last uncertainty is due to the branching fractions $B(D_s^- \to K^-K^+\pi^-)$ and $B(\Lambda_c^+ \to pK^-\pi^+)$ uncertainties.

$\Gamma(p\mu^-\overline{\nu}_\mu)/\Gamma_{\text{total}}$ Γ_{69}/Γ

VALUE (units 10^{-4})	DOCUMENT ID		TECN	COMMENT
4.1±1.0	[1] AAIJ	15BG	LHCB	pp at 8 TeV

[1] The ratio of $B(\Lambda_b^0 \to p\mu^-\overline{\nu}_\mu)$ to $B(\Lambda_b^0 \to \Lambda_c^+\mu^-\overline{\nu}_\mu)$ is measured within a restricted q^2 region. Combined with theoretical calculations of the form factors and the previously measured value of $|V_{cb}|$, the first $|V_{ub}| = (3.27 \pm 0.15 \pm 0.16 \pm 0.06)\times10^{-3}$ measurement from the Λ_b decay is obtained, consistent with the exclusively measured world averages.

CP VIOLATION

A_{CP} is defined as

$$A_{CP} = \frac{B(\Lambda_b^0 \to f) - B(\overline{\Lambda}_b^0 \to \overline{f})}{B(\Lambda_b^0 \to f) + B(\overline{\Lambda}_b^0 \to \overline{f})},$$

the *CP*-violation asymmetry of exclusive Λ_b^0 and $\overline{\Lambda}_b^0$ decay.

CP AND *T* VIOLATION PARAMETERS

Measured values of the triple-product asymmetry parameters, odd under time-reversal, are defined as $A_{c(s)}(\Lambda/\phi) = (N^+_{c(s)} - N^-_{c(s)})$ / (sum) where $N^+_{c(s)}$, $N^-_{c(s)}$ are the number of Λ or ϕ candidates for which the $\cos(\Phi)$ and $\sin(\Phi)$ observables are positive and negative, respectively. Angles $\cos(\Phi)$ and $\sin(\Phi)$ are defined as in LEITNER 07.

[1] Extracted using a Bayesian analysis. The most probable value is given as −0.022, with a 68% credibility interval [-0.048, 0.005]. Transverse polarizations of Λ_b^0 of −0.004 (68% credibility interval [-0.064, 0.051]), 0.001 (68% credibility interval [-0.035, 0.045]), and 0.032 (68% credibility interval [-0.011, 0.065]) are also reported at 7 TeV, 8 TeV and 13 TeV, respectively. Note that both statistical and systematic uncertainties are included.
[2] An angular analysis of $\Lambda_b \to J/\psi\Lambda$ decay is performed. Note that the sign of α in CMS definition is the opposite to that used by AAIJ 13AG and AAD 14L. Λ_b transverse production polarization of $0.00 \pm 0.06 \pm 0.06$ is also reported, as well as squares of the helicity amplitudes.
[3] An angular analysis of $\Lambda_b \to J/\psi\Lambda$ decay is performed and magnitudes of all helicity amplitudes are also reported.
[4] An angular analysis of $\Lambda_b \to J/\psi\Lambda$ decay is performed and a Λ_b transverse production polarization of $0.06 \pm 0.07 \pm 0.02$ is also reported.

Σ_b $I(J^P) = 1(\frac{1}{2}^+)$ Status: ***

I, *J*, *P* need confirmation.

In the quark model Σ_b^+, Σ_b^0, Σ_b^- are an isotriplet (*uub*, *udb*, *ddb*) state. The lowest Σ_b ought to have $J^P = 1/2^+$. None of *I*, *J*, or *P* have actually been measured.

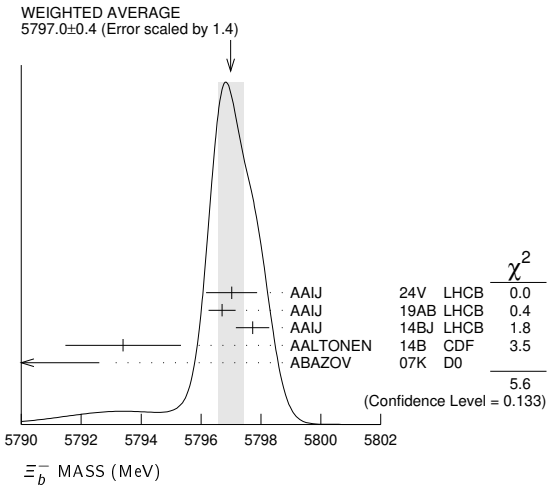
Ξ_b^-

Ξ_b^- $I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

I, *J*, *P* need confirmation.



In the quark model, Ξ_b^0 and Ξ_b^- are an isodoublet (*usb*, *dsb*) state; the lowest Ξ_b^0 and Ξ_b^- ought to have $J^P = 1/2^+$. None of *I*, *J*, or *P* have actually been measured.

Ξ_b^- MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFLAV) and are described at https://hflav.web.cern.ch/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

Ξ_b^0

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

I, *J*, *P* need confirmation.

In the quark model, Ξ_b^0 and Ξ_b^- are an isodoublet (*usb*, *dsb*) state; the lowest Ξ_b^0 and Ξ_b^- ought to have $J^P = 1/2^+$. None of *I*, *J*, or *P* have actually been measured.

Ξ_b^0 MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFLAV) and are described at https://hflav.web.cern.ch/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

$<1.4 \times 10^{-5}$	95	[1,2] AAIJ	20AM	LHCB	pp at 13 TeV

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[1] AAIJ 20AM reports upper limits for $[\Gamma(\Xi_{bc}^0 \to D^0 p K^- \times B(b \to \Xi_{bc}^0)/B(b \to \Lambda_b))/\Gamma_{total}] / [B(\Lambda_b^0 \to p D^0 K^-)] < 3.0 \times 10^{-1}$–$1.7 \times 10^{-2}$ for the considered Ξ_{bc}^0 mass and lifetime hypotheses ranging from 6.7 to 7.2 GeV and from 100 to 500 fs. We use the 3.0×10^{-1} limit for the quoted result.

[2] AAIJ 20AM reports $[\Gamma(\Xi_{bc}^0 \to D^0 p K^- \times B(b \to \Xi_{bc}^0)/B(b \to \Lambda_b))/\Gamma_{total}] / [B(\Lambda_b^0 \to p D^0 K^-)] < 3.0 \times 10^{-1}$ which we multiply by our best (shown rounded) value $B(\Lambda_b^0 \to p D^0 K^-) = 4.6 \times 10^{-5}$.

[1] Combines measurement using $\Omega_b^- \to J/\psi\Omega^-$ decays with results from AAIJ 16O and AAIJ 21AC taking into account correlations amongst systematic uncertainties. Uses Ξ_b^- mass 5797.33 ± 0.24 ± 029 MeV from AAIJ 21.

[2] Uses $\Omega_b^- \to J/\psi\Omega^-$ and $\Omega_c^0\pi^-$ decays, with the first evidence for $\Omega_b^- \to \Omega_c^0\pi^-$ at 3.3 σ significance.

[3] Uses $\Omega_b^- \to J/\psi\Omega^-$ decays.

[4] Uses $\Omega_b^- \to \Xi_c^+ K^-\pi^-$ and $\Xi_c^+ \to p K^-\pi^+$ decays. Reports the value of 6044.3 ± 1.2 ± $1.1^{+0.19}_{-0.22}$ MeV where the last uncertainty is due to the mass of Ξ_c^+. We have combined the two systematic uncertainties in quadrature.

[5] Reconstructed in $\Omega_b^- \to \Omega_c^0\pi^-$, $\Omega_c^0 \to p K^- K^-\pi^+$ decays. Reference Ξ_b^- mass 5797.72 ± 0.6 MeV from AAIJ 14B.

[6] Measured in $\Omega_b^- \to J/\psi\Omega^-$ with 19 ± 5 events.

[7] Observed in $\Omega_b^- \to J/\psi\Omega^-$ decays with 16^{+6}_{-4} candidates, a significance of 5.5 sigma from a combined mass-lifetime fit.

[8] Observed in $\Omega_b^- \to J/\psi\Omega^-$ decays with 17.8 ± 4.9 ± 0.8 candidates, a significance of 5.4 sigma.

b-baryon ADMIXTURE (Λ_b, Ξ_b, Ω_b)

b-baryon ADMIXTURE MEAN LIFE

Each measurement of the b-baryon mean life is an average over an admixture of various b baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different b-baryon mean life. More b-baryon flavor specific channels are not included in the measurement.

b-baryon ADMIXTURE DECAY MODES (Λ_b,Ξ_b,Ω_b)

These branching fractions are actually an average over weakly decaying b-baryons weighted by their production rates at the LHC, LEP, and Tevatron, branching ratios, and detection efficiencies. They scale with the b-baryon production fraction $B(b\to$ b-baryon$)$.

The branching fractions $B(b$-baryon $\to \Lambda\ell^-\overline{\nu}_\ell$anything$)$ and $B(\Lambda_b^0\to \Lambda_c^+\ell^-\overline{\nu}_\ell$anything$)$ are not pure measurements because the underlying measured products of these with $B(b\to b$-baryon$)$ were used to determine $B(b\to b$-baryon$)$, as described in the note "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, *e.g.*, $B\to D^\pm$anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

	Mode	Fraction (Γ_i/Γ)	Scale factor
Γ_1	$p\mu^-\overline{\nu}$anything	$(\ 5.8^{+\ 2.3}_{-\ 2.0})$ %	
Γ_2	$p\ell\overline{\nu}_\ell$anything	$(\ 5.6\pm\ 1.2)$ %	
Γ_3	$p$anything	$(70\ \pm22\ )$ %	
Γ_4	$\Lambda\ell^-\overline{\nu}_\ell$anything	$(\ 3.8\pm\ 0.6)$ %	
Γ_5	$\Lambda\ell^+\nu_\ell$anything	$(\ 3.2\pm\ 0.8)$ %	
Γ_6	Λanything	$(39\ \pm\ 7\ )$ %	
Γ_7	$\Xi^-\ell^-\overline{\nu}_\ell$anything	$(\ 4.6\pm\ 1.4)\times10^{-3}$	1.2

$P_{c\overline{c}}(4380)^+$

$I(J^P) = \frac{1}{2}(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

Was $P_c(4380)^+$.

A resonance seen in $\Lambda_b^0 \to P_c^+ K^-$, then $P_c \to J/\psi p$, with a significance of 9 standard deviations. The $J/\psi p$ quark content is $uudc\overline{c}$, a pentaquark. See also the $P_c(4450)^+$. In the best amplitude fit, the two states have opposite parity, one having $J = 3/2$, the other $J = 5/2$.

Extraction of the pentaquark signals requires some understanding of the dominant $K^- p$ background. AAIJ 15P used a model-dependent approach. AAIJ 16AG reanalyzed the data making minimal assumptions about the $K^- p$ background, and thus confirmed the strong significance of the pentaquark signals.

[1] AAD 25B searches are made for monopoles produced in ultra-peripheral PbPb collisions. Model-dependent mass exclusions between 20–150 GeV are made. Limit given at the mass of 60 GeV.

[2] ACHARYA 25 present cross section and mass limits presented for a suite of searches covering charges between 1 and 10 Dirac charges and interpreted within various model scenarios.

[3] ACHARYA 24 search for monopoles produced by the Schwinger mechanism. Results are model dependent.

[4] AAD 23CO limits given for monopoles pair produced via a Drell-Yan or photon-fusion mechanism. Spins 1/2 and 0 are considered. The quoted limit is representative of the lowest values that were achieved.

[5] ACHARYA 22A give limits for monopoles pair-produced via a Drell-Yan production. Spins 0, 1/2, and 1 are considered. The cross section limit is representative of the lowest values that were achieved. The experiment used a combination of nuclear track detectors to look evidence of passing monopoles and a SQUID magnetometer to look for stopped monopoles.

[6] ACHARYA 22B achieved limits on monopole (point-like included) production via the Schwinger mechanism in Pb-Pb collisions at 5.02 TeV centre-of-mass energy per nucleon pair. The upper cross section limit value quoted here is representative of the lowest values achieved.

[7] ACHARYA 21 search for dyons at LHC. Using a production model limits (we report the lowest) are set for dyons with magnetic charge up to 5 gD, electric charges up to 200 e and spins 0, 1/2, 1. The corresponding mass limits for magnetic monopoles are in the range 870–2040 GeV for magnetic charges in the same range.

[8] AAD 20G give limits for Drell-Yan production with spin-0 and spin-1/2 monopoles. The above limit is for spin = 0 at mass = 3 TeV.

[9] ACHARYA 19B limits both β-dependent and β-independent on monopoles with spins 0, 1/2, and 1 and with magnetic charges ranging from one to five times the Dirac charge in mass ranges between 200 GeV and 5000 GeV.

[10] ACHARYA 18A provide limits on monopoles with spins 0, 1/2, and 1 and with magnetic charges ranging from two to five times the Dirac charge.

[11] The search was sensitive to monopoles which had stopped in aluminium trapping volumes. Monopoles with spins 0 and 1/2 were considered; mass-dependent spin 1/2 monopole limits are quoted here.

[12] AAD 16AB model-independent 95% CL limits estimated using a fiducial region of approximately constant acceptance. Limits are mass-dependent.

[13] ACHARYA 16 limits at 95% CL estimated using a Drell-Yan-like production mechanism for scalar monopoles.

[14] AAD 12CS searched for monopoles as highly ionising objects. The cross section limits are based on an assumed Drell Yan-like production process for spin 1/2 monopoles. The limits are mass- and scenario-dependent.

[15] ABBIENDI 08 assume production of spin 1/2 monopoles with effective charge $g\beta$ (n=1), via $e^+e^- \to \gamma^* \to M\overline{M}$, so that the cross section is proportional to $(1 + \cos^2\theta)$. There is no z information for such highly saturated tracks, so a parabolic track in the jet chamber is projected onto the xy plane. Charge per hit in the chamber produces a clean separation of signal and background.

[16] ABULENCIA 06K searches for high-ionizing signals in CDF central outer tracker and time-of-flight detector. For Drell-Yan $M\overline{M}$ production, the cross section limit implies $M > 360$ GeV at 95% CL.

[17] AKTAS 05A model-dependent limits as a function of monopole mass shown for arbitrary mass of 60 GeV. Based on search for stopped monopoles in the H1 Al beam pipe.

[18] AKTAS 05A limits with assumed elastic spin 0 monopole pair production.

[19] AKTAS 05A limits with assumed inelastic spin 1/2 monopole pair production.

[20] KALBFLEISCH 04 reports searches for stopped magnetic monopoles in Be, Al, and Pb samples obtained from discarded material from the upgrading of DØ and CDF. A large-aperture warm-bore cryogenic detector was used. The approach was an extension of the methods of KALBFLEISCH 00. Cross section results moderately model dependent; interpretation as a mass lower limit depends on possibly invalid perturbation expansion.

[21] KALBFLEISCH 00 used an induction method to search for stopped monopoles in pieces of the DØ (FNAL) beryllium beam pipe and in extensions to the drift chamber aluminum support cylinder. Results are model dependent.

[22] KALBFLEISCH 00 result is for aluminum.

[23] KALBFLEISCH 00 result is for beryllium.

[24] HE 97 used a lead target and barium phosphate glass detectors. Cross-section limits are well below those predicted via the Drell-Yan mechanism.

[25] This work has also been reinterpreted in the framework of monopole production via the thermal Schwinger process (GOULD 17); this gives rise to lower mass limits.

[26] Multiphoton events.

[27] Cherenkov radiation polarization.

[28] Re-examines CERN neutrino experiments.

[1] ABBOTT 98K search for heavy pointlike Dirac monopoles via central production of a pair of photons with high transverse energies.

[2] ACCIARRI 95C finds a limit $B(Z \to \gamma\gamma\gamma) < 0.8 \times 10^{-5}$ (which is possible via a monopole loop) at 95% CL and sets the mass limit via a cross section model.

[1] ABBASI 22 search was based on Cherenkov light detection in an array of optical modules in the Antarctic ice cap. Limits are speed-dependent.

[2] ALBERT 22C search for magnetic monopoles using data taken with the ANTARES neutrino telescope over a period of 10 years. No signal observed. Velocity dependent upper limits set on the flux of magnetic monopoles.

[3] ACERO 21 employ NOvA experiment to set reported 90% CL upper limit on the cosmic monopoles flux for velocity $6 \times 10^{-4} < \beta < 5 \times 10^{-3}$ and mass $> 5 \times 10^{8}$ GeV.

[4] GAPONENKO 21 use data of NT200 two-year operation at Baikal to give speed-dependent limits for different assumed catalysis cross sections. Reported limit is for $\sigma = 10$ mb.

[5] ALBERT 17 limits were estimated using a Cherenkov light in an array of optical modules under the Mediterranean Sea. The limits are for MM masses between 10^{10} and 10^{14} GeV. The limits are speed-dependent.

[6] AAB 16 search was made with a set of telescopes sampling the longitudinal profile of fluorescence light emitted by extensive air showers. Limits are speed dependent.

[7] AARTSEN 16B was based on a Cherenkov signature in an array of optical modules which were sunk in the Antarctic ice cap. Limits are speed-dependent.

[8] Beyond the monopole speed, the limits of AARTSEN 14 depend on the catalysis cross section (σ) which corresponds to the monopole radiating $\hat{l}$ times the light per track length compared to the Cherenkov light from a single electrically charged, relativistic particle. The values quoted here correspond to $\sigma = 1$ barn or $\hat{l} = 30$.

[9] ABBASI 13 and ABBASI 10A were based on a Cherenkov signature in an array of optical modules which were sunk in the Antarctic ice cap. Limits are speed-dependent.

[10] ADRIAN-MARTINEZ 12A measurements were based on a Cherenkov signature in an underwater telescope in the Western Mediterranean Sea. Limits are speed-dependent.

[11] The limits from UENO 12 depend on the monopole speed and are also sensitive to assumed values of monopole mass and the catalysis cross section.

[12] HOGAN 08 and DETRIXHE 11 limits on relativistic monopoles are based on nonobservation of radio Cherenkov signals at the South Pole. Limits are speed-dependent.

[13] BALESTRA 08 exposed of nuclear track detector modules totaling 400 m^2 for 4 years at the Chacaltaya Laboratory (5230 m) in search for intermediate-mass monopoles with $\beta >$ 0.05. The analysis is mainly based on three CR39 modules. For $M > 5 \times 10^{13}$ GeV there can be upward-going monopoles as well, hence the flux limit is half that obtained for less massive monopoles. Previous experiments (e.g. MACRO and OHYA (ORITO 91)) had set limits only for $M > 1 \times 10^{9}$ GeV.

[14] AMBROSIO 02B direct search final result for $m \geq 10^{17}$ GeV, based upon 4.2 to 9.5 years of running, depending upon the subsystem. Limit with CR39 track-etch detector extends the limit from β=4 $\times 10^{-5}$ (3.1×10^{-16} cm^{-2} sr^{-1} s^{-1}) to $\beta = 1 \times 10^{-4}$ (2.1×10^{-16} cm^{-2} sr^{-1} s^{-1}). Limit curve in paper is piecewise continuous due to different detection techniques for different β ranges.

[15] AMBROSIO 02C limit for catalysis of nucleon decay with catalysis cross section of $\approx$ 1 mb. The flux limit increases by $\sim$ 3 at the higher β limit, and increases to 1×10^{-14} cm^{-2} sr^{-1} s^{-1} if the catalysis cross section is 0.01 mb. Based upon 71193 hr of data with the streamer detector, with an acceptance of 4250 m^2 sr.

[16] AMBROSIO 02D result for "more than two years of data." Ionization search using several subsystems. Limit curve as a function of β not given. Included in AMBROSIO 02B.

[17] AMBROSIO 97 global MACRO 90%CL is 0.78×10^{-15} at β=1.1×10^{-4}, goes through a minimum at 0.61×10^{-15} near β=(1.1–2.7) $\times 10^{-3}$, then rises to 0.84×10^{-15} at β=0.1. The global limit in this region is below the Parker bound at 10^{-15}. Less stringent limits are established for $4 \times 10^{-5} < \beta < 1 \times 10^{-4}$. Limits set by various triggers and different subdetectors are given in the paper. All limits assume a catalysis cross section smaller than a few mb.

[18] AHLEN 94 limit for dyons extends down to β=0.9E−4 and a limit of 1.3E−14 extends to β = 0.8E−4. Also see comment by PRICE 94 and reply of BARISH 94. One loophole in the AHLEN 94 result is that in the case of monopoles catalyzing nucleon decay, relativistic particles could veto the events. See AMBROSIO 97 for additional results.

[19] Catalysis of nucleon decay; sensitive to assumed catalysis cross section.

[20] ORITO 91 limits are functions of velocity. Lowest limits are given here.

[21] Used DKMPR mechanism and Penning effect.

[22] Assumes monopole attaches fermion nucleus.

[23] Limit from combining data of CAPLIN 86, BERMON 85, INCANDELA 84, and CABRERA 83. For a discussion of controversy about CAPLIN 86 observed event, see GUY 87. Also see SCHOUTEN 87.

[24] Based on lack of high- energy solar neutrinos from catalysis in the sun.

[25] Anomalous long-range α (^{4}He) tracks.

[26] CABRERA 82 candidate event has single Dirac charge within ±5%.

[27] ALVAREZ 75, FLEISCHER 75, and FRIEDLANDER 75 explain as fragmenting nucleus. EBERHARD 75 and ROSS 76 discuss conflict with other experiments. HAGSTROM 77 reinterprets as antinucleus. PRICE 78 reassesses.

[1] KOBAYASHI 23A found Parker-type bounds on magnetic monopoles with arbitrary magnetic charge based on the survival of galactic, seed, and primordial magnetic fields.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

Bounds are between 3×10^{-21} and 10^{-5} $cm^{-2}sr^{-1}s^{-1}$ for masses $< 10^{18}$ GeV. Reported bound is the most stringent one.

[2] Catalysis of nucleon decay.

[3] ADAMS 93 limit based on "survival and growth of a small galactic seed field" is 10^{-16} $(m/10^{17}$ GeV) $cm^{-2}s^{-1}sr^{-1}$. Above 10^{17} GeV, limit 10^{-16} $(10^{17}$ GeV$/m)$ $cm^{-2}s^{-1}sr^{-1}$ (from requirement that monopole density does not overclose the universe) is more stringent.

[4] Re-evaluates PARKER 70 limit for GUT monopoles.

Supersymmetric Particle Searches

The exclusion of particle masses within a mass range (m_1, m_2) will be denoted with the notation "none m_1–m_2" in the VALUE column of the following Listings. The latest unpublished results are described in the "Supersymmetry: Experiment" review.

See the related review(s):

Supersymmetry, Part I (Theory)
Supersymmetry, Part II (Experiment)

CONTENTS:

$\widetilde{\chi}_1^0$ (Lightest Neutralino) mass limit
– Accelerator limits for stable $\widetilde{\chi}_1^0$
– Bounds on $\widetilde{\chi}_1^0$ from dark matter searches
– $\widetilde{\chi}_1^0$-p elastic cross section
Spin-dependent interactions
Spin-independent interactions
– Other bounds on $\widetilde{\chi}_1^0$ from astrophysics and cosmology
– Unstable $\widetilde{\chi}_1^0$ (Lightest Neutralino) mass limit
$\widetilde{\chi}_2^0$, $\widetilde{\chi}_3^0$, $\widetilde{\chi}_4^0$ (Neutralinos) mass limits
$\widetilde{\chi}_1^\pm$, $\widetilde{\chi}_2^\pm$ (Charginos) mass limits
Long-lived $\widetilde{\chi}^\pm$ (Chargino) mass limit
$\widetilde{\nu}$ (Sneutrino) mass limit
Charged sleptons
– R-parity conserving $\widetilde{e}$ (Selectron) mass limit
– R-partiy violating $\widetilde{e}$ (Selectron) mass limit
– R-parity conserving $\widetilde{\mu}$ (Smuon) mass limit
– R-parity violating $\widetilde{\mu}$ (Smuon) mass limit
– R-parity conserving $\widetilde{\tau}$ (Stau) mass limit
– R-parity violating $\widetilde{\tau}$ (Stau) mass limit
– Long-lived $\widetilde{\ell}$ (Slepton) mass limit
$\widetilde{q}$ (Squark) mass limit
– R-parity conserving $\widetilde{q}$ (Squark) mass limit
– R-parity violating $\widetilde{q}$ (Squark) mass limit
Long-lived $\widetilde{q}$ (Squark) mass limit
$\widetilde{b}$ (Sbottom) mass limit
– R-parity conserving $\widetilde{b}$ (Sbottom) mass limit
– R-parity violating $\widetilde{b}$ (Sbottom) mass limit
$\widetilde{t}$ (Stop) mass limit
– R-parity conserving $\widetilde{t}$ (Stop) mass limit
– R-parity violating $\widetilde{t}$ (Stop) mass limit
Heavy $\widetilde{g}$ (Gluino) mass limit
– R-parity conserving heavy $\widetilde{g}$ (Gluino) mass limit
– R-parity violating heavy $\widetilde{g}$ (Gluino) mass limit
Long-lived $\widetilde{g}$ (Gluino) mass limit
Light $\widetilde{G}$ (Gravitino) mass limits from collider experiments
Supersymmetry miscellaneous results

The results shown below, unless stated otherwise, are based on the Minimal Supersymmetric Standard Model (MSSM), as described in the Note on Supersymmetry. Unless otherwise indicated, this includes the assumption of common gaugino and scalar masses at the scale of Grand Unification (GUT), and use of the resulting relations in the spectrum and decay branching ratios. Unless otherwise indicated, it is also assumed that R-parity (R) is conserved and that:

1) The $\widetilde{\chi}_1^0$ is the lighest supersymmetric particle (LSP),
2) $m_{\widetilde{f}_L} = m_{\widetilde{f}_R}$, where $\widetilde{f}_{L,R}$ refer to the scalar partners of left- and right-handed fermions.

Limits involving different assumptions are identified in the Comments or in the Footnotes, in particular also the many simplified models, see definitions below. We summarize here the notations used in this Chapter to characterize some of the most common deviations from the MSSM (for further details, see the Note on Supersymmetry).

Theories with R-parity violation (RPV) are characterized by a superpotential of the form: $\lambda_{ijk} L_i L_j e_k^c + \lambda'_{ijk} L_i Q_j d_k^c + \lambda''_{ijk} u_i^c d_j^c d_k^c$, where i, j, k are generation indices. The presence of any of these couplings is often identified in the following by the symbols $LL\overline{E}$, $LQ\overline{D}$, and $\overline{UDD}$. Mass limits in the presence of RPV will often refer to "direct" and "indirect" decays. Direct refers to RPV decays of the particle in consideration. Indirect refers to cases where RPV appears in the decays of the LSP. The LSP need not be the $\widetilde{\chi}_1^0$.

In several models, most notably in theories with so-called Gauge Mediated Supersymmetry Breaking (GMSB), the gravitino ($\widetilde{G}$) is the LSP. It is usually much lighter than any other massive particle in the spectrum, and $m_{\widetilde{G}}$ is then neglected in all decay processes involving gravitinos. In these scenarios, particles other than the neutralino are sometimes considered as the next-to-lighest supersymmetric particle (NLSP), and are assumed to decay to their even-R partner plus $\widetilde{G}$. If the lifetime is short enough for the decay to take place within the detector, $\widetilde{G}$ is assumed to be undetected and to give rise to missing energy ($\not{E}$) or missing transverse energy ($\not{E}_T$) signatures.

When needed, specific assumptions on the eigenstate content of $\widetilde{\chi}^0$ and $\widetilde{\chi}^\pm$ states are indicated, using the notation $\widetilde{\gamma}$ (photino), $\widetilde{H}$ (higgsino), $\widetilde{W}$ (wino), and $\widetilde{Z}$ (zino) to signal that the limit of pure states was used. The term gaugino is also used, to generically indicate wino-like charginos and zino-like neutralinos.

In the listings we have made use of the following abbreviations for simplified models employed by the experimental collaborations in supersymmetry searches published in the past year.

WARNING: Experimental lower mass limits determined within simplified models are to be treated with extreme care as they might not be directly applicable to realistic models. This is outlined in detail in the publications and we recommend consulting them before using bounds. For example, branching ratios, typically fixed to specific values in simplified models, can vary substantially in more elaborate models.

Simplified Models Table

Tglu1A: gluino pair production with $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$.

Tglu1B: gluino pair production with $\tilde{g} \to qq'\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$.

Tglu1C: gluino pair production with a 2/3 probability of having a $\tilde{g} \to qq'\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$ decay and a 1/3 probability of having a $\tilde{g} \to qq\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \to Z^\pm\tilde{\chi}_1^0$ decay.

Tglu1D: gluino pair production with one gluino decaying to $q\bar{q}'\tilde{\chi}_1^\pm$ with $\tilde{\chi}_1^\pm \to W^\pm + \tilde{G}$, and the other gluino decaying to $q\bar{q}\tilde{\chi}_1^0$ with $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$.

Tglu1E: gluino pair production with $\tilde{g} \to qq'\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_2^0$ and $\tilde{\chi}_2^0 \to Z^\pm\tilde{\chi}_1^0$ where $m_{\tilde{\chi}_1^\pm} = (m_{\tilde{g}} + m_{\tilde{\chi}_1^0})/2$, $m_{\tilde{\chi}_2^0} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$.

Tglu1F: gluino pair production with $\tilde{g} \to qq'\tilde{\chi}_1^\pm$ or $\tilde{g} \to qq\tilde{\chi}_2^0$ with equal branching ratios, where $\tilde{\chi}_1^\pm$ decays through an intermediate scalar tau lepton or sneutrino to $\tau\nu\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate scalar tau lepton or sneutrino to $\tau^+\tau^-\tilde{\chi}_1^0$ or $\nu\bar{\nu}\tilde{\chi}_1^0$; the mass hierarchy is such that $m_{\chi_1^\pm} \sim m_{\tilde{\chi}_2^0} = (m_{\tilde{g}} + m_{\chi_1^0})/2$ and $m_{\tilde{\tau},\tilde{\nu}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$.

Tglu1G: gluino pair production with $\tilde{g} \to q\bar{q}\tilde{\chi}_2^0$, and $\tilde{\chi}_2^0$ decaying through an intermediate slepton or sneutrino to $l^+l^-\tilde{\chi}_1^0$ or $\nu\bar{\nu}\tilde{\chi}_1^0$ where $m_{\tilde{\chi}_2^0} = (m_{\tilde{g}} + m_{\tilde{\chi}_1^0})/2$ and $m_{\tilde{l},\tilde{\nu}} = (m_{\tilde{\chi}_2^0} + m_{\tilde{\chi}_1^0})/2$.

Tglu1H: gluino pair production with $\tilde{g} \to q\bar{q}\tilde{\chi}_2^0$, and $\tilde{\chi}_2^0 \to \tilde{\chi}_1^0 Z^{0(*)}$.

Tglu1I: gluino pair production with $\tilde{g} \to q\bar{q}\tilde{\chi}_2^0$, and $\tilde{\chi}_2^0 \to \tilde{\chi}_1^0 H$.

Tglu1J: gluino pair production with $\tilde{g} \to q\bar{q}\tilde{\chi}_2^0$, and $\mathrm{BR}(\tilde{\chi}_2^0 \to \tilde{\chi}_1^0 Z^{0(*)}) = \mathrm{BR}(\tilde{\chi}_2^0 \to \tilde{\chi}_1^0 H) = 0.5$.

Tglu1LL gluino pair production where $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$ happens with 1/3 probability and $\tilde{g} \to q\bar{q}\tilde{\chi}_1^\pm$ happens with 2/3 probability. The $\tilde{\chi}_1^\pm$ is assumed to be few hundreds of MeV heavier than the $\tilde{\chi}_1^0$, and decays to $\tilde{\chi}_1^0$ via a pion.

Tglu2A: gluino pair production with $\tilde{g} \to b\bar{b}\tilde{\chi}_1^0$.

Tglu3A: gluino pair production with $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$.

Tglu3B: gluino pair production with $\tilde{g} \to t\bar{t}$ where $\tilde{t}$ decays exclusively to $t\tilde{\chi}_1^0$.

Tglu3C: gluino pair production with $\tilde{g} \to t\bar{\tilde{t}}$ where $\tilde{t}$ decays exclusively to $c\tilde{\chi}_1^0$.

Tglu3D: gluino pair production with $\tilde{g} \to t\bar{b}\tilde{\chi}_1^\pm$ with $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$.

Tglu3E: gluino pair production where the gluino decays 25% of the time through $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$, 25% of the time through $\tilde{g} \to b\bar{b}\tilde{\chi}_1^0$ and 50% of the time through $\tilde{g} \to t\bar{b}\tilde{\chi}_1^\pm$ with $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$.

Tglu3F: gluino pair production with wino-like couplings to electroweakinos, that is: $\tilde{g} \to t\bar{t}\tilde{\chi}_{1,2}^0$ with BR 17%, $\tilde{g} \to b\bar{b}\tilde{\chi}_{1,2}^0$ with BR 17%, $\tilde{g} \to t\bar{t}\tilde{\chi}_1^\pm$ with BR 66%.

Tglu3G: gluino pair production with higgsino-like couplings to electroweakinos, that is: $\tilde{g} \to t\bar{t}\tilde{\chi}_{1,2}^0$ with BR 50%, $\tilde{g} \to t\bar{t}\tilde{\chi}_1^\pm$ with BR 50%.

Tglu4A: gluino pair production with one gluino decaying to $q\bar{q'}\tilde{\chi}_1^\pm$ with $\tilde{\chi}_1^\pm \to W^\pm + \tilde{G}$, and the other gluino decaying to $q\bar{q}\tilde{\chi}_1^0$ with $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$.

Tglu4B: gluino pair production with gluinos decaying to $q\bar{q}\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$.

Tglu4C: gluino pair production with gluinos decaying to $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \to Z + \tilde{G}$.

Tglu4D: gluino pair production with $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$ where the $\tilde{\chi}_1^0$ decays with equal probability to $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$ or to $\tilde{\chi}_1^0 \to H + \tilde{G}$.

Tglu4E: gluino pair production with $\tilde{g} \to b\bar{b}\tilde{\chi}_1^0$ where the $\tilde{\chi}_1^0$ decays with equal probability to $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$ or to $\tilde{\chi}_1^0 \to Z + \tilde{G}$.

Tglu4F: gluino pair production with $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$ where the $\tilde{\chi}_1^0$ decays with equal probability to $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$ or to $\tilde{\chi}_1^0 \to Z + \tilde{G}$.

Tglu4G: gluino pair production with $\tilde{g} \to qq\tilde{\chi}_1^0$ where the $\tilde{\chi}_1^0$ decays with equal probability to $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$ or to $\tilde{\chi}_1^0 \to Z + \tilde{G}$.

Tglu1RPV: gluino pair production with $\tilde{g} \to uds$ via RPV coupling λ''_{112}.

Tglu2RPV: gluino pair production with $\tilde{g} \to (tbd, tbs)$ via RPV coupling λ''_{313} or λ''_{323}.

Tsqk1: squark pair production with $\tilde{q} \to q\tilde{\chi}_1^0$.

Tsqk1LL squark pair production where $\tilde{q} \to q\tilde{\chi}_1^0$ and $\tilde{q} \to q\tilde{\chi}_1^\pm$ each happen with 50% probability. The $\tilde{\chi}_1^\pm$ is assumed to be few hundreds of MeV heavier than the $\tilde{\chi}_1^0$, and decays to $\tilde{\chi}_1^0$ via a pion.

Tsqk2: squark pair production with $\tilde{q} \to q\tilde{\chi}_2^0$ and $\tilde{\chi}_2^0 \to Z + \tilde{\chi}_1^0$.

Tsqk2A: squark pair production with $\tilde{q} \to q\tilde{\chi}_2^0$, where one of the $\tilde{\chi}_2^0 \to Z^{(*)}\tilde{\chi}_1^0 \to f\bar{f}\tilde{\chi}_1^0$ and the other $\tilde{\chi}_2^0 \to \tilde{\ell}\ell^+ \to \ell^+\ell^-\tilde{\chi}_1^0$.

Tsqk3: squark pair production with $\tilde{q} \to q'\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$ (like Tglu1B but for squarks)

Tsqk4: squark pair production with squarks decaying to $q\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$.

Tsqk4A: squark pair production with one squark decaying to $q\tilde{\chi}_1^\pm$ with $\tilde{\chi}_1^\pm \to W^\pm + \tilde{G}$, and the other squark decaying to $q\tilde{\chi}_1^0$ with $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$.

Tsqk4B: squark pair production with squarks decaying to $q\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$.

Tsqk5: squark pair production with four-fold mass degeneracy ($m_{\tilde{u}_L} = m_{\tilde{d}_L} = m_{\tilde{c}_L} = m_{\tilde{s}_L}$), with $\tilde{q}_L \to q'\tilde{\chi}_1^\pm$ or $\tilde{q}_L \to q\tilde{\chi}_2^0$ with equal branching ratios, where $\tilde{\chi}_1^\pm \to \tau\nu\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0 \to \tau^+\tau^-\tilde{\chi}_1^0$ or $\nu\bar{\nu}\tilde{\chi}_1^0$; the mass hierarchy is such that $m_{\tilde{\chi}_1^\pm} \sim m_{\tilde{\chi}_2^0} = (m_{\tilde{q}_L} + m_{\tilde{\chi}_1^0})/2$ and $m_{\tilde{\tau},\tilde{\nu}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$.

Tsqk1RPV: squark pair production with squarks decaying to $q\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \to u_i d_j d_k$ via λ''_{ijk}.

Tsqk2RPV: squark pair production with squarks decaying to $q\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \to (\ell_i u_j d_k, \nu_i d_j d_k)$ via λ'_{ijk}.

Tsqk3RPV: squark pair production with squarks decaying to $q\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \to (\ell_i \nu_j \ell_k, \nu_i \ell_j \ell_k)$ via λ_{ijk}.

Tstop1: stop pair production with $\tilde{t} \to t\tilde{\chi}_1^0$.

Tstop1LL stop pair production where $\tilde{t} \to t\tilde{\chi}_1^0$ and $\tilde{t} \to b\tilde{\chi}_1^\pm$ each happen with 50% probability. The $\tilde{\chi}_1^\pm$ is assumed to be few hundreds of MeV heavier than the $\tilde{\chi}_1^0$, and decays to $\tilde{\chi}_1^0$ via a pion.

Tstop2: stop pair production with $\tilde{t} \to b\tilde{\chi}_1^\pm$ with $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$.

Tstop3: stop pair production with the subsequent four-body decay $\tilde{t} \to bff'\tilde{\chi}_1^0$ where f represents a lepton or a quark.

Tstop4: stop pair production with $\tilde{t} \to c\tilde{\chi}_1^0$.

Tstop5: stop pair production with $\tilde{t} \to b\bar{\nu}\tilde{\tau}$ with $\tilde{\tau} \to \tau\tilde{G}$.

Tstop6: stop pair production with $\tilde{t} \to t + \tilde{\chi}_2^0$, where $\tilde{\chi}_2^0 \to Z + \tilde{\chi}_1^0$ or $H + \tilde{\chi}_1^0$ each with BR 50%.

Tstop6RPV: stop pair production with $\tilde{t} \to t\tilde{\chi}_1^0$, $\tilde{\chi}_1^0 \to qqq$ via RPV coupling λ''_{abc}, with $a, b, c \in \{1, 2\}$.

Tstop7: stop pair production with $\tilde{t}_2 \to \tilde{t}_1 + H/Z$, where $\tilde{t}_1 \to t + \tilde{\chi}_1^0$.

Tstop8: stop pair production with equal probability of the stop decaying via $\tilde{t} \to t\tilde{\chi}_1^0$ or via $\tilde{t} \to b\tilde{\chi}_1^\pm$ with $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$.

Tstop9: stop pair production with equal probability of the stop decaying via $\tilde{t} \to c\tilde{\chi}_1^0$ or via the four-body decay $\tilde{t} \to bff'\tilde{\chi}_1^0$ where f represents a lepton or a quark.

Tstop10: stop pair production with $\tilde{t} \to b\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^\pm \to W^{\pm *}\tilde{\chi}_1^0 \to (f\bar{f'}) + \tilde{\chi}_1^0$ with a virtual W-boson.

Tstop11: stop pair production with $\tilde{t} \to b\tilde{\chi}_1^\pm$ with $\tilde{\chi}_1^\pm$ decaying through an intermediate slepton to $l\nu\tilde{\chi}_1^0$

Tstop12: stop pair production with $\tilde{t} \to t\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$

Tstop13: stop pair production with $\tilde{t} \to t\tilde{\chi}_1^0$ where the $\tilde{\chi}_1^0$ can decay with equal probability to $\tilde{\chi}_1^0 \to \gamma + \tilde{G}$ or to $\tilde{\chi}_1^0 \to Z + \tilde{G}$.

Tstop14: stop pair production with wino-like couplings to electroweakinos, that is: $\tilde{t} \to t\tilde{\chi}_{1,2}^0$ with BR 33%, $\tilde{g} \to b\tilde{\chi}_1^\pm$ with BR 67%.

Tstop15: stop pair production with higgsino-like couplings to electroweakinos, that is: $\tilde{t} \to t\tilde{\chi}_{1,2}^0$ with BR 50%, $\tilde{g} \to b\tilde{\chi}_1^\pm$ with BR 50%.

Tstop16: stop pair production with $\tilde{t} \to b\tilde{\chi}_1^\pm$, followed either by $\tilde{\chi}_1^\pm \to \nu_\tau\tilde{\tau}_1$ and $\tilde{\tau}_1 \to \tau\tilde{\chi}_1^0$, or by $\tilde{\chi}_1^\pm \to \tau\tilde{\nu}_\tau$ and $\tilde{\nu}_\tau \to \nu\tilde{\chi}_1^0$, each with BR 50%.

Tstop1RPV: stop pair production with $\tilde{t} \to \bar{b}\bar{s}$ via RPV coupling λ''_{323}.

Tstop2RPV: stop pair production with $\tilde{t} \to b\ell$, via RPV coupling λ'_{i33}.

Tstop3RPV: stop pair production with $\tilde{t} \to q\mu$, via RPV coupling λ'_{23k}.

Tstop4RPV: stop pair production with $\tilde{t} \to b\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to bbs$ via RPV coupling λ''_{323}.

Tstop5RPV: stop pair production with $\tilde{t} \to t\tilde{\chi}_{1,2}^0$, $\tilde{\chi}_{1,2}^0 \to tbs$ via RPV coupling λ''_{323}.

Tsbot1: sbottom pair production with $\tilde{b} \to b\tilde{\chi}_1^0$.

Tsbot2: sbottom pair production with $\tilde{b} \to t\chi_1^-$, $\chi_1^- \to W^-\tilde{\chi}_1^0$.

Tsbot3: sbottom pair production with $\tilde{b} \to b\tilde{\chi}_2^0$, where one of the $\tilde{\chi}_2^0 \to Z^{(*)}\tilde{\chi}_1^0 \to f\bar{f}\tilde{\chi}_1^0$ and the other $\tilde{\chi}_2^0 \to \tilde{\ell}\ell^+ \to \ell^+\ell^-\tilde{\chi}_1^0$.

Tsbot4: sbottom pair production with $\tilde{b} \to b\tilde{\chi}_2^0$, with $\tilde{\chi}_2^0 \to H\tilde{\chi}_1^0$

Tchi1chi1A: electroweak pair and associated production of nearly mass-degenerate charginos $\tilde{\chi}_1^\pm$ and neutralinos $\tilde{\chi}_1^0$, where $\tilde{\chi}_1^\pm$ decays to $\tilde{\chi}_1^0$ plus soft radiation, and where one of the $\tilde{\chi}_1^0$ decays to $\gamma + \tilde{G}$ while the other one decays to $Z/H + \tilde{G}$ (with equal probability).

Tchi1chi1B: electroweak pair production of charginos $\tilde{\chi}_1^\pm$, where $\tilde{\chi}_1^\pm$ decays through an intermediate slepton or sneutrino to $l\nu\tilde{\chi}_1^0$ and where the slepton or sneutrino mass is 5%, 25%, 50%, 75% and 95% of the $\tilde{\chi}_1^\pm$ mass.

Tchi1chi1C: electroweak pair production of charginos $\tilde{\chi}_1^\pm$, where $\tilde{\chi}_1^\pm$ decays through an intermediate slepton or sneutrino to $l\nu\tilde{\chi}_1^0$ and where $m_{\tilde{l},\tilde{\nu}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$.

Tchi1chi1D: electroweak associated pair production of charginos $\tilde{\chi}_1^\pm$, where $\tilde{\chi}_1^\pm$ decays through an intermediate scalar tau lepton or sneutrino to $\tau\nu\tilde{\chi}_1^0$ and where $m_{\tilde{\tau}}, m_{\tilde{\nu}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$.

Tchi1chi1F: electroweak pair and associated production of nearly mass-degenerate charginos $\tilde{\chi}_1^\pm$ and neutralinos $\tilde{\chi}_1^0$ (*i.e.* $\tilde{\chi}_1^\pm\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^\pm\tilde{\chi}_1^0$ production) where the $\tilde{\chi}_1^\pm$ decays exclusively to $\tilde{\chi}_1^0$ plus soft radiation and the $\tilde{\chi}_1^0$ decays to $\gamma/Z + \tilde{G}$.

Tchi1chi1G: electroweak pair production of charginos $\tilde{\chi}_1^\pm$, which are nearly mass-degenerate with neutralinos $\tilde{\chi}_1^0$. The $\tilde{\chi}_1^\pm$ decays either

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

to $W^{\pm}+\tilde{G}$, or to $\tilde{\chi}_1^0$ plus soft radiation. The $\tilde{\chi}_1^0$ decays exclusively to $\gamma+\tilde{G}$.

Tchi1chi1H: electroweak pair production of charginos $\tilde{\chi}_1^{\pm}$, with $\tilde{\chi}_1^{\pm}\to W^{\pm}+\tilde{\chi}_1^0$ and $W^{\pm}\to\ell^{\pm}+\nu$.

Tchi1chi1I: electroweak pair production of charginos $\tilde{\chi}_1^{\pm}$ with $\tilde{\chi}_1^{\pm}\to W^{\pm}\tilde{\chi}_1^0$ and $W^{\pm}\to q\bar{q}'$.

Tchi1n1A: electroweak associated production of mass-degenerate charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_1^0$, where $\tilde{\chi}_1^{\pm}$ decays exclusively to $W^{\pm}+\tilde{G}$ and $\tilde{\chi}_1^0$ decays exclusively to $\gamma+\tilde{G}$.

Tchi1n2A: electroweak associated production of mass-degenerate charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ decays through an intermediate slepton or sneutrino to $l\nu\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate slepton or sneutrino to $l^+l^-\tilde{\chi}_1^0$ or $\nu\bar{\nu}\tilde{\chi}_1^0$.

Tchi1n2B: electroweak associated production of mass-degenerate charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ decays through an intermediate slepton or sneutrino to $l\nu\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate slepton or sneutrino to $l^+l^-\tilde{\chi}_1^0$ or $\nu\bar{\nu}\tilde{\chi}_1^0$ and where the slepton or sneutrino mass is 5%, 25%, 50%, 75% and 95% of the $\tilde{\chi}_1^{\pm}$ mass.

Tchi1n2C: electroweak associated production of mass-degenerate charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ decays through an intermediate slepton or sneutrino to $l\nu\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate slepton or sneutrino to $l^+l^-\tilde{\chi}_1^0$ or $\nu\bar{\nu}\tilde{\chi}_1^0$ and where $m_{\tilde{\ell},\tilde{\nu}}=(m_{\tilde{\chi}_1^{\pm}}+m_{\tilde{\chi}_1^0})/2$.

Tchi1n2D: electroweak associated production of mass-degenerate charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ decays through an intermediate scalar tau lepton or sneutrino to $\tau\nu\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate scalar tau lepton or sneutrino to $\tau^+\tau^-\tilde{\chi}_1^0$ or $\nu\bar{\nu}\tilde{\chi}_1^0$ and where $m_{\tilde{\tau},\tilde{\nu}}=(m_{\tilde{\chi}_1^{\pm}}+m_{\tilde{\chi}_1^0})/2$.

Tchi1n2E: electroweak associated production of mass-degenerate charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}\to W^{\pm}+\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0\to H+\tilde{\chi}_1^0$.

Tchi1n2F: electroweak associated production of mass-degenerate wino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ decays through an intermediate $W^{\pm *}$ to $l\nu\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate Z^* to $l^+l^-\tilde{\chi}_1^0$ or $\nu\bar{\nu}\tilde{\chi}_1^0$.

Tchi1n2Fa: electroweak associated production of mass-degenerate wino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ decays through an intermediate $W^{\pm *}$ to $q\bar{q}\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate Z^* to $l^+l^-\tilde{\chi}_1^0$ or $\nu\bar{\nu}\tilde{\chi}_1^0$.

Tchi1n2Fb: electroweak associated production of mass-degenerate wino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ decays through an intermediate $W^{(*)}$ to $q\bar{q}\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate $Z^{(*)}$ to $q\bar{q}\tilde{\chi}_1^0$.

Tchi1n2Fc: electroweak associated production of mass-degenerate wino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ decays through an intermediate $W^{(*)}$ to $q\bar{q}\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate $H^{(*)}$ to $q\bar{q}\tilde{\chi}_1^0$.

Tchi1n2G: electroweak associated production of Higgsino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, and electroweak associated production of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^0$, where $m_{\tilde{\chi}_1^{\pm}}=(m_{\tilde{\chi}_2^0}+m_{\tilde{\chi}_1^0})/2$ and where $\tilde{\chi}_1^{\pm}$ decays through an intermediate $W^{\pm *}$ to $q\bar{q}\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate Z^* to $l^+l^-\tilde{\chi}_1^0$.

Tchi1n2Ga: electroweak associated production of Higgsino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, and electroweak associated production of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^0$, where $m_{\tilde{\chi}_1^{\pm}}=(m_{\tilde{\chi}_2^0}+m_{\tilde{\chi}_1^0})/2$ and where $\tilde{\chi}_1^{\pm}$ decays through an intermediate $W^{\pm *}$ to $l\nu\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate Z^* to $l^+l^-\tilde{\chi}_1^0$.

Tchi1n2H: electroweak associated production of mass-degenerate charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ decays through an intermediate slepton or sneutrino to $l\nu\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays through an intermediate scalar tau lepton or sneutrino to $\tau^+\tau^-\tilde{\chi}_1^0$ or $\nu\bar{\nu}\tilde{\chi}_1^0$.

Tchi1n2I: electroweak associated production of mass-degenerate charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ decays to $W^{\pm}+\tilde{\chi}_1^0$ and where $\tilde{\chi}_2^0$ decays 50% of the time to $Z+\tilde{\chi}_1^0$ and 50% of the time to $H+\tilde{\chi}_1^0$.

1n12_GGM: in the framework of General Gauge Mediation (GGM): electroweak pair and associated production of nearly mass-degenerate charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_1^0$, $\tilde{\chi}_2^0$ (*i.e.* $\tilde{\chi}_1^{\pm}\tilde{\chi}_1^{\mp}$, $\tilde{\chi}_1^{\pm}\tilde{\chi}_1^0$ and $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0$ production) where the $\tilde{\chi}_1^{\pm}$ decays exclusively to $W^{\pm}+\tilde{G}$, the $\tilde{\chi}_2^0$ decays to $Z/H+\tilde{G}$ and the $\tilde{\chi}_1^0$ decays to $\gamma/Z+\tilde{G}$. The branching ratios depend on the composition of the gauge eigenstates of the neutralinos in the GGM scenario.

TwinoLSPBL: Electroweak pair production of wino-like $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_1^0$ (i.e. $\tilde{\chi}_1^{\pm}\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_1^0\tilde{\chi}_1^0$). The $\tilde{\chi}_1^{\pm}$ can decay via bi-linear RPV into $Z\ell$, $H\ell$ or $W\nu$; the $\tilde{\chi}_1^0$ can decay into $Z\nu$, $H\nu$ or $W\ell$.

Tn1n1A: electroweak pair and associated production of nearly mass-degenerate Higgsino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_2^0$ decay to $\tilde{\chi}_1^0$ plus soft radiation and where both of the $\tilde{\chi}_1^0$ decay to $H+\tilde{G}$.

Tn1n1B: electroweak pair and associated production of nearly mass-degenerate Higgsino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_2^0$ decay to $\tilde{\chi}_1^0$ plus soft radiation and where the $\tilde{\chi}_1^0$ decays 50% of the time to $H+\tilde{G}$ and 50 % of the time to $Z+\tilde{G}$.

Tn1n1C: electroweak pair and associated production of nearly mass-degenerate Higgsino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0$, where $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_2^0$ decay to $\tilde{\chi}_1^0$ plus soft radiation and where both of the $\tilde{\chi}_1^0$ decay to $Z+\tilde{G}$.

Tn1n1D: electroweak pair and associated production of nearly mass-degenerate Higgsino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_1^0$, $\tilde{\chi}_2^0$.

Tn1n1E: electroweak pair and associated production of nearly mass-degenerate wino-like charginos $\tilde{\chi}_1^{\pm}$ and neutralinos $\tilde{\chi}_1^0$.

Tn1n2A: electroweak associated production of nearly mass-degenerate neutralinos $\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0$, where the $\tilde{\chi}_2^0$ always decays to $\gamma+\tilde{G}$ and $\tilde{\chi}_1^0$ 50% of the time to $H+\tilde{G}$ and 50 % of the time to $Z+\tilde{G}$.

Tn2n3A: electroweak associated production of mass-degenerate neutralinos $\tilde{\chi}_2^0$ and $\tilde{\chi}_3^0$, where $\tilde{\chi}_2^0$ and $\tilde{\chi}_3^0$ decay through intermediate sleptons to $l^+l^-\tilde{\chi}_1^0$ and where the slepton mass is 5%, 25%, 50%, 75% and 95% of the $\tilde{\chi}_2^0$ mass.

Tn2n3B: electroweak associated production of mass-degenerate neutralinos $\tilde{\chi}_2^0$ and $\tilde{\chi}_3^0$, where $\tilde{\chi}_2^0$ and $\tilde{\chi}_3^0$ decay through intermediate sleptons to $l^+l^-\tilde{\chi}_1^0$ and where $m_{\tilde{\ell}}=(m_{\tilde{\chi}_2^0}+m_{\tilde{\chi}_1^0})/2$.

TWinoBinoA: electroweak pair production of mass-degenerate wino-like doublet $(\tilde{\chi}_2^0,\tilde{\chi}_1^{\pm})$ (including all pair-production mechanisms) decaying into a bino singlet $(\tilde{\chi}_1^0)$. Decays happen via Standard Model bosons, assumed to decay via hadrons.

TWinoHinoA: electroweak pair production of mass-degenerate wino-like doublet $(\tilde{\chi}_3^0,\tilde{\chi}_2^{\pm})$ (including all possible pair-production mechanisms) decaying into a quasi-mass-degenerate Higgsino triplet $(\tilde{\chi}_1^0,\tilde{\chi}_2^0,\tilde{\chi}_1^{\pm})$. Decays happen via Standard Model bosons, assumed to decay via hadrons.

THinoBinoA: electroweak pair production of quasi-mass-degenerate higgsino-like triplet $(\tilde{\chi}_2^0,\tilde{\chi}_3^0,\tilde{\chi}_1^{\pm})$ (including all possible pair-production mechanisms) decaying into a bino singlet $(\tilde{\chi}_1^0)$. Decays happen via Standard Model bosons, assumed to decay via hadrons.

THinoWinoA: electroweak pair production of quasi-mass-degenerate higgsino-like triplet $(\tilde{\chi}_2^0,\tilde{\chi}_2^0,\tilde{\chi}_2^{\pm})$ (including all possible pair-production mechanisms) decaying into a mass-degenerate wino doublet $(\tilde{\chi}_1^0,\tilde{\chi}_1^{\pm})$. Decays happen via Standard Model bosons, assumed to decay via hadrons.

$\tilde{\chi}_1^0$ (Lightest Neutralino) mass limit

$\tilde{\chi}_1^0$ is often assumed to be the lightest supersymmetric particle (LSP). See also the $\tilde{\chi}_2^0$, $\tilde{\chi}_3^0$, $\tilde{\chi}_4^0$ section below.

We have divided the $\tilde{\chi}_1^0$ listings below into five sections:

1) Accelerator limits for stable $\tilde{\chi}_1^0$,
2) Bounds on $\tilde{\chi}_1^0$ from dark matter searches,
3) $\tilde{\chi}_1^0-p$ elastic cross section (spin-dependent, spin-independent interactions),
4) Other bounds on $\tilde{\chi}_1^0$ from astrophysics and cosmology, and
5) Unstable $\tilde{\chi}_1^0$ (Lightest Neutralino) mass limit.

Accelerator limits for stable $\tilde{\chi}_1^0$

Unless otherwise stated, results in this section assume spectra, production rates, decay modes, and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

generally study production of $\tilde{\chi}_i^0\tilde{\chi}_j^0$ ($i \geq 1$, $j \geq 2$), $\tilde{\chi}_1^+\tilde{\chi}_1^-$, and (in the case of hadronic collisions) $\tilde{\chi}_1^+\tilde{\chi}_2^0$ pairs. The mass limits on $\tilde{\chi}_1^0$ are either direct, or follow indirectly from the constraints set by the non-observation of $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ states on the gaugino and higgsino MSSM parameters M_2 and μ. In some cases, information is used from the nonobservation of slepton decays.

Obsolete limits obtained from e^+e^- collisions up to $\sqrt{s}$=184 GeV have been removed from this compilation and can be found in the 2000 Edition (The European Physical Journal **C15** 1 (2000)) of this Review. $\Delta m = m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$.

[1] AAD 24Z searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with exactly two same-sign leptons or at least three leptons. Several signal regions, including a $\not{E}_T$ selection targeting RPC models, and selections based on b-jet multiplicities, targeting RPV models, are considered. No significant excess over the Standard Model expectation is found. Exclusion limits at 95% C.L. are set on the gluino or squark mass, in multi-step RPC decays via charginos, neutralinos or sleptons into quarks, leptons and neutralinos, or RPV decays of either the neutralino LSP or directly the stop produced in $\tilde{g} \to t\bar{t}$ into quarks. See their Fig. 7.

[2] LEES 23C search in 398 fb^{-1} of e^+e^- annihilations at 10.58 GeV for SUSY in events with a tagged B meson and one and only one charged track that must be consistent with the hypothesis of being a proton. The results are interpreted in an RPV SUSY model, where a neutralino is produced in the decay of a B meson into a neutralino and a proton with the RPV coupling λ''_{113}. A branching fraction upper limit is determined for the λ''_{113} coupling, divided by the relevant squark mass squared as a function of the neutralino mass, see their figure 6. They also search for a new dark sector antibaryon that could be produced in decays of B mesons.

[3] AAD 22E searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry by measuring the yield asymmetry between events containing $e^-\mu^+$ and those containing $e^+\mu^-$. This was found in agreement with the standard model prediction of 1. Limits are set on the RPV production of $t\tilde{\mu}_L$ events with $\tilde{\mu}_L \to \mu\tilde{\chi}_1^0$ for various values of λ'_{231}, see their figures 6 and 7.

[4] TUMASYAN 22S searched in 137 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for evidence of electroweakino pair production in events with three or four leptons, with up to two hadronically decaying τ leptons, or two same-sign light leptons (e or μ). No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ in the models Tchi1n2B (in flavory-democratic and tau-enriched or -dominated scenarios), Tchi1n2E, Tchi1n2F, see their Figures 16–20, and on the mass of the higgsino-triplet $\tilde{\chi}_2^0$, $\tilde{\chi}_1^\pm$, and $\tilde{\chi}_1^0$ in the models Tn1n1A, Tn1n1B, and Tn1n1C, see their Figure 21.

[5] TUMASYAN 22V searched in 137 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for evidence of electroweakino pair production with decay to two Higgs bosons H, with $H \to b\bar{b}$, resulting either in 4 resolved b-jets or two large-radius jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ in the models Tn1n1A, see their Figures 11 and 12, or in a model where higgsino-like nearly mass degenerate $\tilde{\chi}_2^0$ and $\tilde{\chi}_3^0$ are pair produced and each decay to H and a bino-like $\tilde{\chi}_1^0$, see their Figure 13. Limits are also set on the gluino mass in the model Tglu1l, see their Figure 14.

[6] AAD 21AX searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for pair production of electroweakinos decaying to the LSP via the emission of Standard Model bosons (Higgs, W, Z) decaying into hadrons. The final state in all cases characterised by the presence of $\not{E}_T$, jets, and large-R jets tagged according to the boson of interest. Different assumptions (Higgsino, Wino, Bino) are made for the pair produced electroweakinos and for the LSP multiplet. No significant excess above the Standard Model predictions is observed. Limits are set on the electroweakino masses as a function of the model parameters (in particular $m_{\tilde{\chi}_1^0}$). See Fig. 16.

[7] AAD 21BF searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for pair production of gluinos, stops, electroweakinos decaying RPV either directly or indirectly via the LSP. The final state in all cases is one or two leptons, many jets (up to fifteen) and b-jets. Different models with different branching fractions of the gluino or stop follow from the assumptions on the nature of the electroweakinos. No significant excess above the Standard Model predictions is observed. Limits are set on the *gluino*, $\tilde{t}_1$, electroweakino masses as a function of the $\tilde{\chi}_1^0$ mass in several scenarios of gluino, stop and electroweakino pair production.

[8] DREINER 09 show that in the general MSSM with non-universal gaugino masses there exists no model-independent laboratory bound on the mass of the lightest neutralino. An essentially massless χ_1^0 is allowed by the experimental and observational data, imposing some constraints on other MSSM parameters, including M_2, μ and the slepton and squark masses.

[9] ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192–209 GeV data, combined with the results on leptonic final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region $0 < M_2 < 5000$ GeV, $-1000 < \mu < 1000$ GeV and tanβ from 1 to 40. This limit supersedes ABBIENDI 00H.

[10] HEISTER 04 data collected up to 209 GeV. Updates earlier analysis of selectrons from HEISTER 02E, includes a new analysis of charginos and neutralinos decaying into stau and uses results on charginos with initial state radiation from HEISTER 02J. The limit is based on the direct search for charginos and neutralinos, the constraints from the slepton search and the Higgs mass limits from HEISTER 02 using a top mass of 175 GeV, interpreted in a framework with universal gaugino and sfermion masses. Assuming the mixing in the stau sector to be negligible, the limit improves to 43.1 GeV. Under the assumption of MSUGRA with unification of the Higgs and sfermion masses, the limit improves to 50 GeV, and reaches 53 GeV for $A_0 = 0$. These limits include and update the results of BARATE 01.

[11] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV. A limit on the mass of $\tilde{\chi}_1^0$ is derived from direct searches for neutralinos combined with the chargino search. Neutralinos are searched in the production of $\tilde{\chi}_1^0\tilde{\chi}_2^0$, $\tilde{\chi}_1^0\tilde{\chi}_3^0$, as well as $\tilde{\chi}_2^0\tilde{\chi}_3^0$ and $\tilde{\chi}_2^0\tilde{\chi}_4^0$ giving rise to cascade decays, and $\tilde{\chi}_1^0\tilde{\chi}_2^0$ and $\tilde{\chi}_1^0\tilde{\chi}_2^0$, followed by the decay $\tilde{\chi}_2^0 \to \tilde{\tau}\tau$. The results hold for the parameter space defined by values of $M_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP. The limit is obtained for tanβ = 1 and large m_0, where $\tilde{\chi}_2^0\tilde{\chi}_4^0$ and chargino pair production are important. If the constraint from Higgs searches is also imposed, the limit improves to 49.0 GeV in the $m_h^{\max}$ scenario with m_t=174.3 GeV. These limits update the results of ABREU 00J.

[12] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV. An indirect limit on the mass of $\tilde{\chi}_1^0$ is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays and $\tilde{\tau}\tau$ final states), for charginos (for all Δm_+) and for sleptons, stop and sbottom. The results hold for the full parameter space defined by values of $M_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP. Constraints from the Higgs search in the $m_h^{\max}$ scenario assuming m_t=174.3 GeV are included. The limit is obtained for tan$\beta \geq 5$ when stau mixing leads to mass degeneracy between $\tilde{\tau}_1$ and $\tilde{\chi}_1^0$ and the limit is based on $\tilde{\chi}_2^0$ production followed by its decay to $\tilde{\tau}_1\tau$. In the pathological scenario where m_0 and $|\mu|$ are large, so that the $\tilde{\chi}_2^0$ production cross section is negligible, and where there is mixing in the stau sector but not in stop nor sbottom, the limit is based on charginos with soft decay products and an ISR photon. The limit then degrades to 39 GeV. See Figs. 40–42 for the dependence of the limit on tanβ and $m_{\tilde{\nu}}$. These limits update the results of ABREU 00W.

[13] ACCIARRI 00D data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by $0.7 \leq$ tan$\beta \leq 60$, $0 \leq M_2 \leq 2$ TeV, $m_0 \leq 500$ GeV, $|\mu| \leq 2$ TeV The minimum mass limit is reached for tanβ=1 and large m_0. The results of slepton searches from ACCIARRI 99W are used to help set constraints in the region of small m_0. The limit improves to 48 GeV for $m_0 \gtrsim 200$ GeV and tan$\beta \gtrsim 10$. See their Figs. 6–8 for the tanβ and m_0 dependence of the limits. Updates ACCIARRI 98F.

[14] AAD 14K sets limits on the χ-nucleon spin-dependent and spin-independent cross sections out to m_χ = 10 TeV.

[15] CALIBBI 13 use the fact that if the relic abundance of $\tilde{\chi}_1^0$ does not overclose the universe, scalar lepton and Higgsino masses must be relatively small. Using 8 TeV ATLAS constraints on the scalar tau mass and on invisible Higgs decays, they estimate a lower bound for the $\tilde{\chi}_1^0$ mass.

Bounds on $\tilde{\chi}_1^0$ from dark matter searches

These papers generally exclude regions in the $M_2 - \mu$ parameter plane assuming that $\tilde{\chi}_1^0$ is the dominant form of dark matter in the galactic halo. These limits are based on the lack of detection in laboratory experiments, telescopes, or by the absence of a signal in underground neutrino detectors. The latter signal is expected if $\tilde{\chi}_1^0$ accumulates in the Sun or the Earth and annihilates into high-energy ν's.

none 4–15 GeV

[1] ABBASI 25A is based on 10 years of data collected with IceCube. They looked for interactions of ν's resulting from neutralino annihilations in the Earth over a background of atmospheric neutrinos and set 90% CL limits on the spin independent neutralino-proton cross section for neutralino masses in the range 10–10000 GeV. This updates AARTSEN 17.

[2] MCDANIEL 24 uses 14 years of Fermi-LAT data from Milky Way Dwarf Spheroidals to constrain dark matter annihilation cross sections.

[3] ABBASI 23A sets limits on the dark matter annihilation cross section from searches of monochromatic neutrinos produced in the galactic center. They set a limit on the annihilation cross section for dark matter with masses between 10–40000 GeV annihilating in the Galactic center assuming an NFW profile. The limit is of order 10×10^{-24} cm^{3}s^{-1} in the $\nu_e\overline{\nu}_e$ channel.

[4] ABE 23B sets limits on the dark matter annihilation cross section from line-like features in TeV gamma-rays in the direction of the Galactic center using the MAGIC stereoscopic telescope.

[5] ALBERT 23 uses gamma-ray observation of the Galactic halo to constrain the dark matter annihilation cross section for annihilations for masses between 10–100 TeV.

[6] CHENG 23A uses 13 years of Fermi-LAT data and 5 years of DAMPE data to constrain dark matter annihilation in the Galactic halo from searches of gamma-ray spectral lines.

[7] FOSTER 23 sets limits on the dark matter annihilation cross section from monochromatic gamma-rays in the inner Milky Way using 14 years of data from Fermi-LAT.

[8] GUO 23A sets limits on the dark matter annihilation cross section from 10 years of IceCube muon-track data from 18 dwarf speroidal galaxies.

[9] LAVIS 23 uses a statistical analysis of the radio flux densities within galaxy clusters in data from the MeerKAT Galaxy Cluster Legacy Survey to constrain dark matter annihilations for masses less than 1 TeV.

[10] ABBASI 22B presents 7 years of data from a search of neutrinos from dark matter annihilations in the sun using the DeepCore sub-array of IceCube. Annihilation cross section limits applies to dark matter masses between 5–100 GeV.

[11] ABDALLA 22 uses gamma-ray observations in the Galactic center to constrain the dark matter annihilation cross section for annihilations into WW and $\tau\tau$ for dark matter masses between 200 GeV to 70 TeV. This updates ABDALLAH 18.

[12] ABDALLAH 21 places constraints on the dark matter annihilation cross section for annihilations into gamma-rays from the dwarf irregular galaxy WLM for masses between 0.15 to 10 TeV.

[13] ABAZAJIAN 20 sets constraints on the dark matter annihilation from gamma-ray searches from Fermi LAT observations of the Galactic center.

[14] ABDALLAH 20 places constraints on the dark matter annihilation cross section for annihilations into gamma-rays from Milky Way dwarf galaxy satellites for masses between 0.2 to 40 TeV.

[15] ABE 20G is based on SuperKamiokande data taken from 1996 to 2016 searching for neutrinos produced from dark matter annihilations in the galactic center or halo. They place constraints on the dark matter-nucleon scattering cross section for dark matter masses between 1 GeV and 10 TeV.

[16] ALBERT 20 sets limits on the annihilation cross section of dark matter with mass between 1 and 100 TeV from gamma-ray observations of the local dwarf spheroidal galaxies.

[17] ALBERT 20A set limits on the dark matter annihilation cross section from neutrinos observations in the Galactic center using 11 years of ANTARES data.

[18] ALBERT 20C set limits on the dark matter annihilation cross section from neutrinos observations in the Galactic center combining Antares and IceCube data.

[19] ALVAREZ 20 set limits on the dark matter annihilation from gamma-ray searches from Fermi LAT observations in the directions of dwarf spheroidal galaxies.

[20] HOOF 20 set limits on the dark matter annihilation from gamma-ray searches from Fermi LAT observations in the directions of dwarf spheroidal galaxies.

[21] DI-MAURO 19 sets limits on the dark matter annihilation from gamma-ray searches in M31 and M33 galaxies using Fermi LAT data.

[22] JOHNSON 19 sets limits on p-wave dark matter annihilations in the galactic center using Fermi data.

[23] LI 19D sets limits on dark matter annihilation cross sections searching for line-like signals in the all-sky Fermi data.

[24] AHNEN 18 uses observations of the dwarf satellite galaxy Ursa Major II to obtain upper limits on annihilation cross sections for dark matter in various channels for masses between 0.1–100 TeV.

[25] ALBERT 18B sets limits on the annihilation cross section of dark matter with mass between 1 and 100 TeV from gamma-ray observations of the Andromeda galaxy.

[26] ALBERT 18C sets limits on the spin-dependent coupling of dark matter to protons from dark matter annihilation in the Sun.

[27] AARTSEN 17A is based on data collected during 532 days of livetime with the IceCube 86-string detector including the DeepCore sub-array. They looked for interactions of ν's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the spin dependent neutralino-proton cross section for neutralino masses in the range 10–10000 GeV. This updates AARTSEN 16C.

[28] AARTSEN 17C is based on 1005 days of running with the IceCube detector. They set a limit on the annihilation cross section for dark matter with masses between 10–1000 GeV annihilating in the Galactic center assuming an NFW profile. The limit is of 1.2×10^{23} cm^{3}s^{-1} in the $\tau^+\tau^-$ channel. Supercedes AARTSEN 15E.

[29] ARCHAMBAULT 17 performs a joint statistical analysis of four dwarf galaxies with VERITAS looking for gamma-ray emission from neutralino annihilation. They set limits on the neutralino annihilation cross section.

[30] ADRIAN-MARTINEZ 16 is based on data from the ANTARES neutrino telescope. They looked for interactions of ν's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon neutrino flux. They also obtain limits on the spin dependent and spin independent neutralino-proton cross section for neutralino masses in the range 50 to 5,000 GeV. This updates ADRIAN-MARTINEZ 13.

[31] AHNEN 16 combines 158 hours of Segue 1 observations with MAGIC with 6 year observations of 15 dwarf satellite galaxies by Fermi-LAT to set limits on annihilation cross sections for dark matter masses between 10 GeV and 100 TeV.

[32] AVRORIN 16 is based on 2.76 years with Lake Baikal neutrino telescope. They derive 90% upper limits on the annihilation cross section from dark matter annihilations in the Galactic center.

[33] CIRELLI 16 and LEITE 16 derive bounds on the annihilation cross section from radio observations.

[34] ACKERMANN 15 is based on 5.8 years of data with Fermi-LAT and search for monochromatic gamma-rays in the energy range of 0.2–500 GeV from dark matter annihilations. This updates ACKERMANN 13A.

[35] ACKERMANN 15A is based on 50 months of data with Fermi-LAT and search for dark matter annihilation signals in the isotropic gamma-ray background as well as galactic subhalos in the energy range of a few GeV to a few tens of TeV.

[36] ACKERMANN 15B is based on 6 years of data with Fermi-LAT observations of Milky Way dwarf spheroidal galaxies. Set limits on the annihilation cross section from $m_\chi =$ 2 GeV to 10 TeV. This updates ACKERMANN 14.

[37] BUCKLEY 15 is based on 5 years of Fermi-LAT data searching for dark matter annihilation signals from Large Magellanic Cloud.

[38] CHOI 15 is based on 3903 days of SuperKamiokande data searching for neutrinos produced from dark matter annihilations in the sun. They place constraints on the dark matter-nucleon scattering cross section for dark matter masses between 4–200 GeV.

[39] ALEKSIC 14 is based on almost 160 hours of observations of Segue 1 satellite dwarf galaxy using the MAGIC telescopes between 2011 and 2013. Sets limits on the annihilation cross section out to $m_\chi = 10$ TeV.

[40] AVRORIN 14 is based on almost 2.76 years with Lake Baikal neutrino telescope. They derive 90% upper limits on the fluxes of muons and muon neutrinos from dark matter annihilations in the Sun.

[41] AARTSEN 13C is based on data collected during 339.8 effective days with the IceCube 59-string detector. They looked for interactions of ν_μ's from neutralino annihilations in nearby galaxies and galaxy clusters. They obtain limits on the neutralino annihilation cross section for neutralino masses in the range 30–100, 000 GeV.

[42] BERGSTROM 13, JIN 13, and KOPP 13 derive limits on the mass and annihilation cross section using AMS-02 data. JIN 13 also sets a limit on the lifetime of the dark matter particle.

[43] BOLIEV 13 is based on data collected during 24.12 years of live time with the Bakson Underground Scintillator Telescope. They looked for interactions of ν_μ's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent and spin independent neutralino-proton cross section for neutralino masses in the range 10–1000 GeV.

[44] ACKERMANN 10 place upper limits on the annihilation cross section with $b\overline{b}$ or $\mu^+\mu^-$ final states.

[45] ACHTERBERG 06 is based on data collected during 421.9 effective days with the AMANDA detector. They looked for interactions of ν_μs from the centre of the Earth over a background of atmospheric neutrinos and set 90 % CL limits on the muon flux. Their limit is compared with the muon flux expected from neutralino annihilations into W^+W^- and $b\overline{b}$ at the centre of the Earth for MSSM parameters compatible with the relic dark matter density, see their Fig. 7.

[46] ACKERMANN 06 is based on data collected during 143.7 days with the AMANDA-II detector. They looked for interactions of ν_μs from the Sun over a background of atmospheric neutrinos and set 90 % CL limits on the muon flux. Their limit is compared

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

with the muon flux expected from neutralino annihilations into W^+W^- in the Sun for SUSY model parameters compatible with the relic dark matter density, see their Fig. 3.

[47] DEBOER 06 interpret an excess of diffuse Galactic gamma rays observed with the EGRET satellite as originating from π^0 decays from the annihilation of neutralinos into quark jets. They analyze the corresponding parameter space in a supergravity inspired MSSM model with radiative electroweak symmetry breaking, see their Fig. 3 for the preferred region in the (m_0, $m_{1/2}$) plane of a scenario with large $\tan\beta$.

[48] AMBROSIO 99 and DESAI 04 set new neutrino flux limits which can be used to limit the parameter space in supersymmetric models based on neutralino annihilation in the Sun and the Earth.

[49] LOSECCO 95 reanalyzed the IMB data and places lower limit on $m_{\widetilde{\chi}^0_1}$ of 18 GeV if the LSP is a photino and 10 GeV if the LSP is a higgsino based on LSP annihilation in the sun producing high-energy neutrinos and the limits on neutrino fluxes from the IMB detector.

[50] MORI 93 excludes some region in M_2–μ parameter space depending on $\tan\beta$ and lightest scalar Higgs mass for neutralino dark matter $m_{\widetilde{\chi}^0} > m_W$, using limits on upgoing muons produced by energetic neutrinos from neutralino annihilation in the Sun and the Earth.

[51] BOTTINO 92 excludes some region M_2-μ parameter space assuming that the lightest neutralino is the dark matter, using upgoing muons at Kamiokande, direct searches by Ge detectors, and by LEP experiments. The analysis includes top radiative corrections on Higgs parameters and employs two different hypotheses for nucleon-Higgs coupling. Effects of rescaling in the local neutralino density according to the neutralino relic abundance are taken into account.

[52] BOTTINO 91 excluded a region in $M_2-\mu$ plane using upgoing muon data from Kamioka experiment, assuming that the dark matter surrounding us is composed of neutralinos and that the Higgs boson is not too heavy.

[53] GELMINI 91 exclude a region in $M_2-\mu$ plane using dark matter searches.

[54] KAMIONKOWSKI 91 excludes a region in the M_2–μ plane using IMB limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the sun, assuming that the dark matter is composed of neutralinos and that $m_{H_1^0} \lesssim 50$ GeV. See Fig. 8 in the paper.

[55] MORI 91B exclude a part of the region in the M_2–μ plane with $m_{\widetilde{\chi}^0_1} \lesssim 80$ GeV using a limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the earth, assuming that the dark matter surrounding us is composed of neutralinos and that $m_{H_1^0} \lesssim 80$ GeV.

[56] OLIVE 88 result assumes that photinos make up the dark matter in the galactic halo. Limit is based on annihilations in the sun and is due to an absence of high energy neutrinos detected in underground experiments. The limit is model dependent.

$\widetilde{\chi}^0_1$-p elastic cross section

Experimental results on the $\widetilde{\chi}^0_1$-p elastic cross section are evaluated at $m_{\widetilde{\chi}^0_1}$=100 GeV. The experimental results on the cross section are often mass dependent. Therefore, the mass and cross section results are also given where the limit is strongest, when appropriate. Results are quoted separately for spin-dependent interactions (based on an effective 4-Fermi Lagrangian of the form $\overline{\chi}\gamma^\mu\gamma^5\chi\overline{q}\gamma_\mu\gamma^5 q$) and spin-independent interactions ($\overline{\chi}\chi\overline{q}q$). For calculational details see GRIEST 88B, ELLIS 88D, BARBIERI 89C, DREES 93B, ARNOWITT 96, BERGSTROM 96, and BAER 97 in addition to the theory papers listed in the Tables. For a description of the theoretical assumptions and experimental techniques underlying most of the listed papers, see the review on "Dark matter" in this "Review of Particle Physics," and references therein. Most of the following papers use galactic halo and nuclear interaction assumptions from (LEWIN 96).

Spin-dependent interactions

[1] The strongest upper limit is 9.8×10^{-6} pb at 40 GeV. The limit for scattering on neutrons is 5.3×10^{-7} pb at 100 GeV and is 3.7×10^{-7} pb at 46 GeV. This updates AALBERS 23.

[2] The strongest upper limit is 8.5×10^{-5} pb at 30 GeV. The limit for scattering on neutrons is 6.7×10^{-6} pb at 100 GeV and is 2.8×10^{-6} pb at 30 GeV. This updates APRILE 23A.

[3] The strongest upper limit is 7.7×10^{-5} pb at a WIMP mass of 40 GeV. The limit for scattering on neutrons is 4×10^{-6} pb at 100 GeV and is 2.7×10^{-6} pb at 40 GeV. The corresponding plots are found in the supplementary material on the journal webpage. This updates HUANG 22.

[4] The strongest limit is $< 3.2 \times 10^{-5}$ pb at $m_\chi = 25$ GeV. This updates AMOLE 17.

[5] The strongest limit is $< 2 \times 10^{-4}$ pb at $m_\chi = 30$ GeV. For scatterings on neutrons, the strongest limit is $< 6.3 \times 10^{-6}$ at $m_\chi = 30$ GeV.

[6] The strongest limit is 5×10^{-4} pb at $m_\chi = 35$ GeV. The limit for scattering on neutrons is 3×10^{-5} pb at 100 GeV and is 1.6×10^{-5} pb at 35 GeV. This updates AKERIB 16A.

[7] Directional recoil detector. This updates DAW 12.

[8] This result updates ARCHAMBAULT 12. The strongest limit is 0.013 pb at $m_\chi = 20$ GeV.

[9] The strongest limit is 5×10^{-4} pb at $m_\chi = 80$ GeV.

[10] The strongest limit is 5.2×10^{-3} pb at 50 GeV. The limit for scattering on neutrons is 2.8×10^{-4} pb at 100 GeV and the strongest limit is 2.0×10^{-4} pb at 50 GeV. This updates APRILE 13.

[11] The strongest limit is 0.0043 pb and occurs at $m_\chi = 35$ GeV. FELIZARDO 14 also presents limits for the scattering on neutrons. At $m_\chi = 100$ GeV, the upper limit is 0.13 pb and the strongest limit is 0.066 pb at $m_\chi = 35$ GeV.

[12] This result updates LEBEDENKO 09A. The strongest limit is 8×10^{-3} pb at $m_\chi = 50$ GeV. Limit applies to the neutralino neutron elastic cross section.

[13] The strongest limit is 6×10^{-3} at $m_\chi = 60$ GeV.

[14] The strongest limit is 5.7×10^{-3} at $m_\chi = 35$ GeV.

[15] This result updates LEE 07A. The strongest limit is at $m_\chi = 80$ GeV.

[16] Predictions for the spin-dependent elastic cross section based on a frequentist approach to electroweak observables in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[17] The strongest limit is 0.6 pb and occurs at m_χ= 30 GeV. The limit for scattering on neutrons is 0.01 pb at m_χ= 100 GeV, and the strongest limit is 0.0045 pb at m_χ= 30 GeV.

[18] Limit applies to neutron elastic cross section.

[19] The strongest upper limit is 0.25 pb and occurs at $m_\chi \simeq 40$ GeV.

[20] The strongest upper limit is 4 pb and occurs at $m_\chi \simeq 60$ GeV. The limit on the neutron spin-dependent elastic cross section is 0.07 pb. This latter limit is improved in AHMED 09, where a limit of 0.02 pb is obtained at $m_\chi = 100$ GeV. The strongest limit in AHMED 09 is 0.018 pb and occurs at $m_\chi = 60$ GeV.

[21] The strongest upper limit is 1.2 pb and occurs at $m_\chi \simeq 40$ GeV. The limit on the neutron spin-dependent cross section is 35 pb.

[22] The strongest upper limit is 0.35 pb and occurs at $m_\chi \simeq 60$ GeV.

[23] The strongest upper limit is 1.2 pb and occurs $m_\chi \simeq 30$ GeV.

[24] ELLIS 04 calculates the χp elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry, but without universal scalar masses. In the case of universal squark and slepton masses, but non-universal Higgs masses, the limit becomes 2×10^{-4}, see ELLIS 03E.

[25] The strongest upper limit is 0.75 pb and occurs at $m_\chi \approx 70$ GeV.

[26] The strongest upper limit is 30 pb and occurs at $m_\chi \approx 20$ GeV.

[27] The strongest upper limit is 8 pb and occurs at $m_\chi \simeq 30$ GeV.

[28] ELLIS 01C calculates the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. In models with nonuniversal Higgs masses, the upper limit to the cross section is 6×10^{-4}.

[29] The strongest upper limit is 3 pb and occurs at $m_\chi \simeq 60$ GeV. The limits are for inelastic scattering $X^0 + {}^{129}Xe \rightarrow X^0 + {}^{129}Xe^*$ (39.58 keV).

[30] The strongest upper limit is 4.4 pb and occurs at $m_\chi \simeq 60$ GeV.

[31] The strongest upper limit is about 35 pb and occurs at $m_\chi \simeq 15$ GeV.

Spin-independent interactions

[1] The strongest upper limit is 2.2×10^{-12} pb at 40 GeV. This updates AALBERS 23.
[2] The strongest upper limit is 1.7×10^{-11} pb at 30 GeV. This updates APRILE 23A.
[3] The strongest limit is 1.6×10^{-11} pb at $m_\chi = 40$ GeV. This updates MENG 21B.
[4] The strongest limit is 7×10^{-8} at m = 85 GeV. This updates ADHIKARI 18.
[5] ABE 23E strongest upper limit is 1.4×10^{-8} pb at 60 GeV. Updates ABE 19.
[6] WANG 20G strongest limit is 2.2×10^{-10} pb at 30 GeV using 132 ton-day full exposure of PandaX-II. This updates CUI 17A, though the results here provide weaker constraints.
[7] This updates AMAUDRUZ 18.
[8] This updates AMOLE 16.
[9] The strongest limit is 1.09×10^{-8} pb at $m_\chi = 126$ GeV. This updates AGNES 15.
[10] The strongest limit is 1.0×10^{-8} pb at $m_\chi = 46$ GeV. This updates AGNESE 15B.
[11] Based on 278.8 days of data collection. The strongest limit is 4.1×10^{-11} pb at $m_\chi = 30$ GeV. This updates APRILE 17G.
[12] AKERIB 17. The strongest limit is 1.1×10^{-10} pb at 50 GeV. This updates AKERIB 16.
[13] The strongest limit is 1.1×10^{-9} pb at 50 GeV. This updates APRILE 12.
[14] The strongest upper limit is 7.6×10^{-10} at $m_\chi = 33$ GeV.
[15] Predictions for the spin-independent elastic cross section based on a frequentist approach to electroweak observables in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using the 20 fb^{-1} 8 TeV and the 5 fb^{-1} 7 TeV LHC data and the LUX data.
[16] The strongest limit is 3.6×10^{-6} pb and occurs at $m_\chi = 35$ GeV. Felizardo 2014 updates Felizardo 2012.
[17] Predictions for the spin-independent elastic cross section based on a Bayesian approach to electroweak observables in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using the 20 fb^{-1} LHC data and LUX.
[18] AGNESE 13 presents 90% CL limits on the elastic cross section for masses in the range 7–100 GeV using the Si based detector. The strongest upper limit is 1.8×10^{-6} pb at $m_\chi = 50$ GeV. This limit is improved to 7×10^{-7} pb in AGNESE 13A.
[19] This result updates LEBEDENKO 09. The strongest limit is 3.9×10^{-8} pb at $m_\chi = 52$ GeV.
[20] ANGLOHER 12 presents results of 730 kg days from the CRESST-II dark matter detector. They find two maxima in the likelihood function corresponding to best fit WIMP masses of 25.3 and 11.6 GeV with elastic cross sections of 1.6×10^{-6} and 3.7×10^{-5} pb respectively, see their Table 4. The statistical significance is more than 4σ. ANGLOHER 12 updates ANGLOHER 09
[21] Predictions for the spin-independent elastic cross section based on a frequentist approach to electroweak observables in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using the 5 fb^{-1} LHC data and XENON100.
[22] The strongest limit is 1.4×10^{-7} at $m_\chi = 60$ GeV.
[23] This result updates LEE 07A. The strongest limit is 2.1×10^{-7} at $m_\chi = 70$ GeV.
[24] AHMED 11A gives combined results from CDMS and EDELWEISS. The strongest limit is at $m_\chi = 90$ GeV.
[25] ARMENGAUD 11 updates result of ARMENGAUD 10. Strongest limit at $m_\chi = 85$ GeV.
[26] The strongest upper limit is 5.1×10^{-8} pb and occurs at $m_\chi \simeq 30$ GeV. The values quoted here are based on the analysis performed in ANGLE 08 with the update from SORENSEN 09.
[27] The strongest upper limit is 6.6×10^{-7} pb and occurs at $m_\chi \simeq 65$ GeV.
[28] AKERIB 06A updates the results of AKERIB 05. The strongest upper limit is 1.6×10^{-7} pb and occurs at $m_\chi \approx 60$ GeV.
[29] The strongest upper limit is also close to 1.0×10^{-6} pb and occurs at $m_\chi \simeq 70$ GeV. BENOIT 06 claim that the discrimination power of ZEPLIN-I measurement (ALNER 05A) is not reliable enough to obtain a limit better than 1×10^{-3} pb. However, SMITH 06 do not agree with the criticisms of BENOIT 06.
[30] AKERIB 04 is incompatible with BERNABEI 00 most likely value, under the assumption of standard WIMP-halo interactions. The strongest upper limit is 4×10^{-7} pb and occurs at $m_\chi \simeq 60$ GeV.
[31] Predictions for the spin-independent elastic cross section in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
[32] KIM 02 and ELLIS 04 calculate the χp elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry, but without universal scalar masses.
[33] In the case of universal squark and slepton masses, but non-universal Higgs masses, the limit becomes 2×10^{-6} (2×10^{-11} when constraint from the BNL $g-2$ experiment are included), see ELLIS 03E. ELLIS 05 display the sensitivity of the elastic scattering cross section to the π-Nucleon Σ term.
[34] PIERCE 04A calculates the χp elastic scattering cross section in the framework of models with very heavy scalar masses. See Fig. 2 of the paper.
[35] The strongest upper limit is 1.8×10^{-5} pb and occurs at $m_\chi \approx 80$ GeV.
[36] Under the assumption of standard WIMP-halo interactions, Akerib 03 is incompatible with BERNABEI 00 most likely value at the 99.98% CL. See Fig. 4.
[37] BAER 03A calculates the χp elastic scattering cross section in several models including the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.
[38] The strongest upper limit is 7×10^{-6} pb and occurs at $m_\chi \simeq 30$ GeV.
[39] ABRAMS 02 is incompatible with the DAMA most likely value at the 99.9% CL. The strongest upper limit is 3×10^{-6} pb and occurs at $m_\chi \simeq 30$ GeV.
[40] The strongest upper limit is 2×10^{-5} pb and occurs at $m_\chi \simeq 40$ GeV.
[41] The strongest upper limit is 7×10^{-6} pb and occurs at $m_\chi \simeq 46$ GeV.
[42] The strongest upper limit is 1.8×10^{-5} pb and occurs at $m_\chi \simeq 32$ GeV
[43] BOTTINO 01 calculates the χ-p elastic scattering cross section in the framework of the following supersymmetric models: N=1 supergravity with the radiative breaking of the electroweak gauge symmetry, N=1 supergravity with nonuniversal scalar masses and an effective MSSM model at the electroweak scale.
[44] Calculates the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.
[45] ELLIS 01C calculates the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. ELLIS 02B find a range 2×10^{-8}–1.5×10^{-7} at $\tan\beta$=50. In models with nonuniversal Higgs masses, the upper limit to the cross section is 4×10^{-7}.
[46] ACCOMANDO 00 calculate the χ-p elastic scattering cross section in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. The limit is relaxed by at least an order of magnitude when models with nonuniversal scalar masses are considered. A subset of the authors in ARNOWITT 02 updated the limit to $< 9 \times 10^{-8}$ ($\tan\beta < 55$).
[47] BERNABEI 00 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 4σ and are consistent, for a particular model framework quoted there, with m_{χ^0}=44^{+12}_{-9} GeV and a spin-independent χ^0-proton cross section of $(5.4 \pm 1.0) \times 10^{-6}$ pb. See also BERNABEI 01 and BERNABEI 00C.
[48] FENG 00 calculate the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry with a particular emphasis on focus point models. At $\tan\beta$=50, the range is 8×10^{-8}–4×10^{-7}.

Other bounds on $\tilde{\chi}_1^0$ from astrophysics and cosmology

Most of these papers generally exclude regions in the $M_2 - \mu$ parameter plane by requiring that the $\tilde{\chi}_1^0$ contribution to the overall cosmological density is less than some maximal value to avoid overclosure of the Universe. Those not based on the cosmological density are indicated. Many of these papers also include LEP and/or other bounds.

[1] ELLIS 00 updates ELLIS 98. Uses LEP e^+e^- data at $\sqrt{s}$=202 and 204 GeV to improve bound on neutralino mass to 51 GeV when scalar mass universality is assumed and 46 GeV when Higgs mass universality is relaxed. Limits on tanβ improve to > 2.7 ($\mu > 0$), > 2.2 ($\mu < 0$) when scalar mass universality is assumed and > 1.9 (both signs of μ) when Higgs mass universality is relaxed.

[2] ATHRON 17B places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using all Run I and the 13 fb^{-1} 13 TeV Run II LHC searches and other experimental data.

[3] BECHTLE 16 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using all Run I LHC searches.

[4] BAGNASCHI 15 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using all Run I LHC searches.

[5] Implications of the LHC result on the Higgs mass and on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[6] BUCHMUELLER 14A places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches using the 20 fb^{-1} 8 TeV and the 5 fb^{-1} 7 TeV LHC and the LUX data.

[7] ROSZKOWSKI 14 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using Bayesian statistics and indirect experimental searches using the 20 fb^{-1} LHC and the LUX data.

[8] CABRERA 13 and STREGE 13 place constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry with and without non-universal Higgs masses using the 5.8 fb^{-1}, $\sqrt{s} = 7$ TeV ATLAS supersymmetry searches and XENON100 results.

[9] ELLIS 13B place constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry with and without Higgs mass universality. Models with universality below the GUT scale are also considered.

[10] BALAZS 12 and STREGE 12 place constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using the 1 fb^{-1} LHC supersymmetry searches, the 5 fb^{-1} Higgs mass constraints, both with $\sqrt{s} = 7$ TeV, and XENON100 results.

[11] BECHTLE 12 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches, using the 5 fb^{-1} LHC and XENON100 data.

[12] BESKIDT 12 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches, the 5 fb^{-1} LHC and the XENON100 data.

[13] BELANGER 04 and BOTTINO 12 (see also BOTTINO 03, BOTTINO 03A and BOTTINO 04) do not assume gaugino or scalar mass unification.

[14] FENG 12B places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry and large sfermion masses using the 1 fb^{-1} LHC supersymmetry searches, the 5 fb^{-1} LHC Higgs mass constraints both with $\sqrt{s} = 7$ TeV, and XENON100 results.

[15] BUCHMUELLER 11 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches and including supersymmetry breaking relations between A and B parameters.

[16] Places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry but non-Universal Higgs masses.

[17] ELLIS 10 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry with universality above the GUT scale.

[18] BUCHMUELLER 09 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches.

[19] DREINER 09 show that in the general MSSM with non-universal gaugino masses there exists no model-independent laboratory bound on the mass of the lightest neutralino. An essentially massless χ_1^0 is allowed by the experimental and observational data, imposing some constraints on other MSSM parameters, including M_2, μ and the slepton and squark masses.

[20] BUCHMUELLER 08 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches.

[21] CALIBBI 07 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry with universality above the GUT scale including the effects of right-handed neutrinos.

[22] ELLIS 07 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry with universality below the GUT scale.

[23] ALLANACH 06 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[24] DE-AUSTRI 06 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[25] BALTZ 04 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[26] Limit assumes a pseudo scalar mass < 200 GeV. For larger pseudo scalar masses, $m_\chi > 18(29)$ GeV for tan$\beta = 50(10)$. Bounds from WMAP, $(g-2)_\mu$, $b \to s\gamma$, LEP.

[27] ELLIS 04B places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry including supersymmetry breaking relations between A and B parameters. See also ELLIS 03D.

[28] PIERCE 04A places constraints on the SUSY parameter space in the framework of models with very heavy scalar masses.

[29] BAER 03, CHATTOPADHYAY 03, ELLIS 03C and LAHANAS 03 place constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry based on WMAP results for the cold dark matter density.

[30] BOEHM 00B and ELLIS 03 place constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Includes the effect of χ-$\tilde{t}$ co-annihilations.

[31] LAHANAS 02 places constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on the role of pseudo-scalar Higgs exchange.

[32] BARGER 01C use the cosmic relic density inferred from recent CMB measurements to constrain the parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[33] ELLIS 01B places constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on models with large tanβ.

[34] FENG 00 explores cosmologically allowed regions of MSSM parameter space with multi-TeV masses.

[35] ELLIS 98B assumes a universal scalar mass and radiative supersymmetry breaking with universal gaugino masses. The upper limit to the LSP mass is increased due to the inclusion of $\chi - \tilde{\tau}_R$ coannihilations.

[36] EDSJO 97 included all coannihilation processes between neutralinos and charginos for any neutralino mass and composition.

[37] Notes the location of the neutralino Z resonance and h resonance annihilation corridors in minimal supergravity models with radiative electroweak breaking.

[38] Mass of the bino (=LSP) is limited to $m_{\tilde{B}} \lesssim 350$ GeV for $m_t = 174$ GeV.

[39] DREES 93, KELLEY 93 compute the cosmic relic density of the LSP in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[40] FALK 93 relax the upper limit to the LSP mass by considering sfermion mixing in the MSSM.

[41] MIZUTA 93 include coannihilations to compute the relic density of Higgsino dark matter.

[42] LOPEZ 92 calculate the relic LSP density in a minimal SUSY GUT model.

[43] MCDONALD 92 calculate the relic LSP density in the MSSM including exact tree-level annihilation cross sections for all two-body final states.

[44] GRIEST 91 improve relic density calculations to account for coannihilations, pole effects, and threshold effects.

[45] NOJIRI 91 uses minimal supergravity mass relations between squarks and sleptons to narrow cosmologically allowed parameter space.

[46] Mass of the bino (=LSP) is limited to $m_{\widetilde{B}} \lesssim 350$ GeV for $m_t \leq 200$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\widetilde{H}} \lesssim 1$ TeV for $m_t \leq 200$ GeV.

[47] ROSZKOWSKI 91 calculates LSP relic density in mixed gaugino/higgsino region.

[48] Mass of the bino (=LSP) is limited to $m_{\widetilde{B}} \lesssim 550$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\widetilde{H}} \lesssim 3.2$ TeV.

[49] KRAUSS 83 finds $m_{\widetilde{\gamma}}$ not 30 eV to 2.5 GeV. KRAUSS 83 takes into account the gravitino decay. Find that limits depend strongly on reheated temperature. For example a new allowed region $m_{\widetilde{\gamma}} = 4$–20 MeV exists if $m_{\text{gravitino}}$ <40 TeV. See figure 2.

Unstable $\widetilde{\chi}_1^0$ (Lightest Neutralino) mass limit

Unless otherwise stated, results in this section assume spectra and production rates as evaluated in the MSSM. Unless otherwise stated, the goldstino or gravitino mass $m_{\widetilde{G}}$ is assumed to be negligible relative to all other masses. In the following, $\widetilde{G}$ is assumed to be undetected and to give rise to a missing energy ($\not{E}$) signature.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 25BJ searched in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for an excess of 0-lepton events with at least one hadronically decaying τ and at least 3 b-jet. The search is performed by training a neural network to separate a signal of vector-like leptons from the Standard Model background. No significant excess above the Standard Model expectations is observed. Limits are set also in a model of SUSY, where members of either a higgsino LSP triplet or a wino LSP doublet are produced, and decay via a RPV λ'_{333} coupling to b, t quarks and τ, ν_τ leptons, see their Figs. 13 and 14.

[2] AAD 24AX searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of higgsino pair production in events with two photons and two b-tagged jets. No significant excess above the Standard Model expectations is observed. Limits are set in the model Tn1n1A, see their Fig. 5, and in a model similar to Tn1n1B, but with variable branching ratios of $\widetilde{\chi}_1^0 \to h\widetilde{G}$ and $\widetilde{\chi}_1^0 \to Z\widetilde{G}$, to reflect the dependency on the neutralino mixing matrix, see their Fig. 6.

[3] AAD 24U searched in 126–139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of higgsino pair production in events with ≥ 3 b-tagged jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set in the model Tn1n1A, see their Fig. 12, which also contains upper limits on the branching ratio, reaching as low as 14% for a higgsino mass of 400 GeV. Model-independent limits are also set on the visible cross section for new physics processes.

[4] HAYRAPETYAN 24AP searched in 128 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of pair-produced multijet signatures probing fully hadronic final states. No significant excess above the Standard Model expectations is observed. Limits are set in three RPV SUSY models: higgsino pair production with decay to merged trijets, stop pair production with decay to merged dijets, and pair-produced gluinos decaying to resolved trijets, see their Fig. 4.

[5] HAYRAPETYAN 24N searched in up to 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of wino-like chargino-neutralino pairs, Higgsino-like neutralino pair production in a gauge-mediated SUSY breaking inspired scenario, a Higgsino-bino interpretation, and slepton pair production in a combination of a number of previously reported searches for SUSY in different final states. No significant excess above the Standard Model expectations is observed. Limits are set on the $\widetilde{\chi}_1^\pm$ mass in the wino-bino models Tchi1n2E1, Tchi1n2E, and Tchi1n2l, see their Fig. 11, and on the $\widetilde{\chi}_1^0$ in the higgsino-like GMSB models Tn1n1A, Tn1n1B, and Tn1n1C, see their Fig. 13. In addition, Fig. 14 shows the mass exclusion limit as a function of the branching fraction to the H boson. Limits are also set in a Higgsino-bino interpretation as in THinoBinoA, but also including leptonic decays, see their Fig. 15. Limits are also set on slepton ($\widetilde{e}$, $\widetilde{\mu}$) production with the decay $\widetilde{\ell} \to \ell\widetilde{\chi}_1^0$, see their Fig. 16.

[6] AAD 23AE searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 2 ℓ with same flavour and opposite sign, plus jets and $\not{E}_T$, defining signal region with the dilepton invariant mass both on- and off-shell with respect to the Z boson. No significant excess above the Standard Model predictions is observed. Limits are set on models of strong and electroweak production. In this case, limits are placed on production of mass-degenerate, higgsino triplet NLSP with $\widetilde{\chi}_1^0 \to Z\widetilde{G}$ in a GGM-like scenario, see figure 15.

[7] AAD 23AM searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing electron/photon pairs with invariant mass compatible with h/Z and originating from a common displaced vertex. No significant excess above the Standard Model predictions is observed. Limits are set on a model where members of a nearly degenerate higgsino triplet are pair-produced, yielding long-lived $\widetilde{\chi}_1^0$ followed by $\widetilde{\chi}_1^0 \to h/Z\widetilde{G}$. Limits are set on $m_{\widetilde{\chi}_1^0}$ as a function of its lifetime and of the B($\widetilde{\chi}_1^0 \to h\widetilde{G}$) assuming B($\widetilde{\chi}_1^0 \to h\widetilde{G}$) + B($\widetilde{\chi}_1^0 \to Z\widetilde{G}$) = 1, see Figure 10.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[8] AAD 23CP searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with 2 ℓ with same charge or 3 ℓ plus at least one jet and $\not{E}_T$, defining signal region based on 'stransverse mass' of the dilepton system, $\not{E}_T$ significance and effective mass. No significant excess above the Standard Model predictions is observed. Limits are set on the mass of a mass-degenerate higgsino triplet decaying into a lepton (neutral or charged) and a W via a bilinear RPV coupling, see figure 14.

[9] TUMASYAN 23AO searched in 138 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for evidence of neutralino-chargino production in events with nearly trackless and out-of-time jets that are used to identify decays of long-lived particles. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of the long-lived $\widetilde{\chi}_1^0$ in the model Tn1n1B, see their figures 8–10.

[10] AAD 21Y searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with four or more leptons (electrons, muons and tau-leptons). No significant excess above the Standard Model expectations is observed. Limits are set on Tchi1n12-GGM, and RPV models similar to Tchi1n2l, Tglu1A (with q = u, d, s, c, b, with equal branching fractions), and $\widetilde{\ell}_L/\widetilde{\nu} \rightarrow \ell/\nu\widetilde{\chi}_1^0$ (mass-degenerate $\widetilde{\ell}_L$ and $\widetilde{\nu}$ of all 3 generations), all with $\widetilde{\chi}_1^0 \rightarrow \ell^{\pm}\ell^{\mp}\nu$ via λ_{12k} or λ_{i33} (where $i,k \in 1,2$), see their Figure 11.

[11] AAIJ 21V searched in 5.38 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for long-lived particles (LLP) decaying to $e^{\pm}\mu^{\mp}\nu$. The LLP can be a $\widetilde{\chi}_1^0$ in RPV SUSY, or a right-handed neutrino, and can be produced in pairs, in the decay of the Higgs boson, or from charged current processes. No significant excess above the Standard Model expectations is observed. Limits are set on the cross section times branching ratio for all three production mechanisms, see their Figures 6–8.

[12] SIRUNYAN 21AF searched in 140 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with with two displaced vertices from long-lived particles decaying into multijet or dijet final states. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu2RPV with λ''_{323} coupling, on the $\widetilde{\chi}_1^0$ mass in an RPV model with $\widetilde{\chi}_1^0$ pair production and the RPV decay $\widetilde{\chi}_1^0 \rightarrow tbs$ with λ''_{323} coupling and on the $\widetilde{t}$ mass in an RPV model with top squark pair production and the RPV decay $\widetilde{t} \rightarrow \overline{d}_i\,\overline{d}_j$ with λ''_{3ij} coupling, see their Figure 7.

[13] SIRUNYAN 21M searched in 137 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with two opposite-sign same-flavor leptons (electrons, muons) and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu4C, see their Figure 10, on the $\widetilde{\chi}_2^0$ and $\widetilde{\chi}_1^{\pm}$ mass in Tchi1n2Fa, see their Figure 11, on the $\widetilde{\chi}_1^0$ mass in Tn1n1C and Tn1n1B for $m_{\widetilde{\chi}_2^0}$=$m_{\widetilde{\chi}_1^{\pm}}$=$m_{\widetilde{\chi}_1^0}$, see their Figure 12. Limits are also set on the light squark mass for the simplified model Tsqk2A, on the sbottom mass in Tsbot3, see their Figure 13, and on the slepton mass in direct electroweak pair production of mass-degenerate left- and right-handed sleptons (selectrons and smuons), see their Figure 14.

[14] AAD 20AN searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with two photons and missing transverse momentum. Events are further categorised in terms of lepton or jet multiplicity. No significant excess over the expected background is observed. Limits at 95% C.L. are set on the Higgsino mass in the T1n1n1A simplified model, see their Figure 11.

[15] SIRUNYAN 19CA searched in 77.4 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events containing delayed photons in both single and diphoton plus $\not{E}_T$ final states. No excess is observed above the background expected from Standard Model processes. The results are used to set 95% C.L. exclusion limits in the context of GMSB, using the SPS8 benchmark model. For neutralino proper decay lengths of 0.1, 1, 10, and 100 m, masses up to about 320, 525, 360, and 215 GeV are excluded, respectively. See their Fig. 5. The searches involve the simplified models Tglu1D, Tglu4A,B,C, Tsqk4,4A,4B.

[16] SIRUNYAN 19CI searched in 77.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with one or more high-momentum Higgs bosons, decaying to pairs of photons, jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in the Tsbot4 simplified model, see Figure 3, and on the wino mass in the Tchi1n2E simplified model, see their Figure 4. Limits are also set on the higgsino mass in the Tn1n1A and Tn1n1B simplified models, see their Figure 5.

[17] SIRUNYAN 19K searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with a photon, an electron or muon, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. In the framework of GMSB, limits are set on the chargino and neutralino mass in the Tchi1n1A simplified model, see their Figure 6. Limits are also set on the gluino mass in the Tglu4A simplified model, and on the squark mass in the Tsqk4A simplified model, see their Figure 7.

[18] AABOUD 18CK searched for events with at least 3 b-jets and large missing transverse energy in two datasets of pp collisions at $\sqrt{s}$ = 13 TeV of 36.1 fb^{-1} and 24.3 fb^{-1} depending on the trigger requirements. The analyses aimed to reconstruct two Higgs bosons decaying to pairs of b-quarks. No significant excess above the Standard Model expectations is observed. Limits are set on the Higgsino mass in the Tn1n1A simplified model, see their Figure 15(a). Constraints are also presented as a function of the BR of Higgsino decaying into an higgs boson and a gravitino, see their Figure 15(b).

[19] AABOUD 18Z searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events containing four or more charged leptons (electrons, muons and up to two hadronically decaying taus). No significant deviation from the expected SM background is observed. Limits are set on the Higgsino mass in simplified models of general gauge mediated supersymmetry Tn1n1A/Tn1n1B/Tn1n1C, see their Figure 9. Limits are also set on the wino, slepton, sneutrino and gluino mass in a simplified model of NLSP pair production with R-parity violating decays of the LSP via λ_{12k} or λ_{i33} to charged leptons, see their Figures 7, 8.

[20] SIRUNYAN 18AO searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of charginos and neutralinos in events with either two or more leptons (electrons or muons) of the same electric charge, or with three or more leptons, which can include up to two hadronically decaying tau leptons. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino/neutralino mass in the Tchi1n2A, Tchi1n2H, Tchi1n2D, Tchi1n2E and Tchi1n2F simplified models, see their Figures 14, 15, 16, 17 and 18. Limits are also set on the higgsino mass in the Tn1n1A, Tn1n1B and Tn1n1C simplified models, see their Figure 19.

[21] SIRUNYAN 18AP searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of charginos and neutralinos by combining a number of previous and new searches. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino/neutralino mass in the Tchi1n2E, Tchi1n2F and Tchi1n2l simplified models, see their Figures 7, 8, 9 an 10. Limits are also set on the higgsino mass in the Tn1n1A, Tn1n1B and Tn1n1C simplified models, see their Figure 11, 12, 13 and 14.

[22] SIRUNYAN 18AR searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events containing two opposite-charge, same-flavour leptons (electrons or muons), jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu4C simplified model, see their Figure 7. Limits are also set on the chargino/neutralino mass in the Tchi1n2F simplified models, see their Figure 8, and on the higgsino mass in the Tn1n1B and Tn1n1C simplified models, see their Figure 9. Finally, limits are set on the sbottom mass in the Tsbot3 simplified model, see their Figure 10.

[23] SIRUNYAN 18O searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with two Higgs bosons, decaying to pairs of b-quarks, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the Higgsino mass in the T1n1n1A simplified model, see their Figure 9.

[24] SIRUNYAN 18X searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with one or more high-momentum Higgs bosons, decaying to pairs of photons, jets and $\not{E}_T$. The razor variables (M_R and R^2) are used to categorise the events. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in the Tsbot4 simplified model and on the wino mass in the Tchi1n2E simplified model, see their Figure 5. Limits are also set on the higgsino mass in the Tn1n1A and Tn1n1B simplified models, see their Figure 6.

[25] KHACHATRYAN 14L searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for evidence of direct pair production of neutralinos with Higgs or Z-bosons in the decay chain, leading to HH, HZ and ZZ final states with missing transverse energy. The decays of 16–20. a Higgs boson to a b-quark pair, to a photon pair, and to final states with leptons are considered in conjunction with hadronic and leptonic decay modes of the Z and W bosons. No significant excesses over the expected SM backgrounds are observed. The results are interpreted in the context of GMSB simplified models where the decays $\widetilde{\chi}_1^0 \rightarrow H\widetilde{G}$ or $\widetilde{\chi}_1^0 \rightarrow Z\widetilde{G}$ take place either 100% or 50% of the time, see Figs. 16–20.

[26] AAD 20D searched in 32.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events containing an oppositely charge lepton pair (ee, $\mu\mu$ or $e\mu$) coming from long-lived neutralinos decaying through the R-parity-violating decay $\widetilde{\chi}_1^0 \rightarrow \ell\ell\nu$ with $\lambda_{121} \neq 0$ or $\lambda_{122} \neq 0$. No excess over the expected background is observed. Limits are derived for decay lengths of the neutralino between 1 mm and 10 m in a scenario where a squark-antisquark pair is produced, with the squark decaying to a quark and a $\widetilde{\chi}_1^0$, with either $\widetilde{\chi}_1^0 \rightarrow ee\nu/e\mu\nu$ ($\lambda_{121} \neq 0$) or $\widetilde{\chi}_1^0 \rightarrow e\mu\nu/\mu\mu\nu$ ($\lambda_{122} \neq 0$), see their Figures 4 and 5.

[27] AABOUD 19G searched in 32.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for evidence of neutralinos decaying into a Z-boson and a gravitino, in events characterized by the presence of dimuon vertices with displacements from the pp interaction point in the range of 1400 cm. Neutralinos are assumed to be produced in the decay chain of gluinos as in Tglu1A models. No significant excess is observed in the number of vertices relative to the predicted background. In GGM with a gluino mass of 1100 GeV, neutralino masses in the range 300–1000 GeV are excluded for certain values of $c\tau$, see their Figure 7.

[28] AAIJ 17Z searched in 1 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV and in 2 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing a displaced vertex with one associated high transverse momentum μ. No excess is observed above the background expected from Standard Model processes. The results are used to set 95% C.L. upper limits on the cross section times branching fractions of pair-produced neutralinos decaying non-promptly into a muon and two quarks. Long-lived particles in a mass range 23–198 GeV are considered, see their Fig. 5 and Fig. 6.

[29] KHACHATRYAN 16BX searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing 3 or more leptons coming from the electroweak production of wino- or higgsino-like neutralinos, assuming non-zero R-parity-violating leptonic couplings λ_{122}, λ_{123}, and λ_{233} or semileptonic couplings λ'_{131}, λ'_{233}, λ'_{331}, and λ'_{333}. No excess over the expected background is observed and limits are derived on the neutralino mass, see Figs. 24 and 25.

[30] AAD 14BH searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing non-pointing photons in a diphoton plus missing transverse energy final state. No excess is observed above the background expected from Standard Model processes. The results are used to set 95% C.L. exclusion limits in the contact of gauge-mediated supersymmetric breaking models, with the lightest neutralino being the next-to-lightest supersymmetric particle and decaying with a lifetime in the range from 0.25 ns to about 100 ns into a photon and a gravitino. For limits on the NLSP lifetime versus Λ plane, for the SPS8 model, see their Fig. 7.

[31] AAD 13AP searched in 4.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing non-pointing photons in a diphoton plus missing transverse energy final state. No excess is observed above the background expected from Standard Model processes. The results are used to set 95% C.L. exclusion limits in the context of gauge-mediated supersymmetric breaking models, with the lightest neutralino being the next-to-lightest supersymmetric particle and decaying with a lifetime in excess of 0.25 ns into a photon and a gravitino. For limits in the NLSP lifetime versus Λ plane, for the SPS8 model, see their Fig. 8.

[32] AAD 13Q searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing a high-p_T isolated photon, at least one jet identified as originating from a bottom quark, and high missing transverse momentum. Such signatures may originate from supersymmetric models with gauge-mediated supersymmetry breaking in events in which one of a pair of higgsino-like neutralinos decays into a photon and a gravitino while the other decays into a Higgs boson and a gravitino. No significant excess above the expected background was found and limits were set on the neutralino mass in a generalized GMSB model (GGM) with a higgsino-like neutralino NLSP, see their Fig. 4. Intermediate neutralino masses between 220 and 380 GeV are excluded at 95% C.L, regardless of the squark and gluino masses, purely on the basis of the expected weak production.

[33] AAD 13R looked in 4.4 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing new, heavy particles that decay at a significant distance from their production point into a final state containing a high-momentum muon and charged hadrons. No excess over the expected background is observed and limits are placed on the production cross-section of neutralinos via squarks for various $m_{\widetilde{q}}$, $m_{\widetilde{\chi}_1^0}$ in an R-parity violating scenario with $\lambda'_{211} \neq 0$, as a function of the neutralino lifetime, see their Fig. 6.

[34] AALTONEN 13I searched in 6.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events containing $\not{E}_T$ and a delayed photon that arrives late in the detector relative to the time expected from prompt production. No evidence of delayed photon production is observed.

[35] CHATRCHYAN 13AH searched in 4.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing $\not{E}_T$ and a delayed photon that arrives late in the detector relative to the time expected from prompt production. No significant excess above the expected background was found and limits were set on the pair production of $\widetilde{\chi}_1^0$ depending on the neutralino proper decay length, see Fig. 8. Supersedes CHATRCHYAN 12BK.

[36] AAD 12CP searched in 4.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two photons and large $\not{E}_T$ due to $\tilde{\chi}_1^0 \to \gamma\tilde{G}$ decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the neutralino mass in a generalized GMSB model (GGM) with a bino-like neutralino NLSP, see Figs. 6 and 7. The other sparticle masses were decoupled, tanβ = 2 and $c\tau_{NLSP} < 0.1$ mm. Also, in the framework of the SPS8 model, limits are presented in Fig. 8.

[37] AAD 12CT searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing four or more leptons (electrons or muons) and either moderate values of missing transverse momentum or large effective mass. No significant excess is found in the data. Limits are presented in a simplified model of R-parity violating supersymmetry in which charginos are pair-produced and then decay into a W-boson and a $\tilde{\chi}_1^0$, which in turn decays through an RPV coupling into two charged leptons ($e^{\pm}e^{\mp}$ or $\mu^{\pm}\mu^{\mp}$) and a neutrino. In this model, limits are set on the neutralino mass as a function of the charging mass, see Fig. 3a. Limits are also set in an R-parity violating mSUGRA model, see Fig. 3b.

[38] AAD 12R looked in 33 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing new, heavy particles that decay at a significant distance from their production point into a final state containing a high-momentum muon and charged hadrons. No excess over the expected background is observed and limits are placed on the production cross-section of neutralinos via squarks for various ($m_{\tilde{q}}$, $m_{\tilde{\chi}_1^0}$) in an R-parity violating scenario with $\lambda'_{211} \neq 0$, as a function of the neutralino lifetime, see their Fig. 8. Superseded by AAD 13R.

[39] ABAZOV 12AD looked in 6.2 fb^{-1} of pp collisions at $\sqrt{s}$ = 1.96 TeV for events with a photon, a Z-boson, and large $\not{E}_T$ in the final state. This topology corresponds to a GMSB model where pairs of neutralino NLSPs are either pair produced promptly or from decays of other supersymmetric particles and then decay to either $Z\tilde{G}$ or $\gamma\tilde{G}$. No significant excess over the SM expectation is observed and a limit at 95% C.L. on the cross section is derived as a function of the effective SUSY breaking scale Λ, see Fig. 3. Assuming N_{mes} = 2, M_{mes} = 3 Λ, tanβ = 3, μ = 0.75 M_1, and C_{grav} = 1, the model is excluded at 95% C.L. for values of Λ < 87 TeV.

[40] CHATRCHYAN 12BK searched in 2.23 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two photons and large $\not{E}_T$ due to $\tilde{\chi}_1^0 \to \gamma\tilde{G}$ decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the pair production of $\tilde{\chi}_1^0$ depending on the neutralino lifetime, see Fig. 6.

[41] CHATRCHYAN 11B looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$=7 TeV for events with an isolated lepton (e or μ), a photon and $\not{E}_T$ which may arise in a generalized gauge mediated model from the decay of Wino-like NLSPs. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark/gluino mass versus Wino mass (see Fig. 4). Mass degeneracy of the produced squarks and gluinos is assumed.

[42] AALTONEN 10 searched in 2.6 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for diphoton events with large $\not{E}_T$. They may originate from the production of $\tilde{\chi}^{\pm}$ in pairs or associated to a $\tilde{\chi}_2^0$, decaying into $\tilde{\chi}_1^0$ which itself decays in GMSB to $\gamma\tilde{G}$. There is no excess of events beyond expectation. An upper limit on the cross section is calculated in the GMSB model as a function of the $\tilde{\chi}_1^0$ mass and lifetime, see their Fig. 2. A limit is derived on the $\tilde{\chi}_1^0$ mass of 149 GeV for $\tau_{\tilde{\chi}_1^0} \ll 1$ ns, which improves the results of previous searches.

[43] ABAZOV 10P looked in 6.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with at least two isolated γs and large $\not{E}_T$. These could be the signature of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^{\pm}$ production, decaying to $\tilde{\chi}_1^0$ and finally $\tilde{\chi}_1^0 \to \gamma\tilde{G}$ in a GMSB framework. No significant excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section is derived for N_{mes} = 1, tanβ = 15 and μ > 0, see their Fig. 2. This allows them to set a limit on the effective SUSY breaking scale Λ > 124 TeV, from which the excluded $\tilde{\chi}_1^0$ mass range is obtained.

[44] ABAZOV 08F looked in 1.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for diphoton events with large $\not{E}_T$. They may originate from the production of $\tilde{\chi}^{\pm}$ in pairs or associated to a $\tilde{\chi}_2^0$, decaying to a $\tilde{\chi}_1^0$ which itself decays promptly in GMSB to $\tilde{\chi}_1^0 \to \gamma\tilde{G}$. No significant excess was found compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\Lambda$, N = 1, tanβ = 15 and μ > 0, see Figure 2. It also excludes Λ < 91.5 TeV. Supersedes the results of ABAZOV 05A. Superseded by ABAZOV 10P.

[45] ABULENCIA 07H searched in 346 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with at least three leptons (e or μ) from the decay of $\tilde{\chi}_1^0$ via $LL\overline{E}$ couplings. The results are consistent with the hypothesis of no signal. Upper limits on the cross-section are extracted and a limit is derived in the framework of mSUGRA on the masses of $\tilde{\chi}_1^0$ and $\tilde{\chi}_1^{\pm}$, see e.g. their Fig. 3 and Tab. II.

[46] ABBIENDI 06B use 600 pb^{-1} of data from $\sqrt{s}$ = 189–209 GeV. They look for events with diphotons + $\not{E}$ final states originating from prompt decays of pair-produced neutralinos in a GMSB scenario with $\tilde{\chi}_1^0$ NLSP. Limits on the cross-section are computed as a function of m($\tilde{\chi}_1^0$), see their Fig. 14. The limit on the $\tilde{\chi}_1^0$ mass is for a pure Bino state assuming a prompt decay, with lifetimes up to 10^{-9}s. Supersedes the results of ABBIENDI 04N.

[47] ABDALLAH 05B use data from $\sqrt{s}$ = 180–209 GeV. They look for events with single photons + $\not{E}$ final states. Limits are computed in the plane (m($\tilde{G}$) , m($\tilde{\chi}_1^0$)), shown in their Fig. 9b for a pure Bino state in the GMSB framework and in Fig. 9c for a no-scale supergravity model. Supersedes the results of ABREU 00Z.

[48] ABDALLAH 05B use data from $\sqrt{s}$ = 130–209 GeV. They look for events with diphotons + $\not{E}$ final states and single photons not pointing to the vertex, expected in GMSB when the $\tilde{\chi}_1^0$ is the NLSP. Limits are computed in the plane (m($\tilde{G}$), m($\tilde{\chi}_1^0$)), see their Fig. 10. The lower limit is derived on the $\tilde{\chi}_1^0$ mass for a pure Bino state assuming a prompt decay and $m_{\tilde{e}_R} = m_{\tilde{e}_L} = 2\, m_{\tilde{\chi}_1^0}$. It improves to 100 GeV for $m_{\tilde{e}_R} = m_{\tilde{e}_L} = 1.1\, m_{\tilde{\chi}_1^0}$. and the limit in the plane (m($\tilde{\chi}_1^0$), m($\tilde{e}_R$)) is shown in Fig. 10b. For long-lived neutralinos, cross-section limits are displayed in their Fig 11. Supersedes the results of ABREU 00Z.

$\tilde{\chi}_2^0$, $\tilde{\chi}_3^0$, $\tilde{\chi}_4^0$ (Neutralinos) mass limits

Neutralinos are unknown mixtures of photinos, z-inos, and neutral higgsinos (the supersymmetric partners of photons and of Z and Higgs bosons). The limits here apply only to $\tilde{\chi}_2^0$, $\tilde{\chi}_3^0$, and $\tilde{\chi}_4^0$. $\tilde{\chi}_1^0$ is the lightest supersymmetric particle (LSP); see $\tilde{\chi}_1^0$ Mass Limits. It is not possible to quote rigorous mass limits because they are extremely model dependent; i.e. they depend on branching ratios of various $\tilde{\chi}^0$ decay modes, on the masses of decay products ($\tilde{e}$, $\tilde{\gamma}$, $\tilde{q}$, $\tilde{g}$), and on the $\tilde{e}$ mass exchanged in $e^+e^- \to \tilde{\chi}_i^0\tilde{\chi}_j^0$. Limits arise either from direct searches, or from the MSSM constraints set on the gaugino and higgsino mass parameters M_2 and μ through searches for lighter charginos and neutralinos. Often limits are given as contour plots in the $m_{\tilde{\chi}^0} - m_{\tilde{e}}$ plane vs other parameters. When specific assumptions are made, e.g, the neutralino is a pure photino ($\tilde{\gamma}$), pure z-ino ($\tilde{Z}$), or pure neutral higgsino ($\tilde{H}^0$), the neutralinos will be labelled as such.

Limits obtained from e^+e^- collisions at energies up to 136 GeV, as well as other limits from different techniques, are now superseded and have not been included in this compilation. They can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review. Some later papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 25BJ searched in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for an excess of 0-lepton events with at least one hadronically decaying τ and at least 3 b-jet. The search is performed by training a neural network to separate a signal of vector-like leptons from the Standard Model background. No significant excess above the Standard Model expectations is observed. Limits are set also in a model of SUSY, where members of either a higgsino LSP triplet or a wino LSP doublet are produced, and decay via a RPV λ'_{333} coupling to b, t quarks and τ, ν_τ leptons, see their Figs. 13 and 14.

[2] CHEKHOVSKY 25M searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of SUSY models with compressed mass spectra in events with a high transverse momentum system from initial-state-radiation jets recoiling against a potential sparticle system with significant missing transverse momentum. These events are further categorized based on their lepton multiplicity, jet multiplicity, number of b-tagged jets, and kinematic variables sensitive to the sparticle masses and mass splittings. No significant excess above the Standard Model expectations is observed. The results are interpreted in models of top squark, electroweakino and slepton pair production. Limits are set for top squark pair production in the models Tstop1 and Tstop2, see their figure 25, and in Tstop4, see their figure 26. The results are also interpreted in models describing the production of mass-degenerate $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ with decays $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ and $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$, applying both a wino-like and higgsino-like $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ production cross section, see their figure 27. Limits are also set for wino-like $\tilde{\chi}_1^\pm$ pair production, either with $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$ or in the model Tchi1chi1C. This paper also addresses direct slepton production, taking into account pure right-handed, pure left-handed and combined production of either selectrons, smuons, or mass-degenerate sleptons of the first and second generation, see their figures 30 and 31.

[3] HAYRAPETYAN 25AH searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for new physics in jet multiplicity patterns in three-lepton events with and without b quarks. No significant excess above the Standard Model expectations is observed. The results are interpreted in a model similar to Tchi1n2E, but with additional prompt hadronic R-parity violating decay of $\tilde{\chi}_1^0$ to three quarks, either as $\tilde{\chi}_1^0 \to uds$ or $\tilde{\chi}_1^0 \to udb$, see their figure 3.

[4] AAD 24AJ searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of direct stau pair production, or electroweakino pair production with decay via an intermediate stau, in events with two taus decaying hadronically (including a same-charge channel), no b-jets and moderate $\not{E}_T$, using a BDT for the direct stau search and a more traditional cut-and-count selection for the electroweakino search. No significant excess above the Standard Model expectations is observed. Limits are set in models of direct stau production $\tilde{\tau} \to \tau\tilde{\chi}_1^0$, $\tilde{\tau}_L$, $\tilde{\tau}_R$ or degenerate production. Limits are also set in models of pair production of charginos (Tchichi1D) or of charginos and neutralinos (Tchi1n2D) followed by the decay via intermediate staus, or (for the latter) via Wh (Tchi1n2E). See their figures 12, 14 and 16.

[5] AAD 24G searched in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of higgsino pair production in events with low-momentum mildly displaced tracks. No significant excess above the Standard Model expectations is observed. Limits are set in the model Tn1n1D, see their Fig. 3, assuming that the $\tilde{\chi}_1^\pm$ has a flight length of about 0.11 mm from the pp interaction point and decays to $\tilde{\chi}_1^0$ and a charged particle (usually a soft pion) that is measured as low-momentum track.

[6] AAD 24I provides a statistical combination of the results of a number of analyses targeting electroweak production performed using 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV. The combination was used to set limits on the pair-produced particle masses as a function of the LSP mass for wino-like $\tilde{\chi}_1^\pm\tilde{\chi}_1^\pm$ followed by $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$, wino-like $\tilde{\chi}_2^0\tilde{\chi}_1^\pm$ followed by $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$ and either $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ or $\tilde{\chi}_2^0 \to h\tilde{\chi}_1^0$, or a GGM-like model with a full higgsino triplet decaying to a gravitino. See their Fig. 2.

[7] HAYRAPETYAN 24N searched in up to 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of wino-like chargino-neutralino pairs, Higgsino-like neutralino pair production in a gauge-mediated SUSY breaking inspired scenario, a Higgsino-bino interpretation, and slepton pair production in a combination of a number of previously reported searches for SUSY in different final states. No significant excess above the Standard Model expectations is observed. Limits are set on the $\tilde{\chi}_1^\pm$ mass in the wino-bino models Tchi1n2E1, Tchi1n2E, and Tchi1n2l, see their Fig. 11, and on the $\tilde{\chi}_1^0$ in the higgsino-like GMSB models Tn1n1A, Tn1n1B, and Tn1n1C, see their Fig. 13. In addition, Fig. 14 shows the mass exclusion limit as a function of the branching fraction to the H boson. Limits are also set in a Higgsino-bino interpretation as in THinoBinoA, but also including leptonic decays, see their Fig. 15. Limits are also set on slepton ($\tilde{e}$, $\tilde{\mu}$) production with the decay $\tilde{\ell} \to \ell\tilde{\chi}_1^0$, see their Fig. 16.

[8] AAD 23AE searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 2 ℓ with same flavour and opposite sign, plus jets and $\not{E}_T$, defining signal region with the dilepton invariant mass both on- and off-shell with respect to the Z boson. No significant excess above the Standard Model predictions is observed. Limits are set on models of strong and electroweak production. For electroweak production, limits are placed on production of mass-degenerate, wino-like $\tilde{\chi}_2^0\,\tilde{\chi}_1$ with $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ and $\tilde{\chi}_1 \to W\tilde{\chi}_1^0$, see figure 15.

[9] AAD 23CI searched in 139 fb^{-1} of pp collisions for events containing 1 ℓ (e or μ), jets, and $\not{E}_T$. Final states consistent with the production of a diboson system plus $\not{E}_T$ were identified also by making use of large-R jet tagging techniques. No excess on top of the Standard Model background was observed. Limits were set on the production of $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm\tilde{\chi}_1^\pm$ (assuming wino cross sections) decaying to $WZ\tilde{\chi}_1^0\tilde{\chi}_1^0$ or $WW\tilde{\chi}_1^0\tilde{\chi}_1^0$. See their figure 9.

[10] AAD 23CI searched in 139 fb^{-1} of pp collisions for events containing 1 ℓ (e or μ), jets, and $\not{E}_T$. Final states consistent with the production of a boson + Higgs system plus $\not{E}_T$ were identified via a BDT. No excess on top of the Standard Model background was observed. Limits were set on the production of degenerate $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ (assuming wino cross sections) decaying into $Wh\tilde{\chi}_1^0\tilde{\chi}_1^0$. See their figure 10.

[11] AAD 23CP searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 2 ℓ with same charge plus at least one jet and $\not{E}_T$, defining signal region based on 'stransverse mass' of the dilepton system, $\not{E}_T$ significance and effective mass. No significant excess above the Standard Model predictions is observed. Limits are set on the mass of mass-degenerate $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ for the wino-like production of $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ followed by the decay into either $WZ\tilde{\chi}_1^0\tilde{\chi}_1^0$ or $Wh\tilde{\chi}_1^0\tilde{\chi}_1^0$, see figure 13.

[12] AAD 23CR searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for RPV SUSY in final states with multiple leptons and b-tagged jets. No significant excess above the Standard Model expectations is observed. Limits are set on the production of electroweakinos (wino or higgsino) that decay via RPV coupling λ'_{133} to a charged lepton or a neutrino, a b quark, and an additional t or b quark, see their figure 16. A second model addresses direct $\tilde{\mu}_{L,R}$ production and decay to a muon and a bino-like neutralino, which decays in the same way as in the first model, see their figure 17.

[13] HAYRAPETYAN 23E searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of gluino, top squark and electroweakino pair production in events with at least one photon, multiple jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set in models for strong production, Tglu4D, Tglu4E, Tglu4F and Tstop13, see their figure 9. They also interpret the results in the models for electroweak production, shown in their figure 10. Tchi1n1A assumes wino-like $\tilde{\chi}_1^\pm\tilde{\chi}_1^0$ production, while Tchi1chi1A assumes higgsino-like cross sections and includes $\tilde{\chi}_1^\pm\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^0\tilde{\chi}_2^0$ and $\tilde{\chi}_{1,2}^0\tilde{\chi}_1^\pm$ production. For $\tilde{\chi}_1^0\tilde{\chi}_2^0$ alone no mass point can be excluded in the model Tchi1chi1A, but in another model for $\tilde{\chi}_1^0\tilde{\chi}_2^0$ production, Tn1n2A.

[14] TUMASYAN 23B searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of electroweakino pair production with decays including hadronically decaying bosons, WW, WZ, WH, or ZH, identified with a DNN classifying large-area (AK8) jets. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of the nearly mass degenerate wino-like $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ in the models Tchi1chi1l , Tchi1n2Fb, and Tchi1n2Fc, see their figure 4. They also consider a model that contains both $\tilde{\chi}_2^0\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^\pm\tilde{\chi}_1^\pm$ production, see their figure 5 (upper). Results are also interpreted in the model THinoBinoA with nearly mass-degenerate higgsino-like $\tilde{\chi}_3^0$, $\tilde{\chi}_2^0$, $\tilde{\chi}_1^\pm$, and a lighter bino-like $\tilde{\chi}_1^0$, see their figure 5 (lower).

[15] TUMASYAN 22Q searched in up to 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of electroweakino and top squark pair production with a small mass difference between the produced supersymmetric particles and the lightest neutralino in events with two or three low-momentum leptons and missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ in the model Tchi1n2F, see their Figure 8. Limits are also set in a higgsino simplified model with both $\tilde{\chi}_2^0\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0\tilde{\chi}_1^0$ production, where $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ and $m_{\tilde{\chi}_1^\pm} = 1/2(m_{\tilde{\chi}_2^0} + m_{\tilde{\chi}_1^0})$. A model inspired by the pMSSM is used for further interpretations in the case of a higgsino LSP, see their Figure 9. Limits are also set on the mass of the top squark in the models Tstop2 and Tstop3, see their Figure 10.

[16] TUMASYAN 22S searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of electroweakino pair production in events with three or four leptons, with up to two hadronically decaying τ leptons, or two same-sign light leptons (e or μ). No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ in the models Tchi1n2B (in flavory-democratic and tau-enriched or -dominated scenarios), Tchi1n2E, Tchi1n2F, see their Figures 16–20, and on the mass of the higgsino-triplet $\tilde{\chi}_2^0$, $\tilde{\chi}_1^\pm$, and $\tilde{\chi}_1^0$ in the models Tn1n1A, Tn1n1B, and Tn1n1C, see their Figure 21.

[17] TUMASYAN 22V searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of electroweakino pair production with decay to two Higgs bosons H, with $H \to b\bar{b}$, resulting either in 4 resolved b-jets or two large-radius jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ in the models Tn1n1A, see their Figures 11 and 12, or in a model where higgsino-like nearly mass degenerate $\tilde{\chi}_2^0$ and $\tilde{\chi}_3^0$ are pair produced and each decay to H and a bino-like $\tilde{\chi}_1^0$, see their Figure 13. Limits are also set on the gluino mass in the model Tglu1l, see their Figure 14.

[18] AAD 21BG searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for pair production $\tilde{\chi}_2^0\tilde{\chi}_1^\pm$ in final states with three leptons, with and without assuming the presence of a $Z\rightarrow\ \ell\ell$ decay. No significant excess above the Standard Model predictions is observed. Limits are set on the $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ mass in Tchi1n2E, Tchi1n2F and Tchi1n2Ga. See their Fig. 16.

[19] AAD 21Y searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with four or more leptons (electrons, muons and tau-leptons). No significant excess above the Standard Model expectations is observed. Limits are set on Tchi1n12-GGM, and RPV models similar to Tchi1n2l, Tglu1A (with q = u, d, s, c, b, with equal branching fractions), and $\tilde{\ell}_L/\tilde{\nu}\rightarrow\ \ell/\nu\tilde{\chi}_1^0$ (mass-degenerate $\tilde{\ell}_L$ and $\tilde{\nu}$ of all 3 generations), all with $\tilde{\chi}_1^0\rightarrow\ \ell^\pm\ell^\mp\nu$ via λ_{12k} or λ_{i33} (where $i,k\in$ 1,2), see their Figure 11.

[20] SIRUNYAN 21M searched in 137 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with two opposite-sign same-flavor leptons (electrons, muons) and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu4C, see their Figure 10, on the $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ mass in Tchi1n2Fa, see their Figure 11, on the $\tilde{\chi}_1^0$ mass in Tn1n1C and Tn1n1B for $m_{\tilde{\chi}_2^0}$=$m_{\tilde{\chi}_1^\pm}$=$m_{\tilde{\chi}_1^0}$, see their Figure 12. Limits are also set on the light squark mass for the simplified model Tsqk2A, on the sbottom mass in Tsbot3, see their Figure 13, and on the slepton mass in direct electroweak pair production of mass-degenerate left- and right-handed sleptons (selectrons and smuons), see their Figure 14.

[21] TUMASYAN 21C searched in 137 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with with one lepton, a Higgs boson decaying to a pair of bottom quarks, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Lower limits are set on the masses of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ in the simplified model Tchi1n2E, see their Figure 6.

[22] AAD 20AN searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with two photons and missing transverse momentum. Events are further categorised in terms of lepton or jet multiplicity. No significant excess over the expected background is observed. Limits at 95% C.L. are set on the Higgsino mass in the T1n1n1A simplified model, see their Figure 11.

[23] AAD 20I reported on ATLAS searches for electroweak production in models with compressed mass spectra as Tchi1n2Ga. A dataset of pp collisions at $\sqrt{s}$ = 13 TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Events with $\not{E}_T$, two same-flavour, opposite-charge, low-transverse-momentum leptons, and jets from initial-state radiation or characteristic of vector-boson fusion production are selected. Constraints at 95% C.L. are placed in Higgsino models on the mass of the $\tilde{\chi}_2^0$ (the $\tilde{\chi}_1^\pm$ mass is halfway between the $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^0$ masses) at 193 GeV for a mass splitting between $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^0$ of 9.3 GeV and extend down to a mass splitting of 2.4 GeV at the LEP chargino mass limit. See their Fig. 14(a).

[24] AAD 20I reported on ATLAS searches for electroweak production in models with compressed mass spectra as Tchi1n2Fa. A dataset of pp collisions at $\sqrt{s}$ = 13 TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Events with $\not{E}_T$, two same-flavour, opposite-charge, low-transverse-momentum leptons, and jets from initial-state radiation or characteristic of vector-boson fusion production are selected. Constraints at 95% C.L. are placed in Wino-Bino models on the mass of the $\tilde{\chi}_2^0$ (degenerate with $\tilde{\chi}_1^\pm$) at 240 GeV for a mass splitting between $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^0$ of 7 GeV and extend down to a mass splitting of 1.5 GeV at the LEP chargino mass limit of 92.4 GeV. See their Fig. 14(b,c).

[25] AAD 20K reported on a search for electroweak production in models with mass splittings near the electroweak scale as Tchi1n2F and exploiting three-lepton final state events with an emulated recursive jigsaw reconstruction method. The analysis uses a dataset of pp collisions at $\sqrt{s}$ = 13 TeV corresponding to an integrated luminosity of 139 fb^{-1}. Exclusion limits at 95% C.L. are derived on next-to-lightest neutralinos and charginos with masses up to 345 GeV for a massless lightest neutralino, see their Fig. 7.

[26] AAD 20R searched for electroweak production in the model Tchi1n2E, selecting events with a pair of b-tagged jets consistent with those from a Higgs boson decay, either an electron or a muon from the W boson decay and $\not{E}_T$. The analysis uses a dataset of pp collisions at $\sqrt{s}$ = 13 TeV corresponding to an integrated luminosity of 139 fb^{-1}. Exclusion limits at 95% C.L. are derived on next-to-lightest neutralinos and charginos with masses up to 740 GeV for a massless lightest neutralino, assuming pure wino cross-sections. See their Fig. 6.

[27] SIRUNYAN 20AU searched in 77.2 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events containing one soft, hadronically decaying tau lepton, one energetic jet from initial-state radiation, and large $\not{E}_T$. No excess over the expected background is observed. Limits are derived on the wino mass in the Tchi1n2D simplified model, see their Figure 2.

[28] AABOUD 19AU searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of charginos and next-to-lightest neutralinos decaying into lightest neutralinos and a W and a Higgs boson, respectively. Fully hadronic, semileptonic, diphoton, and multilepton (electrons, muons) final states with missing transverse momentum are considered in this search. Observations are consistent with the Standard Model expectations, and 95% confidence-level limits of up to 680 GeV on the chargino/next-to-lightest neutralino masses are set (Tchi1n2E model). See their Figure 14 for an overlay of exclusion contours from all searches.

[29] SIRUNYAN 19BU searched for pair production of gauginos via vector boson fusion assuming the gaugino spectrum is compressed, in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV. The final states explored included zero leptons plus two jets, one lepton plus two jets, and one hadronic tau plus two jets. A similar bound is obtained in the light slepton limit.

[30] AABOUD 18AY searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of charginos and neutralinos as in Tchi1n2D models, in events characterised by the presence of at least two hadronically decaying tau leptons and large missing transverse energy. No significant deviation from the expected SM background is observed. Assuming decays via intermediate $\tilde{\tau}_L$ and $m_{\tilde{\chi}_1^\pm}=m_{\tilde{\chi}_2^0}$, the observed limits rule out $\tilde{\chi}_2^0$ masses up to 760 GeV for a massless $\tilde{\chi}_1^0$. See their Fig.7 (right). Interpretations are also provided in Fig 8 (bottom) for different assumptions on the ratio between $m_{\tilde{\tau}}$ and $m_{\tilde{\chi}_2^0}+m_{\tilde{\chi}_1^0}$.

[31] AABOUD 18BT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of charginos, chargino and next-to-lightest neutralinos and sleptons in events with two or three leptons (electrons or muons), with or without jets, and large missing transverse energy. No significant excess above the Standard Model expectations is observed. Limits are set on the next-to-lightest neutralino mass up to 1100 GeV for massless $\tilde{\chi}_1^0$ in the Tchi1n2C simplified model exploiting the 3ℓ signature, see their Figure 8(c).

[32] AABOUD 18BT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of charginos, chargino and next-to-lightest neutralinos and sleptons in events with two or three leptons (electrons or muons), with or without jets, and large missing transverse energy. No significant excess above the Standard Model expectations is observed. Limits are set on the next-to-lightest neutralino mass up to 580 GeV for massless $\tilde{\chi}_1^0$ in the Tchi1n2F simplified model exploiting the 2ℓ+2 jets and 3ℓ signatures, see their Figure 8(d).

[33] AABOUD 18CK searched for events with at least 3 b-jets and large missing transverse energy in two datasets of pp collisions at $\sqrt{s}$ = 13 TeV of 36.1 fb^{-1} and 24.3 fb^{-1} depending on the trigger requirements. The analyses aimed to reconstruct two Higgs bosons decaying to pairs of b-quarks. No significant excess above the Standard Model expectations is observed. Limits are set on the Higgsino mass in the T1n1n1A simplified model, see their Figure 15(a). Constraints are also presented as a function of the BR of Higgsino decaying into an higgs boson and a gravitino, see their Figure 15(b).

[34] AABOUD 18CO searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of mass-degenerate charginos and next-to-lightest neutralinos in events with two or three leptons (electrons or muons), with or without jets, and large missing transverse energy. The search channels are based on recursive jigsaw reconstruction. Limits are set on the next-to-lightest neutralinos mass up to 600 GeV for massless neutralinos in the Tchi1n2F simplified model exploiting the statistical combination of 2ℓ+2 jets and 3ℓ channels. Next-to-lightest neutralinos masses below 220 GeV are not excluded due to an excess of events above the SM prediction in the dedicated regions. See their Figure 13(d).

[35] AABOUD 18R searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for electroweak production in scenarios with compressed mass spectra in final states with two low-momentum leptons and missing transverse momentum. The data are found to be consistent with the SM prediction. Results are interpreted in Tchi1n2G higgsino models, and $\tilde{\chi}_2^0$ masses are excluded up to 145 GeV for $m_{\tilde{\chi}_2^0}-m_{\tilde{\chi}_1^0}$ = 5 GeV. The exclusion limits extend down to mass splittings of 2.5 GeV, see their Fig. 10 (top). Results are also interpreted in terms of exclusion bounds on the production cross-sections for the NUHM2 scenario as a function of the universal gaugino mass $m_{1/2}$ and $m_{\tilde{\chi}_2^0}-m_{\tilde{\chi}_1^0}$, see their Fig. 12.

[36] AABOUD 18R searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for electroweak production in scenarios with compressed mass spectra in final states with two low-momentum leptons and missing transverse momentum. The data are found to be consistent with the SM prediction. Results are interpreted in Tchi1n2F wino models, and $\tilde{\chi}_2^0$ masses are excluded up to 175 GeV for $m_{\tilde{\chi}_2^0}-m_{\tilde{\chi}_1^0}$ = 10 GeV. The exclusion limits extend down to mass splittings of 2 GeV, see their Fig. 10 (bottom). Results are also interpreted in terms of exclusion bounds on the production cross-sections for the NUHM2 scenario as a function of the universal gaugino mass $m_{1/2}$ and $m_{\tilde{\chi}_2^0}-m_{\tilde{\chi}_1^0}$, see their Fig. 12.

[37] AABOUD 18U searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV in events with at least one isolated photon, possibly jets and significant transverse momentum targeting generalised models of gauge-mediated SUSY breaking. No significant excess of events is observed above the SM prediction. Results of the diphoton channel are interpreted in terms of lower limits on the masses of gauginos Tchi1chi1A models, which reach as high as 1.3 TeV. Gaugino masses below 1060 GeV are excluded for any NLSP mass, see their Fig. 10.

[38] SIRUNYAN 18AJ searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events containing two low-momentum, oppositely charged leptons (electrons or muons) and $\not{E}_T$. No excess over the expected background is observed. Limits are derived on the wino mass in the Tchi1n2F simplified model, see their Figure 5. Limits are also set on the stop mass in the Tstop10 simplified model, see their Figure 6. Finally, limits are set on the Higgsino mass in the Tchi1n2G simplified model, see Figure 8 and in the pMSSM, see Figure 7.

[39] SIRUNYAN 18DP searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of charginos and neutralinos or of chargino pairs in events with a tau lepton pair and significant missing transverse momentum. Both hadronic and leptonic decay modes are considered for the tau lepton. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino mass in the Tchi1chi1D and Tchi1n2 simplified models, see their Figures 14 and 15. Also, excluded stau pair production cross sections are shown in Figures 11, 12, and 13.

[40] SIRUNYAN 17AW searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with a charged lepton (electron or muon), two jets identified as originating from a b-quark, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of the chargino and the next-to-lightest neutralino in the Tchi1n2E simplified model, see their Figure 6.

[41] AAD 16AA summarized and extended ATLAS searches for electroweak supersymmetry in final states containing several charged leptons, $\not{E}_T$, with or without hadronic jets, in 20 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV. The paper reports the results of new interpretations and statistical combinations of previously published analyses, as well as new analyses. Exclusion limits at 95% C.L. are set on mass-degenerate $\tilde{\chi}_2^0$ and $\tilde{\chi}_3^0$ masses in the Tn2n3A and Tn2n3B simplified models. See their Fig. 15.

[42] AAD 15BA searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for electroweak production of charginos and neutralinos decaying to a final state containing a W boson and a 125 GeV Higgs boson, plus missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of direct chargino and next-to-lightest neutralino production, with the decays $\tilde{\chi}_1^\pm\rightarrow\ W^\pm\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0\rightarrow\ H\tilde{\chi}_1^0$ having 100% branching fraction, see Fig. 8. A combination of the multiple final states for the Higgs decay yields the best limits (Fig. 8d).

[43] AAD 14H searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for electroweak production of charginos and neutralinos decaying to a final sate with three leptons and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of direct chargino and next-to-lightest neutralino production, with decays to the lightest neutralino via either all three generations of leptons, staus only, gauge bosons, or Higgs bosons, see Fig. 7. An interpretation in the pMSSM is also given, see Fig. 8.

[44] AAD 14X searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the neutralino mass in an R-parity conserving simplified model where the decay $\tilde{\chi}_{2,3}^0\rightarrow\ \ell^\pm\ell^\mp\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 10.

[45] AAD 13 searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for charginos and neutralinos decaying to a final state with three leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 and 3, and in simplified models, see Fig. 4. For the simplified models with intermediate slepton decays, degenerate $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ masses up to 500 GeV are excluded at 95% C.L. for very large mass differences with the $\tilde{\chi}_1^0$. Supersedes AAD 12AS.

[46] CHATRCHYAN 12BJ searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for direct electroweak production of charginos and neutralinos in events with at least two leptons, jets and missing transverse momentum. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of $\tilde{\chi}_1^\pm \tilde{\chi}_2^0$ pair production were set in a number of simplified models, see Figs. 7 to 12. Most limits are for exactly 3 jets.

[47] ABREU 00W combines data collected at $\sqrt{s}$=189 GeV with results from lower energies. The mass limit is obtained by constraining the MSSM parameter space with gaugino and sfermion mass universality at the GUT scale, using the results of negative direct searches for neutralinos (including cascade decays and $\tilde{\tau}\tau$ final states) from ABREU 01, for charginos from ABREU 00J and ABREU 00T (for all Δm_+), and for charged sleptons from ABREU 01B. The results hold for the full parameter space defined by all values of M_2 and $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP.

[48] AAD 20AN searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two photons and missing transverse momentum. Events are further categorised in terms of lepton or jet multiplicity. No significant excess over the expected background is observed. Limits at 95% C.L. are derived in Tchi1n2E simplified models. Next-to-lightest neutralinos and charginos with masses up to 310 GeV for a massless lightest neutralino are excluded. See their Fig. 10.

[49] AAD 14G searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for electroweak production of chargino-neutralino pairs, decaying to a final sate with two leptons (e and μ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of chargino and next-to-lightest neutralino production, with decays to the lightest neutralino via gauge bosons, see Fig. 7. An interpretation in the pMSSM is also given, see Fig. 10.

[50] KHACHATRYAN 14I searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for electroweak production of charginos and neutralinos decaying to a final state with three leptons (e or μ) and missing transverse momentum, or with a Z-boson, dijets and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models, see Figs. 12–16.

[51] AAD 12AS searched in 2.06 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for charginos and neutralinos decaying to a final state with three leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 (top), and in simplified models, see Fig. 2 (bottom).

[52] AAD 12T looked in 1 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for the production of supersymmetric particles decaying into final states with missing transverse momentum and exactly two isolated leptons (e or μ). Same-sign dilepton events were separately studied. Additionally, in opposite-sign events, a search was made for an excess of same-flavor over different-flavor lepton pairs. No excess over the expected background is observed and limits are placed on the effective production cross section of opposite-sign dilepton events with $\not{E}_T > 250$ GeV and on same-sign dilepton events with $\not{E}_T > 100$ GeV. The latter limit is interpreted in a simplified electroweak gaugino production model.

$\tilde{\chi}_1^\pm$, $\tilde{\chi}_2^\pm$ (Charginos) mass limits

Charginos are unknown mixtures of w-inos and charged higgsinos (the supersymmetric partners of W and Higgs bosons). A lower mass limit for the lightest chargino ($\tilde{\chi}_1^\pm$) of approximately 45 GeV, independent of the field composition and of the decay mode, has been obtained by the LEP experiments from the analysis of the Z width and decays. These results, as well as other now superseded limits from e^+e^- collisions at energies below 136 GeV, and from hadronic collisions, can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

Unless otherwise stated, results in this section assume spectra, production rates, decay modes and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers generally study production of $\tilde{\chi}_1^0 \tilde{\chi}_2^0$, $\tilde{\chi}_1^+ \tilde{\chi}_1^-$ and (in the case of hadronic collisions) $\tilde{\chi}_1^+ \tilde{\chi}_2^0$ pairs, including the effects of cascade decays. The mass limits on $\tilde{\chi}_1^\pm$ are either direct, or follow indirectly from the constraints set by the non-observation of $\tilde{\chi}_2^0$ states on the gaugino and higgsino MSSM parameters M_2 and μ. For generic values of the MSSM parameters, limits from high-energy e^+e^- collisions coincide with the highest value of the mass allowed by phase-space, namely $m_{\tilde{\chi}_1^\pm} \lesssim \sqrt{s}/2$. The still unpublished combination of the results of the four LEP collaborations from the 2000 run of LEP2 at $\sqrt{s}$ up to $\simeq 209$ GeV yields a lower mass limit of 103.5 GeV valid for general MSSM models. The limits become however weaker in certain regions of the MSSM parameter space where the detection efficiencies or production cross sections are suppressed. For example, this may happen when: (i) the mass differences $\Delta m_+ = m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0}$ or $\Delta m_\nu = m_{\tilde{\chi}_1^\pm} - m_{\tilde{\nu}}$ are very small, and the detection efficiency is reduced; (ii) the electron sneutrino mass is small, and the $\tilde{\chi}_1^\pm$ production rate is suppressed due to a destructive interference between s and t channel exchange diagrams. The regions of MSSM parameter space where the following limits are valid are indicated in the comment lines or in the footnotes.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 25BJ searched in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for an excess of 0-lepton events with at least one hadronically decaying τ and at least 3 b-jet. The search is performed by training a neural network to separate a signal of vector-like leptons from the Standard Model background. No significant excess above the Standard Model expectations is observed. Limits are set also in a model of SUSY, where members of either a higgsino LSP triplet or a wino LSP doublet are produced, and decay via a RPV λ'_{333} coupling to b, t quarks and τ, ν_τ leptons, see their Figs. 13 and 14.

[2] AAD 25M searched for an excess of displaced leptons (e or μ) in pp collisions (140 fb^{-1} at $\sqrt{s} = 13$ TeV and 56.3 at fb^{-1} at $\sqrt{s} = 13.6$ TeV). The models considered were long-lived slepton (electron or muon) pair production followed by $\tilde{\ell} \to \ell\tilde{G}$, and long-lived chargino pair production in a dark sector model, followed by $\tilde{\chi}_1^\pm \to \tilde{\chi}_1^0 W$. Displaced leptons were reconstructed thanks to an improved large radius tracking and to the pointing capabilities of the electromagnetic calorimeter. Two different analyses (ABCD and EM-BDT) are combined to obtain limits on $\tilde{e}$ pair production, while the ABCD analysis only is used for $\tilde{\mu}$, $\tilde{\tau}$ and $\tilde{\chi}_1^\pm$ pair production. No significant excess of events is observed over the background prediction. 95% CL limits are extracted in the lifetime vs mass plane, see their figures 6 and 8.

[3] CHEKHOVSKY 25M searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of SUSY models with compressed mass spectra in events with a high transverse momentum system from initial-state-radiation jets recoiling against a potential sparticle system with significant missing transverse momentum. These events are further categorized based on their lepton multiplicity, jet multiplicity, number of b-tagged jets, and kinematic variables sensitive to the sparticle masses and mass splittings. No significant excess above the Standard Model expectations is observed. The results are interpreted in models of top squark, electroweakino and slepton pair production. Limits are set for top squark pair production in the models Tstop1 and Tstop2, see their figure 25, and in Tstop4, see their figure 26. The results are also interpreted in models describing the production of mass-degenerate $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ with decays $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ and $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$, applying both a wino-like and higgsino-like $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ production cross section, see their figure 27. Limits are also set for wino-like $\tilde{\chi}_1^\pm$ pair production, either with $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$ or in the model Tchi1chi1C. This paper also addresses direct slepton production, taking into account pure right-handed, pure left-handed and combined production of either selectrons, smuons, or mass-degenerate sleptons of the first and second generation, see their figures 30 and 31.

[4] HAYRAPETYAN 25AH searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for new physics in jet multiplicity patterns in three-lepton events with and without b quarks. No significant excess above the Standard Model expectations is observed. The results are interpreted in a model similar to Tchi1n2E, but with additional prompt hadronic R-parity violating decay of $\tilde{\chi}_1^0$ to three quarks, either as $\tilde{\chi}_1^0 \to uds$ or $\tilde{\chi}_1^0 \to udb$, see their figure 3.

[5] AAD 24AJ searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of direct stau pair production, or electroweakino pair production with decay via an intermediate stau, in events with two taus decaying hadronically (including a same-charge channel), no b-jets and moderate $\not{E}_T$, using a BDT for the direct stau search and a more traditional cut-and-count selection for the electroweakino search. No significant excess above the Standard Model expectations is observed. Limits are set in models of direct stau production $\tilde{\tau} \to \tau\tilde{\chi}_1^0$, $\tilde{\tau}_L$, $\tilde{\tau}_R$ or degenerate production. Limits are also set in models of pair production of charginos (Tchichi1D) or of charginos and neutralinos (Tchi1n2D) followed by the decay via intermediate staus, or (for the latter) via Wh (Tchi1n2E). See their figures 12, 14 and 16.

[6] AAD 24CE searched for VBF production of a wino pair almost mass-degenerate with a bino-like LSP, in events with two jets with a large rapidity gap between them and no leptons in 140 fb^{-1} of pp collisions. Care was taken into including interference effects between VBF QCD and electroweak diagrams for the cross section estimate. A BDT was trained based on the two jet kinematics and the missing transverse momentum. Results are interpreted in a scenario where wino-like degenerate charginos and neutralinos are pair produced and decay into a nearly degenerate bino-like neutralino LSP, see their Figure 8.

[7] AAD 24G searched in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of higgsino pair production in events with low-momentum mildly displaced tracks. No significant excess above the Standard Model expectations is observed. Limits are set in the model Tn1n1D, see their Fig. 3, assuming that the $\tilde{\chi}_1^\pm$ has a flight length of about 0.11 mm from the pp interaction point and decays to $\tilde{\chi}_1^0$ and a charged particle (usually a soft pion) that is measured as low-momentum track.

[8] AAD 24I provides a statistical combination of the results of a number of analyses targeting electroweak production performed using 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV. The combination was used to set limits on the pair-produced particle masses as a function of the LSP mass for wino-like $\tilde{\chi}_1^\pm\tilde{\chi}_1^\pm$ followed by $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$, wino-like $\tilde{\chi}_2^0\tilde{\chi}_1^\pm$ followed by $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$ and either $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ or $\tilde{\chi}_2^0 \to h\tilde{\chi}_1^0$, or a GGM-like model with a full higgsino triplet decaying to a gravitino. See their Fig. 2.

[9] HAYRAPETYAN 24M searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of wino- and Higgsino-like charginos in final states with one or more disappearing tracks from the decay $\tilde{\chi}_1^\pm \to \pi^\pm\tilde{\chi}_1^0$ where the soft pion is not reconstructed, $\not{E}_T$, and varying numbers of jets, b-tagged jets, electrons, and muons. No significant excess above the Standard Model expectations is observed. Limits are set on the $\tilde{b}$ mass in the model Tbot1LL for various proper decay lengths $c\tau$ of the $\tilde{\chi}_1^\pm$ as well as on the $\tilde{t}$ mass in the model Tstop1LL, see their Fig. 10. Limits are also set in the model Tglu1LL, see their Fig. 11. In addition, limits are set in specific pure wino as well as pure higgsino dark matter models, in which the relationships among the electroweakino masses, the $\tilde{\chi}_1^\pm$ lifetime, and the $\tilde{\chi}_1^\pm$ decay width are constrained by radiative corrections that account for a large difference between the LSP mass and the SUSY-breaking scale, see their Fig. 12.

[10] HAYRAPETYAN 24N searched in up to 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of wino-like chargino-neutralino pairs, Higgsino-like neutralino pair production in a gauge-mediated SUSY breaking inspired scenario, a Higgsino-bino interpretation, and slepton pair production in a combination of a number of previously reported searches for SUSY in different final states. No significant excess above the Standard Model expectations is observed. Limits are set on the $\tilde{\chi}_1^\pm$ mass in the wino-bino models Tchi1n2E1, Tchi1n2E, and Tchi1n2l, see their Fig. 11, and on the $\tilde{\chi}_1^0$ in the higgsino-like GMSB models Tn1n1A, Tn1n1B, and Tn1n1C, see their Fig. 13. In addition, Fig. 14 shows the mass exclusion limit as a function of the branching fraction to the H boson. Limits are also set in a Higgsino-bino interpretation as in THinoBinoA, but also including leptonic decays, see their Fig. 15. Limits are also set on slepton ($\tilde{e}$, $\tilde{\mu}$) production with the decay $\tilde{\ell} \to \ell\tilde{\chi}_1^0$, see their Fig. 16.

[11] AAD 23AE searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 2 ℓ with same flavour and opposite sign, plus jets and $\not{E}_T$, defining signal region with the dilepton invariant mass both on- and off-shell with respect to the Z boson. No significant excess above the Standard Model predictions is observed. Limits are set on models of strong and electroweak production. For electroweak production, limits are placed on production of mass-degenerate, wino-like $\tilde{\chi}_2^0\,\tilde{\chi}_1$ with $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ and $\tilde{\chi}_1 \to W\tilde{\chi}_1^0$, see figure 15.

[12] AAD 23CI searched in 139 fb^{-1} of pp collisions for events containing 1 ℓ (e or μ), jets, and $\not{E}_T$. Final states consistent with the production of a diboson system plus $\not{E}_T$ were identified also by making use of large-R jet tagging techniques. No excess on top of the Standard Model background was observed. Limits were set on the production of $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm\tilde{\chi}_1^\pm$ (assuming wino cross sections) decaying to $WZ\tilde{\chi}_1^0\tilde{\chi}_1^0$ or $WW\tilde{\chi}_1^0\tilde{\chi}_1^0$. See their figure 9.

[13] AAD 23CI searched in 139 fb^{-1} of pp collisions for events containing 1 ℓ (e or μ), jets, and $\not{E}_T$. Final states consistent with the production of a boson + Higgs system plus $\not{E}_T$ were identified via a BDT. No excess on top of the Standard Model background was

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

observed. Limits were set on the production of degenerate $\widetilde{\chi}_1^{\pm}\widetilde{\chi}_2^0$ (assuming wino cross sections) decaying into $Wh\widetilde{\chi}_1^0\widetilde{\chi}_1^0$. See their figure 10.

[14] AAD 23CP searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 2 ℓ with same charge plus at least one jet and $\not{E}_T$, defining signal region based on 'stransverse mass' of the dilepton system, $\not{E}_T$ significance and effective mass. No significant excess above the Standard Model predictions is observed. Limits are set on the mass of mass-degenerate $\widetilde{\chi}_1^{\pm}$ and $\widetilde{\chi}_2^0$ for the wino-like production of $\widetilde{\chi}_1^{\pm}\widetilde{\chi}_2^0$ followed by the decay into either $WZ\widetilde{\chi}_1^0\widetilde{\chi}_1^0$ or $Wh\widetilde{\chi}_1^0\widetilde{\chi}_1^0$, see figure 13.

[15] AAD 23CR searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for RPV SUSY in final states with multiple leptons and b-tagged jets. No significant excess above the Standard Model expectations is observed. Limits are set on the production of electroweakinos (wino or higgsino) that decay via RPV coupling λ'_{i33} to a charged lepton or a neutrino, a b quark, and an additional t or b quark, see their figure 16. A second model addresses direct $\widetilde{\mu}_{L,R}$ production and decay to a muon and a bino-like neutralino, which decays in the same way as in the first model, see their figure 17.

[16] AAD 23M searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for $\widetilde{\chi}_1^{\pm}$ pair production, followed by $\widetilde{\chi}_1^{\pm} \to W^{\pm}\widetilde{\chi}_1^0 \to \ell^{\pm}\nu\widetilde{\chi}_1^0$ in events with two leptons. The focus is on models where $m_{\widetilde{\chi}_1^{\pm}} - m_{\widetilde{\chi}_1^0}$ is close to the W mass. No significant excess above the Standard Model predictions is observed. Limits are set on the $\widetilde{\chi}_1^{\pm}$ mass as a function of $m_{\widetilde{\chi}_1^0}$, see Figure 9.

[17] HAYRAPETYAN 23E searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of gluino, top squark and electroweakino pair production in events with at least one photon, multiple jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set in models for strong production, Tglu4D, Tglu4E, Tglu4F and Tstop13, see their figure 9. They also interpret the results in the models for electroweak production, shown in their figure 10. Tchi1n1A assumes wino-like $\widetilde{\chi}_1^{\pm}\widetilde{\chi}_1^0$ production, while Tchi1chi1A assumes higgsino-like cross sections and includes $\widetilde{\chi}_1^{\pm}\widetilde{\chi}_1^{\pm}$, $\widetilde{\chi}_1^0\widetilde{\chi}_2^0$ and $\widetilde{\chi}_{1,2}^0\widetilde{\chi}_1^{\pm}$ production. For $\widetilde{\chi}_1^0\widetilde{\chi}_2^0$ alone no mass point can be excluded in the model Tchi1chi1A, but in another model for $\widetilde{\chi}_1^0\widetilde{\chi}_2^0$ production, Tn1n2A.

[18] TUMASYAN 23B searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of electroweakino pair production with decays including hadronically decaying bosons, WW, WZ, WH, or ZH, identified with a DNN classifying large-area (AK8) jets. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of the nearly mass degenerate wino-like $\widetilde{\chi}_2^0$ and $\widetilde{\chi}_1^{\pm}$ in the models Tchi1chi1l , Tchi1n2Fb, and Tchi1n2Fc, see their figure 4. They also consider a model that contains both $\widetilde{\chi}_2^0\widetilde{\chi}_1^{\pm}$ and $\widetilde{\chi}_1^{\pm}\widetilde{\chi}_1^{\pm}$ production, see their figure 5 (upper). Results are also interpreted in the model THinoBinoA with nearly mass-degenerate higgsino-like $\widetilde{\chi}_3^0$, $\widetilde{\chi}_2^0$, $\widetilde{\chi}_1^{\pm}$, and a lighter bino-like $\widetilde{\chi}_1^0$, see their figure 5 (lower).

[19] TUMASYAN 22Q searched in up to 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of electroweakino and top squark pair production with a small mass difference between the produced supersymmetric particles and the lightest neutralino in events with two or three low-momentum leptons and missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\widetilde{\chi}_2^0$ and $\widetilde{\chi}_1^{\pm}$ in the model Tchi1n2F, see their Figure 8. Limits are also set in a higgsino simplified model with both $\widetilde{\chi}_2^0\widetilde{\chi}_1^{\pm}$ and $\widetilde{\chi}_2^0\widetilde{\chi}_1^0$ production, where $\widetilde{\chi}_2^0 \to Z\widetilde{\chi}_1^0$ and $m_{\widetilde{\chi}_1^{\pm}} = 1/2(m_{\widetilde{\chi}_2^0} + m_{\widetilde{\chi}_1^0})$. A model inspired by the pMSSM is used for further interpretations in the case of a higgsino LSP, see their Figure 9. Limits are also set on the mass of the top squark in the models Tstop2 and Tstop3, see their Figure 10.

[20] TUMASYAN 22S searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of electroweakino pair production in events with three or four leptons, with up to two hadronically decaying τ leptons, or two same-sign light leptons (e or μ). No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\widetilde{\chi}_2^0$ and $\widetilde{\chi}_1^{\pm}$ in the models Tchi1n2B (in flavory-democratic and tau-enriched or -dominated scenarios), Tchi1n2E, Tchi1n2F, see their Figures 16–20, and on the mass of the higgsino-triplet $\widetilde{\chi}_2^0$, $\widetilde{\chi}_1^{\pm}$, and $\widetilde{\chi}_1^0$ in the models Tn1n1A, Tn1n1B, and Tn1n1C, see their Figure 21.

[21] AAD 21AX searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of electroweakinos decaying to the LSP via the emission of Standard Model bosons (Higgs, W, Z) decaying into hadrons. The final state in all cases characterised by the presence of $\not{E}_T$, jets, and large-R jets tagged according to the boson of interest. Different assumptions (Higgsino, Wino, Bino) are made for the pair produced electroweakinos and for the LSP multiplet. No significant excess above the Standard Model predictions is observed. Limits are set on the electroweakino masses as a function of the model parameters (in particular $m_{\widetilde{\chi}_1^0}$). See Figs. 12, 14, 15.

[22] AAD 21BG searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production $\widetilde{\chi}_2^0\widetilde{\chi}_1^{\pm}$ in final states with three leptons, with and without assuming the presence of a $Z \to \ell\ell$ decay. No significant excess above the Standard Model predictions is observed. Limits are set on the $\widetilde{\chi}_2^0$ and $\widetilde{\chi}_1^{\pm}$ mass in Tchi1n2E, Tchi1n2F and Tchi1n2Ga. See their Fig. 16.

[23] AAD 21E searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for production of wino-like $\widetilde{\chi}_1^{\pm}\widetilde{\chi}_1^{\pm}$ and $\widetilde{\chi}_1^{\pm}\widetilde{\chi}_1^0$, followed by the RPV decay of $\widetilde{\chi}_1^{\pm}$ into $Z\ell$, $H\ell$ or $W\nu$ and of $\widetilde{\chi}_1^0$ into $Z\nu$, $H\nu$ or $W\ell$, in events with three leptons, looking for $Z\ell$ resonances. No significant excess above the Standard Model predictions is observed. Limits are set on the common $m_{\widetilde{\chi}_1^{\pm}}/m_{\widetilde{\chi}_1^0}$ mass in the TwinoLSPRPV simplified model, as a function of the common $\widetilde{\chi}_1^{\pm}/\widetilde{\chi}_1^0$ branching fraction to a Z boson. See Figure 9.

[24] AAD 21Y searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for supersymmetry in events with four or more leptons (electrons, muons and tau-leptons). No significant excess above the Standard Model expectations is observed. Limits are set on Tchi1n12-GGM, and RPV models similar to Tchi1n2l, Tglu1A (with $q = u, d, s, c, b$, with equal branching fractions), and $\widetilde{\ell}_L/\widetilde{\nu} \to \ell/\nu\widetilde{\chi}_1^0$ (mass-degenerate $\widetilde{\ell}_L$ and $\widetilde{\nu}$ of all 3 generations), all with $\widetilde{\chi}_1^0 \to \ell^{\pm}\ell^{\mp}\nu$ via λ_{12k} or λ_{i33} (where $i,k \in 1,2$), see their Figure 11.

[25] SIRUNYAN 21M searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for supersymmetry in events with two opposite-sign same-flavor leptons (electrons, muons) and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu4C, see their Figure 10, on the $\widetilde{\chi}_2^0$ and $\widetilde{\chi}_1^{\pm}$ mass in Tchi1n2Fa, see their Figure 11, on the $\widetilde{\chi}_1^0$ mass in Tn1n1C and Tn1n1B for $m_{\widetilde{\chi}_2^0} = m_{\widetilde{\chi}_1^{\pm}} = m_{\widetilde{\chi}_1^0}$, see their Figure 12. Limits are also set on the light squark mass for the simplified model Tsqk2A, on the sbottom mass in Tsbot3, see their Figure 13, and on the slepton mass in direct electroweak pair production of mass-degenerate left- and right-handed sleptons (selectrons and smuons), see their Figure 14.

[26] TUMASYAN 21C searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for supersymmetry in events with with one lepton, a Higgs boson decaying to a pair of bottom quarks, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Lower limits are set on the masses of $\widetilde{\chi}_2^0$ and $\widetilde{\chi}_1^{\pm}$ in the simplified model Tchi1n2E, see their Figure 6.

[27] AAD 20AN searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two photons and missing transverse momentum. Events are further categorised in terms of lepton or jet multiplicity. No significant excess over the expected background is observed. Limits at 95% C.L. are set on the Higgsino mass in the T1n1n1A simplified model, see their Figure 11.

[28] AAD 20I reported on ATLAS searches for electroweak production in models with compressed mass spectra as Tchi1n2Fa. A dataset of pp collisions at $\sqrt{s} = 13$ TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Events with $\not{E}_T$, two same-flavour, opposite-charge, low-transverse-momentum leptons, and jets from initial-state radiation or characteristic of vector-boson fusion production are selected. Constraints at 95% C.L. are placed on the mass of the $\widetilde{\chi}_1^{\pm}$ (degenerate with $\widetilde{\chi}_2^0$) at 240 GeV for a mass splitting between $\widetilde{\chi}_1^{\pm}$ and $\widetilde{\chi}_1^0$ of 7 GeV and extend down to a mass splitting of 1.5 GeV at the LEP chargino mass limit of 92.4 GeV. See their Fig. 14(b,c).

[29] AAD 20K reported on a search for electroweak production in models with mass splittings near the electroweak scale as Tchi1n2F and exploiting three-lepton final state events with an emulated recursive jigsaw reconstruction method. The analysis uses a dataset of pp collisions at $\sqrt{s} = 13$ TeV corresponding to an integrated luminosity of 139 fb^{-1}. Exclusion limits at 95% C.L. are derived on next-to-lightest neutralinos and charginos with masses up to 345 GeV for a massless lightest neutralino, see their Fig. 7.

[30] AAD 20O reported on a search for electroweak production in models with charginos and sleptons decaying into final states with exactly two oppositely charged leptons and missing transverse momentum. A dataset of pp collisions at $\sqrt{s} = 13$ TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Exclusion limits at 95% C.L. are derived on $m_{\widetilde{\chi}_1^{\pm}}$ decaying according to the Tchi1chi1H simplified model. Chargino masses up to 420 GeV are excluded for a massless lightest neutralino, see their Fig. 7(a).

[31] AAD 20O reported on a search for electroweak production in models with charginos and sleptons decaying into final states with exactly two oppositely charged leptons and missing transverse momentum. A dataset of pp collisions at $\sqrt{s} = 13$ TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Exclusion limits at 95% C.L. are derived on $m_{\widetilde{\chi}_1^{\pm}}$ decaying according to the Tchi1chi1C simplified model. Chargino masses up to 1000 GeV are excluded for a massless lightest neutralino, see their Fig. 7(b).

[32] AAD 20R searched for electroweak production in the model Tchi1n2E, selecting events with a pair of b-tagged jets consistent with those from a Higgs boson decay, either an electron or a muon from the W boson decay and $\not{E}_T$. The analysis uses a dataset of pp collisions at $\sqrt{s} = 13$ TeV corresponding to an integrated luminosity of 139 fb^{-1}. Exclusion limits at 95% C.L. are derived on next-to-lightest neutralinos and charginos with masses up to 740 GeV for a massless lightest neutralino, assuming pure wino cross-sections. See their Fig. 6.

[33] SIRUNYAN 20AU searched in 77.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing one soft, hadronically decaying tau lepton, one energetic jet from initial-state radiation, and large $\not{E}_T$. No excess over the expected background is observed. Limits are derived on the wino mass in the Tchi1n2D simplified model, see their Figure 2.

[34] SIRUNYAN 20B searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one photon and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on chargino masses in a general gauge-mediated SUSY breaking (GGM) scenario Tchi1n12-GGM, see Figure 4. Limits are also set on the NLSP mass in the Tchi1chi1F and Tchi1chi1G simplified models, see their Figure 5. Finally, limits are set on the gluino mass in the Tglu4A simplified model, see Figure 6.

[35] AABOUD 19AU searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos and next-to-lightest neutralinos decaying into lightest neutralinos and a W, and a Higgs boson, respectively. Fully hadronic, semileptonic, diphoton, and multilepton (electrons, muons) final states with missing transverse momentum are considered in this search. Observations are consistent with the Standard Model expectations, and 95% confidence-level limits of up to 680 GeV on the chargino/next-to-lightest neutralino masses are set (Tchi1n2E model). See their Figure 14 for an overlay of exclusion contours from all searches.

[36] SIRUNYAN 19BU searched for pair production of gauginos via vector boson fusion assuming the gaugino spectrum is compressed, in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV. The final states explored included zero leptons plus two jets, one lepton plus two jets, and one hadronic tau plus two jets. A similar bound is obtained in the light slepton limit.

[37] SIRUNYAN 19CI searched in 77.5 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more high-momentum Higgs bosons, decaying to pairs of photons, jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in the Tsbot4 simplified model, see Figure 3, and on the wino mass in the Tchi1n2E simplified model, see their Figure 4. Limits are also set on the higgsino mass in the Tn1n1A and Tn1n1B simplified models, see their Figure 5.

[38] SIRUNYAN 19K searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with a photon, an electron or muon, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. In the framework of GMSB, limits are set on the chargino and neutralino mass in the Tchi1n1A simplified model, see their Figure 6. Limits are also set on the gluino mass in the Tglu4A simplified model, and on the squark mass in the Tsqk4A simplified model, see their Figure 7.

[39] AABOUD 18AY searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos as in Tchi1chi1D models in events characterised by the presence of at least two hadronically decaying tau leptons and large missing transverse energy. No significant deviation from the expected SM background is observed. In the Tchi1chi1D model, assuming decays via intermediate $\widetilde{\tau}_L$, the observed limits rule out $\widetilde{\chi}_1^{\pm}$ masses up to 630 GeV for a massless $\widetilde{\chi}_1^0$. See their Fig.7 (left). Interpretations are

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

also provided in Fig 8 (top) for different assumptions on the ratio between $m_{\tilde{\tau}}$ and $m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0}$.

[40] AABOUD 18AY searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos and neutralinos as in Tchi1n2D models, in events characterised by the presence of at least two hadronically decaying tau leptons and large missing transverse energy. No significant deviation from the expected SM background is observed. Assuming decays via intermediate $\tilde{\tau}_L$ and $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, the observed limits rule out $\tilde{\chi}_1^\pm$ masses up to 760 GeV for a massless $\tilde{\chi}_1^0$. See their Fig.7 (right). Interpretations are also provided in Fig 8 (bottom) for different assumptions on the ratio between $m_{\tilde{\tau}}$ and $m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0}$.

[41] AABOUD 18BT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos, chargino and next-to-lightest neutralinos and sleptons in events with two or three leptons (electrons or muons), with or without jets and large missing transverse energy. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino mass up to 750 GeV for massless neutralinos in the Tchi1chi1C simplified model exploiting $2\ell + 0$ jets signatures, see their Figure 8(a).

[42] AABOUD 18BT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos, chargino and next-to-lightest neutralinos and sleptons in events with two or three leptons (electrons or muons), with or without jets, and large missing transverse energy. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino mass up to 1100 GeV for massless neutralinos in the Tchi1n2C simplified model exploiting 3ℓ signature, see their Figure 8(c).

[43] AABOUD 18BT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos, chargino and next-to-lightest neutralinos and sleptons in events with two or three leptons (electrons or muons), with or without jets, and large missing transverse energy. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino mass up to 580 GeV for massless neutralinos in the Tchi1n2F simplified model exploiting 2ℓ+2 jets and 3ℓ signatures, see their Figure 8(d).

[44] AABOUD 18CK searched for events with at least 3 b-jets and large missing transverse energy in two datasets of pp collisions at $\sqrt{s} = 13$ TeV of 36.1 fb^{-1} and 24.3 fb^{-1} depending on the trigger requirements. The analyses aimed to reconstruct two Higgs bosons decaying to pairs of b-quarks. No significant excess above the Standard Model expectations is observed. Limits are set on the Higgsino mass in the T1n1n1A simplified model, see their Figure 15(a). Constraints are also presented as a function of the BR of Higgsino decaying into an higgs boson and a gravitino, see their Figure 15(b).

[45] AABOUD 18CO searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of mass-degenerate charginos and next-to-lightest neutralinos in events with two or three leptons (electrons or muons), with or without jets, and large missing transverse energy. The search channels are based on recursive jigsaw reconstruction. Limits are set on the chargino mass up to 600 GeV for massless neutralinos in the Tchi1n2F simplified model exploiting the statistical combination of 2ℓ+2 jets and 3ℓ channels. Chargino masses below 220 GeV are not excluded due to an excess of events above the SM prediction in the dedicated regions. See their Figure 13(d).

[46] AABOUD 18R searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for electroweak production in scenarios with compressed mass spectra in final states with two low-momentum leptons and missing transverse momentum. The data are found to be consistent with the SM prediction. Results are interpreted in Tchi1n2G wino models and $\tilde{\chi}_1^\pm$ masses are excluded up to 175 GeV for $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 10$ GeV. The exclusion limits extend down to mass splittings of 2 GeV, see their Fig. 10 (bottom).

[47] AABOUD 18R searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for electroweak production in scenarios with compressed mass spectra in final states with two low-momentum leptons and missing transverse momentum. The data are found to be consistent with the SM prediction. Results are interpreted in Tchi1n2G higgsino models and $\tilde{\chi}_1^\pm$ masses are excluded up to 145 GeV for $m_{\tilde{\chi}_1^\pm}$ - $m_{\tilde{\chi}_1^0} = 5$ GeV. The exclusion limits extend down to mass splittings of 2.5 GeV, see their Fig. 10 (top).

[48] AABOUD 18U searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with at least one isolated photon, possibly jets and significant transverse momentum targeting generalised models of gauge-mediated SUSY breaking. No significant excess of events is observed above the SM prediction. Results of the diphoton channel are interpreted in terms of lower limits on the masses of gauginos Tchi1chi1A models, which reach as high as 1.3 TeV. Gaugino masses below 1060 GeV are excluded for any NLSP mass, see their Fig. 10.

[49] AABOUD 18Z searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing four or more charged leptons (electrons, muons and up to two hadronically decaying taus). No significant deviation from the expected SM background is observed. Limits are set on the Higgsino mass in simplified models of general gauge mediated supersymmetry Tn1n1A/Tn1n1B/Tn1n1C, see their Figure 9. Limits are also set on the wino, slepton, sneutrino and gluino mass in a simplified model of NLSP pair production with R-parity violating decays of the LSP via λ_{12k} or λ_{i33} to charged leptons, see their Figures 7, 8.

[50] SIRUNYAN 18AA searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one photon and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on wino masses in a general gauge-mediated SUSY breaking (GGM) scenario with bino-like $\tilde{\chi}_1^0$ and wino-like $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$, see Figure 7. Limits are also set on the NLSP mass in the Tchi1n1A and Tchi1chi1A simplified models, see their Figure 8. Finally, limits are set on the gluino mass in the Tglu4A and Tglu4B simplified models, see their Figure 9, and on the squark mass in the Tsqk4A and Tsqk4B simplified models, see their Figure 10.

[51] SIRUNYAN 18AJ searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing two low-momentum, oppositely charged leptons (electrons or muons) and $\not{E}_T$. No excess over the expected background is observed. Limits are derived on the wino mass in the Tchi1n2F simplified model, see their Figure 5. Limits are also set on the stop mass in the Tstop10 simplified model, see their Figure 6. Finally, limits are set on the Higgsino mass in the Tchi1n2G simplified model, see Figure 8 and in the pMSSM, see Figure 7.

[52] SIRUNYAN 18AO searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos and neutralinos in events with either two or more leptons (electrons or muons) of the same electric charge, or with three or more leptons, which can include up to two hadronically decaying tau leptons. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino/neutralino mass in the Tchi1n2A, Tchi1n2H, Tchi1n2D, Tchi1n2E and Tchi1n2F simplified models, see their Figures 14, 15, 16, 17 and 18. Limits are also set on the higgsino mass in the Tn1n1A, Tn1n1B and Tn1n1C simplified models, see their Figure 19.

[53] SIRUNYAN 18AP searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos and neutralinos by combining a number of previous and new searches. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino/neutralino mass in the Tchi1n2E, Tchi1n2F and Tchi1n2l simplified models, see their Figures 7, 8, 9 an 10. Limits are also set on the higgsino mass in the Tn1n1A, Tn1n1B and Tn1n1C simplified models, see their Figure 11, 12, 13 and 14.

[54] SIRUNYAN 18AR searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing two opposite-charge, same-flavour leptons (electrons or muons), jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu4C simplified model, see their Figure 7. Limits are also set on the chargino/neutralino mass in the Tchi1n2F simplified models, see their Figure 8, and on the higgsino mass in the Tn1n1B and Tn1n1C simplified models, see their Figure 9. Finally, limits are set on the sbottom mass in the Tsbot3 simplified model, see their Figure 10.

[55] SIRUNYAN 18DN searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos and for pair production of top squarks in events with two leptons (electrons or muons) of the opposite electric charge. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino mass in the Tchi1chi1C and Tchi1chi1E simplified models, see their Figure 8. Limits are also set on the stop mass in the Tstop1 and Tstop2 simplified models, see their Figure 9.

[56] SIRUNYAN 18DP searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos and neutralinos or of chargino pairs in events with a tau lepton pair and significant missing transverse momentum. Both hadronic and leptonic decay modes are considered for the tau lepton. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino mass in the Tchi1chi1D and Tchi1n2 simplified models, see their Figures 14 and 15. Also, excluded stau pair production cross sections are shown in Figures 11, 12, and 13.

[57] SIRUNYAN 18X searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more high-momentum Higgs bosons, decaying to pairs of photons, jets and $\not{E}_T$. The razor variables (M_R and R^2) are used to categorise the events. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in the Tsbot4 simplified model and on the wino mass in the Tchi1n2E simplified model, see their Figure 5. Limits are also set on the higgsino mass in the Tn1n1A and Tn1n1B simplified models, see their Figure 6.

[58] KHACHATRYAN 17L searched in about 19 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with two τ (at least one decaying hadronically) and $\not{E}_T$. In the Tchi1chi1C model, assuming decays via intermediate $\tilde{\tau}$ or $\tilde{\nu}_\tau$ with equivalent mass, the observed limits rule out $\tilde{\chi}_1^\pm$ masses up to 420 GeV for a massless $\tilde{\chi}_1^0$. See their Fig.5.

[59] SIRUNYAN 17AW searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with a charged lepton (electron or muon), two jets identified as originating from a b-quark, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of the chargino and the next-to-lightest neutralino in the Tchi1n2E simplified model, see their Figure 6.

[60] AAD 16AA summarized and extended ATLAS searches for electroweak supersymmetry in final states containing several charged leptons, $\not{E}_T$, with or without hadronic jets, in 20 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV. The paper reports the results of new interpretations and statistical combinations of previously published analyses, as well as new analyses. Exclusion limits at 95% C.L. are set on the $\tilde{\chi}_1^\pm$ mass in the Tchi1chi1B and Tchi1chi1C simplified models. See their Fig. 13.

[61] AAD 16AA summarized and extended ATLAS searches for electroweak supersymmetry in final states containing several charged leptons, $\not{E}_T$, with or without hadronic jets, in 20 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV. The paper reports the results of new interpretations and statistical combinations of previously published analyses, as well as new analyses. Exclusion limits at 95% C.L. are set on mass-degenerate $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ masses in the Tchi1n2B, Tchi1n2C, and Tchi1n2D simplified models. See their Figs. 16, 17, and 18. Interpretations in phenomenological-MSSM, two-parameter Non Universal Higgs Masses (NUHM2), and gauge-mediated symmetry breaking (GMSB) models are also given in their Figs. 20, 21 and 22.

[62] KHACHATRYAN 16R searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with one or more photons, one electron or muon, and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on wino masses in a general gauge-mediated SUSY breaking model (GGM), for a wino-like neutralino NLSP scenario, see Fig. 5. Limits are also set in the Tglu1D and Tchi1n1A simplified models, see Fig. 6. The Tchi1n1A limit is reduced to 340 GeV for a branching ratio reduced by the weak mixing angle.

[63] AAD 15BA searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for electroweak production of charginos and neutralinos decaying to a final state containing a W boson and a 125 GeV Higgs boson, plus missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of direct chargino and next-to-lightest neutralino production, with the decays $\tilde{\chi}_1^\pm \to W^\pm \tilde{\chi}_1^0$ and $\tilde{\chi}_2^0 \to H\tilde{\chi}_1^0$ having 100% branching fraction, see Fig. 8. A combination of the multiple final states for the Higgs decay yields the best limits (Fig. 8d).

[64] AAD 15CA searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with one or more photons and $\not{E}_T$, with or without leptons (e, μ). No significant excess above the Standard Model expectations is observed. Limits are set on wino masses in the general gauge-mediated SUSY breaking model (GGM), for wino-like NLSP, see Fig. 9, 12

[65] AAD 14H searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for electroweak production of charginos and neutralinos decaying to a final sate with three leptons and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of direct chargino and next-to-lightest neutralino production, with decays to the lightest neutralino via either all three generations of leptons, staus only, gauge bosons, or Higgs bosons, see Fig. 7. An interpretation in the pMSSM is also given, see Fig. 8.

[66] AAD 14X searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the wino-like chargino mass in an R-parity violating simplified model where the decay $\tilde{\chi}_1^\pm \to W^{(*)\pm}\tilde{\chi}_1^0$, with $\tilde{\chi}_1^0 \to \ell^\pm\ell^\mp\nu$, takes place with a branching ratio of 100%, see Fig. 8.

[67] KHACHATRYAN 14L searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for evidence of chargino-neutralino $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ pair production with Higgs or W-bosons in the decay chain,

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com

leading to HW final states with missing transverse energy. The decays of a Higgs boson to a photon pair are considered in conjunction with hadronic and leptonic decay modes of the W bosons. No significant excesses over the expected SM backgrounds are observed. The results are interpreted in the context of simplified models where the decays $\tilde{\chi}_2^0 \to H\tilde{\chi}_1^0$ and $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$ take place 100% of the time, see Figs. 22–23.

[68] AAD 13 searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for charginos and neutralinos decaying to a final state with three leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 and 3, and in simplified models, see Fig. 4. For the simplified models with intermediate slepton decays, degenerate $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ masses up to 500 GeV are excluded at 95% C.L. for very large mass differences with the $\tilde{\chi}_1^0$. Supersedes AAD 12AS.

[69] AAD 13B searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for gauginos decaying to a final state with two leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Limits are derived in a simplified model of wino-like chargino pair production, where the chargino always decays to the lightest neutralino via an intermediate on-shell charged slepton, see Fig. 2(b). Chargino masses between 110 and 340 GeV are excluded at 95% C.L. for $m_{\tilde{\chi}_1^0} = 10$ GeV. Exclusion limits are also derived in the phenomenological MSSM, see Fig. 3.

[70] AAD 12CT searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events containing four or more leptons (electrons or muons) and either moderate values of missing transverse momentum or large effective mass. No significant excess is found in the data. Limits are presented in a simplified model of R-parity violating supersymmetry in which charginos are pair-produced and then decay into a W-boson and a $\tilde{\chi}_1^0$, which in turn decays through an RPV coupling into two charged leptons ($e^\pm e^\mp$ or $e^\pm\mu^\mp$) and a neutrino. In this model, chargino masses up to 540 GeV are excluded at 95% C.L. for $m_{\tilde{\chi}_1^0}$ above 300 GeV, see Fig. 3a. The limit deteriorates for lighter $\tilde{\chi}_1^0$. Limits are also set in an R-parity violating mSUGRA model, see Fig. 3b.

[71] CHATRCHYAN 12BJ searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for direct electroweak production of charginos and neutralinos in events with at least two leptons, jets and missing transverse momentum. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ pair production were set in a number of simplified models, see Figs. 7 to 12.

[72] ABDALLAH 03M uses data from $\sqrt{s} = 192$–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass of charginos is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays), for charginos and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP. Constraints from the Higgs search in the $m_h^{\max}$ scenario assuming m_t= 174.3 GeV are included. The quoted limit applies if there is no mixing in the third family or when $m_{\tilde{\tau}_1} - m_{\tilde{\chi}_1^0} > 6$ GeV. If mixing is included the limit degrades to 90 GeV. See Fig. 43 for the mass limits as a function of $\tan\beta$. These limits update the results of ABREU 00W.

[73] AAD 20AN searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two photons and missing transverse momentum. Events are further categorised in terms of lepton or jet multiplicity. No significant excess over the expected background is observed. Limits at 95% C.L. are derived in Tchi1n2E simplified models. Next-to-lightest neutralinos and charginos with masses up to 310 GeV for a massless lightest neutralino are excluded. See their Fig. 10.

[74] KHACHATRYAN 16AA searched in 7.4 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with one or more photons, hadronic jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on wino masses in the general gauge-mediated SUSY breaking model (GGM), for a wino-like neutralino NLSP scenario and with the wino mass fixed at 10 GeV above the bino mass, see Fig. 4. Limits are also set in the Tchi1chi1A and Tchi1n1A simplified models, see Fig. 3.

[75] KHACHATRYAN 16R searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with one or more photons, one electron or muon, and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are also set in the Tglu1F simplified model, see Fig. 6.

[76] KHACHATRYAN 16Y searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with one or two soft isolated leptons, hadronic jets, and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the $\tilde{\chi}_1^\pm$ mass (which is degenerate with the $\tilde{\chi}_2^0$) in the Tchi1n2A simplified model, see Fig. 4.

[77] AAD 14AV searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for the direct production of charginos, neutralinos and staus in events containing at last two hadronically decaying τ-leptons, large missing transverse momentum and low jet activity. The quoted limit was derived for direct $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm\tilde{\chi}_1^\mp$ production with $\tilde{\chi}_2^0 \to \tilde{\tau}\tau \to \tau\tau\tilde{\chi}_1^0$ and $\tilde{\chi}_1^\pm \to \tilde{\tau}\nu(\tilde{\nu}_\tau\tau) \to \tau\nu\tilde{\chi}_1^0$, $m_{\tilde{\chi}_2^0} = m_{\tilde{\chi}_1^\pm}$, $m_{\tilde{\tau}} = 0.5\,(m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})$, $m_{\tilde{\chi}_1^0} = 0$ GeV. No excess over the expected SM background is observed. Exclusion limits are set in simplified models of $\tilde{\chi}_1^\pm\tilde{\chi}_1^\mp$ and $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ pair production, see their Figure 7. Upper limits on the cross section and signal strength for direct di-stau production are derived, see Figures 8 and 9. Also, limits are derived in a pMSSM model where the only light slepton is the $\tilde{\tau}_R$, see Figure 10.

[78] AAD 14AV searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for the direct production of charginos, neutralinos and staus in events containing at last two hadronically decaying τ-leptons, large missing transverse momentum and low jet activity. The quoted limit was derived for direct $\tilde{\chi}_1^\pm\tilde{\chi}_1^\mp$ production with $\tilde{\chi}_1^\pm \to \tilde{\tau}\nu(\tilde{\nu}_\tau\tau) \to \tau\nu\tilde{\chi}_1^0$, $m_{\tilde{\tau}} = 0.5\,(m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})$, $m_{\tilde{\chi}_1^0} = 0$ GeV. No excess over the expected SM background is observed. Exclusion limits are set in simplified models of $\tilde{\chi}_1^\pm\tilde{\chi}_1^\mp$ and $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ pair production, see their Figure 7. Upper limits on the cross section and signal strength for direct di-stau production are derived, see Figures 8 and 9. Also, limits are derived in a pMSSM model where the only light slepton is the $\tilde{\tau}_R$, see Figure 10.

[79] AAD 14G searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for electroweak production of chargino pairs, or chargino-neutralino pairs, decaying to a final sate with two leptons (e and μ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of chargino pair production, with chargino decays to the lightest neutralino via either sleptons or gauge bosons, see Fig 5.; or in simplified models of chargino and next-to-lightest neutralino production, with decays to the lightest neutralino via gauge bosons, see Fig. 7. An interpretation in the pMSSM is also given, see Fig. 10.

[80] AALTONEN 14 searched in 5.8 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for evidence of chargino and next-to-lightest neutralino associated production in final states consisting of three leptons (electrons, muons or taus) and large missing transverse momentum. The results are consistent with the Standard Model predictions within 1.85 σ. Limits on the chargino mass are derived in an mSUGRA model with $m_0 = 60$ GeV, $\tan\beta = 3$, $A_0 = 0$ and $\mu > 0$, see their Fig. 2.

[81] KHACHATRYAN 14I searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for electroweak production of chargino pairs decaying to a final state with opposite-sign lepton pairs (e or μ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models, see Fig. 18.

[82] AALTONEN 13Q searched in 6.0 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for evidence of chargino-neutralino associated production in like-sign dilepton final states. One lepton is identified as the hadronic decay of a tau lepton, while the other is an electron or muon. Good agreement with the Standard Model predictions is observed and limits are set on the chargino-neutralino cross section for simplified gravity- and gauge-mediated models, see their Figs. 2 and 3.

[83] AAD 12AS searched in 2.06 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for charginos and neutralinos decaying to a final state with three leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 (top), and in simplified models, see Fig. 2 (bottom).

[84] AAD 12T looked in 1 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for the production of supersymmetric particles decaying into final states with missing transverse momentum and exactly two isolated leptons (e or μ). Opposite-sign and same-sign dilepton events were separately studied. Additionally, in opposite-sign events, a search was made for an excess of same-flavor over different-flavor lepton pairs. No excess over the expected background is observed and limits are placed on the effective production cross section of opposite-sign dilepton events with $\not{E}_T > 250$ GeV and on same-sign dilepton events with $\not{E}_T > 100$ GeV. The latter limit is interpreted in a simplified electroweak gaugino production model as a lower chargino mass limit.

[85] CHATRCHYAN 11B looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$=7 TeV for events with an isolated lepton (e or μ), a photon and $\not{E}_T$ which may arise in a generalized gauge mediated model from the decay of Wino-like NLSPs. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark/gluino mass versus Wino mass (see Fig. 4). Mass degeneracy of the produced squarks and gluinos is assumed.

[86] CHATRCHYAN 11V looked in 35 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with ≥ 3 isolated leptons (e, μ or τ), with or without jets and $\not{E}_T$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0, m_{1/2})$ plane for $\tan\beta = 3$ (see Fig. 5).

Long-lived $\tilde{\chi}^\pm$ (Chargino) mass limit

Limits on charginos which leave the detector before decaying.

[1] AAD 25AE searched for massive, charged long-lived particles in 140 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV. Two analyses are conducted: one looking for a single track, with high specific ionisation losses in the pixel detector and long time of flight to the hadron calorimeter, and one looking for two tracks, both with high specific ionisation in the pixel detector. No excess above the expected background is found. Limits are set in scenarios of long-lived R-hadrons (gluino) production, chargino production or stau pair production, see their figures 13 and 14.

[2] AAD 23G searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for chargino/neutralino pair production (wino-like LSP) in events with high-pt tracks with large ionisation in the pixel detector. No significant excess above the Standard Model predictions is observed. Limits are set on the chargino mass as a function of its lifetime, see Figure 19.

[3] AAD 22U searched for the signature of disappearing track from a long-lived chargino in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV. Long-lived charginos decay into quasi-degenerate neutralino emitting a low-momentum particle whose identification is not attempted. The signal is identified by requiring short tracklets in the four pixel layers with no continuation in the SCT (strip) detector. The main background from fake tracklets is estimated directly with the data. No significant excess above the background prediction is found. The results are interpreted in an AMSB scenario (wino LSP), on $pp \to \tilde{\chi}^\pm\tilde{\chi}^\pm$ and $pp \to \tilde{\chi}^\pm\tilde{\chi}_1^0$, assuming B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0\pi^\pm$) = 100%, see their figure 7. Results are also interpreted in a higgsino-LSP model, with $pp \to \tilde{\chi}^\pm\tilde{\chi}^\mp$, and $pp \to \tilde{\chi}^\pm\tilde{\chi}_{1,2}^0$, assuming B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0\pi^\pm$) = 95.5%, B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0 e^\pm$) = 3%, B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0\mu^\pm$) = 1.5%, see their figure 8. Finally, results are interpreted in a simplified model of gluino pair production, with $pp \to \tilde{g}\tilde{g}$ and B($\tilde{g} \to qq\tilde{\chi}_1^0$) = B($\tilde{g} \to qq\tilde{\chi}^+$) = B($\tilde{g} \to qq\tilde{\chi}^-$) = 1/3, see their figure 9.

[4] SIRUNYAN 20N searched in 101 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of long-lived charginos in events containing isolated tracks with missing hits in the outer layer of the silicon tracker and little or no associated calorimetric energy deposits (disappearing tracks). No significant excess above the Standard Model expectations is observed. In an AMSB context and assuming a wino LSP, limits are set on the cross section of direct chargino production through $pp \to \tilde{\chi}^\pm\tilde{\chi}^\mp$ and $pp \to \tilde{\chi}^\pm\tilde{\chi}_1^0$, assuming B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0\pi^\pm$) = 100%, as a function of the chargino mass and mean proper lifetime, see Figure 2. In the case of a Higgsino LSP, limits are set on the cross section of direct chargino production through $pp \to \tilde{\chi}^\pm\tilde{\chi}^\mp$ and $pp \to \tilde{\chi}^\pm\tilde{\chi}_{1,2}^0$, assuming B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0\pi^\pm$) = 95.5%, B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0 e^\pm$) = 3%, B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0\mu^\pm$) = 1.5%, as a function of the chargino mass and mean proper lifetime, see Figure 3.

[5] AABOUD 19AT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for metastable R-hadrons. Multiple search strategies for a wide range of lifetimes, corresponding to path lengths of a few meters, are defined. No significant deviations from the expected Standard Model background are observed. Results are interpreted in terms of direct electroweak production of long-lived charginos in the context of mAMSB scenarios. Chargino masses are excluded at 95% C.L. below 1090 GeV. See their Figure 10 (right).

[6] AABOUD 18AS searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of long-lived charginos in the context of AMSB or phenomenological MSSM scenarios with wino-like LSP. Events with a disappearing track due to a low-momentum pion accompanied by at least one jet with high transverse momentum from initial-state radiation are considered. No significant excess above the Standard Model expectations is observed. Exclusion limits are set at 95% confidence level on the mass of charginos for different chargino lifetimes. For a pure wino with a lifetime of about 0.2 ns, corresponding to a mass-splitting between the charged and neutral wino of around 160 MeV, chargino masses up to 460 GeV are excluded, see their Fig. 8.

[7] SIRUNYAN 18BR searched in 38.4 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of long-lived charginos in events containing isolated tracks with missing hits in the outer layer of the silicon tracker and little or no associated calorimetric energy deposits (disappearing tracks). No significant excess above the Standard Model expectations is observed. In an AMSB context, limits are set on the cross section of direct chargino production through $pp \to \tilde{\chi}^\pm\tilde{\chi}^\mp$ and $pp \to \tilde{\chi}^\pm\tilde{\chi}_1^0$, assuming BR($\tilde{\chi}^\pm \to \tilde{\chi}_1^0\pi^\pm$) = 100%, as a function of the chargino mass and mean proper lifetime, see Figures 3, 4 and 5.

[8] AAD 15AE searched in 19.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for heavy long-lived charged particles, measured through their specific ionization energy loss in the ATLAS pixel detector or their time-of-flight in the ALTAS muon system. In the absence of an excess of events above the expected backgrounds, limits are set on stable charginos, see Fig. 10.

[9] AAD 15BM searched in 18.4 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for stable and metastable non-relativistic charged particles through their anomalous specific ionization energy loss in the ATLAS pixel detector. In absence of an excess of events above the expected backgrounds, limits are set on stable charginos (see Table 5) and on metastable charginos decaying to $\tilde{\chi}_1^0\pi^\pm$, see Fig. 11.

[10] AAD 13H searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for direct electroweak production of long-lived charginos in the context of AMSB scenarios. The search is based on the signature of a high-momentum isolated track with few associated hits in the outer part of the tracking system, arising from a chargino decay into a neutralino and a low-momentum pion. The p_T spectrum of the tracks was found to be consistent with the SM expectations. Constraints on the lifetime and the production cross section were obtained, see Fig. 6. In the minimal AMSB framework with tanβ = 5, and μ > 0, a chargino having a mass below 103 (85) GeV for a chargino-neutralino mass splitting $\Delta m_{\tilde{\chi}_1^0}$ of 160 (170) MeV is excluded at the 95% C.L. See Fig. 7 for more precise bounds.

[11] AAD 12BJ looked in 1.02 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for signatures of decaying charginos resulting in isolated tracks with few associated hits in the outer region of the tracking system. The p_T spectrum of the tracks was found to be consistent with the SM expectations. Constraints on the lifetime and the production cross section were obtained. In the minimal AMSB framework with $m_{3/2}$ < 32 TeV, m_0 < 1.5 TeV, tanβ = 5, and μ > 0, a chargino having a mass below 92 GeV and a lifetime between 0.5 ns and 2 ns is excluded at the 95% C.L. See their Fig. 8 for more precise bounds.

[12] ABAZOV 09M searched in 1.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with direct production of a pair of charged massive stable particles identified by their TOF. The number of the observed events is consistent with the predicted background. The data are used to constrain the production cross section as a function of the $\tilde{\chi}_1^\pm$ mass, see their Fig. 2. The quoted limit improves to 206 GeV for gaugino-like charginos.

[13] ABBIENDI 03L used e^+e^- data at $\sqrt{s}$ = 130–209 GeV to select events with two high momentum tracks with anomalous dE/dx. The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The bounds are valid for colorless fermions with lifetime longer than 10^{-6} s. Supersedes the results from ACKERSTAFF 98P.

[14] ABREU 00T searches for the production of heavy stable charged particles, identified by their ionization or Cherenkov radiation, using data from $\sqrt{s}$= 130 to 189 GeV. These limits include and update the results of ABREU 98P.

[15] KHACHATRYAN 15AB searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing tracks with little or no associated calorimeter energy deposits and with missing hits in the outer layers of the tracking system (disappearing-track signature). Such disappearing tracks can result from the decay of charginos that are nearly mass degenerate with the lightest neutralino. The number of observed events is in agreement with the background expectation. Limits are set on the cross section of electroweak chargino production in terms of the chargino mass and mean proper lifetime, see Fig. 4. In the minimal AMSB model, a chargino mass below 260 GeV is excluded at 95% C.L., see their Fig. 5.

[16] KHACHATRYAN 15O searched in 18.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for evidence of long-lived charginos in the context of AMSB and pMSSM scenarios. The results are based on a previously published search for heavy stable charged particles at 7 and 8 TeV. In the minimal AMSB framework with tanβ = 5 and $\mu \geq$ 0, constraints on the chargino mass and lifetime were placed, see Fig. 5. Charginos with a mass below 800 (100) GeV are excluded at the 95% C.L. for lifetimes above 100 ns (3 ns). Constraints are also placed on the pMSSM parameter space, see Fig. 3.

[17] KHACHATRYAN 15W searched in up to 20.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for evidence of long-lived neutralinos produced through $\tilde{q}$-pair production, with $\tilde{q} \to q\tilde{\chi}^0$ and $\tilde{\chi}^0 \to \ell^+\ell^-\nu$ (RPV: λ_{121}, $\lambda_{122} \neq 0$). 95% C.L. exclusion limits on cross section times branching ratio are set as a function of mean proper decay length of the neutralino, see Figs. 6 and 9.

[18] AAD 13BD searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing tracks with no associated hits in the outer region of the tracking system resulting from the decay of charginos that are nearly mass degenerate with the lightest neutralino, as is often the case in AMSB scenarios. No significant excess above the background expectation is observed for candidate tracks with large transverse momentum. Constraints on chargino properties are obtained and in the minimal AMSB model, a chargino mass below 270 GeV is excluded at 95% C.L., see their Fig. 7.

[19] ABAZOV 13B looked in 6.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for charged massive long-lived particles in events with muon-like particles that have both speed and ionization energy loss inconsistent with muons produced in beam collisions. In the absence of an excess, limits are set at 95% C.L. on gaugino- and higgsino-like charginos, see their Table 20 and Fig. 23.

$\tilde{\nu}$ (Sneutrino) mass limit

The limits may depend on the number, $N(\tilde{\nu})$, of sneutrinos assumed to be degenerate in mass. Only $\tilde{\nu}_L$ (not $\tilde{\nu}_R$) is assumed to exist. It is possible that $\tilde{\nu}$ could be the lightest supersymmetric particle (LSP).

We report here, but do not include in the Listings, the limits obtained from the fit of the final results obtained by the LEP Collaborations on the invisible width of the Z boson ($\Delta\Gamma_{\text{inv.}}$ < 2.0 MeV, LEP-SLC 06): $m_{\tilde{\nu}}$ > 43.7 GeV ($N(\tilde{\nu})$=1) and $m_{\tilde{\nu}}$ > 44.7 GeV ($N(\tilde{\nu})$=3) .

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 25L searched for an excess of three-lepton events in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV. The search targets scenarios connected with potential anomalous muon magnetic moment: pair-produced sleptons (either charged or neutral) are assumed to decay to a bino-like $\tilde{\chi}^0_3$, decaying to a mass-degenerate higgsino triplet LSP via the emission of a W, Z or h boson (with branching ratio 50%, 25% and 25% respectively). Three sets of signal regions are defined (with a SFOS pair on- and off-shell of the Z boson, and with three SS leptons). No significant excess is observed over the background prediction. 95% CL limits are extracted assuming degenerate $\tilde{e}_L$, $\tilde{\nu}_e$, $\tilde{\mu}_L$, $\tilde{\nu}_\mu$, degenerate $\tilde{e}_L$, $\tilde{\nu}_e$, and degenerate $\tilde{\mu}_L$, $\tilde{\nu}_\mu$, see their figures 15, 16a, and 16b.

[2] AAD 23CB searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for heavy particles decaying into an $e\mu$, $e\tau$, $\mu\tau$ final state. No significant deviation from the expected SM background is observed. Limits are set on the mass of a stau neutrino with R-parity-violating couplings, with decays $\tilde{\nu}_\tau \to e\mu$, $\tilde{\nu}_\tau \to e\tau$, $\tilde{\nu}_\tau \to \mu\tau$, see figures 4b, 5b, 6b.

[3] TUMASYAN 23H searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of resonant $\tilde{\nu}_\tau$ production in events with two charged leptons, $e\mu$, $e\tau$, or $\mu\tau$. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\tilde{\nu}_\tau$ in an RPV model for resonant sneutrino production, where all RPV couplings vanish, except for those that are connected to the production and decay of the $\tilde{\nu}_\tau$, considering a SUSY mass hierarchy with $\tilde{\nu}_\tau$ as the LSP. The $\tilde{\nu}_\tau$ is produced resonantly through λ'_{311} coupling, and decays via λ_{i3k} coupling to two leptons, see their figure 3 for couplings of 0.1 and 0.01. Exclusion limits are also shown in the plane of $\tilde{\nu}_\tau$ mass and λ' coupling, for four values of λ couplings, see their figure 6. In addition, limits are set on heavy Z' gauge bosons with lepton flavor violating decays, see their figure 4, and on nonresonant quantum black hole production in models with extra spatial dimensions, see their figure 5. Model-independent upper limits on the product of the cross section, the branching fraction, acceptance, and efficiency are given as well, see their figure 7.

[4] AABOUD 18CM searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for heavy particles decaying into an $e\mu$, $e\tau$, $\mu\tau$ final state. No significant deviation from the expected SM background is observed. Limits are set on the mass of a stau neutrino with R-parity-violating couplings. For $\tilde{\nu}_\tau \to e\mu$, masses below 3.4 TeV are excluded at 95% CL, see their Figure 4(b). Upper limits on the RPV couplings $|\lambda_{312}|$ versus $|\lambda'_{311}|$ are also performed, see their Figure 8(a-b).

[5] AABOUD 18CM searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for heavy particles decaying into an $e\mu$, $e\tau$, $\mu\tau$ final state. No significant deviation from the expected SM background is observed. Limits are set on the mass of a stau neutrino with R-parity-violating couplings. For $\tilde{\nu}_\tau \to e\tau$, masses below 2.9 TeV are excluded at 95% CL, see their Figure 5(b). Upper limits on the RPV couplings $|\lambda_{313}|$ versus $|\lambda'_{311}|$ are also performed, see their Figure 8(c).

[6] AABOUD 18CM searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for heavy particles decaying into an $e\mu$, $e\tau$, $\mu\tau$ final state. No significant deviation from the expected SM background is observed. Limits are set on the mass of a stau neutrino with R-parity-violating couplings. For $\tilde{\nu}_\tau \to \mu\tau$, masses below 2.6 TeV are excluded at 95% CL, see their Figure 6(b). Upper limits on the RPV couplings $|\lambda_{323}|$ versus $|\lambda'_{311}|$ are also performed, see their Figure 8(d).

[7] AABOUD 18Z searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing four or more charged leptons (electrons, muons and up to two hadronically decaying taus). No significant deviation from the expected SM background is observed. Limits are set on the Higgsino mass in simplified models of general gauge mediated supersymmetry Tn1n1A/Tn1n1B/Tn1n1C, see their Figure 9. Limits are also set on the wino, slepton, sneutrino and gluino mass in a simplified model of NLSP pair production with R-parity violating decays of the LSP via λ_{12k} or λ_{i33} to charged leptons, see their Figures 7, 8.

[8] SIRUNYAN 18AT searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for heavy resonances decaying into $e\mu$ final states. No significant excess above the Standard Model expectation is observed and 95% C.L. exclusions are placed on the cross section times branching ratio for the R-parity-violating production and decay of a supersymmetric tau sneutrino, see their Fig. 3.

[9] AABOUD 16P searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with different flavour dilepton pairs ($e\mu$, $e\tau$, $\mu\tau$) from the production of $\tilde{\nu}_\tau$ via an RPV λ'_{311} coupling and followed by a decay via $\lambda_{312} = \lambda_{321} = 0.07$ for $e + \mu$, via $\lambda_{313} = \lambda_{331} = 0.07$ for $e + \tau$ and via $\lambda_{323} = \lambda_{332} = 0.07$ for $\mu + \tau$. No evidence for a dilepton resonance over the SM expectation is observed, and limits are derived on $m_{\tilde{\nu}}$ at 95% CL, see their Figs. 2(b), 3(b), 4(b), and Table 3.

[10] AAD 14X searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the sneutrino mass in an R-parity violating simplified model where the decay $\tilde{\nu} \to \nu\tilde{\chi}^0_1$, with $\tilde{\chi}^0_1 \to \ell^\pm\ell^\mp\nu$, takes place with a branching ratio of 100%, see Fig. 9.

[11] AAD 11Z looked in 1.07 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with one electron and one muon of opposite charge from the production of $\tilde{\nu}_\tau$ via an RPV λ'_{311} coupling and followed by a decay via λ_{312} into $e + \mu$. No evidence for an (e, μ) resonance over the SM expectation is observed, and a limit is derived in the plane of λ'_{311} versus $m_{\tilde{\nu}}$ for three values of λ_{312}, see their Fig. 2. Masses $m_{\tilde{\nu}} < 1.32$ (1.45) TeV are excluded for $\lambda'_{311} = 0.10$ and $\lambda_{312} = 0.05$ ($\lambda'_{311} = 0.11$ and $\lambda_{312} = 0.07$).

[12] ABDALLAH 03M uses data from $\sqrt{s} = 192$–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 1$ TeV with the $\tilde{\chi}^0_1$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of $\tan\beta$. These limits update the results of ABREU 00W.

[13] HEISTER 02N derives a bound on $m_{\tilde{\nu}_e}$ by exploiting the mass relation between the $\tilde{\nu}_e$ and $\tilde{e}$, based on the assumption of universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 and the search described in the $\tilde{e}$ section. In the MSUGRA framework with radiative electroweak symmetry breaking, the limit improves to $m_{\tilde{\nu}_e} > 130$ GeV, assuming a trilinear coupling $A_0 = 0$ at the GUT scale. See Figs. 5 and 7 for the dependence of the limits on $\tan\beta$.

[14] DECAMP 92 limit is from Γ(invisible)/$\Gamma(\ell\ell) = 5.91 \pm 0.15$ ($N_\nu = 2.97 \pm 0.07$).

[15] SIRUNYAN 19AO searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing two same-sign muons and at last two jets, originating from resonant production of second-generation sleptons ($\tilde{\mu}_L$, $\tilde{\nu}_\mu$) via the R-parity violating coupling λ'_{211} to quarks. No significant excess above the Standard Model expectations is observed. Upper limits on cross sections are derived in the context of two simplified models, see their Figure 4. The cross section limits are translated into limits on λ'_{211} for a modified CMSSM, see their Figure 5.

[16] KHACHATRYAN 16BE searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for evidence of narrow resonances decaying into $e\mu$ final states. No significant excess above the Standard Model expectation is observed and 95% C.L. exclusions are placed on the cross section times branching ratio for the production of an R-parity-violating supersymmetric tau sneutrino, see their Fig. 3.

[17] AAD 15O searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for evidence of heavy particles decaying into $e\mu$, $e\tau$ or $\mu\tau$ final states. No significant excess above the Standard Model expectation is observed, and 95% C.L. exclusions are placed on the cross section times branching ratio for the production of an R-parity-violating supersymmetric tau sneutrino, applicable to any sneutrino flavour, see their Fig. 2.

[18] AAD 13AI searched in 4.6 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for evidence of heavy particles decaying into $e\mu$, $e\tau$ or $\mu\tau$ final states. No significant excess above the Standard Model expectation is observed, and 95% C.L. exclusions are placed on the cross section times branching ratio for the production of an R-parity-violating supersymmetric tau sneutrino, see their Fig. 2. For couplings $\lambda'_{311} = 0.10$ and $\lambda_{i3k} = 0.05$, the lower limits on the $\tilde{\nu}_\tau$ mass are 1610, 1110, 1100 GeV in the $e\mu$, $e\tau$, and $\mu\tau$ channels, respectively.

[19] AAD 11H looked in 35 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with one electron and one muon of opposite charge from the production of $\tilde{\nu}_\tau$ via an RPV λ'_{311} coupling and followed by a decay via λ_{312} into $e + \mu$. No evidence for an excess over the SM expectation is observed, and a limit is derived in the plane of λ'_{311} versus $m_{\tilde{\nu}}$ for several values of λ_{312}, see their Fig. 2. Superseded by AAD 11Z.

[20] AALTONEN 10Z searched in 1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events from the production $d\overline{d} \to \tilde{\nu}_\tau$ with the subsequent decays $\tilde{\nu}_\tau \to e\mu$, $\mu\tau$, $e\tau$ in the MSSM framework with RPV. Two isolated leptons of different flavor and opposite charges are required, with τs identified by their hadronic decay. No statistically significant excesses are observed over the SM background. Upper limits on λ'^2_{311} times the branching ratio are listed in their Table III for various $\tilde{\nu}_\tau$ masses. Limits on the cross section times branching ratio for $\lambda'_{311} = 0.10$ and $\lambda_{i3k} = 0.05$, displayed in Fig. 2, are used to set limits on the $\tilde{\nu}_\tau$ mass of 558 GeV for the $e\mu$, 441 GeV for the $\mu\tau$ and 442 GeV for the $e\tau$ channels.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[21] ABAZOV 10M looked in 5.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with exactly one pair of high p_T isolated $e\mu$ and a veto against hard jets. No evidence for an excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section times branching ratio is derived, see their Fig. 3. These limits are translated into limits on couplings as a function of $m_{\widetilde{\nu}_\tau}$ as shown on their Fig. 4. As an example, for $m_{\widetilde{\nu}_\tau}$ = 100 GeV and $\lambda_{312} \leq 0.07$, couplings $\lambda'_{311} > 7.7 \times 10^{-4}$ are excluded.

[22] ABDALLAH 04H use data from LEP 1 and $\sqrt{s}$ = 192–208 GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_{3/2} < 50$ TeV, $0 < m_0 < 1000$ GeV, $1.5 < \tan\beta < 35$, both signs of μ. The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for m_t = 174.3 GeV (see Table 2 for other m_t values). The limit improves to 114 GeV for $\mu < 0$.

[23] ADRIANI 93M limit from $\Delta\Gamma(Z)$(invisible)< 16.2 MeV.

[24] ALEXANDER 91F limit is for one species of $\widetilde{\nu}$ and is derived from Γ(invisible, new)/$\Gamma(\ell\ell)$ < 0.38.

Charged sleptons

This section contains limits on charged scalar leptons ($\widetilde{\ell}$, with ℓ=e,μ,τ). Studies of width and decays of the Z boson (use is made here of $\Delta\Gamma_{\rm inv}$ < 2.0 MeV, LEP 00) conclusively rule out $m_{\widetilde{\ell}_R}$ < 40 GeV (41 GeV for $\widetilde{\ell}_L$) , independently of decay modes, for each individual slepton. The limits improve to 43 GeV (43.5 GeV for $\widetilde{\ell}_L$) assuming all 3 flavors to be degenerate. Limits on higher mass sleptons depend on model assumptions and on the mass splitting $\Delta m = m_{\widetilde{\ell}} - m_{\widetilde{\chi}^0_1}$. The mass and composition of $\widetilde{\chi}^0_1$ may affect the selectron production rate in e^+e^- collisions through t-channel exchange diagrams. Production rates are also affected by the potentially large mixing angle of the lightest mass eigenstate $\widetilde{\ell}_1 = \widetilde{\ell}_R \sin\theta_\ell + \widetilde{\ell}_L \cos\theta_\ell$. It is generally assumed that only $\widetilde{\tau}$ may have significant mixing. The coupling to the Z vanishes for θ_ℓ=0.82. In the high-energy limit of e^+e^- collisions the interference between γ and Z exchange leads to a minimal cross section for θ_ℓ=0.91, a value which is sometimes used in the following entries relative to data taken at LEP2. When limits on $m_{\widetilde{\ell}_R}$ are quoted, it is understood that limits on $m_{\widetilde{\ell}_L}$ are usually at least as strong.

Possibly open decays involving gauginos other than $\widetilde{\chi}^0_1$ will affect the detection efficiencies. Unless otherwise stated, the limits presented here result from the study of $\widetilde{\ell}^+\widetilde{\ell}^-$ production, with production rates and decay properties derived from the MSSM. Limits made obsolete by the recent analyses of e^+e^- collisions at high energies can be found in previous Editions of this Review.

For decays with final state gravitinos ($\widetilde{G}$), $m_{\widetilde{G}}$ is assumed to be negligible relative to all other masses.

R-parity conserving $\widetilde{e}$ (Selectron) mass limit

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 25AH searched for an excess in same-flavour dilepton production events in 140 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV using a BDT selection optimised on simplified models including sleptons and neutralinos with $m_{\widetilde{e}} - m_{\widetilde{\chi}^0_1} < m_W$: pair-produced sleptons decay to a lepton and a neutralino. Several signal regions are defined, depending on the BDT score. Despite some local excess at the level of 2.4 σ, the data agree with the background prediction. 95% CL limits are extracted a s a function of $m_{\widetilde{e}} - m_{\widetilde{\chi}^0_1}$, see their figure 13.

[2] AAD 25L searched for an excess of three-lepton events in 140 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV. The search targets scenarios connected with potential anomalous muon magnetic moment: pair-produced sleptons (either charged or neutral) are assumed to decay to a bino-like $\widetilde{\chi}^0_3$, decaying to a mass-degenerate higgsino triplet LSP via the emission of a W, Z or h boson (with branching ratio 50%, 25% and 25% respectively). Three sets of signal regions are defined (with a SFOS pair on- and off-shell of the Z boson, and with three SS leptons). No significant excess is observed over the background prediction. 95% CL limits are extracted assuming degenerete $\widetilde{e}_L$, $\widetilde{\nu}_e$, $\widetilde{\mu}_L$, $\widetilde{\nu}_\mu$, degenerate $\widetilde{e}_L$, $\widetilde{\nu}_e$, and degenerete $\widetilde{\mu}_L$, $\widetilde{\nu}_\mu$, see their figures 15, 16a, and 16b.

[3] AAD 25M searched for an excess of displaced leptons (e or μ) in pp collisions (140 fb^{-1} at $\sqrt{s}$ = 13 TeV and 56.3 at fb^{-1} at $\sqrt{s}$ = 13.6 TeV). The models considered were long-lived slepton (electron or muon) pair production followed by $\widetilde{\ell} \to \ell\widetilde{G}$, and long-lived chargino pair production in a dark sector model, followed by $\widetilde{\chi}^\pm_1 \to \widetilde{\chi}^0_1 W$. Displaced leptons were reconstructed thanks to an improved large radius tracking and to the pointing capabilities of the electromagnetic calorimeter. Two different analyses (ABCD and EM-BDT) are combined to obtain limits on $\widetilde{e}$ pair production, while the ABCD analysis only is used for $\widetilde{\mu}$, $\widetilde{\tau}$ and $\widetilde{\chi}^\pm_1$ pair production. No significant excess of events is observed over the background prediction. 95% CL limits are extracted in the lifetime vs mass plane, see their figures 6 and 8.

[4] CHEKHOVSKY 25M searched in 138 fb^{-1} of pp collisions at $\sqrt{s}=13$ TeV for evidence of SUSY models with compressed mass spectra in events with a high transverse momentum system from initial-state-radiation jets recoiling against a potential sparticle system with significant missing transverse momentum. These events are further categorized based on their lepton multiplicity, jet multiplicity, number of b-tagged jets, and kinematic variables sensitive to the sparticle masses and mass splittings. No significant excess above the Standard Model expectations is observed. The results are interpreted in models of top squark, electroweakino and slepton pair production. Limits are set for top squark pair production in the models Tstop1 and Tstop2, see their figure 25, and in Tstop4, see their figure 26. The results are also interpreted in models describing the production of mass-degenerate $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ with decays $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ and $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$, applying both a wino-like and higgsino-like $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ production cross section, see their figure 27. Limits are also set for wino-like $\tilde{\chi}_1^\pm$ pair production, either with $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$ or in the model Tchi1chi1C. This paper also addresses direct slepton production, taking into account pure right-handed, pure left-handed and combined production of either selectrons, smuons, or mass-degenerate sleptons of the first and second generation, see their figures 30 and 31.

[5] HAYRAPETYAN 24N searched in up to 137 fb^{-1} of pp collisions at $\sqrt{s}=13$ TeV for evidence of wino-like chargino-neutralino pairs, Higgsino-like neutralino pair production in a gauge-mediated SUSY breaking inspired scenario, a Higgsino-bino interpretation, and slepton pair production in a combination of a number of previously reported searches for SUSY in different final states. No significant excess above the Standard Model expectations is observed. Limits are set on the $\tilde{\chi}_1^\pm$ mass in the wino-bino models Tchi1n2E1, Tchi1n2E, and Tchi1n2l, see their Fig. 11, and on the $\tilde{\chi}_1^0$ in the higgsino-like GMSB models Tn1n1A, Tn1n1B, and Tn1n1C, see their Fig. 13. In addition, Fig. 14 shows the mass exclusion limit as a function of the branching fraction to the H boson. Limits are also set in a Higgsino-bino interpretation as in THinoBinoA, but also including leptonic decays, see their Fig. 15. Limits are also set on slepton ($\tilde{e}$, $\tilde{\mu}$) production with the decay $\tilde{\ell} \to \ell\tilde{\chi}_1^0$, see their Fig. 16.

[6] AAD 23M searched in 139 fb^{-1} of pp collisions at $\sqrt{s}=13$ TeV for $\tilde{\ell}^\pm$ pair production, followed by $\tilde{\ell}^\pm \to \ell^\pm\tilde{\chi}_1^0$ in events with two leptons. The focus is on models where $m_{\tilde{\ell}^\pm} - m_{\tilde{\chi}_1^0}$ is close to the W mass. No significant excess above the Standard Model predictions is observed. Limits were set on the $\tilde{\ell}$ mass (assuming $\tilde{e}-\tilde{\mu}$ and $L-R$ degeneracy), as a function of $m_{\tilde{\chi}_1^0}$, see Figure 6. Limits were also derived for single $\tilde{e}$ or $\tilde{\mu}$, and for L and R independently, see Figure 7.

[7] SIRUNYAN 21M searched in 137 fb^{-1} of pp collisions at $\sqrt{s}=13$ TeV for supersymmetry in events with two opposite-sign same-flavor leptons (electrons, muons) and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu4C, see their Figure 10, on the $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ mass in Tchi1n2Fa, see their Figure 11, on the $\tilde{\chi}_1^0$ mass in Tn1n1C and Tn1n1B for $m_{\tilde{\chi}_2^0}=m_{\tilde{\chi}_1^\pm}=m_{\tilde{\chi}_1^0}$, see their Figure 12. Limits are also set on the light squark mass for the simplified model Tsqk2A, on the sbottom mass in Tsbot3, see their Figure 13, and on the slepton mass in direct electroweak pair production of mass-degenerate left- and right-handed sleptons (selectrons and smuons), see their Figure 14.

[8] AAD 20O reported on a search for electroweak production in models with charginos and sleptons decaying into final states with exactly two oppositely charged leptons and missing transverse momentum. A dataset of pp collisions at $\sqrt{s}=13$ TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Light-flavour sleptons $\tilde{e}$ and $\tilde{\mu}$ are constrained at 95% C.L. to have masses above 700 GeV for massless lightest neutralino, see their Fig. 7(c). Exclusion limits are also set for selectrons and smuons separately, considering either right- or left-handed components, by including only the di-electron and di-muon same-flavour signal regions defined in the search, see their Fig. 8.

[9] SIRUNYAN 19AW searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}=13$ TeV for direct electroweak pair production of selectrons or smuons in events with two leptons (electrons or muons) of the opposite electric charge and same flavour, no jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the selectron mass assuming left-handed, right-handed or both left- and right-handed (mass degenerate) production, see their Figure 6. Similarly, limits are set on the smuon mass, see their Figure 7. Limits are also set on slepton masses under the assumption that the selectron and smuon are mass degenerate, see their Figure 5.

[10] AABOUD 18BT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}=13$ TeV for direct electroweak production of charginos, chargino and next-to-lightest neutralinos and sleptons in events with two or three leptons (electrons or muons), with or without jets, and large missing transverse energy. No significant excess above the Standard Model expectations is observed. Limits are set on the slepton mass up to 500 GeV for massless $\tilde{\chi}_1^0$, assuming degeneracy of $\tilde{e}$, $\tilde{\mu}$, and $\tilde{\tau}$ and exploiting the 2ℓ signature, see their Figure 8(b).

[11] AABOUD 18R searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}=13$ TeV for electroweak production in scenarios with compressed mass spectra in final states with two low-momentum leptons and missing transverse momentum. The data are found to be consistent with the SM prediction. Results are interpreted in slepton pair production models with a fourfold degeneracy assumed in selectron and smuon masses. The $\tilde{e}$ masses are excluded up to 190 GeV for $m_{\tilde{e}} - m_{\tilde{\chi}_1^0} = 5$ GeV. The exclusion limits extend down to mass splittings of 1 GeV, see their Fig. 11.

[12] CHATRCHYAN 14R searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}=8$ TeV for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the slepton mass in a stau (N)NLSP simplified model (GMSB) where the decay $\tilde{\ell} \to \ell^\pm\tau^\pm\tau^\mp\tilde{G}$ takes place with a branching ratio of 100%, see Fig. 8.

[13] AAD 13B searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for sleptons decaying to a final state with two leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Limits are derived in a simplified model of direct left-handed slepton pair production, where left-handed slepton masses between 85 and 195 GeV are excluded at 95% C.L. for $m_{\tilde{\chi}_1^0}=20$ GeV. See also Fig. 2(a). Exclusion limits are also derived in the phenomenological MSSM, see Fig. 3.

[14] ABBIENDI 04 search for $\tilde{e}_R\tilde{e}_R$ production in acoplanar di-electron final states in the 183–208 GeV data. See Fig. 13 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$ and for the limit at $\tan\beta$=35 This limit supersedes ABBIENDI 00G.

[15] ACHARD 04 search for $\tilde{e}_R\tilde{e}_L$ and $\tilde{e}_R\tilde{e}_R$ production in single- and acoplanar di-electron final states in the 192–209 GeV data. Absolute limits on $m_{\tilde{e}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, $1 \le \tan\beta \le 60$ and $-2 \le \mu \le 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$. This limit supersedes ACCIARRI 99W.

[16] ABDALLAH 03M looked for acoplanar dielectron $+\not{E}$ final states at $\sqrt{s}=189$–208 GeV. The limit assumes μ=−200 GeV and $\tan\beta$=1.5 in the calculation of the production cross section and B($\tilde{e} \to e\tilde{\chi}_1^0$). See Fig. 15 for limits in the ($m_{\tilde{e}_R}$, $m_{\tilde{\chi}_1^0}$) plane. These limits include and update the results of ABREU 01

[17] ABDALLAH 03M uses data from $\sqrt{s}=192$–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of M_2 <1 TeV, $|\mu| \le 1$ TeV with the $\tilde{\chi}_1^0$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of $\tan\beta$. These limits update the results of ABREU 00W.

[18] HEISTER 02E looked for acoplanar dielectron $+\not{E}_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes $\mu < -200$ GeV and $\tan\beta$=2 for the production cross section and B($\tilde{e} \to e\tilde{\chi}_1^0$)=1. See their Fig. 4 for the dependence of the limit on Δm. These limits include and update the results of BARATE 01.

[19] HEISTER 02N search for $\tilde{e}_R\tilde{e}_L$ and $\tilde{e}_R\tilde{e}_R$ production in single- and acoplanar di-electron final states in the 183–208 GeV data. Absolute limits on $m_{\tilde{e}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, $1 \le \tan\beta \le 50$ and $-10 \le \mu \le 10$ TeV. The region of small $|\mu|$, where cascade decays are important, is covered by a search for $\tilde{\chi}_1^0\tilde{\chi}_3^0$ in final states with leptons and possibly photons. Limits on $m_{\tilde{e}_L}$ are derived by exploiting the mass relation between the $\tilde{e}_L$ and $\tilde{e}_R$, based on universal m_0 and $m_{1/2}$. When the constraint from the mass limit of the lightest Higgs from HEISTER 02 is included, the bounds improve to $m_{\tilde{e}_R}$ >77(75) GeV and $m_{\tilde{e}_L}$ >115(115) GeV for a top mass of 175(180) GeV. In the MSUGRA framework with radiative electroweak symmetry breaking, the limits improve further to $m_{\tilde{e}_R}$ >95 GeV and $m_{\tilde{e}_L}$ >152 GeV, assuming a trilinear coupling A_0=0 at the GUT scale. See Figs. 4, 5, 7 for the dependence of the limits on $\tan\beta$.

[20] AAD 20I reported on ATLAS searches for slepton pair production in models with compressed mass spectra. A dataset of pp collisions at $\sqrt{s}=13$ TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Events with $\not{E}_T$, two same-flavour, opposite-charge, low-transverse-momentum leptons, and jets from initial-state radiation or characteristic of vector-boson fusion production are selected. Light-flavour sleptons $\tilde{e}$ and $\tilde{\mu}$ are constrained at 95% C.L. to have masses above 251 GeV for a mass splitting slepton−$\tilde{\chi}_1^0$ of 10 GeV, with constraints extending down to mass splittings of 550 MeV at the LEP slepton limits (73 GeV), see their Fig. 16(a). If only selectrons are considered, and $\tilde{e}=\tilde{e}_R$, masses below 101 GeV are excluded for mass splitting $\tilde{e}_R$, $\tilde{\chi}_1^0$ of 7.5 GeV. See their Fig. 16(b).

[21] AAD 20I reported on ATLAS searches for slepton pair production in models with compressed mass spectra. A dataset of pp collisions at $\sqrt{s}=13$ TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Events with $\not{E}_T$, two same-flavour, opposite-charge, low-transverse-momentum leptons, and jets from initial-state radiation or characteristic of vector-boson fusion production are selected. Light-flavour sleptons $\tilde{e}$ and $\tilde{\mu}$ are constrained at 95% C.L. to have masses above 251 GeV for a mass splitting slepton−$\tilde{\chi}_1^0$ of 10 GeV, with constraints extending down to mass splittings of 550 MeV at the LEP slepton limits (73 GeV). See their Fig. 16(a). If only selectron are considered, and $\tilde{e}=\tilde{e}_L$, masses below 169 GeV are excluded for mass splitting $\tilde{e}_L$, $\tilde{\chi}_1^0$ of 7.1 GeV. See their Fig. 16(b).

[22] AAD 14G searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}=8$ TeV for electroweak production of slepton pairs, decaying to a final sate with two leptons (e and μ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of slepton pair production, see Fig. 8. An interpretation in the pMSSM is also given, see Fig. 10.

[23] KHACHATRYAN 14I searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}=8$ TeV for electroweak production of slepton pairs decaying to a final state with opposite-sign lepton pairs (e or μ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models, see Fig. 18.

R-partiy violating $\tilde{e}$ (Selectron) mass limit

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 21Y searched in 139 fb^{-1} of pp collisions at $\sqrt{s}=13$ TeV for supersymmetry in events with four or more leptons (electrons, muons and tau-leptons). No significant excess above the Standard Model expectations is observed. Limits are set on Tchi1n12-GGM, and RPV models similar to Tchi1n2l, Tglu1A (with $q=u$, d, s, c, b, with

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

equal branching fractions), and $\tilde{\ell}_L/\tilde{\nu} \to \ell/\nu\tilde{\chi}_1^0$ (mass-degenerate $\tilde{\ell}_L$ and $\tilde{\nu}$ of all 3 generations), all with $\tilde{\chi}_1^0 \to \ell^\pm\ell^\mp\nu$ via λ_{12k} or λ_{i33} (where $i,k \in 1,2$), see their Figure 11.

[2] AABOUD 18Z searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing four or more charged leptons (electrons, muons and up to two hadronically decaying taus). No significant deviation from the expected SM background is observed. Limits are set on the Higgsino mass in simplified models of general gauge mediated supersymmetry Tn1n1A/Tn1n1B/Tn1n1C, see their Figure 9. Limits are also set on the wino, slepton, sneutrino and gluino mass in a simplified model of NLSP pair production with R-parity violating decays of the LSP via λ_{12k} or λ_{i33} to charged leptons, see their Figures 7, 8.

[3] AAD 14X searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the slepton mass in an R-parity violating simplified model where the decay $\tilde{\ell} \to \ell\tilde{\chi}_1^0$, with $\tilde{\chi}_1^0 \to \ell^\pm\ell^\mp\nu$, takes place with a branching ratio of 100%, see Fig. 9.

[4] ABBIENDI 04F use data from $\sqrt{s} = 189$–209 GeV. They derive limits on sparticle masses under the assumption of RPV with $LL\overline{E}$ or $LQ\overline{D}$ couplings. The results are valid for $\tan\beta = 1.5$, $\mu = -200$ GeV, with, in addition, $\Delta m \geq 5$ GeV for indirect decays via $LQ\overline{D}$. The limit quoted applies to direct decays via $LL\overline{E}$ or $LQ\overline{D}$ couplings. For indirect decays, the limits on the $\tilde{e}_R$ mass are respectively 99 and 92 GeV for $LL\overline{E}$ and $LQ\overline{D}$ couplings and $m_{\tilde{\chi}_1^0} = 10$ GeV and degrade slightly for larger $\tilde{\chi}_1^0$ mass. Supersedes the results of ABBIENDI 00.

[5] ABDALLAH 04M use data from $\sqrt{s} = 192$–208 GeV to derive limits on sparticle masses under the assumption of RPV with $LL\overline{E}$ or $\overline{UDD}$ couplings. The results are valid for $\mu = -200$ GeV, $\tan\beta = 1.5$, $\Delta m \geq 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect $\overline{UDD}$ decays using the neutralino constraint of 39.5 GeV for $LL\overline{E}$ and of 38.0 GeV for $\overline{UDD}$ couplings, also derived in ABDALLAH 04M. For indirect decays via $LL\overline{E}$ the limit improves to 95 GeV if the constraint from the neutralino is used and to 94 GeV if it is not used. For indirect decays via $\overline{UDD}$ couplings it remains unchanged when the neutralino constraint is not used. Supersedes the result of ABREU 00U.

[1] AAD 25AH searched for an excess in same-flavour dilepton production events in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV using a BDT selection optimised on simplified models including sleptons and neutralinos with $m_{\tilde{\mu}} - m_{\tilde{\chi}_1^0} < m_W$: pair-produced sleptons decay to a lepton and a neutralino. Several signal regions are defined, depending on the BDT score. Despite some local excess at the level of 2.4 σ, the data agree with the background prediction. 95% CL limits are extracted a s a function of $m_{\tilde{\mu}} - m_{\tilde{\chi}_1^0}$, see their figure 13.

[2] AAD 25L searched for an excess of three-lepton events in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV. The search targets scenarios connected with potential anomalous muon magnetic moment: pair-produced sleptons (either charged or neutral) are assumed to decay to a bino-like $\tilde{\chi}_3^0$, decaying to a mass-degenerate higgsino triplet LSP via the emission of a W, Z or h boson (with branching ratio 50%, 25% and 25% respectively). Three sets of signal regions are defined (with a SFOS pair on- and off-shell of the Z boson, and with three SS leptons). No significant excess is observed over the background prediction. 95% CL limits are extracted assuming degenerete $\tilde{e}_L$, $\tilde{\nu}_e$, $\tilde{\mu}_L$, $\tilde{\nu}_\mu$, degenerete $\tilde{e}_L$, $\tilde{\nu}_e$, and degenerete $\tilde{\mu}_L$, $\tilde{\nu}_\mu$, see their figures 15, 16a, and 16b.

[3] AAD 25M searched for an excess of displaced leptons (e or μ) in pp collisions (140 fb^{-1} at $\sqrt{s} = 13$ TeV and 56.3 at fb^{-1} at $\sqrt{s} = 13.6$ TeV). The models considered were long-lived slepton (electron or muon) pair production followed by $\tilde{\ell} \to \ell\tilde{G}$, and long-lived chargino pair production in a dark sector model, followed by $\tilde{\chi}_1^\pm \to \tilde{\chi}_1^0 W$. Displaced leptons were reconstructed thanks to an improved large radius tracking and to the pointing capabilities of the electromagnetic calorimeter. Two different analyses (ABCD and EM-BDT) are combined to obtain limits on $\tilde{e}$ pair production, while the ABCD analysis only is used for $\tilde{\mu}$, $\tilde{\tau}$ and $\tilde{\chi}_1^\pm$ pair production. No significant excess of events is observed over the background prediction. 95% CL limits are extracted in the lifetime vs mass plane, see their figures 6 and 8.

[4] CHEKHOVSKY 25M searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of SUSY models with compressed mass spectra in events with a high transverse momentum system from initial-state-radiation jets recoiling against a potential sparticle system with significant missing transverse momentum. These events are further categorized based on their lepton multiplicity, jet multiplicity, number of b-tagged jets, and kinematic variables sensitive to the sparticle masses and mass splittings. No significant excess above the Standard Model expectations is observed. The results are interpreted in models of top squark, electroweakino and slepton pair production. Limits are set for top squark pair production in the models Tstop1 and Tstop2, see their figure 25, and in Tstop4, see their figure 26. The results are also interpreted in models describing the production of mass-degenerate $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ with decays $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ and $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$, applying both a wino-like and higgsino-like $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ production cross section, see their figure 27. Limits are also set for wino-like $\tilde{\chi}_1^\pm$ pair production, either with $\tilde{\chi}_1^\pm \to W\tilde{\chi}_1^0$ or in the model Tchi1chi1C. This paper also addresses direct slepton production, taking into account pure right-handed, pure left-handed and combined production of either selectrons, smuons, or mass-degenerate sleptons of the first and second generation, see their figures 30 and 31.

[5] HAYRAPETYAN 24N searched in up to 137 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for evidence of wino-like chargino-neutralino pairs, Higgsino-like neutralino pair production in a gauge-mediated SUSY breaking inspired scenario, a Higgsino-bino interpretation, and slepton pair production in a combination of a number of previously reported searches for SUSY in different final states. No significant excess above the Standard Model expectations is observed. Limits are set on the $\widetilde{\chi}_1^{\pm}$ mass in the wino-bino models Tchi1n2E1, Tchi1n2E, and Tchi1n2l, see their Fig. 11, and on the $\widetilde{\chi}_1^0$ in the higgsino-like GMSB models Tn1n1A, Tn1n1B, and Tn1n1C, see their Fig. 13. In addition, Fig. 14 shows the mass exclusion limit as a function of the branching fraction to the H boson. Limits are also set in a Higgsino-bino interpretation as in THinoBinoA, but also including leptonic decays, see their Fig. 15. Limits are also set on slepton ($\widetilde{e}$, $\widetilde{\mu}$) production with the decay $\widetilde{\ell} \rightarrow \ell\widetilde{\chi}_1^0$, see their Fig. 16.

[6] AAD 23CR searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for RPV SUSY in final states with multiple leptons and b-tagged jets. No significant excess above the Standard Model expectations is observed. Limits are set on the production of electroweakinos (wino or higgsino) that decay via RPV coupling λ'_{i33} to a charged lepton or a neutrino, a b quark, and an additional t or b quark, see their figure 16. A second model addresses direct $\widetilde{\mu}_{L,R}$ production and decay to a muon and a bino-like neutralino, which decays in the same way as in the first model, see their figure 17.

[7] AAD 23M searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for $\widetilde{\ell}^{\pm}$ pair production, followed by $\widetilde{\ell}^{\pm} \rightarrow \ell^{\pm}\widetilde{\chi}_1^0$ in events with two leptons. The focus is on models where $m_{\widetilde{\ell}^{\pm}} - m_{\widetilde{\chi}_1^0}$ is close to the W mass. No significant excess above the Standard Model predictions is observed. Limits were set on the $\widetilde{\ell}$ mass (assuming $\widetilde{e} - \widetilde{\mu}$ and $L - R$ degeneracy), as a function of $m_{\widetilde{\chi}_1^0}$, see Figure 6. Limits were also derived for single $\widetilde{e}$ or $\widetilde{\mu}$, and for L and R independently, see Figure 7.

[8] SIRUNYAN 21M searched in 137 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with two opposite-sign same-flavor leptons (electrons, muons) and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu4C, see their Figure 10, on the $\widetilde{\chi}_2^0$ and $\widetilde{\chi}_1^{\pm}$ mass in Tchi1n2Fa, see their Figure 11, on the $\widetilde{\chi}_1^0$ mass in Tn1n1C and Tn1n1B for $m_{\widetilde{\chi}_2^0} = m_{\widetilde{\chi}_1^{\pm}} = m_{\widetilde{\chi}_1^0}$, see their Figure 12. Limits are also set on the light squark mass for the simplified model Tsqk2A, on the sbottom mass in Tsbot3, see their Figure 13, and on the slepton mass in direct electroweak pair production of mass-degenerate left- and right-handed sleptons (selectrons and smuons), see their Figure 14.

[9] AAD 20I reported on ATLAS searches for slepton pair production in models with compressed mass spectra. A dataset of pp collisions at $\sqrt{s}$ = 13 TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Events with $\not{E}_T$, two same-flavour, opposite-charge, low-transverse-momentum leptons, and jets from initial-state radiation or characteristic of vector-boson fusion production are selected. Light-flavour sleptons $\widetilde{e}$ and $\widetilde{\mu}$ are constrained at 95% C.L. to have masses above 251 GeV for a mass splitting slepton$-\widetilde{\chi}_1^0$ of 10 GeV, with constraints extending down to mass splittings of 550 MeV at the LEP slepton limits (73 GeV). See their Fig. 16(a). If only smuon are considered, and $\widetilde{\mu} = \widetilde{\mu}_R$, masses below 150 GeV are excluded for mass splitting $\widetilde{\mu}_R$, $\widetilde{\chi}_1^0$ of 8.2 GeV. See their Fig. 16(b).

[10] AAD 20I reported on ATLAS searches for slepton pair production in models with compressed mass spectra. A dataset of pp collisions at $\sqrt{s}$ = 13 TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Events with $\not{E}_T$, two same-flavour, opposite-charge, low-transverse-momentum leptons, and jets from initial-state radiation or characteristic of vector-boson fusion production are selected. Light-flavour sleptons $\widetilde{e}$ and $\widetilde{\mu}$ are constrained at 95% C.L. to have masses above 251 GeV for a mass splitting slepton$-\widetilde{\chi}_1^0$ of 10 GeV, with constraints extending down to mass splittings of 550 MeV at the LEP slepton limits (73 GeV). See their Fig. 16(a). If only smuon are considered, and $\widetilde{\mu} = \widetilde{\mu}_L$, masses below 216 GeV are excluded for mass splitting $\widetilde{\mu}_L$, $\widetilde{\chi}_1^0$ of 10 GeV. See their Fig. 16(b).

[11] AAD 20O reported on a search for electroweak production in models with charginos and sleptons decaying into final states with exactly two oppositely charged leptons and missing transverse momentum. A dataset of pp collisions at $\sqrt{s}$ = 13 TeV corresponding to an integrated luminosity of 139 fb^{-1} was used. Light-flavour sleptons $\widetilde{e}$ and $\widetilde{\mu}$ are constrained at 95% C.L. to have masses above 700 GeV for massless lightest neutralino, see their Fig. 7(c). Exclusion limits are also set for selectrons and smuons separately, considering either right- or left-handed components, by including only the di-electron and di-muon same-flavour signal regions defined in the search, see their Fig. 8.

[12] SIRUNYAN 19AW searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak pair production of selectrons or smuons in events with two leptons (electrons or muons) of the opposite electric charge and same flavour, no jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the selectron mass assuming left-handed, right-handed or both left- and right-handed (mass degenerate) production, see their Figure 6. Similarly, limits are set on the smuon mass, see their Figure 7. Limits are also set on slepton masses under the assumption that the selectron and smuon are mass degenerate, see their Figure 5.

[13] AABOUD 18R searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for electroweak production in scenarios with compressed mass spectra in final states with two low-momentum leptons and missing transverse momentum. The data are found to be consistent with the SM prediction. Results are interpreted in slepton pair production models with a fourfold degeneracy assumed in selectron and smuon masses. The $\widetilde{\mu}$ masses are excluded up to 190 GeV for $m_{\widetilde{\mu}} - m_{\widetilde{\chi}_1^0} = 5$ GeV. The exclusion limits extend down to mass splittings of 1 GeV, see their Fig. 11.

[14] CHATRCHYAN 14R searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the slepton mass in a stau (N)NLSP simplified model (GMSB) where the decay $\widetilde{\ell} \rightarrow \ell^{\pm}\tau^{\pm}\tau^{\mp}\widetilde{G}$ takes place with a branching ratio of 100%, see Fig. 8.

[15] AAD 13B searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for sleptons decaying to a final state with two leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Limits are derived in a simplified model of direct left-handed slepton pair production, where left-handed slepton masses between 85 and 195 GeV are excluded at 95% C.L. for $m_{\widetilde{\chi}_1^0}$ = 20 GeV. See also Fig. 2(a). Exclusion limits are also derived in the phenomenological MSSM, see Fig. 3.

[16] ABBIENDI 04 search for $\widetilde{\mu}_R\widetilde{\mu}_R$ production in acoplanar di-muon final states in the 183–208 GeV data. See Fig. 14 for the dependence of the limits on $m_{\widetilde{\chi}_1^0}$ and for the limit at tanβ=35. Under the assumption of 100% branching ratio for $\widetilde{\mu}_R \rightarrow \mu\widetilde{\chi}_1^0$, the limit improves to 94.0 GeV for $\Delta m > 4$ GeV. See Fig. 11 for the dependence of the limits on $m_{\widetilde{\chi}_1^0}$ at several values of the branching ratio. This limit supersedes ABBIENDI 00G.

[17] ACHARD 04 search for $\widetilde{\mu}_R\widetilde{\mu}_R$ production in acoplanar di-muon final states in the 192–209 GeV data. Limits on $m_{\widetilde{\mu}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, $1 \leq \tan\beta \leq 60$ and $-2 \leq \mu \leq 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\widetilde{\chi}_1^0}$. This limit supersedes ACCIARRI 99W.

[18] ABDALLAH 03M looked for acoplanar dimuon + $\not{E}$ final states at $\sqrt{s}$ = 189–208 GeV. The limit assumes B($\widetilde{\mu} \rightarrow \mu\widetilde{\chi}_1^0$) = 100%. See Fig. 16 for limits on the ($m_{\widetilde{\mu}_R}$, $m_{\widetilde{\chi}_1^0}$) plane. These limits include and update the results of ABREU 01.

[19] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 1$ TeV with the $\widetilde{\chi}_1^0$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of tanβ. These limits update the results of ABREU 00W.

[20] HEISTER 02E looked for acoplanar dimuon + $\not{E}_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes B($\widetilde{\mu} \rightarrow \mu\widetilde{\chi}_1^0$)=1. See their Fig. 4 for the dependence of the limit on Δm. These limits include and update the results of BARATE 01.

[21] AABOUD 18BT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of charginos, chargino and next-to-lightest neutralinos and sleptons in events with two or three leptons (electrons or muons), with or without jets, and large missing transverse energy. No significant excess above the Standard Model expectations is observed. Limits are set on the slepton mass up to 500 GeV for massless $\widetilde{\chi}_1^0$, assuming degeneracy of $\widetilde{e}$, $\widetilde{\mu}$, and $\widetilde{\tau}$ and exploiting the 2ℓ signature, see their Figure 8(b).

[22] AAD 14G searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for electroweak production of slepton pairs, decaying to a final sate with two leptons (e and μ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of slepton pair production, see Fig. 8. An interpretation in the pMSSM is also given, see Fig. 10.

[23] KHACHATRYAN 14I searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for electroweak production of slepton pairs decaying to a final state with opposite-sign lepton pairs (e or μ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models, see Fig. 18.

[24] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\widetilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. For limits at different $m_{\widetilde{G}}$, see their Fig. 12.

[1] AAD 22E searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry by measuring the yield asymmetry between events containing $e^-\mu^+$ and those containing $e^+\mu^-$. This was found in agreement with the standard model prediction of 1. Limits are set on the RPV production of $t\widetilde{\mu}_L$ events with $\widetilde{\mu}_L \rightarrow \mu\widetilde{\chi}_1^0$ for various values of λ'_{231}, see their figures 6 and 7.

[2] AAD 21Y searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with four or more leptons (electrons, muons and tau-leptons). No significant excess above the Standard Model expectations is observed. Limits are set on Tchi1n12-GGM, and RPV models similar to Tchi1n2l, Tglu1A (with q = u, d, s, c, b, with equal branching fractions), and $\widetilde{\ell}_L/\widetilde{\nu} \rightarrow \ell/\nu\widetilde{\chi}_1^0$ (mass-degenerate $\widetilde{\ell}_L$ and $\widetilde{\nu}$ of all 3 generations), all with $\widetilde{\chi}_1^0 \rightarrow \ell^{\pm}\ell^{\mp}\nu$ via λ_{12k} or λ_{i33} (where $i,k \in 1,2$), see their Figure 11.

[3] AABOUD 18Z searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events containing four or more charged leptons (electrons, muons and up to two hadronically decaying taus). No significant deviation from the expected SM background is observed. Limits are set on the Higgsino mass in simplified models of general gauge mediated supersymmetry Tn1n1A/Tn1n1B/Tn1n1C, see their Figure 9. Limits are also set on the wino, slepton,

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

sneutrino and gluino mass in a simplified model of NLSP pair production with R-parity violating decays of the LSP via λ_{12k} or λ_{i33} to charged leptons, see their Figures 7, 8.

[4] AAD 14X searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the slepton mass in an R-parity violating simplified model where the decay $\tilde{\ell} \rightarrow \ell\tilde{\chi}_1^0$, with $\tilde{\chi}_1^0 \rightarrow \ell^{\pm}\ell^{\mp}\nu$, takes place with a branching ratio of 100%, see Fig. 9.

[5] SIRUNYAN 19AO searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events containing two same-sign muons and at last two jets, originating from resonant production of second-generation sleptons ($\tilde{\mu}_L$, $\tilde{\nu}_\mu$) via the R-parity violating coupling λ'_{211} to quarks. No significant excess above the Standard Model expectations is observed. Upper limits on cross sections are derived in the context of two simplified models, see their Figure 4. The cross section limits are translated into limits on λ'_{211} for a modified CMSSM, see their Figure 5.

[6] ABDALLAH 04M use data from $\sqrt{s}$ = 192–208 GeV to derive limits on sparticle masses under the assumption of RPV with $LL\overline{E}$ or $\overline{UDD}$ couplings. The results are valid for μ = −200 GeV, tanβ = 1.5, Δm > 5 GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect $\overline{UDD}$ decays using the neutralino constraint of 39.5 GeV for $LL\overline{E}$ and of 38.0 GeV for $\overline{UDD}$ couplings, also derived in ABDALLAH 04M. For indirect decays via $LL\overline{E}$ the limit improves to 90 GeV if the constraint from the neutralino is used and remains at 87 GeV if it is not used. For indirect decays via $\overline{UDD}$ couplings it degrades to 85 GeV when the neutralino constraint is not used. Supersedes the result of ABREU 00U.

[7] HEISTER 03G searches for the production of smuons in the case of RPV prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$ = 189–209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for direct decays mediated by RPV $LQ\overline{D}$ couplings and improves to 90 GeV for indirect decays (for Δm > 10 GeV). Limits are also given for $LL\overline{E}$ direct ($m_{\tilde{\mu}R}$ > 87 GeV) and indirect decays ($m_{\tilde{\mu}R}$ > 96 GeV for $m(\tilde{\chi}_1^0)$ > 23 GeV from BARATE 98S) and for $\overline{UDD}$ indirect decays ($m_{\tilde{\mu}R}$ > 85 GeV for Δm > 10 GeV). Supersedes the results from BARATE 01B.

R-parity conserving $\tilde{\tau}$ (Stau) mass limit

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 25M searched for an excess of displaced leptons (e or μ) in pp collisions (140 fb^{-1} at $\sqrt{s}$ = 13 TeV and 56.3 at fb^{-1} at $\sqrt{s}$ = 13.6 TeV). The models considered were long-lived slepton (electron or muon) pair production followed by $\tilde{\ell} \rightarrow \ell\tilde{G}$, and long-lived chargino pair production in a dark sector model, followed by $\tilde{\chi}_1^{\pm} \rightarrow \tilde{\chi}_1^0 W$. Displaced leptons were reconstructed thanks to an improved large radius tracking and to the pointing capabilities of the electromagnetic calorimeter. Two different analyses (ABCD and EM-BDT) are combined to obtain limits on $\tilde{e}$ pair production, while the ABCD analysis only is used for $\tilde{\mu}$, $\tilde{\tau}$ and $\tilde{\chi}_1^{\pm}$ pair production. No significant excess of events is observed over the background prediction. 95% CL limits are extracted in the lifetime vs mass plane, see their figures 6 and 8.

[2] AAD 24AJ searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for evidence of direct stau pair production, or electroweakino pair production with decay via an intermediate stau, in events with two taus decaying hadronically (including a same-charge channel), no b-jets and moderate $\not{E}_T$, using a BDT for the direct stau search and a more traditional cut-and-count selection for the electroweakino search. No significant excess above the Standard Model expectations is observed. Limits are set in models of direct stau production $\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0$, $\tilde{\tau}_L$, $\tilde{\tau}_R$ or degenerate production. Limits are also set in models of pair production of charginos (Tchichi1D) or of charginos and neutralinos (Tchi1n2D) followed by the decay via intermediate staus, or (for the latter) via Wh (Tchi1n2E). See their figures 12, 14 and 16.

[3] TUMASYAN 23AG searched in 138 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for or direct pair production of tau sleptons in events with two hadronically decaying tau leptons. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of the tau slepton in models with $\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0$ for mass-degenerate, pure left-handed and pure right-handed tau sleptons, see their figures 4–7. Limits are also set for the maximally mixed scenario with long-lived tau sleptons and $\tilde{\tau}$ lifetimes of 0.01 mm to 2.5 mm, see their figure 8.

[4] AAD 20H presented ATLAS searches for direct production for $\tilde{\tau}$ in final states with two hadronically decaying leptons and $\not{E}_T$. The analysis uses a dataset of pp collisions at $\sqrt{s}$ = 13 TeV corresponding to an integrated luminosity of 139 fb^{-1}. Exclusion limits at 95% C.L. are derived in scenarios of direct production of $\tilde{\tau}$ pairs with each $\tilde{\tau}$ decaying into a τ and the lightest neutralino $\tilde{\chi}_1^0$ in simplified models where the $\tilde{\tau}_R$ and $\tilde{\tau}_L$ mass eigenstates are degenerate. Stau masses from 120GeV to 390GeV are excluded for a massless lightest neutralino, see their Fig. 7(a). If $\tilde{\tau}_L$-only pair production is considered, the exclusion region extends between 155 GeV to 310 GeV, see their Fig. 7(b).

[5] SIRUNYAN 20P searched in 77.2 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct pair production of tau sleptons in events with a tau lepton pair and significant missing transverse momentum. Final states with two double hadronic decay of the tau leptons are considered, as well as where one of the tau leptons decays into an electron or a muon. No significant excess above the Standard Model expectations is observed. Limits are set on the stau mass in a simplified models where two tau sleptons are pair produced and decay to a tau lepton and the lightest neutralino, assuming either only left-handed stau production, see Figure 8, or assuming degenerate left- and right-handed stau production, see Figure 9.

[6] ABBIENDI 04 search for $\tilde{\tau}\tilde{\tau}$ production in acoplanar di-tau final states in the 183–208 GeV data. See Fig. 15 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$ and for the limit at tanβ=35. Under the assumption of 100% branching ratio for $\tilde{\tau}_R \rightarrow \tau\tilde{\chi}_1^0$, the limit improves to 89.8 GeV for Δm > 8 GeV. See Fig. 12 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$ at several values of the branching ratio and for their dependence on θ_τ. This limit supersedes ABBIENDI 00G.

[7] ACHARD 04 search for $\tilde{\tau}\tilde{\tau}$ production in acoplanar di-tau final states in the 192–209 GeV data. Limits on $m_{\tilde{\tau}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, 1 $\leq$ tan$\beta \leq$ 60 and $-2 \leq \mu \leq$ 2 TeV. See Fig. 4 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$.

[8] ABDALLAH 03M looked for acoplanar ditaus + $\not{E}$ final states at $\sqrt{s}$ = 130–208 GeV. A dedicated search was made for low mass $\tilde{\tau}$s decoupling from the Z^0. The limit assumes B($\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0$) = 100%. See Fig. 20 for limits on the ($m_{\tilde{\tau}}$,$m_{\tilde{\chi}_1^0}$) plane and as function of the $\tilde{\chi}_1^0$ mass and of the branching ratio. The limit in the low-mass region improves to 29.6 and 31.1 GeV for $\tilde{\tau}_R$ and $\tilde{\tau}_L$, respectively, at $\Delta m > m_\tau$. The limit in the high-mass region improves to 84.7 GeV for $\tilde{\tau}_R$ and Δm > 15 GeV. These limits include and update the results of ABREU 01.

[9] HEISTER 02E looked for acoplanar ditau + $\not{E}_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes B($\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0$)=1. See their Fig. 4 for the dependence of the limit on Δm. These limits include and update the results of BARATE 01.

[10] AABOUD 18BT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for direct electroweak production of charginos, chargino and next-to-lightest neutralinos and sleptons in events with two or three leptons (electrons or muons), with or without jets, and large missing transverse energy. No significant excess above the Standard Model expectations is observed. Limits are set on the slepton mass up to 500 GeV for massless $\tilde{\chi}_1^0$, assuming degeneracy of $\tilde{e}$, $\tilde{\mu}$, and $\tilde{\tau}$ and exploiting the 2ℓ signature, see their Figure 8(b).

[11] KHACHATRYAN 17L searched in about 19 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with two τ (at least one decaying hadronically) and $\not{E}_T$. Results were interpreted to set constraints on the cross section for production of $\tilde{\tau}_L$ pairs for $m_{\tilde{\chi}_1^0}$=1 GeV. No mass constraints are set, see their Fig. 7.

[12] AAD 16AA summarized and extended ATLAS searches for electroweak supersymmetry in final states containing several charged leptons, $\not{E}_T$, with or without hadronic jets, in 20 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV. The paper reports 95% C.L. exclusion limits on the cross-section for production of $\tilde{\tau}_R$ and $\tilde{\tau}_L$ pairs for various $m_{\tilde{\chi}_1^0}$, using the 2 hadronic $\tau + \not{E}_T$ analysis. The $m_{\tilde{\tau}_{R/L}}$ = 109 GeV is excluded for $m_{\tilde{\chi}_1^0}$ = 0 GeV, with the constraints being stronger for $\tilde{\tau}_R$. See their Fig. 12.

[13] AAD 12AF searched in 2 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two tau leptons, jets and large $\not{E}_T$ in a GMSB framework. No significant excess above the expected background was found and an upper limit on the visible cross section for new phenomena is set. A 95% C.L. lower limit of 32 TeV on the mGMSB breaking scale Λ is set for M_{mess} = 250 TeV, N_S = 3, μ > 0 and C_{grav} = 1, independent of tanβ.

[14] AAD 12AG searched in 2.05 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with at least one hadronically decaying tau lepton, jets, and large $\not{E}_T$ in a GMSB framework. No significant excess above the expected background was found and an upper limit on

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

the visible cross section for new phenomena is set. A 95% C.L. lower limit of 30 TeV on the mGMSB breaking scale Λ is set for $M_{mess} = 250$ TeV, $N_5 = 3$, $\mu > 0$ and $C_{grav} = 1$, independent of tanβ. For large values of tanβ, the limit on Λ increases to 43 TeV.

[15] AAD 12CM searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$=7 TeV for events with at least one tau lepton, zero or one additional light lepton (e/μ) jets, and large $\not{E}_T$ in a GMSB framework. No significant excess above the expected background was found and an upper limit on the visible cross section for new phenomena is set. A 95% C. L. lower limit of 54 TeV on the mGMSB breaking scale Λ is set for $M_{mess} = 250$ TeV, $N_5 = 3$, $\mu > 0$ and $C_{grav} = 1$, for tan$\beta > 20$. Here the $\widetilde{\tau}_1$ is the NLSP.

[16] ABBIENDI 06B use 600 pb^{-1} of data from $\sqrt{s} = 189$–209 GeV. They look for events from pair-produced staus in a GMSB scenario with $\widetilde{\tau}$ NLSP including prompt $\widetilde{\tau}$ decays to ditaus + $\not{E}$ final states, large impact parameters, kinked tracks and heavy stable charged particles. Limits on the cross-section are computed as a function of m($\widetilde{\tau}$) and the lifetime, see their Fig. 7. The limit is compared to the $\sigma \cdot BR^2$ from a scan over the GMSB parameter space.

[17] ABDALLAH 04H use data from LEP 1 and $\sqrt{s} = 192$–208 GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region 1< $m_{3/2}$ <50 TeV, 0< m_0 <1000 GeV, 1.5<tanβ <35, both signs of μ. The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for $m_t = 174.3$ GeV (see Table 2 for other m_t values). The limit improves to 75 GeV for $\mu < 0$.

R-parity violating $\widetilde{\tau}$ (Stau) mass limit

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 21Y searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for supersymmetry in events with four or more leptons (electrons, muons and tau-leptons). No significant excess above the Standard Model expectations is observed. Limits are set on Tchi1n12-GGM, and RPV models similar to Tchi1n2l, Tglu1A (with $q = u, d, s, c, b$, with equal branching fractions), and $\widetilde{\ell}_L/\widetilde{\nu} \rightarrow \ell/\nu\widetilde{\chi}_1^0$ (mass-degenerate $\widetilde{\ell}_L$ and $\widetilde{\nu}$ of all 3 generations), all with $\widetilde{\chi}_1^0 \rightarrow \ell^{\pm}\ell^{\mp}\nu$ via λ_{12k} or λ_{i33} (where $i,k \in 1,2$), see their Figure 11.

[2] AABOUD 18Z searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing four or more charged leptons (electrons, muons and up to two hadronically decaying taus). No significant deviation from the expected SM background is observed. Limits are set on the Higgsino mass in simplified models of general gauge mediated supersymmetry Tn1n1A/Tn1n1B/Tn1n1C, see their Figure 9. Limits are also set on the wino, slepton, sneutrino and gluino mass in a simplified model of NLSP pair production with R-parity violating decays of the LSP via λ_{12k} or λ_{i33} to charged leptons, see their Figures 7, 8.

[3] ABDALLAH 04M use data from $\sqrt{s} = 192$–208 GeV to derive limits on sparticle masses under the assumption of RPV with $LL\overline{E}$ couplings. The results are valid for $\mu = -200$ GeV, tan$\beta = 1.5$, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect decays using the neutralino constraint of 39.5 GeV, also derived in ABDALLAH 04M. For indirect decays via $LL\overline{E}$ the limit decreases to 86 GeV if the constraint from the neutralino is not used. Supersedes the result of ABREU 00U.

[4] ABBIENDI 04F use data from $\sqrt{s} = 189$–209 GeV. They derive limits on sparticle masses under the assumption of RPV with $LL\overline{E}$ or $LQ\overline{D}$ couplings. The results are valid for tan$\beta = 1.5$, $\mu = -200$ GeV, with, in addition, $\Delta m > 5$ GeV for indirect decays via $LQ\overline{D}$. The limit quoted applies to direct decays with $LL\overline{E}$ couplings and improves to 75 GeV for $LQ\overline{D}$ couplings. The limit on the $\widetilde{\tau}_R$ mass for indirect decays is 92 GeV for $LL\overline{E}$ couplings at $m_{\widetilde{\chi}^0} = 10$ GeV and no exclusion is obtained for $LQ\overline{D}$ couplings. Supersedes the results of ABBIENDI 00.

Long-lived $\widetilde{\ell}$ (Slepton) mass limit

Limits on scalar leptons which leave detector before decaying. Limits from Z decays are independent of lepton flavor. Limits from continuum e^+e^- annihilation are also independent of flavor for smuons and staus. Selectron limits from e^+e^- collisions in the continuum depend on MSSM parameters because of the additional neutralino exchange contribution.

[1] AAD 25AE searched for massive, charged long-lived particles in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV. Two analyses are conducted: one looking for a single track, with high specific ionisation losses in the pixel detector and long time of flight to the hadron calorimeter, and one looking for two tracks, both with high specific ionisation in the pixel detector. No excess above the expected background is found. Limits are set in scenarios of long-lived R-hadrons (gluino) production, chargino production or stau pair production, see their figures 13 and 14.

[2] HAYRAPETYAN 25V searched in 101 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for heavy, long-lived, charged particles with large ionization energy loss within the silicon tracker of the CMS experiment. No significant excess above the Standard Model expectations is observed. Limits are set on the pair production of gluino R-hadrons, top squark R-hadrons, and detector-stable $\widetilde{\tau}_{R,L}$, see their figure 6. Limits are also set in a model predicting a pair of single- and double-charged τ' fermions from a Z' boson decay, see their figure 7.

[3] AAD 23BQ searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of long-lived $\widetilde{\mu}$ in events with muons with impact parameters in the millimeter range. No significant excess above the Standard Model predictions is observed. Limits are set on $m_{\widetilde{\mu}}$ as a function of the $\widetilde{\mu}$ lifetime, assuming the $\widetilde{\mu} \rightarrow \mu\widetilde{G}$ decay and mass-degenerate $\widetilde{\mu}_L$ and $\widetilde{\mu}_R$. See Figure 4.

[4] AAD 23G searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for stau pair production in events with high-pt tracks with large ionisation in the pixel detector. No significant excess above the Standard Model predictions is observed. Limits are set on the stau mass as a function of its lifetime, see Figure 19.

[5] TUMASYAN 23AG searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for or direct pair production of tau sleptons in events with two hadronically decaying tau leptons. No significant excess above the Standard Model expectations is observed. Limits are set for the maximally mixed scenario with long-lived tau sleptons and $\widetilde{\tau}$ lifetimes of 0.01 mm

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

to 2.5 mm, see their figure 8. Limits are also set on the mass of the tau slepton in models with $\tilde{\tau} \to \tau\tilde{\chi}_1^0$ for mass-degenerate, pure left-handed and pure right-handed tau sleptons, see their figures 4–7.

[6] TUMASYAN 22AF searched for evidence of new long-lived particles decaying to leptons in pp collisions at $\sqrt{s} = 13$ TeV, corresponding to 118 (113) fb^{-1} in the ee channel ($e\mu$ and $\mu\mu$) channels. The leptons are required to have transverse impact parameter values between 0.01 and 10 cm and are not required to form a common vertex. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of the top squark in RPV models with top squark pair production and $\tilde{t} \to b\bar{\ell}$ and $\tilde{t} \to d\bar{\ell}$, see their Figure 4, which contains a wider range of lifetime limits. Limits are also set on a gauge-mediated SUSY breaking model, where the next-to-lightest SUSY particle is a slepton and the lightest SUSY particle a gravitino $\tilde{G}$, see their Figure 5, which also contains a wider range of lifetime limits. Limits are also set in a model that produces BSM Higgs bosons (H) with a mass of 125 GeV through gluongluon fusion, where the H decays to two long-lived scalars S, each of which decays to two oppositely charged and same-flavor leptons.

[7] AAD 21AL searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of long-lived sleptons in events with highly displaced leptons. No significant excess above the Standard Model predictions is observed. Limits are set on $m_{\tilde{e}}$, $m_{\tilde{\mu}}$, $m_{\tilde{\tau}}$ as a function of the slepton lifetime, assuming the $\tilde{\ell} \to \ell\tilde{G}$ decay and mass-degenerate $\tilde{\ell}_L$ and $\tilde{\ell}_R$. See Figures 2.

[8] AABOUD 19AT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for metastable and stable R-hadrons. Multiple search strategies for a wide range of lifetimes, corresponding to path lengths of a few meters, are defined. No significant deviations from the expected Standard Model background are observed. Results are interpreted in terms of exclusion limits on long-lived stau in the context of GMSB models. Lower limits on the mass for direct production of staus are set at 430 GeV, see their Fig. 10 (left).

[9] KHACHATRYAN 16BW searched in 2.5 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with heavy stable charged particles, identified by their anomalously high energy deposits in the silicon tracker and/or long time-of-flight measurements by the muon system. No evidence for an excess over the expected background is observed. Limits are derived for pair production of tau sleptons as a function of mass, depending on their direct or inclusive production in a minimal GMSB scenario along the Snowmass Points and Slopes (SPS) line 7, see Fig. 4 and Table 7.

[10] AAD 15AE searched in 19.1 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for heavy long-lived charged particles, measured through their specific ionization energy loss in the ATLAS pixel detector or their time-of-flight in the ALTAS muon system. In the absence of an excess of events above the expected backgrounds, limits are set on stable $\tilde{\tau}$ sleptons in various scenarios, see Figs. 5-7.

[11] AAIJ 15BD searched in 3.0 fb^{-1} of pp collisions at $\sqrt{s} = 7$ and 8 TeV for evidence of Drell–Yan pair production of long-lived $\tilde{\tau}$ particles. No evidence for such particles is observed and 95% C.L. upper limits on the cross section of $\tilde{\tau}$ pair production are derived, see Fig. 7. In the mGMSB, assuming the SPS7 benchmark scenario $\tilde{\tau}$ masses between 124 and 309 GeV are excluded at 95% C.L.

[12] ABBIENDI 03L used e^+e^- data at $\sqrt{s} =$ 130–209 GeV to select events with two high momentum tracks with anomalous dE/dx. The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The limit improves to 98.5 GeV for $\tilde{\mu}_L$ and $\tilde{\tau}_L$. The bounds are valid for colorless spin 0 particles with lifetimes longer than 10^{-6} s. Supersedes the results from ACKERSTAFF 98P.

[13] ABREU 00Q searches for the production of pairs of heavy, charged stable particles in e^+e^- annihilation at $\sqrt{s}$= 130–189 GeV. The upper bound improves to 88 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$. These limits include and update the results of ABREU 98P.

[14] ACCIARRI 99H searched for production of pairs of back-to-back heavy charged particles at $\sqrt{s}$=130–183 GeV. The upper bound improves to 82.2 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$.

[15] The BARATE 98K mass limit improves to 82 GeV for $\tilde{\mu}_L$,$\tilde{\tau}_L$. Data collected at $\sqrt{s}$=161–184 GeV.

[16] AAD 13AA searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events containing long-lived massive particles in a GMSB framework. No significant excess above the expected background was found. A 95% C.L. lower limit of 300 GeV is placed on long-lived $\tilde{\tau}$'s in the GMSB model with $M_{mess} = 250$ TeV, $N_S = 3$, $\mu > 0$, for tanβ = 5–20. The lower limit on the GMSB breaking scale Λ was found to be 99–110 TeV, for tanβ values between 5 and 40, see Fig. 4 (top). Also, directly produced long-lived sleptons, or sleptons decaying to long-lived ones, are excluded at 95% C.L. up to a $\tilde{\tau}$ mass of 278 GeV for models with slepton splittings smaller than 50 GeV.

[17] ABAZOV 13B looked in 6.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for charged massive long-lived particles in events with muon-like particles that have both speed and ionization energy loss inconsistent with muons produced in beam collisions. In the absence of an excess, limits are set at 95% C.L. on the production cross section of stau leptons in the mass range 100–300 GeV, see their Table 20 and Fig. 23.

[18] CHATRCHYAN 13AB looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV and in 18.8 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{\tau}_1$'s. No evidence for an excess over the expected background is observed. Supersedes CHATRCHYAN 12L.

[19] CHATRCHYAN 13AB limits are derived for pair production of $\tilde{\tau}_1$ as a function of mass in minimal GMSB scenarios along the Snowmass Points and Slopes (SPS) line 7 (see Fig. 8 and Table 7). The limit given here is valid for direct pair $\tilde{\tau}_1$ production.

[20] CHATRCHYAN 13AB limits are derived for the production of $\tilde{\tau}_1$ as a function of mass in minimal GMSB scenarios along the Snowmass Points and Slopes (SPS) line 7 (see Fig. 8 and Table 7). The limit given here is valid for the production of $\tilde{\tau}_1$ from both direct pair production and from the decay of heavier supersymmetric particles.

[21] CHATRCHYAN 12L looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{\tau}_1$'s. No evidence for an excess over the expected background is observed. Limits are derived for the production of $\tilde{\tau}_1$ as a function of mass in minimal GMSB scenarios along the Snowmass Points and Slopes (SPS) line 7 (see Fig. 3). The limit given here is valid for the production of $\tilde{\tau}_1$ in the decay of heavier supersymmetric particles.

[22] AAD 11P looked in 37 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with two heavy stable particles, reconstructed in the Inner tracker and the Muon System and identified by their time of flight in the Muon System. No evidence for an excess over the SM expectation is observed. Limits on the mass are derived, see Fig. 3, for $\tilde{\tau}$ in a GMSB scenario and for sleptons produced by electroweak processes only, in which case the limit degrades to 110 GeV.

$\tilde{q}$ (Squark) mass limit

For $m_{\tilde{q}} > 60$–70 GeV, it is expected that squarks would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

Limits from e^+e^- collisions depend on the mixing angle of the lightest mass eigenstate $\tilde{q}_1 = \tilde{q}_R \sin\theta_q + \tilde{q}_L \cos\theta_q$. It is usually assumed that only the sbottom and stop squarks have non-trivial mixing angles (see the stop and sbottom sections). Here, unless otherwise noted, squarks are always taken to be either left/right degenerate, or purely of left or right type. Data from Z decays have set squark mass limits above 40 GeV, in the case of $\tilde{q} \to q\tilde{\chi}_1$ decays if $\Delta m = m_{\tilde{q}} - m_{\tilde{\chi}_1^0} \gtrsim 5$ GeV. For smaller values of Δm, current constraints on the invisible width of the Z ($\Delta\Gamma_{\rm inv} < 2.0$ MeV, LEP 00) exclude $m_{\tilde{u}_{L,R}} < 44$ GeV, $m_{\tilde{d}_R} < 33$ GeV, $m_{\tilde{d}_L} < 44$ GeV and, assuming all squarks degenerate, $m_{\tilde{q}} < 45$ GeV.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 25BM searched in 140 fb^{-1} (at $\sqrt{s}$ = 13 TeV) and 58.6 fb^{-1} (at $\sqrt{s}$ = 13.6 TeV) of pp collisions for an excess of events with taus and $\not{E}_T$. Several signal regions are defined requiring one τ and no other leptons, one τ and one e or μ, or two τ, and then using both a BDT or a cut-and-count analysis to target scenarios with different kinematic regimes. No significant excess over the Standard Model expectation is found. Exclusion limits at 95% C.L. are set on the gluino or squark mass, assuming that the squark (other intermediate or pair-produced) decays to intermediate wino-like $\widetilde{\chi}_1^{\pm}$ or $\widetilde{\chi}_2^0$, which, in turn, decays to the $\widetilde{\chi}_1^0$ LSP via staus or tau sneutrinos, as in model Tglu1F for gluinos (and similar for squarks). See their Figs. 13 and 14.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[2] AAD 24Z searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with exactly two same-sign leptons or at least three leptons. Several signal regions, including a $\not{E}_T$ selection targeting RPC models, and selections based on b-jet multiplicities, targeting RPV models, are considered. No significant excess over the Standard Model expectation is found. Exclusion limits at 95% C.L. are set on the gluino or squark mass, in multi-step RPC decays via charginos, neutralinos or sleptons into quarks, leptons and neutralinos, or RPV decays of either the neutralino LSP or the stop produced in $\tilde{g} \to t\bar{t}$ into quarks. See their Fig. 7.

[3] HAYRAPETYAN 24Q searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of stealth supersymmetry in final states with two photons and jets, and low $\not{E}_T$. No significant excess above the Standard Model expectations is observed. The investigated models include a singlet scalar boson S, and its SUSY fermion $\tilde{S}$. In the investigated models, either gluinos or squarks are pair produced and each decay to a $\tilde{\chi}_1^0$ and a gluon or squark, respectively, followed by the decays $\tilde{\chi}_1^0 \to \gamma\tilde{S}$, $\tilde{S} \to \tilde{G}S$ and $S \to gg$. Limits are set on the $\tilde{g}$ and the $\tilde{q}$ mass, see their Fig. 4.

[4] AAD 23AE searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 2 ℓ with same flavour and opposite sign, plus jets and $\not{E}_T$, defining signal region with the dilepton invariant mass both on- and off-shell with respect to the Z boson. No significant excess above the Standard Model predictions is observed. Limits are set on models of strong and electroweak production. In this case, limits are placed on the mass of pair-produced squarks, assuming a scenario like in Tsqk2, see figure 16.

[5] TUMASYAN 23X searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for squark pair production with cascade decays to CP-even singlet-like Higgs bosons (H_1), leading to final states with small missing transverse momentum. This search targets H_1 decays to $b\bar{b}$-pairs that are reconstructed in large-area (AK8) jets. No significant excess above the Standard Model expectations is observed. Limits are set in the next-to-minimal supersymmetric extension of the SM, where a singlino of small mass leads to squark and gluino cascade decays that can predominantly end in a highly Lorentz-boosted singlet-like H_1 and a singlino-like neutralino $\tilde{\chi}_S^0$ of small transverse momentum. The eight first- and second-generation squarks are assumed mass-degenerate, and the gluino mass is set at 1% larger.

[6] AAD 21AK searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of gluinos and squarks in events with a single isolated electron or muon, originating from the decay of a W boson, multiple jets and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1B simplified model and on the squark mass in the Tsqk3 simplified model, see their Figure 8.

[7] AAD 21F searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of squarks in events with a high-p_T jet and $\not{E}_T$. No significant excess above the Standard Model predictions is observed. Limits are set on the $\tilde{t}$ mass in the Tstop3 and Tstop4, on the $\tilde{b}$ mass in the Tsbot1, and on the $\tilde{q}$ mass in the Tsqk1 simplified model (four-flavour, two chirality states degeneracy).

[8] AAD 21L searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of gluinos and squarks in events with jets, large missing transverse momentum but no electrons or muons. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A and Tglu1B simplified models, on the squark mass in the Tsqk1 and Tsqk3 simplified models and in a simplified model for gluino-squark production, see their Figures 13-17.

[9] SIRUNYAN 21M searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for supersymmetry in events with two opposite-sign same-flavor leptons (electrons, muons) and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu4C, see their Figure 10, on the $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ mass in Tchi1n2Fa, see their Figure 11, on the $\tilde{\chi}_1^0$ mass in Tn1n1C and Tn1n1B for $m_{\tilde{\chi}_2^0} = m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_1^0}$, see their Figure 12. Limits are also set on the light squark mass for the simplified model Tsqk2A, on the sbottom mass in Tsbot3, see their Figure 13, and on the slepton mass in direct electroweak pair production of mass-degenerate left- and right-handed sleptons (selectrons and smuons), see their Figure 14.

[10] SIRUNYAN 19AG searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two photons and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu4B simplified model and on the squark mass in the Tsqk4B simplified model, see their Figure 3.

[11] SIRUNYAN 19CH searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing multiple jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu1C, Tglu2A and Tglu3A simplified models, see their Figure 13. Limits are also set on squark, sbottom and stop masses in the Tsqk1, Tsbot1, Tstop1 simplified models, see their Figure 14.

[12] SIRUNYAN 19K searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with a photon, an electron or muon, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. In the framework of GMSB, limits are set on the chargino and neutralino mass in the Tchi1n1A simplified model, see their Figure 6. Limits are also set on the gluino mass in the Tglu4A simplified model, and on the squark mass in the Tsqk4A simplified model, see their Figure 7.

[13] AABOUD 18BJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with two opposite-sign charged leptons (electrons and muons), jets and missing transverse momentum, with various requirements to be sensitive to signals with different kinematic endpoint values in the dilepton invariant mass distribution. The data are found to be consistent with the SM expectation. Results are interpreted in the Tsqk2 model in case of $m_{\tilde{\chi}_1^0} = 1$ GeV: for any $m_{\tilde{\chi}_2^0}$, squark masses below 1200 GeV are excluded, see their Fig. 14(b).

[14] AABOUD 18BV searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one jet identified as c-jet, large missing transverse energy and no leptons. Good agreement is observed between the number of events in data and Standard Model predictions. The results are translated into exclusion limits in Tsqk1 models considering only $\tilde{c}_1$. In scenarios with massless neutralinos, scharm masses below 850 GeV are excluded. If the differences of the $\tilde{c}_1$ and $\tilde{\chi}_1^0$ masses is below 100 GeV, scharm masses below 500 GeV are excluded. See their Fig.6 and Fig.7.

[15] AABOUD 18I searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one jet with a transverse momentum above 250 GeV and no leptons. Good agreement is observed between the number of events in data and Standard Model predictions. The results are translated into exclusion limits in Tsqk1 models. In the compressed scenario with similar squark and neutralino masses, squark masses below 710 GeV are excluded. See their Fig.10(b).

[16] AABOUD 18U searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with at least one isolated photon, possibly jets and significant transverse momentum targeting generalised models of gauge-mediated SUSY breaking. No significant excess of events is observed above the SM prediction. Results are interpreted in terms of lower limits on the masses of squark in Tsqk4B models. Masses below 1820 GeV are excluded for any NLSP mass, see their Fig. 9.

[17] AABOUD 18V searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with no charged leptons, jets and missing transverse momentum. The data are found to be consistent with the SM expectation. Results are interpreted in the Tsqk1 model: squark masses below 1550 GeV are excluded for massless LSP, see their Fig. 13(a).

[18] AABOUD 18V searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with no charged leptons, jets and missing transverse momentum. The data are found to be consistent with the SM expectation. Results are interpreted in the Tsqk3 model. Assuming that $m_{\tilde{\chi}_1^\pm} = 0.5\ (m_{\tilde{q}} + m_{\tilde{\chi}_1^0})$, squark masses below 1150 GeV are excluded for massless LSP, see their Fig. 14(a). Exclusions are also shown assuming $m_{\tilde{\chi}_1^0} = 60$ GeV, see their Fig. 14(b).

[19] SIRUNYAN 18AA searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one photon and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on wino masses in a general gauge-mediated SUSY breaking (GGM) scenario with bino-like $\tilde{\chi}_1^0$ and wino-like $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$, see Figure 7. Limits are also set on the NLSP mass in the Tchi1n1A and Tchi1chi1A simplified models, see their Figure 8. Finally, limits are set on the gluino mass in the Tglu4A and Tglu4B simplified models, see their Figure 9, and on the squark mass in the Tskq4A and Tsqk4B simplified models, see their Figure 10.

[20] SIRUNYAN 18AY searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing one or more jets and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A and Tglu3A simplified models, see their Figure 3. Limits are also set on squark, sbottom and stop masses in the Tsqk1, Tsbot1, Tstop1 and Tstop4 simplified models, see their Figure 3. Finally, limits are set on long-lived gluino masses in a Tglu1A simplified model where the gluino is metastable or long-lived with proper decay lengths in the range 10^{-3} mm $< c\tau < 10^5$ mm, see their Figure 4.

[21] AABOUD 17AR searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one isolated lepton, at least two jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 1.25 TeV are set on the 1st and 2nd generation squark masses in Tsqk3 simplified models, with $x = (m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0}) / (m_{\tilde{q}} - m_{\tilde{\chi}_1^0}) = 1/2$. Similar limits are obtained for variable x and fixed neutralino mass, $m_{\tilde{\chi}_1^0} = 60$ GeV. See their Figure 13.

[22] AABOUD 17N searched in 14.7 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 2 same-flavour, opposite-sign leptons (electrons or muons), jets and large missing transverse momentum. The results are interpreted as 95% C.L. limits in Tsqk2 models, assuming $m_{\tilde{\chi}_1^0} = 0$ GeV and $m_{\tilde{\chi}_2^0} = 600$ GeV. See their Fig. 12 for exclusion limits as a function of $m_{\tilde{\chi}_2^0}$.

[23] KHACHATRYAN 17P searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A, Tglu3A, Tglu3B, Tglu3C and Tglu3D simplified models, see their Figures 7 and 8. Limits are also set on the squark mass in the Tsqk1 simplified model, see their Fig. 7, and on the sbottom mass in the Tsbot1 simplified model, see Fig. 8. Finally, limits are set on the stop mass in the Tstop1, Tstop3, Tstop4, Tstop6 and Tstop7 simplified models, see Fig. 8.

[24] KHACHATRYAN 17V searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two photons and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino and squark mass in the context of general gauge mediation models Tglu4B and Tsqk4, see their Fig. 4.

[25] SIRUNYAN 17AY searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one photon, jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu4A and Tglu4B simplified models, and on the squark mass in the Tskq4A and Tsqk4B simplified models, see their Figure 6.

[26] SIRUNYAN 17AZ searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A, Tglu3A simplified models, see their Figures 6. Limits are also set on the squark mass in the Tsqk1 simplified model (for single light squark and for 8 degenerate light squarks), on the sbottom mass in the Tsbot1 simplified model and on the stop mass in the Tstop1 simplified model, see their Fig. 7. Finally, limits are set on the stop mass in the Tstop2, Tstop4 and Tstop8 simplified models, see Fig. 8.

[27] SIRUNYAN 17P searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with multiple jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu1C, Tglu2A, Tglu3A and Tglu3D simplified models, see their Fig. 12. Limits are also set on the squark mass in the Tsqk1 simplified model, on the stop mass in the Tstop1 simplified model, and on the sbottom mass in the Tsbot1 simplified model, see Fig. 13.

[28] AABOUD 16D searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with an energetic jet and large missing transverse momentum. The results are interpreted as 95% C.L. limits on masses of first and second generation squarks decaying into a quark and the lightest neutralino in scenarios with $m_{\tilde{q}} - m_{\tilde{\chi}_1^0} < 25$ GeV. See their Fig. 6.

[29] AABOUD 16N searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing hadronic jets, large $\not{E}_T$, and no electrons or muons. No significant excess above the Standard Model expectations is observed. First- and second-generation squark masses below 1030 GeV are excluded at the 95% C.L. decaying to quarks and a massless lightest neutralino. See their Fig. 7a.

[30] KHACHATRYAN 16BS searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one energetic jet , no isolated leptons, and significant $\not{E}_T$, using the transverse mass variable M_{T2} to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the squark mass in the Tskq1 simplified model, both in the assumption of a single light squark and of 8 degenerate squarks, see Fig. 11 and Table 3.

[31] AAD 15BV summarized and extended ATLAS searches for gluinos and first- and second-generation squarks in final states containing jets and missing transverse momentum, with or without leptons or b-jets in the $\sqrt{s} = 8$ TeV data set collected in 2012. The paper reports the results of new interpretations and statistical combinations of previously

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

published analyses, as well as new analyses. Exclusion limits at 95% C.L. are set on the squark mass in several R-parity conserving models. See their Figs. 9, 11, 18, 22, 24, 27, 28.

[32] AAD 15CS searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for evidence of pair production of squarks, decaying into a quark and a neutralino, where a photon was radiated either from an initial-state quark, from an intermediate squark, or from a final-state quark. No evidence was found for an excess above the expected level of Standard Model background and a 95% C.L. exclusion limit was set on the squark mass as a function of the squark-neutralino mass difference, see Fig. 19.

[33] AAD 15K searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing at least two jets, where the two leading jets are each identified as originating from c-quarks, and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the mass of superpartners of charm quarks ($\tilde{c}$). Assuming that the decay $\tilde{c} \rightarrow c\tilde{\chi}_1^0$ takes place 100% of the time, a scalar charm mass below 490 GeV is excluded for $m_{\tilde{\chi}_1^0} < 200$ GeV. For more details, see their Fig. 2.

[34] KHACHATRYAN 15AF searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least two energetic jets and significant $\not{E}_T$, using the transverse mass variable M_{T2} to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the squark mass in simplified models where the decay $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, both for the case of a single light squark or 8 degenerate squarks, see Fig. 12. See also Table 5. Exclusions in the CMSSM, assuming $\tan\beta = 30$, $A_0 = -2$ max(m_0, $m_{1/2}$) and $\mu > 0$, are also presented, see Fig. 15.

[35] AAD 14AE searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for strongly produced supersymmetric particles in events containing jets and large missing transverse momentum, and no electrons or muons. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing squarks that decay via $\tilde{q} \rightarrow q\tilde{\chi}_1^0$, where either a single light state or two degenerate generations of squarks are assumed, see Fig. 10.

[36] CHATRCHYAN 14AH searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with at least two energetic jets and significant $\not{E}_T$, using the razor variables (M_R and R^2) to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on squark masses in simplified models where the decay $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 28. Exclusions in the CMSSM, assuming $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, are also presented, see Fig. 26.

[37] CHATRCHYAN 14I searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing multijets and large $\not{E}_T$. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing squarks that decay via $\tilde{q} \rightarrow q\tilde{\chi}_1^0$, where either a single light state or two degenerate generations of squarks are assumed, see Fig. 7a.

[38] AAD 13L searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for the production of squarks and gluinos in events containing jets, missing transverse momentum and no high-p_T electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, squarks and gluinos of equal mass are excluded for masses below 1360 GeV at 95% C.L. In a simplified model containing only squarks of the first two generations, a gluino octet and a massless neutralino, squark masses below 1320 GeV are excluded at 95% C.L. for gluino masses below 2 TeV. See Figures 10–15 for more precise bounds.

[39] AAD 13Q searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events containing a high-p_T isolated photon, at least one jet identified as originating from a bottom quark, and high missing transverse momentum. Such signatures may originate from supersymmetric models with gauge-mediated supersymmetry breaking in events in which one of a pair of higgsino-like neutralinos decays into a photon and a gravitino while the other decays into a Higgs boson and a gravitino. No significant excess above the expected background was found and limits were set on the squark mass as a function of the neutralino mass in a generalized GMSB model (GGM) with a higgsino-like neutralino NLSP, see their Fig. 4. For neutralino masses greater than 220 GeV, squark masses below 1020 GeV are excluded at 95% C.L.

[40] CHATRCHYAN 13 looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with two opposite-sign leptons (e, μ, τ), jets and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the mSUGRA/CMSSM model with $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, see Fig. 6.

[41] CHATRCHYAN 13G searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for the production of squarks and gluinos in events containing 0,1,2, ≥ 3 b-jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with $\tan\beta = 10$, $A_0 = 0$, and $\mu > 0$, squarks and gluinos of equal mass are excluded for masses below 1250 GeV at 95% C.L. Exclusions are also derived in various simplified models, see Fig. 7.

[42] CHATRCHYAN 13H searched in 4.96 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with two photons, ≥ 4 jets and low $\not{E}_T$ due to $\tilde{q} \rightarrow \gamma\tilde{\chi}_1^0$ decays in a stealth SUSY framework, where the $\tilde{\chi}_1^0$ decays through a singlino ($\tilde{S}$) intermediate state to $\gamma S \tilde{G}$, with the singlet state S decaying to two jets. No significant excess above the expected background was found and limits were set in a particular R-parity conserving stealth SUSY model. The model assumes $m_{\tilde{\chi}_1^0} = 0.5\ m_{\tilde{q}}$, $m_{\tilde{S}} = 100$ GeV and $m_S = 90$ GeV. Under these assumptions, squark masses less than 1430 GeV were excluded at the 95% C.L.

[43] CHATRCHYAN 13T searched in 11.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least two energetic jets and significant $\not{E}_T$, using the α_T variable to discriminate between processes with genuine and misreconstructed $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on squark masses in simplified models where the decay $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, assuming an eightfold degeneracy of the masses of the first two generation squarks, see Fig. 8 and Table 9. Also limits in the case of a single light squark are given.

[44] AAD 12AX searched in 1.04 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for supersymmetry in events containing jets, missing transverse momentum and one isolated electron or muon. No excess over the expected SM background is observed and model-independent limits are set on the cross section of new physics contributions to the signal regions. In mSUGRA/CMSSM models with $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, squarks and gluinos of equal mass are excluded for masses below 820 GeV at 95% C.L. Limits are also set on simplified models for squark production and decay via an intermediate chargino and on supersymmetric models with bilinear R-parity violation. Supersedes AAD 11G.

[45] AAD 12CJ searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events containing one or more isolated leptons (electrons or muons), jets and $\not{E}_T$. The observations are in good agreement with the SM expectations and exclusion limits have been set in number of SUSY models. In the mSUGRA/CMSSM model with $\tan\beta = 10$, $A_0 = 0$, and $\mu > 0$, 95% C.L. exclusion limits have been derived for $m_{\tilde{q}} < 1200$ GeV, assuming equal squark and gluino masses. In minimal GMSB, values of the effective SUSY breaking scale $\Lambda <$ 50 TeV are excluded at 95% C.L. for $\tan\beta < 45$. Also exclusion limits in a number of simplified models have been presented, see Figs. 10 and 12.

[46] AAD 12CP searched in 4.8 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with two photons and large $\not{E}_T$ due to $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$ decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the squark mass as a function of the neutralino mass in a generalized GMSB model (GGM) with a bino-like neutralino NLSP. The other sparticle masses were decoupled, $\tan\beta = 2$ and $c\tau_{NLSP}$ < 0.1 mm. Also, in the framework of the SPS8 model, a 95% C.L. lower limit was set on the breaking scale Λ of 196 TeV.

[47] AAD 12W searched in 1.04 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for the production of squarks and gluinos in events containing jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, squarks and gluinos of equal mass are excluded for masses below 950 GeV at 95% C.L. In a simplified model containing only squarks of the first two generations, a gluino octet and a massless neutralino, squark masses below 875 GeV are excluded at 95% C.L.

[48] CHATRCHYAN 12 looked in 35 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with e and/or μ and/or jets, a large total transverse energy, and $\not{E}_T$. The event selection is based on the dimensionless razor variable R, related to the $\not{E}_T$ and M_R, an indicator of the heavy particle mass scale. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for $\tan\beta = 3$, 10 and 50 (see Fig. 7 and 8). Limits are also obtained for Simplified Model Spectra.

[49] CHATRCHYAN 12AE searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with at least three jets and large missing transverse momentum. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of squarks in a scenario where $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ with a 100% branching ratio, see Fig. 3. For $m_{\tilde{\chi}_1^0} < 200$ GeV, values of $m_{\tilde{q}}$ below 760 GeV are excluded at 95% C.L. Also limits in the CMSSM are presented, see Fig. 2.

[50] CHATRCHYAN 12AT searched in 4.73 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for the production of squarks and gluinos in events containing jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, squarks with masses below 1110 GeV are excluded at 95% C.L. Squarks and gluinos of equal mass are excluded for masses below 1180 GeV at 95% C.L. Exclusions are also derived in various simplified models, see Fig. 6.

[51] AABOUD 18V searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with no charged leptons, jets and missing transverse momentum. The data are found to be consistent with the SM expectation. Results are interpreted in the Tsqk5 model. Squark masses below 1100 GeV are excluded if $(m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0})/(m_{\tilde{q}} - m_{\tilde{\chi}_1^0}) < 0.95$ and $m_{\tilde{\chi}_1^0}$ = 60 GeV, see their Fig. 16(a).

[52] KHACHATRYAN 16BT performed a global Bayesian analysis of a wide range of CMS results obtained with data samples corresponding to 5.0 fb^{-1} of pp collisions at $\sqrt{s} =$ 7 TeV and in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV. The set of searches considered, both individually and in combination, includes those with all-hadronic final states, same-sign and opposite-sign dileptons, and multi-lepton final states. An interpretation was given in a scan of the 19-parameter pMSSM. No scan points with a gluino mass less than 500 GeV survived and 98% of models with a squark mass less than 300 GeV were excluded.

[53] AAD 15AI searched in 20 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing at least one isolated lepton (electron or muon), jets, and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the squark masses in the CMSSM/mSUGRA, see Fig. 15, in the NUHMG, see Fig. 16, and in various simplified models, see Figs. 19–21.

[54] KHACHATRYAN 15AR searched in 19.7 of fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing jets, either a charged lepton or a photon, and low missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the squark mass in a stealth SUSY model where the decays $\tilde{q} \rightarrow q\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^{\pm} \rightarrow \tilde{S}W^{\pm}$, $\tilde{S} \rightarrow S\tilde{G}$ and $S \rightarrow gg$, with $m_{\tilde{S}} = 100$ GeV and $m_S = 90$ GeV, take place with a branching ratio of 100%. See Fig. 6 for γ or Fig. 7 for $\ell^{\pm}$ analyses.

[55] KHACHATRYAN 15AZ searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with either at least one photon, hadronic jets and $\not{E}_T$ (single photon channel) or with at least two photons and at least one jet and using the razor variables. No significant excess above the Standard Model expectations is observed. Limits are set on gluino masses in the general gauge-mediated SUSY breaking model (GGM), for both a bino-like and wino-like neutralino NLSP scenario, see Fig. 8 and 9.

[56] AAD 14E searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for strongly produced supersymmetric particles in events containing jets and two same-sign leptons or three leptons. The search also utilises jets originating from b-quarks, missing transverse momentum and other variables. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing gluinos and squarks, see Figures 5 and 6. In the $\tilde{q} \rightarrow q'\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^{\pm} \rightarrow W^{(*)\pm}\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \rightarrow Z^{(*)}\tilde{\chi}_1^0$ simplified model, the following assumptions have been made: $m_{\tilde{\chi}_1^{\pm}} = 0.5\ m_{\tilde{\chi}_2^0} + m_{\tilde{g}}$, $m_{\tilde{\chi}_2^0} = 0.5\ (m_{\tilde{\chi}_1^0}$ + $m_{\tilde{\chi}_1^{\pm}}$). In the $\tilde{q} \rightarrow q'\tilde{\chi}_1^{\pm}$ or $\tilde{q} \rightarrow q'\tilde{\chi}_2^0$, $\tilde{\chi}_1^{\pm} \rightarrow \ell^{\pm}\nu\tilde{\chi}_1^0$ or $\tilde{\chi}_2^0 \rightarrow \ell^{\pm}\ell^{\mp}(\nu\nu)\tilde{\chi}_1^0$ simplified model, the following assumptions have been made: $m_{\tilde{\chi}_1^{\pm}} = m_{\tilde{\chi}_2^0} = 0.5\ (m_{\tilde{\chi}_1^0}$ + $m_{\tilde{q}}$), $m_{\tilde{\chi}_1^0} < 460$ GeV. Limits are also derived in the mSUGRA/CMSSM, bRPV and GMSB models, see their Fig. 8.

[57] CHATRCHYAN 13AO searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with two opposite-sign isolated leptons accompanied by hadronic jets and $\not{E}_T$. No significant excesses over the expected SM backgrounds are observed and 95% C.L. exclusion limits are derived in the mSUGRA/CMSSM model with $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, see Fig. 8.

[58] CHATRCHYAN 13AV searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for new heavy particle pairs decaying into jets (possibly b-tagged), leptons and $\not{E}_T$ using the Razor variables. No significant excesses over the expected SM backgrounds are observed

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

and 95% C.L. exclusion limits are derived in the mSUGRA/CMSSM model with $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, see Fig. 3. The results are also interpreted in various simplified models, see Fig. 4.

[59] CHATRCHYAN 13W searched in 4.93 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with one or more photons, hadronic jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on squark masses in the general gauge-mediated SUSY breaking model (GGM), for both a wino-like and bino-like neutralino NLSP scenario, see Fig. 5.

[60] DREINER 12A reassesses constraints from CMS (at 7 TeV, $\sim$ 4.4 fb^{-1}) under the assumption that the fist and second generation squarks and the lightest SUSY particle are quasi-degenerate in mass (compressed spectrum).

[61] DREINER 12A reassesses constraints from CMS (at 7 TeV, $\sim$ 4.4 fb^{-1}) under the assumption that the first and second generation squarks, the gluino, and the lightest SUSY particle are quasi-degenerate in mass (compressed spectrum).

R-parity violating $\tilde{q}$ (Squark) mass limit

[1] HAYRAPETYAN 24Y searched in 36.6 fb^{-1} of pp collisions at $\sqrt{s} = 13.6$ TeV for evidence of R-parity violating (RPV) SUSY in events with a pair of oppositely charged muons originating from a secondary vertex spatially separated from the pp interaction point by distances ranging from several hundred μm to several meters. No significant excess above the Standard Model expectations is observed. Limits are set in the model Tsqk3RPV on the lifetime of the $\widetilde{\chi}_1^0$ for several values of the $\tilde{q}$ mass, see their Fig. 16. Limits are also interpreted in the framework of a hidden Abelian Higgs model, in which the Higgs boson decays to a pair of long-lived dark photons, see their Figs. 14 and 15.

[2] SIRUNYAN 18EA searched in 38.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for the pair production of resonances, each decaying to at least four quarks. Reconstructed particles are clustered into two large jets of similar mass, each consistent with four-parton substructure. No statistically significant excess over the Standard Model expectation is observed. Limits are set on the squark and gluino mass in RPV supersymmetry models where squarks (gluinos) decay, through intermediate higgsinos, to four (five) quarks, see their Figure 4.

[3] KHACHATRYAN 16BX searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing 4 leptons coming from R-parity-violating decays of $\widetilde{\chi}_1^0 \to \ell\ell\nu$ with $\lambda_{121} \neq 0$ or $\lambda_{122} \neq 0$. No excess over the expected background is observed. Limits are derived on the gluino, squark and stop masses, see Fig. 23.

[4] AAD 15CB searched for events containing at least one long-lived particle that decays at a significant distance from its production point (displaced vertex, DV) into two leptons or into five or more charged particles in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV. The dilepton signature is characterised by DV formed from at least two lepton candidates. Four different final states were considered for the multitrack signature, in which the DV must be accompanied by a high-transverse momentum muon or electron candidate that originates from the DV, jets or missing transverse momentum. No events were observed in any of the signal regions. Results were interpreted in SUSY scenarios involving R-parity violation, split supersymmetry, and gauge mediation. See their Fig. 14–20.

[5] AAD 12AX searched in 1.04 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for supersymmetry in events containing jets, missing transverse momentum and one isolated electron or muon. No excess over the expected SM background is observed and model-independent limits are set on the cross section of new physics contributions to the signal regions. In mSUGRA/CMSSM models with $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, squarks and gluinos of equal mass are excluded for masses below 820 GeV at 95% C.L. Limits are also set on simplified models for squark production and decay via an intermediate chargino and on supersymmetric models with bilinear R-parity violation. Supersedes AAD 11G.

[6] CHATRCHYAN 12AL looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for anomalous production of events with three or more isolated leptons. Limits on squark and gluino masses are set in RPV SUSY models with leptonic $LL\overline{E}$couplings, $\lambda_{123} > 0.05$, and hadronic $\overline{UDD}$ couplings, $\lambda''_{112} > 0.05$, see their Fig. 5. In the $\overline{UDD}$ case the leptons arise from supersymmetric cascade decays. A very specific supersymmetric spectrum is assumed. All decays are prompt.

Long-lived $\tilde{q}$ (Squark) mass limit

The following are bounds on long-lived scalar quarks, assumed to hadronise into hadrons with lifetime long enough to escape the detector prior to a possible decay. Limits may depend on the mixing angle of mass eigenstates: $\tilde{q}_1 = \tilde{q}_L \cos\theta_q + \tilde{q}_R \sin\theta_q$. The coupling to the Z^0 boson vanishes for up-type squarks when $\theta_u = 0.98$, and for down type squarks when $\theta_d = 1.17$.

[1] HAYRAPETYAN 25V searched in 101 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for heavy, long-lived, charged particles with large ionization energy loss within the silicon tracker of the CMS experiment. No significant excess above the Standard Model expectations is observed. Limits are set on the pair production of gluino R-hadrons, top squark R-hadrons, and detector-stable $\tilde{\tau}_{R,L}$, see their figure 6. Limits are also set in a model predicting a pair of single- and double-charged τ' fermions from a Z' boson decay, see their figure 7.

[2] AABOUD 19AT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for metastable and stable R-hadrons. Multiple search strategies for a wide range of lifetimes, corresponding to path lengths of a few meters, are defined. No significant deviations from the expected Standard Model background are observed. Sbottom R-hadrons are excluded at 95% C.L. for masses below 1250 GeV. Less stringent constraints are achieved with the muon-spectrometer agnostic analysis. See their Figure 9 (bottom-left).

[3] AABOUD 19AT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for metastable and stable R-hadrons. Multiple search strategies for a wide range of lifetimes, corresponding to path lengths of a few meters, are defined. No significant deviations from the expected Standard Model background are observed. Stop R-hadrons are excluded at 95% C.L. for masses below 1340 GeV. Similar constraints are achieved with the muon-spectrometer agnostic analysis. See their Figure 9 (bottom-right).

[4] SIRUNYAN 19BH searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for long-lived particles decaying into jets, with each long-lived particle having a decay vertex well displaced from the production vertex. The selected events are found to be consistent with standard model predictions. Limits are set on the gluino mass in a GMSB model where the gluino is decaying via $\tilde{g} \to g\widetilde{G}$, see their Figure 4 and in an RPV model of supersymmetry where the gluino is decaying via $\tilde{g} \to t\overline{b}\overline{s}$, see their Figures 5. Limits are also set on the stop mass in two RPV models, see their Figure 6 (for $t \to b\ell$ decays) and Figure 7 (for $\tilde{t} \to \overline{d}\overline{d}$ decays).

[5] AABOUD 16B searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for long-lived R-hadrons using observables related to large ionization losses and slow propagation velocities, which are signatures of heavy charged particles traveling significantly slower than the speed of light. Exclusion limits at 95% C.L. are set on the long-lived sbottom masses exceeding 805 GeV. See their Fig. 5.

[6] AABOUD 16B searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for long-lived R-hadrons using observables related to large ionization losses and slow propagation velocities, which are signatures of heavy charged particles traveling significantly slower than the speed of light. Exclusion limits at 95% C.L. are set on the long-lived stop masses exceeding 890 GeV. See their Fig. 5.

[7] KHACHATRYAN 16BW searched in 2.5 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with heavy stable charged particles, identified by their anomalously high energy deposits in the silicon tracker and/or long time-of-flight measurements by the muon system. No evidence for an excess over the expected background is observed. Limits are derived for pair production of top squarks as a function of mass, depending on the interaction model, see Fig. 4 and Table 7.

[8] AAD 15AE searched in 19.1 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for heavy long-lived charged particles, measured through their specific ionization energy loss in the ATLAS pixel detector or their time-of-flight in the ALTAS muon system. In the absence of an excess of events above the expected backgrounds, limits are set R-hadrons in various scenarios, see Fig. 11. Limits are also set in LeptoSUSY models where the gluino decays to stable 300 GeV leptons, see Fig. 9.

[9] AAD 15BM searched in 18.4 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for stable and metastable non-relativistic charged particles through their anomalous specific ionization energy loss in the ATLAS pixel detector. In absence of an excess of events above the expected backgrounds, limits are set on stable bottom and top squark R-hadrons, see Table 5.

[10] KHACHATRYAN 15AK looked in a data set corresponding to fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV, and a search interval corresponding to 281 h of trigger lifetime, for long-lived particles that have stopped in the CMS detector. No evidence for an excess over the expected background in a cloud interaction model is observed. Assuming the decay $\tilde{t} \to t\widetilde{\chi}_1^0$ and lifetimes between 1 μ and 1000 s, limits are derived on $\tilde{t}$ production as a function of $m_{\widetilde{\chi}_1^0}$, see Figs. 4 and 7. The exclusions require that $m_{\widetilde{\chi}_1^0}$ is kinematically consistent with the minimum values of the jet energy thresholds used.

[11] AAD 13AA searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events containing colored long-lived particles that hadronize forming R-hadrons. No significant excess above the expected background was found. Long-lived R-hadrons containing a $\tilde{t}$ are excluded for masses up to 683 GeV at 95% C.L in a general interaction model. Also, limits independent of the fraction of R-hadrons that arrive charged in the muon system were derived, see Fig. 6.

[12] AAD 13AA searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing colored long-lived particles that hadronize forming R-hadrons. No significant excess above the expected background was found. Long-lived R-hadrons containing a $\tilde{b}$ are excluded for masses up to 612 GeV at 95% C.L in a general interaction model. Also, limits independent of the fraction of R-hadrons that arrive charged in the muon system were derived, see Fig. 6.

[13] AAD 13BC searched in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV and in 22.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for bottom squark R-hadrons that have come to rest within the ATLAS calorimeter and decay at some later time to hadronic jets and a neutralino. In absence of an excess of events above the expected backgrounds, limits are set on sbottom masses for the decay $\tilde{b} \rightarrow b\tilde{\chi}_1^0$, for different lifetimes, and for a neutralino mass of 100 GeV, see their Table 6 and Fig 10.

[14] AAD 13BC searched in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV and in 22.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for bottom squark R-hadrons that have come to rest within the ATLAS calorimeter and decay at some later time to hadronic jets and a neutralino. In absence of an excess of events above the expected backgrounds, limits are set on stop masses for the decay $\tilde{t} \rightarrow t\tilde{\chi}_1^0$, for different lifetimes, and for a neutralino mass of 100 GeV, see their Table 6 and Fig 10.

[15] CHATRCHYAN 13AB looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV and in 18.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{t}_1$'s. No evidence for an excess over the expected background is observed. Limits are derived for pair production of stops as a function of mass in the cloud interaction model (see Fig. 8 and Table 6). In the charge-suppressed model, the limit decreases to 818 GeV.

$\tilde{b}$ (Sbottom) mass limit

Limits in e^+e^- depend on the mixing angle of the mass eigenstate $\tilde{b}_1 = \tilde{b}_L \cos\theta_b + \tilde{b}_R \sin\theta_b$. Coupling to the Z vanishes for $\theta_b \sim 1.17$. As a consequence, no absolute constraint in the mass region $\lesssim$40 GeV is available in the literature at this time from e^+e^- collisions. In the Listings below, we use $\Delta m = m_{\tilde{b}_1} - m_{\tilde{\chi}_1^0}$.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] HAYRAPETYAN 24M searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of wino- and Higgsino-like charginos in final states with one or more disappearing tracks from the decay $\tilde{\chi}_1^\pm \to \pi^\pm\tilde{\chi}_1^0$ where the soft pion is not reconstructed, $\not{E}_T$, and varying numbers of jets, b-tagged jets, electrons, and muons. No significant excess above the Standard Model expectations is observed. Limits are set on the $\tilde{b}$ mass in the model Tbot1LL for various proper decay lengths $c\tau$ of the $\tilde{\chi}_1^\pm$ as well as on the $\tilde{t}$ mass in the model Tstop1LL, see their Fig. 10. Limits are also set in the model Tglu1LL, see their Fig. 11. In addition, limits are set in specific pure wino as well as pure higgsino dark matter models, in which the relationships among the electroweakino masses, the $\tilde{\chi}_1^\pm$ lifetime, and the $\tilde{\chi}_1^\pm$ decay width are constrained by radiative corrections that account for a large difference between the LSP mass and the SUSY-breaking scale, see their Fig. 12.

[2] AAD 21AM searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of bottom squarks in events with hadronically decaying $\tau^\pm$-leptons, b-tagged jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the bottom squark mass in the Tsbot4 simplified model, assuming $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0} = 130$ GeV, see their Figure 8.

[3] AAD 21S searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of sbottoms, LQ or dark matter in events with b-jets and $\not{E}_T$, also using dedicated secondary-vertex-finding techniques. No significant excess above the Standard Model predictions is observed. Limits are set on $m_{\tilde{b}_1}$ in the Tsbot1 simplified model, on the LQ masses depending on the BR in $b\nu$, on scalar and pseudoscalar dark matter mediator masses. See Figures 8, 9, 10.

[4] SIRUNYAN 21M searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for supersymmetry in events with two opposite-sign same-flavor leptons (electrons, muons) and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu4C, see their Figure 10, on the $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ mass in Tchi1n2Fa, see their Figure 11, on the $\tilde{\chi}_1^0$ mass in Tn1n1C and Tn1n1B for $m_{\tilde{\chi}_2^0}=m_{\tilde{\chi}_1^\pm}=m_{\tilde{\chi}_1^0}$, see their Figure 12. Limits are also set on the light squark mass for the simplified model Tsqk2A, on the sbottom mass in Tsbot3, see their Figure 13, and on the slepton mass in direct electroweak pair production of mass-degenerate left- and right-handed sleptons (selectrons and smuons), see their Figure 14.

[5] AAD 20V searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign charged leptons (electrons or muons) and jets. No significant excess above the Standard Model expectations is observed. Exclusion limits at 95% C.L. are set on the bottom squark masses in the Tsbot2 simplified model for $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_1^0} + 100$ GeV, see their Fig. 8(a).

[6] SIRUNYAN 20T searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least two jets, and two isolated same-sign or three or more charged leptons (electrons or muons). No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A, Tglu3B, Tglu3C and Tglu3D simplified models, see their Figure 7, and in the Tglu1C and Tglu1B simplified models, see their Figures 8 and 9. Limits are also set on the sbottom mass in the Tsbot2 simplified model, see their Figure 10, and on the stop mass in the Tstop7 simplified model, see their Figure 11. Finally, limits are set on the gluino mass in RPV simplified models where the gluino decays either via $\tilde{g} \to qq\bar{q}\bar{q} + e/\mu/\tau$ or via $\tilde{g} \to tbs$, see Figure 12.

[7] AAD 19H searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with no charged leptons, three or more b-jets, and large $\not{E}_T$. Higgs boson candidates are reconstructed as b-jet pairs. No significant excess above the Standard Model expectations is observed. Limits up to 1500 GeV are set on the sbottom mass in the Tsbot4 simplified model, see Figure 8(a), for fixed $m_{\tilde{\chi}_1^0} = 60$ GeV and for $m_{\tilde{\chi}_2^0}$ up to 1200 GeV.

[8] AAD 19H searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with no charged leptons, three or more b-jets, and large $\not{E}_T$. Higgs boson candidates are reconstructed as b-jet pairs. No significant excess above the Standard Model expectations is observed. Limits up to 1300 GeV are set on the sbottom mass in the Tsbot4 simplified model, see Figure 8(b), for $m_{\tilde{\chi}_2^0} = m_{\tilde{\chi}_1^0} + 130$ GeV and $m_{\tilde{\chi}_2^0}$ from 200 to 750 GeV.

[9] SIRUNYAN 19CH searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing multiple jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu1C, Tglu2A and Tglu3A simplified models, see their Figure 13. Limits are also set on squark, sbottom and stop masses in the Tsqk1, Tsbot1, Tstop1 simplified models, see their Figure 14.

[10] SIRUNYAN 19CI searched in 77.5 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more high-momentum Higgs bosons, decaying to pairs of photons, jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in the Tsbot4 simplified model, see Figure 3, and on the wino mass in the Tchi1n2E simplified model, see their Figure 4. Limits are also set on the higgsino mass in the Tn1n1A and Tn1n1B simplified models, see their Figure 5.

[11] AABOUD 18I searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one jet with a transverse momentum above 250 GeV and no leptons. Good agreement is observed between the number of events in data and Standard Model predictions. The results are translated into exclusion limits in Tsbot1 models. In the compressed scenario with sbottom and neutralino masses differing by m_b, sbottom masses below 430 GeV are excluded. For $m_{\tilde{\chi}_1^0} = 0$ they exclude sbottom masses up to 610 GeV. See their Fig.10(a).

[12] SIRUNYAN 18AL searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least three charged leptons, in any combination of electrons and muons, jets and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A and Tglu1C simplified models, see their Figure 5. Limits are also set on the sbottom mass in the Tsbot2 simplified model, see their Figure 6, and on the stop mass in the Tstop7 simplified model, see their Figure 7.

[13] SIRUNYAN 18AR searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing two opposite-charge, same-flavour leptons (electrons or muons), jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu4C simplified model, see their Figure 7. Limits are also set on the chargino/neutralino mass in the Tchi1n2F simplified model, see their Figure 8, and on the neutralino mass in the Tn1n1B and Tn1n1C simplified models, see their Figure 9. Finally, limits are set on the sbottom mass in the Tsbot3 simplified model, see their Figure 10.

[14] SIRUNYAN 18AY searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing one or more jets and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A and Tglu3A simplified models, see their Figure 3. Limits are also set on squark, sbottom and stop masses in the Tsqk1, Tsbot1, Tstop1 and Tstop4 simplified models, see their Figure 3. Finally, limits are set on long-lived gluino masses in a Tglu1A simplified model where the gluino is metastable or long-lived with proper decay lengths in the range 10^{-3} mm $< c\tau < 10^5$ mm, see their Figure 4.

[15] SIRUNYAN 18B searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for the pair production of third-generation squarks in events with jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in the Tsbot1 simplified model, see their Figure 5, and on the stop mass in the Tstop4 simplified model, see their Figure 6.

[16] SIRUNYAN 18X searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more high-momentum Higgs bosons, decaying to pairs of photons, jets and $\not{E}_T$. The razor variables (M_R and R^2) are used to categorise the events. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in the Tsbot4 simplified model and on the wino mass in the Tchi1n2E simplified model, see their Figure 5. Limits are also set on the higgsino mass in the Tn1n1A and Tn1n1B simplified models, see their Figure 6.

[17] AABOUD 17AJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign or three leptons, jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 700 GeV are set on the bottom squark mass in Tsbot2 simplified models assuming $m_{\tilde{\chi}_1^0} = 0$ GeV. See their Figure 4(d).

[18] AABOUD 17AX searched in 36 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing two jets identified as originating from b-quarks and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of bottom squarks. In the Tsbot1 simplified model, a $\tilde{b}_1$ mass below 950 GeV is excluded for $m_{\tilde{\chi}_1^0} = 0$ (<420) GeV. See their Fig. 7(a).

[19] AABOUD 17AX searched in 36 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing two jets identified as originating from b-quarks and large missing transverse momentum, with or without leptons. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of bottom squarks. Assuming 50% BR for Tsbot1 and Tsbot2 simplified models, a $\tilde{b}_1$ mass below 880 (860) GeV is excluded for $m_{\tilde{\chi}_1^0} = 0$ (<250) GeV. See their Fig. 7(b).

[20] KHACHATRYAN 17A searched in 18.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with two forward jets, produced through vector boson fusion, and missing transverse momentum. No significant excess above the Standard Model expectations is observed. A limit is set on sbottom masses in the Tsbot1 simplified model, see Fig. 3.

[21] KHACHATRYAN 17AW searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least three charged leptons, in any combination of electrons and muons, and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A and Tglu1C simplified models, and on the sbottom mass in the Tsbot2 simplified model, see their Figure 4.

[22] KHACHATRYAN 17P searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A, Tglu3A, Tglu3B, Tglu3C and Tglu3D simplified models, see their Figures 7 and 8. Limits are also set on the squark mass in the Tsqk1 simplified model, see their Fig. 7, and on the sbottom mass in the Tsbot1 simplified model, see Fig. 8. Finally, limits are set on the stop mass in the Tstop1, Tstop3, Tstop4, Tstop6 and Tstop7 simplified models, see Fig. 8.

[23] SIRUNYAN 17AZ searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A, Tglu3A simplified models, see their Figures 6. Limits are also set on the squark mass in the Tsqk1 simplified model (for single light squark and for 8 degenerate light squarks), on the sbottom mass in the Tsbot1 simplified model and on the stop mass in the Tstop1 simplified model, see their Fig. 7. Finally, limits are set on the stop mass in the Tstop2, Tstop4 and Tstop8 simplified models, see Fig. 8.

[24] SIRUNYAN 17K searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct production of stop or sbottom pairs in events with multiple jets and significant $\not{E}_T$. A second search also requires an isolated lepton and is combined with the all-hadronic search. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1, Tstop8 and Tstop4 simplified models, see their Figures 7, 8 and 9 (for the Tstop4 limits, only the results of the all-hadronic search are used). Limits are also set on the sbottom mass in the Tsbot1 simplified model, see Fig. 10 (also here, only the results of the all-hadronic search are used).

[25] SIRUNYAN 17S searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two isolated same-sign leptons, jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of the gluino mass

in the Tglu3A, Tglu3B, Tglu3C, Tglu3D and Tglu1B simplified models, see their Figures 5 and 6, and on the sbottom mass in the Tsbot2 simplified model, see their Figure 6.

[26] AABOUD 16D searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with an energetic jet and large missing transverse momentum. The results are interpreted as 95%C.L. limits on mass of sbottom decaying into a b-quark and the lightest neutralino in scenarios with $m_{\tilde{b}_1} - m_{\tilde{\chi}_1^0}$ between 5 and 20 GeV. See their Fig. 6.

[27] AABOUD 16Q searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events containing two jets identified as originating from b-quarks and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks. Assuming that the decay $\tilde{b}_1 \to b\tilde{\chi}_1^0$ (Tsbot1) takes place 100% of the time, a $\tilde{b}_1$ mass below 840 (800) GeV is excluded for $m_{\tilde{\chi}_1^0} < 100$ (360) GeV. Differences in mass above 100 GeV between the $\tilde{b}_1$ and the $\tilde{\chi}_1^0$ are excluded up to a $\tilde{b}_1$ mass of 500 GeV. For more details, see their Fig. 4.

[28] AAD 16BB searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with exactly two same-sign leptons or at least three leptons, multiple hadronic jets, b-jets, and $\not{E}_T$. No significant excess over the Standard Model expectation is found. Exclusion limits at 95% C.L. are set on the sbottom mass for the Tsbot2 model, assuming $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_1^0}$ + 100 GeV. See their Fig. 4c.

[29] KHACHATRYAN 16BJ searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in the Tsbot2 simplified model, see Fig. 6.

[30] KHACHATRYAN 16BS searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with at least one energetic jet , no isolated leptons, and significant $\not{E}_T$, using the transverse mass variable M_{T2} to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in the Tsbot1 simplified model, see Fig. 11 and Table 3.

[31] KHACHATRYAN 16BY searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with two opposite-sign, same-flavour leptons, jets, and missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu4C simplified model, see Fig. 4, and on sbottom masses in the Tsbot3 simplified model, see Fig. 5.

[32] AAD 15CJ searched in 20 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for evidence of third generation squarks by combining a large number of searches covering various final states. Limits on the sbottom mass are shown, either assuming the $\tilde{b} \to b\tilde{\chi}_1^0$ decay, see Fig. 11, or assuming the $\tilde{b} \to t\tilde{\chi}_1^\pm$ decay, with $\tilde{\chi}_1^\pm \to W^{(*)}\tilde{\chi}_1^0$, see Fig. 12a, or assuming the $\tilde{b} \to b\tilde{\chi}_2^0$ decay, with $\tilde{\chi}_2^0 \to h\tilde{\chi}_1^0$, see Fig. 12b. Interpretations in the pMSSM are also discussed, see Figures 13–15.

[33] KHACHATRYAN 15AF searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with at least two energetic jets and significant $\not{E}_T$, using the transverse mass variable M_{T2} to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in simplified models where the decay $\tilde{b} \to b\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 12. See also Table 5. Exclusions in the CMSSM, assuming tanβ = 30, $A_0 = -2$ max(m_0, $m_{1/2}$) and $\mu > 0$, are also presented, see Fig. 15.

[34] KHACHATRYAN 15AH searched in 19.4 or 19.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing either a fully reconstructed top quark, or events containing dijets requiring one or both jets to originate from b-quarks, or events containing a mono-jet. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in simplified models where the decay $\tilde{b} \to b\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 12. Limits are also set in a simplified model where the decay $\tilde{b} \to c\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 12.

[35] KHACHATRYAN 15I searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events in which b-jets and four W-bosons are produced. Five individual search channels are combined (fully hadronic, single lepton, same-sign dilepton, opposite-sign dilepton, multilepton). No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in a simplified model where the decay $\tilde{b} \to t\tilde{\chi}_1^\pm$, with $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$, takes place with a branching ratio of 100%, see Fig. 7.

[36] AAD 14T searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for monojet-like events. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks in simplified models which assume that the decay $\tilde{b}_1 \to b\tilde{\chi}_1^0$ takes place 100% of the time, see Fig. 12.

[37] CHATRCHYAN 14AH searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with at least two energetic jets and significant $\not{E}_T$, using the razor variables (M_R and R^2) to discriminate between signal and background processes. A second analysis requires at least one of the jets to be originating from a b-quark. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay $\tilde{b} \to b\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Figs. 28 and 29. Exclusions in the CMSSM, assuming tanβ = 10, A_0 = 0 and μ >0, are also presented, see Fig. 26.

[38] CHATRCHYAN 14R searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in a simplified model where the decay $\tilde{b} \to t\tilde{\chi}_1^\pm$, with $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$, takes place with a branching ratio of 100%, see Fig. 11.

[39] KHACHATRYAN 15AD searched in 19.4 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with two opposite-sign same flavor isolated leptons featuring either a kinematic edge, or a peak at the Z-boson mass, in the invariant mass spectrum. No evidence for a statistically significant excess over the expected SM backgrounds is observed and 95% C.L. exclusion limits are derived in a simplified model of sbottom pair production where the sbottom decays into a b-quark, two opposite-sign dileptons and a neutralino LSP, through an intermediate state containing either an off-shell Z-boson or a slepton, see Fig. 8.

[40] AAD 14AX searched in 20.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for the strong production of supersymmetric particles in events containing either zero or at last one high high-p_T lepton, large missing transverse momentum, high jet multiplicity and at least three jets identified as originating from b-quarks. No excess over the expected SM background is observed. Limits are derived in mSUGRA/CMSSM models with tanβ = 30, A_0 = $-2\ m_0$ and $\mu > 0$, see their Fig. 14. Also, exclusion limits are set in simplified models containing scalar bottom quarks, where the decay $\tilde{b} \to b\tilde{\chi}_2^0$ and $\tilde{\chi}_2^0 \to h\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see their Figures 11.

[41] AAD 14E searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for strongly produced supersymmetric particles in events containing jets and two same-sign leptons or three leptons. The search also utilises jets originating from b-quarks, missing transverse momentum and other variables. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing bottom, see Fig. 7. Limits are also derived in the mSUGRA/CMSSM, bRPV and GMSB models, see their Fig. 8.

[42] CHATRCHYAN 14H searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in a simplified models where the decay $\tilde{b} \to t\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, with varying mass of the $\tilde{\chi}_1^\pm$, for $m_{\tilde{\chi}_1^0}$ = 50 GeV, see Fig. 6.

[43] AAD 13AU searched in 20.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing two jets identified as originating from b-quarks and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks. Assuming that the decay $\tilde{b}_1 \to b\tilde{\chi}_1^0$ takes place 100% of the time, a $\tilde{b}_1$ mass below 620 GeV is excluded for $m_{\tilde{\chi}_1^0} < 120$ GeV. For more details, see their Fig. 5.

[44] CHATRCHYAN 13AT provides interpretations of various searches for supersymmetry by the CMS experiment based on 4.73–4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV in the framework of simplified models. Limits are set on the sbottom mass in a simplified models where sbottom quarks are pair-produced and the decay $\tilde{b} \to b\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 4.

[45] CHATRCHYAN 13T searched in 11.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with at least two energetic jets and significant $\not{E}_T$, using the α_T variable to discriminate between processes with genuine and misreconstructed $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay $\tilde{b} \to b\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 8 and Table 9.

[46] CHATRCHYAN 13V searched in 10.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with two isolated same-sign dileptons and at least two b-jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the bottom mass in a simplified models where the decay $\tilde{b} \to t\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, with varying mass of the $\tilde{\chi}_1^\pm$, for $m_{\tilde{\chi}_1^0}$ = 50 GeV, see Fig. 4.

[47] AAD 12AN searched in 2.05 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for scalar bottom quarks in events with large missing transverse momentum and two b-jets in the final state. The data are found to be consistent with the Standard Model expectations. Limits are set in an R-parity conserving minimal supersymmetric scenario, assuming B($\tilde{b}_1 \to b\tilde{\chi}_1^0$) = 100%, see their Fig. 2.

[48] CHATRCHYAN 12AI looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two same-sign leptons (e, μ), but not necessarily same flavor, at least 2 b-jets and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in a simplified model for sbottom pair production, where the sbottom decays through $\tilde{b}_1 \to t\tilde{\chi}_1 W$, see Fig. 8.

[49] CHATRCHYAN 12BO searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for scalar bottom quarks in events with large missing transverse momentum and two b-jets in the final state. The data are found to be consistent with the Standard Model expectations. Limits are set in an R-parity conserving minimal supersymmetric scenario, assuming B($\tilde{b}_1 \to b\tilde{\chi}_1^0$) = 100%, see their Fig. 2.

[50] AAD 11K looked in 34 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the tile calorimeter, from pair production of $\tilde{b}$. No evidence for an excess over the SM expectation is observed and limits on the mass are derived for pair production of sbottom, see Fig. 4.

[51] AAD 11O looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with jets, of which at least one is a b-jet, and $\not{E}_T$. No excess above the Standard Model was found. Limits are derived in the ($m_{\tilde{g}}$, $m_{\tilde{b}_1}$) plane (see Fig. 2) under the assumption of 100% branching ratios and $\tilde{b}_1$ being the lightest squark. The quoted limit is valid for $m_{\tilde{b}_1} <$ 500 GeV. A similar approach for $\tilde{t}_1$ as the lightest squark with $\tilde{g} \to \tilde{t}_1 t$ and $\tilde{t}_1 \to b\tilde{\chi}_1^\pm$ with 100% branching ratios leads to a gluino mass limit of 520 GeV for 130 < $m_{\tilde{t}_1}$ < 300 GeV. Limits are also derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 40, see Fig. 4, and in scenarios based on the gauge group SO(10).

[52] CHATRCHYAN 11D looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 2 jets, at least one of which is b-tagged, and $\not{E}_T$, where the b-jets are decay products of $\tilde{t}$ or $\tilde{b}$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 50 (see Fig. 2).

[53] AALTONEN 10R searched in 2.65 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with $\not{E}_T$ and exactly two jets, at least one of which is b-tagged. The results are in agreement with the SM prediction, and a limit on the cross section of 0.1 pb is obtained for the range of masses 80 < $m_{\tilde{b}_1}$ < 280 GeV assuming that the sbottom decays exclusively to $b\tilde{\chi}_1^0$. The excluded mass region in the framework of conserved R_p is shown in a plane of ($m_{\tilde{b}_1}$, $m_{\tilde{\chi}_1^0}$), see their Fig.2.

[54] ABAZOV 10L looked in 5.2 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with at least 2 b-jets and $\not{E}_T$ from the production of $\tilde{b}_1\tilde{b}_1$. No evidence for an excess over the SM expectation is observed, and a limit on the cross section is derived under the assumption of 100% branching ratio. The excluded mass region in the framework of conserved R_p is shown in a plane of ($m_{\tilde{b}_1}$,$m_{\tilde{\chi}_1^0}$), see their Fig. 3b. The exclusion also extends to $m_{\tilde{\chi}_1^0}$ = 110 GeV for 160< $m_{\tilde{b}_1}$ < 200 GeV.

R-parity violating $\tilde{b}$ (Sbottom) mass limit

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>307	95	[1] KHACHATRY...16BX		CMS	RPV, $\tilde{b} \to t d$ or $t s$, λ''_{332} or λ''_{331} coupling
• • • We do not use the following data for averages, fits, limits, etc. • • •					
		[2] AAD	14E	ATLS	$\ell^{\pm}\ell^{\pm}(\ell^{\mp})$ + jets, $\tilde{b}_1 \to t\tilde{\chi}_1^{\pm}$ with $\tilde{\chi}_1^{\pm} \to W^{(*)\pm}\tilde{\chi}_1^0$ simplified model, $m_{\tilde{\chi}_1^{\pm}} = 2\, m_{\tilde{\chi}_1^0}$

[1] KHACHATRYAN 16BX searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing 2 leptons coming from R-parity-violating decays of supersymmetric particles. No excess over the expected background is observed. Limits are derived on the sbottom mass, assuming the RPV $\tilde{b} \to t d$ or $\tilde{b} \to t s$ decay, see Fig. 15.

[2] AAD 14E searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for strongly produced supersymmetric particles in events containing jets and two same-sign leptons or three leptons. The search also utilises jets originating from b-quarks, missing transverse momentum and other variables. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing bottom, see Fig. 7. Limits are also derived in the mSUGRA/CMSSM, bRPV and GMSB models, see their Fig. 8.

$\tilde{t}$ (Stop) mass limit

Limits depend on the decay mode. In e^+e^- collisions they also depend on the mixing angle of the mass eigenstate $\tilde{t}_1 = \tilde{t}_L \cos\theta_t + \tilde{t}_R \sin\theta_t$. The coupling to the Z vanishes when $\theta_t = 0.98$. In the Listings below, we use $\Delta m \equiv m_{\tilde{t}_1} - m_{\tilde{\chi}_1^0}$ or $\Delta m \equiv m_{\tilde{t}_1} - m_{\tilde{\nu}}$, depending on relevant decay mode. See also bounds in "$\tilde{q}$ (Squark) MASS LIMIT."

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 25V searched in 139fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of pair-produced charm or top squarks, each decaying into a charm quark and the $\tilde{\chi}_1^0$. No significant excess above the Standard Model expectations is observed. Limits are set in two RPC SUSY models resulting in a final state with two charm quarks and missing transverse momentum, either in the decay of pair produced top squarks (Tstop4) or of pair-produced charm squarks, see their figure 8. Limits are also shown for a varying branching fraction of the top squark decay either into a top or charm quark and a $\tilde{\chi}_1^0$ as two-dimensional projections in the plane of the squark mass and assumed branching fraction, shown in figure 9. Limits are also set for up-type scalar leptoquarks coupled to first- or second-generation leptons, see their figure 10.

[2] CHEKHOVSKY 25M searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of SUSY models with compressed mass spectra in events with a high transverse momentum system from initial-state-radiation jets recoiling against a potential sparticle system with significant missing transverse momentum. These events are further categorized based on their lepton multiplicity, jet multiplicity, number of b-tagged jets, and kinematic variables sensitive to the sparticle masses and mass splittings. No significant excess above the Standard Model expectations is observed. The results are interpreted in models of top squark, electroweakino and slepton pair production. Limits are set for top squark pair production in the models Tstop1 and Tstop2, see their Figure 25, and in Tstop4, see their Figure 26. The results are also interpreted in models describing the production of mass-degenerate $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^{\pm}$ with decays $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ and $\tilde{\chi}_1^{\pm} \to W\tilde{\chi}_1^0$, applying both a wino-like and higgsino-like $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0$ production cross section, see their Figure 27. Limits are also set for wino-like $\tilde{\chi}_1^{\pm}$ pair production, either with $\tilde{\chi}_1^{\pm} \to W\tilde{\chi}_1^0$ or in the model Tchi1chi1C. This paper also addresses direct slepton production, taking into account pure right-handed, pure left-handed and combined production of either selectrons, smuons, or mass-degenerate sleptons of the first and second generation, see their Figures 30 and 31.

[3] AAD 24AC searched in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of stop pair production in events with one lepton, multiple jets, and large $\not{E}_T$, using a neural network for the top system reconstruction. The stop analysis is optimised for scenarios with $m_{\tilde{t}_1} - m_{\tilde{\chi}_1^0} \sim m_t$. No significant excess above the Standard Model expectations is observed. Limits are set in models for stop pair production, Tstop1 (with the t possibly off-shell), see their figures 10 and 11.

[4] AAD 24AO searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of stop pair production in events with no leptons, jets, b- and c-jets, and large $\not{E}_T$. The search analysis is optimized for events where a top quark and a c quarks are produced in the decay of the stops. No significant excess above the Standard Model expectations is observed. Limits are set on models for stop pair production with equal branching ratio for $\tilde{t} \to t\tilde{\chi}_1^0$ and $\tilde{t} \to c\tilde{\chi}_1^0$, Tstop9 (but also investigating large mass gaps between $\tilde{t}$ and $\tilde{\chi}_1^0$). See their figures 9 and 10.

[5] HAYRAPETYAN 24M searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of wino- and Higgsino-like charginos in final states with one or more disappearing tracks from the decay $\tilde{\chi}_1^{\pm} \to \pi^{\pm}\tilde{\chi}_1^0$ where the soft pion is not reconstructed, $\not{E}_T$, and varying numbers of jets, b-tagged jets, electrons, and muons. No significant excess above the Standard Model expectations is observed. Limits are set on the $\tilde{b}$ mass in the model Tbot1LL for various proper decay lengths $c\tau$ of the $\tilde{\chi}_1^{\pm}$ as well as on the $\tilde{t}$ mass in the model Tstop1LL, see their Fig. 10. Limits are also set in the model Tglu1LL, see their Fig. 11. In addition, limits are set in specific pure wino as well as pure higgsino dark matter models, in which the relationships among the electroweakino masses, the $\tilde{\chi}_1^{\pm}$ lifetime, and the $\tilde{\chi}_1^{\pm}$ decay width are constrained by radiative corrections that account for a large difference between the LSP mass and the SUSY-breaking scale, see their Fig. 12.

[6] HAYRAPETYAN 23E searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of gluino, top squark and electroweakino pair production in events with at least one photon, multiple jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set in models for strong production, Tglu4D, Tglu4E, Tglu4F and Tstop13, see their figure 9. They also interpret the results in the models for electroweak production, shown in their figure 10. Tchi1n1A assumes wino-like $\tilde{\chi}_1^{\pm}\tilde{\chi}_1^0$ production, while Tchi1chi1A assumes higgsino-like cross sections and includes $\tilde{\chi}_1^{\pm}\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^0\tilde{\chi}_2^0$ and $\tilde{\chi}_{1,2}^0\tilde{\chi}_1^{\pm}$ production. For $\tilde{\chi}_1^0\tilde{\chi}_2^0$ alone no mass point can be excluded in the model Tchi1chi1A, but in another model for $\tilde{\chi}_1^0\tilde{\chi}_2^0$ production, Tn1n2A.

[7] TUMASYAN 23AB searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of top squark pair production in a final state with at least one hadronically decaying tau lepton and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\tilde{t}$ for the model Tstop16, see their Figure 9. The exclusion limits are not very sensitive to the choice of the $\tilde{\tau}$ mass parameter, chosen between $0.25 < (m_{\tilde{\tau}_1^{\pm}} - m_{\tilde{\chi}_1^0})/(m_{\tilde{\chi}_1^{\pm}} - m_{\tilde{\chi}_1^0}) < 0.75$ because of the complementary nature of the signal diagrams.

[8] TUMASYAN 23K searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of top squark pair production in events with a high-momentum jet, an electron or muon with low transverse momentum, and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the top squark mass in the simplified model Tstop3 for 10 GeV $< m_{\tilde{t}} - m_{\tilde{\chi}_1^0} < 80$ GeV, see their Figure 10.

[9] TUMASYAN 22Q searched in up to 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of electroweakino and top squark pair production with a small mass difference between the produced supersymmetric particles and the lightest neutralino in events with two or three low-momentum leptons and missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^{\pm}$ in the model Tchi1n2F, see their Figure 8. Limits are also set in a higgsino simplified model with both $\tilde{\chi}_2^0\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_2^0\tilde{\chi}_1^0$ production, where $\tilde{\chi}_2^0 \to Z\tilde{\chi}_1^0$ and $m_{\tilde{\chi}_1^{\pm}} = 1/2(m_{\tilde{\chi}_2^0} + m_{\tilde{\chi}_1^0})$. A model inspired by the pMSSM is used for further interpretations in the case of a higgsino LSP, see their Figure 9. Limits are also set on the mass of the top squark in the models Tstop2 and Tstop3, see their Figure 10.

[10] AAD 21AW searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of stops in events with one or two hadronically decaying τ leptons, jets, b-jets and $\not{E}_T$. No significant excess above the Standard Model predictions is observed. Limits are set on the $\tilde{t}_1$ mass as a function of the $\tilde{\tau}_1$ in the Tstop5 scenario. See their Fig. 8.

[11] AAD 21O searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of top squarks in events with one electron or muon, jets, and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the top squark mass in the Tstop1 and Tstop3 simplified models and dark matter models, see their Figures 13, 14 and 15.

[12] AAD 21P searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of top squarks in events with two opposite-sign leptons, jets, and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the top squark mass in the Tstop1, Tstop2, and Tstop3 simplified models, see their Figures 14.

[13] SIRUNYAN 21AD searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for supersymmetry in events with multiple jets, no leptons, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the top squark mass in the simplified models Tstop1, Tstop2 with $m_{\tilde{\chi}_1^{\pm}} = (m_{\tilde{t}} + m_{\tilde{\chi}_1^0})/2$, and a 50:50 mixture of these with $m_{\tilde{\chi}_1^{\pm}} - m_{\tilde{\chi}_1^0} = 5$ GeV, see their Figure 8. Limits are also set on the top squark mass for 10 GeV $< m_{\tilde{t}} - m_{\tilde{\chi}_1^{\pm}} < 80$ GeV in the simplified models Tstop2, Tstop 3, and Tstop4, see their Figure 9. For indirect top squark production, limits are set on the gluino mass in the simplified models Tglu3A, Tglu3C with $m_{\tilde{t}} - m_{\tilde{\chi}_1^0} = 20$ GeV, and Tglu3D with $m_{\tilde{\chi}_1^{\pm}} - m_{\tilde{\chi}_1^0} = 5$ GeV, see their Figure 10.

[14] SIRUNYAN 21B searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for the pair production of top squarks in events with two oppositely charged leptons (electrons or muons), jets identified as originating from a b-quark and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1, Tstop2 and Tstop11 simplified models, see their Figures 6 and 7.

[15] TUMASYAN 21I searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of top squarks in events with at least two jets and large $\not{E}_T$, categorized into events with 0, 1, or 2 leptons. No significant excess above the Standard Model expectations is observed. Limits are set on the top squark mass in the simplified model Tstop1 in the top corridor $|m_{\tilde{t}} - m_{\tilde{\chi}_1^0} - 175\ \text{GeV}| < 30$ GeV using dilepton events, see their Figure 7. Limits are also set for a combination of earlier searches with 0, 1, and 2 leptons in the models Tstop1, Tstop2 and a 50:50 mixture of these models, see their Figure 9. The results are interpreted in an alternative signal model of dark matter production via a spin-0 mediator in association with a top quark pair as well.

[16] AABOUD 20 searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing one electron-muon pair with opposite charge. The search targets a region of parameter space where the kinematics of top squark pair production and top quark pair production is very similar and makes use of the double-differential angular distributions of the leptons. No excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1 model, see Figures 16 and 17.

[17] AAD 20AS searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of top squarks in events containing either a pair of jets consistent with SM Higgs boson decay into b-quarks or a same-flavour opposite-sign dilepton pair with an invariant mass consistent with a Z boson. No significant excess over the expected background is observed. Limits at 95% C.L. are set in Tstop6 simplified model. Assuming $m_{\widetilde{\chi}_1^0} = 0$ GeV, $\widetilde{t}_1$ masses up to 1220 GeV are excluded for $m_{\widetilde{\chi}_2^0}$ around 900 GeV. Limits reduce down to $\widetilde{t}_1$ masses up to 900 GeV for $m_{\widetilde{\chi}_2^0}$=130 GeV. See their Fig. 10. Limits are presented also in case of B($\widetilde{\chi}_2^0 \to \widetilde{\chi}_1^0 h$) = 0 and 1, see their Fig. 11.

[18] AAD 20AS searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of top squarks in events containing either a pair of jets consistent with SM Higgs boson decay into b-quarks or a same-flavour opposite-sign dilepton pair with an invariant mass consistent with a Z boson. No significant excess over the expected background is observed. Limits at 95% C.L. are set in simplified model featuring $\widetilde{t}_2$ pair production, $\widetilde{t}_2 \to \widetilde{t}_1 Z$ and $\widetilde{t}_1 \to b f f' \widetilde{\chi}_1^0$. Assuming $m_{\widetilde{\chi}_1^0} = 300$ GeV, and a mass difference between $\widetilde{t}_1$ and $\widetilde{\chi}_1^0$ of 40 GeV, $\widetilde{t}_2$ masses up to 860 GeV are excluded. See their Fig. 12.

[19] AAD 20S searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing multiple jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Exclusion limits at 95% C.L. are set on top squark masses in the Tstop1 model up to 1250 GeV for lightest neutralino masses below 200 GeV. Additional constraints are set in the case where $m_{\widetilde{t}} - m_{\widetilde{\chi}_1^0} \sim m_t$ for which top squark masses in the range 300–630 GeV are excluded. See their Fig. 13.

[20] AAD 20S searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing multiple jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Exclusion limits at 95% C.L. are set on top squark masses in the Tstop3 model in the range 300–660 GeV. In case $m_{\widetilde{t}} - m_{\widetilde{\chi}_1^0} \sim 5$ GeV or above, $m_{\widetilde{t}}$ below 500 GeV are excluded. See their Fig. 13(b).

[21] AAD 20V searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign charged leptons (electrons or muons) and jets. No significant excess above the Standard Model expectations is observed. Exclusion limits at 95% C.L. are set on the top squark mass up to 765 GeV assuming $\widetilde{t}_1 \to t\widetilde{\chi}_2^0$ with $\widetilde{\chi}_2^0 \to \widetilde{\chi}_1^{\pm} W$ and $\widetilde{\chi}_1^{\pm} \to \widetilde{\chi}_1^0 W$. Masses of the charginos and lightest neutralinos are set as $m_{\widetilde{\chi}_1^0} = m_{\widetilde{t}_1} - 275$ GeV, $m_{\widetilde{\chi}_2^0} = m_{\widetilde{\chi}_1^0} + 100$ GeV and $m_{\widetilde{\chi}_1^{\pm}} \sim m_{\widetilde{\chi}_1^0}$. See their Fig. 8(b).

[22] SIRUNYAN 20AH searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of top squarks in events with a single isolated electron or muon, multiple jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1, Tstop2 and Tstop8 simplified models, see Figures 6, 7 and 8, respectively.

[23] SIRUNYAN 20T searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least two jets, and two isolated same-sign or three or more charged leptons (electrons or muons). No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A, Tglu3B, Tglu3C and Tglu3D simplified models, see their Figure 7, and in the Tglu1C and Tglu1B simplified models, see their Figures 8 and 9. Limits are also set on the sbottom mass in the Tsbot2 simplified model, see their Figure 10, and on the stop mass in the Tstop7 simplified model, see their Figure 11. Finally, limits are set on the gluino mass in RPV simplified models where the gluino decays either via $\widetilde{g} \to q q \overline{q} \overline{q} + e/\mu/\tau$ or via $\widetilde{g} \to t b s$, see Figure 12.

[24] SIRUNYAN 20U searched in 77.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for the pair production of top squarks in events with two hadronically decaying taus, jets identified as originating from a b-quark and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop11 simplified model assuming the final state leptons are taus. Different values of the scalar tau mass are considered; the impact on the lower bound is negligible.

[25] SIRUNYAN 19AU searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at last one photon, jets, some of which are identified as originating from b-quarks, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. In the framework of GMSB, limits are set on the gluino mass in the Tglu4C, Tglu4D and Tglu4E simplified models, and on the top squark mass in the Tstop13 simplified model, see their Figure 5.

[26] SIRUNYAN 19CH searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing multiple jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu1C, Tglu2A and Tglu3A simplified models, see their Figure 13. Limits are also set on squark, sbottom and stop masses in the Tsqk1, Tsbot1, Tstop1 simplified models, see their Figure 14.

[27] SIRUNYAN 19S searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with zero or one charged leptons, jets and $\not{E}_T$. The razor variables (M_R and R^2) are used to categorize the events. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A and Tglu3C simplified models, see Figures 22 and 23, and on the stop mass in the Tstop1 simplified model, see their Figure 24.

[28] SIRUNYAN 19U searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing one electron-muon pair with opposite charge. The search targets a region of parameter space where the kinematics of top squark pair production and top quark pair production is very similar, due to the mass difference between the top squark and the neutralino being close to the top quark mass. No excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1 model, with $m_{\widetilde{t}_1} - m_{\widetilde{\chi}_1^0}$ close to m_t, see Figure 5.

[29] AABOUD 18AQ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for top squark pair production in final states with one isolated electron or muon, several energetic jets, and missing transverse momentum. No significant excess over the Standard Model prediction is observed. In case of Tstop1 models, top squark masses up to 940 GeV are excluded assuming $m_{\widetilde{\chi}_1^0} = 0$ GeV, see their Fig. 20. If the top quark is not on-shell (3-body) decay, exclusions up to 500 GeV are obtained for $m_{\widetilde{\chi}_1^0} = 300$ GeV. Exclusions as a function of $m_{\widetilde{t}_1} - m_{\widetilde{\chi}_1^0}$ are given in their Fig. 21.

[30] AABOUD 18AQ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for top squark pair production in final states with one isolated electron or muon, several energetic jets, and missing transverse momentum. No significant excess over the Standard Model prediction is observed. In case of Tstop3 models (4-body), top squark masses up to 370 GeV are excluded for $m_{\widetilde{t}} - m_{\widetilde{\chi}_1^0}$ as low as 20 GeV. Top squark masses below 195 GeV are excluded for all $m_{\widetilde{\chi}_1^0}$, see their Fig. 20 and Fig. 21.

[31] AABOUD 18AQ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for top squark pair production in final states with one isolated electron or muon, several energetic jets, and missing transverse momentum. No significant excess over the Standard Model prediction is observed. In case of Tstop2 models, top squark masses up to 840 GeV are excluded for $m_{\widetilde{t}} - m_{\widetilde{\chi}_1^{\pm}} = 10$ GeV. See their Fig. 23. Exclusion limits for this decay mode are presented also in the context of Higgsino-LSP phenomenological MSSM models, where $m_{\widetilde{\chi}_1^{\pm}} - m_{\widetilde{\chi}_1^0} = 5$ GeV, see their Fig 26.

[32] AABOUD 18BV searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one jet identified as c-jet, large missing transverse energy and no leptons. Good agreement is observed between the number of events in data and Standard Model predictions. The results are translated into exclusion limits in Tstop4 models. In scenarios with differences of the stop and neutralino masses below 100 GeV, stop masses below 500 GeV are excluded. See their Fig.6 and Fig.7.

[33] AABOUD 18BV searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one jet identified as c-jet, large missing transverse energy and no leptons. Good agreement is observed between the number of events in data and Standard Model predictions. The results are translated into exclusion limits in Tstop1 models. In scenarios with massless neutralinos, top squark masses below 850 GeV are excluded. See their Fig.6.

[34] AABOUD 18I searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one jet with a transverse momentum above 250 GeV and no leptons. Good agreement is observed between the number of events in data and Standard Model predictions. The results are translated into exclusion limits in Tstop3 models. Stop masses below 390 GeV are excluded for $m_{\widetilde{t}} - m_{\widetilde{\chi}_1^0} = m_b$. See their Fig.9(b).

[35] AABOUD 18I searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one jet with a transverse momentum above 250 GeV and no leptons. Good agreement is observed between the number of events in data and Standard Model predictions. The results are translated into exclusion limits in Tstop4 models. In scenarios with differences of the stop and neutralino masses around 5 GeV, stop masses below 430 GeV are excluded. See their Fig.9(a).

[36] AABOUD 18Y searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct pair production of top squarks in final states with two tau leptons, b-jets, and missing transverse momentum. At least one hadronic τ is required. No significant deviation from the SM predictions is observed in the data. The analysis results are interpreted in Tstop5 models with a nearly massless gravitino. Top squark masses up to 1.16 TeV and tau slepton masses up to 1 TeV are excluded, see their Fig 7.

[37] SIRUNYAN 18AJ searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing two low-momentum, oppositely charged leptons (electrons or muons) and $\not{E}_T$. No excess over the expected background is observed. Limits are derived on the wino mass in the Tchi1n2F simplified model, see their Figure 5. Limits are also set on the stop mass in the Tstop10 simplified model, see their Figure 6. Finally, limits are set on the Higgsino mass in the Tchi1n2G simplified model, see Figure 8 and in the pMSSM, see Figure 7.

[38] SIRUNYAN 18AL searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least three charged leptons, in any combination of electrons and muons, jets and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A and Tglu1C simplified models, see their Figure 5. Limits are also set on the sbottom mass in the Tsbot2 simplified model, see their Figure 6, and on the stop mass in the Tstop7 simplified model, see their Figure 7.

[39] SIRUNYAN 18AN searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing one or two photons and a pair of top quarks from the decay of a pair of top squark in a natural gauge-mediated scenario. The final state consists of a lepton (electron or muon), jets and one or two photons. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop12 simplified model, see their Figure 6.

[40] SIRUNYAN 18AY searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing one or more jets and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A and Tglu3A simplified models, see their Figure 3. Limits are also set on squark, sbottom and stop masses in the Tsqk1, Tsbot1, Tstop1 and Tstop4 simplified models, see their Figure 3. Finally, limits are set on long-lived gluino masses in a Tglu1A simplified model where the gluino is metastable or long-lived with proper decay lengths in the range 10^{-3} mm $< c\tau < 10^5$ mm, see their Figure 4.

[41] SIRUNYAN 18B searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for the pair production of third-generation squarks in events with jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in the Tsbot1 simplified model, see their Figure 5, and on the stop mass in the Tstop4 simplified model, see their Figure 6.

[42] SIRUNYAN 18C searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for the pair production of top squarks in events with two oppositely charged leptons (electrons or muons), jets identified as originating from a b-quark and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1, Tstop2 and Tstop11 simplified models, see their Figures 11 and 12. The Tstop1 and Tstop2 results are combined with complementary searches in the all-hadronic and single lepton channels, see their Figures 13 and 14.

[43] SIRUNYAN 18D searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing identified hadronically decaying top quarks, no leptons, and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1 simplified model, see their Figure 8, and on the gluino mass in the Tglu3A, Tglu3B, Tglu3C and Tglu3E simplified models, see their Figure 9.

[44] SIRUNYAN 18DI searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of top squarks in events with a low transverse momentum lepton (electron or muon), a high-momentum jet and significant missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop3 and Tstop10 simplified models, see their Figures 7 and 8. A combination of this search with the all-hadronic search is presented in Figure 9.

[45] SIRUNYAN 18DN searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct electroweak production of charginos and for pair production of top squarks in events with two leptons (electrons or muons) of the opposite electric charge. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino mass in the Tchi1chi1C and Tchi1chi1E simplified models, see their Figure 8. Limits are also set on the stop mass in the Tstop1 and Tstop2 simplified models, see their Figure 9.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[46] AABOUD 17AJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign or three leptons, jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 700 GeV are set on the top squark mass in Tstop11 simplified models, assuming $m_{\widetilde{\chi}_1^0} = m_{\widetilde{t}} - 275$ GeV and $m_{\widetilde{\chi}_2^0} = m_{\widetilde{\chi}_1^0} + 100$ GeV. See their Figure 4(e).

[47] AABOUD 17AX searched in 36 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing two jets identified as originating from b-quarks and large missing transverse momentum, with or without leptons. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of top squarks. Assuming 50% BR for Tstop1 and Tstop2 simplified models, a $\widetilde{t}_1$ mass below 880 (860) GeV is excluded for $m_{\widetilde{\chi}_1^0} = 0$ (<250) GeV. See their Fig. 7(b).

[48] AABOUD 17AY searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least four jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits in the range 250–1000 GeV are set on the top squark mass in Tstop1 simplified models. For the first time, additional constraints are set for the region $m_{\widetilde{t}_1} \sim m_t + m_{\widetilde{\chi}_1^0}$, with exclusion of the $\widetilde{t}_1$ mass range 235–590 GeV. See their Figure 8.

[49] AABOUD 17AY searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least four jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits in the range 450-850 GeV are set on the top squark mass in a mixture of Tstop1 and Tstop2 simplified models with BR=50% and assuming $m_{\widetilde{\chi}_1^\pm} - m_{\widetilde{\chi}_1^0} = 1$ GeV and $m_{\chi_1^0} < 240$ GeV. Constraints are given for various values of the BR. See their Figure 9.

[50] AABOUD 17BE searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two opposite-charge leptons (electrons and muons) and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 720 GeV are set on the top squark mass in Tstop1 simplified models, assuming massless neutralinos. See their Figure 9 (2-body area).

[51] AABOUD 17BE searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two opposite-charge leptons (electrons and muons) and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 400 GeV are set on the top squark mass in Tstop3 simplified models, assuming $m_{\widetilde{t}_1} - m_{\widetilde{\chi}_1^0} = 40$ GeV. See their Figure 9 (4-body area).

[52] AABOUD 17BE searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two opposite-charge leptons (electrons and muons) and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 430 GeV are set on the top squark mass in Tstop1 simplified models where top quarks are offshell, assuming $m_{\widetilde{t}_1} - m_{\widetilde{\chi}_1^0}$ close to the W mass. See their Figure 9 (3-body area).

[53] AABOUD 17BE searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two opposite-charge leptons (electrons and muons) and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 700 GeV are set on the top squark mass in Tstop2 simplified models, assuming $m_{\widetilde{t}_1} - m_{\widetilde{\chi}_1^\pm} = 10$ GeV and massless neutralinos. See their Figure 10.

[54] KHACHATRYAN 17 searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing four or more jets, no more than one lepton, and missing transverse momentum, using the razor variables (M_R and R^2) to discriminate between signal and background processes. No evidence for an excess over the expected background is observed. Limits are derived on the stop mass in the Tstop1 simplified model, see Fig. 17.

[55] KHACHATRYAN 17AD searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing at least four jets (including b-jets), missing transverse momentum and tagged top quarks. No evidence for an excess over the expected background is observed. Top squark masses in the range 250–740 GeV and neutralino masses up to 240 GeV are excluded at 95% C.L. See Fig. 12.

[56] KHACHATRYAN 17AD searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing at least four jets (including b-jets), missing transverse momentum and tagged top quarks. No evidence for an excess over the expected background is observed. Limits are derived on the $\widetilde{t}$ mass in simplified models that are a mixture of Tstop1 and Tstop2 with branching fractions 50% for each of the two decay modes: top squark masses of up to 610 GeV and neutralino masses up to 190 GeV are excluded at 95% C.L. The $\widetilde{\chi}_1^\pm$ and the $\widetilde{\chi}_1^0$ are assumed to be nearly degenerate in mass, with a 5 GeV difference between their masses. See Fig. 12.

[57] KHACHATRYAN 17P searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A, Tglu3A, Tglu3B, Tglu3C and Tglu3D simplified models, see their Figures 7 and 8. Limits are also set on the squark mass in the Tsqk1 simplified model, see their Fig. 7, and on the sbottom mass in the Tsbot1 simplified model, see Fig. 8. Finally, limits are set on the stop mass in the Tstop1, Tstop3, Tstop4, Tstop6 and Tstop7 simplified models, see Fig. 8.

[58] KHACHATRYAN 17S searched in 18.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing multiple jets and missing transverse momentum, using the α_T variable to discriminate between signal and background processes. No evidence for an excess over the expected background is observed. Limits are derived on the stop mass in the Tstop4 model: for $\Delta m = m_{\widetilde{t}} - m_{\widetilde{\chi}_1^0}$ equal to 10 and 80 GeV, masses of stop below 240 and 260 GeV are excluded, respectively. See their Fig.3.

[59] KHACHATRYAN 17S searched in 18.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing multiple jets and missing transverse momentum, using the α_T variable to discriminate between signal and background processes. No evidence for an excess over the expected background is observed. Limits are derived on the stop mass in the Tstop3 model: for $\Delta m = m_{\widetilde{t}} - m_{\widetilde{\chi}_1^0}$ equal to 10 and 80 GeV, masses of stop below 225 and 130 GeV are excluded, respectively. See their Fig.3.

[60] KHACHATRYAN 17S searched in 18.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing multiple jets and missing transverse momentum, using the α_T variable to discriminate between signal and background processes. No evidence for an excess over the expected background is observed. Limits are derived on the stop mass in the Tstop2 model: assuming $m_{\widetilde{\chi}_1^\pm} = 0.25\ m_{\widetilde{t}} + 0.75\ m_{\widetilde{\chi}_1^0}$, masses of stop up to 325 GeV and masses of the neutralino up to 225 GeV are excluded. See their Fig.3.

[61] KHACHATRYAN 17S searched in 18.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing multiple jets and missing transverse momentum, using the α_T variable to discriminate between signal and background processes. No evidence for an excess over the expected background is observed. Limits are derived on the stop mass in the Tstop2 model: assuming $m_{\widetilde{\chi}_1^\pm} = 0.75\ m_{\widetilde{t}} + 0.25\ m_{\widetilde{\chi}_1^0}$, masses of stop up to 400 GeV are excluded for low neutralino masses. See their Fig.3.

[62] KHACHATRYAN 17S searched in 18.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing multiple jets and missing transverse momentum, using the α_T variable to discriminate between signal and background processes. No evidence for an excess over the expected background is observed. Limits are derived on the stop mass in the Tstop1 model: assuming masses of stop up to 500 GeV and masses of the neutralino up to 105 GeV are excluded. See their Fig.3.

[63] SIRUNYAN 17AS searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with a single lepton (electron or muon), jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1, Tstop2 and Tstop8 simplified models, see their Figures 5, 6 and 7.

[64] SIRUNYAN 17AT searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct production of top squarks in events with jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1, Tstop2 , Tstop3, Tstop4, Tstop8 and Tstop10 simplified models, see their Figures 9 to 14.

[65] SIRUNYAN 17AZ searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A, Tglu3A simplified models, see their Figures 6. Limits are also set on the squark mass in the Tsqk1 simplified model (for single light squark and for 8 degenerate light squarks), on the sbottom mass in the Tsbot1 simplified model and on the stop mass in the Tstop1 simplified model, see their Fig. 7. Finally, limits are set on the stop mass in the Tstop2, Tstop4 and Tstop8 simplified models, see Fig. 8.

[66] SIRUNYAN 17K searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for direct production of stop or sbottom pairs in events with multiple jets and significant $\not{E}_T$. A second search also requires an isolated lepton and is combined with the all-hadronic search. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1, Tstop8 and Tstop4 simplified models, see their Figures 7, 8 and 9 (for the Tstop4 limits, only the results of the all-hadronic search are used). Limits are also set on the sbottom mass in the Tsbot1 simplified model, see Fig. 10 (also here, only the results of the all-hadronic search are used).

[67] SIRUNYAN 17P searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with multiple jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu1C, Tglu2A, Tglu3A and Tglu3D simplified models, see their Fig. 12. Limits are also set on the squark mass in the Tsqk1 simplified model, on the stop mass in the Tstop1 simplified model, and on the sbottom mass in the Tsbot1 simplified model, see Fig. 13.

[68] AABOUD 16D searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with an energetic jet and large missing transverse momentum. The results are interpreted as 95% C.L. limits on mass of stop decaying into a charm-quark and the lightest neutralino in scenarios with $m_{\widetilde{t}_1} - m_{\widetilde{\chi}_1^0}$ between 5 and 20 GeV. See their Fig. 5.

[69] AABOUD 16J searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in final states with one isolated electron or muon, jets, and missing transverse momentum. For the direct stop pair production model where the stop decays via top and lightest neutralino, the results exclude at 95% C.L. stop masses between 745 GeV and 780 GeV for a massless $\widetilde{\chi}_1^0$. See their Fig. 8.

[70] AAD 16AY searched in 20 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with either two hadronically decaying tau leptons, one hadronically decaying tau and one light lepton, or two light leptons. No significant excess over the Standard Model expectation is found. Exclusion limits at 95% C.L. on the mass of top squarks decaying via $\widetilde{\tau}$ to a nearly massless gravitino are placed depending on $m_{\widetilde{\tau}}$ which is ranging from the 87 GeV LEP limit to $m_{\widetilde{t}_1}$. See their Figs. 9 and 10.

[71] KHACHATRYAN 16AV searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with one or two isolated leptons, hadronic jets, b-jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1 and Tstop2 simplified models, see Fig. 11.

[72] KHACHATRYAN 16BK searched in 18.9 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with hadronic jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1 and Tstop2 simplified models, see Fig. 16.

[73] KHACHATRYAN 16BS searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one energetic jet , no isolated leptons, and significant $\not{E}_T$, using the transverse mass variable M_{T2} to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1 simplified model, see Fig. 11 and Table 3.

[74] KHACHATRYAN 16Y searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with one or two soft isolated leptons, hadronic jets, and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop3 simplified model, see Fig. 3.

[75] AAD 15CJ searched in 20 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for evidence of third generation squarks by combining a large number of searches covering various final states. Stop decays with and without charginos in the decay chain are considered and summaries of all ATLAS Run 1 searches for direct stop production can be found in Fig. 4 (no intermediate charginos) and Fig. 7 (intermediate charginos). Limits are set on stop masses in compressed mass regions regions, with $B(\widetilde{t} \to c\widetilde{\chi}_1^0) + B(\widetilde{t} \to bff'\widetilde{\chi}_1^0) = 1$, see Fig. 5. Limits are also set on stop masses assuming that both the decay $\widetilde{t} \to t\widetilde{\chi}_1^0$ and $\widetilde{t} \to b\widetilde{\chi}_1^\pm$ are possible, with both their branching rations summing up to 1, assuming $\widetilde{\chi}_1^\pm \to W^{(*)}\widetilde{\chi}_1^0$ and $m_{\widetilde{\chi}_1^\pm} = 2\ m_{\widetilde{\chi}_1^0}$, see Fig. 6. Limits on the mass of the next-to-lightest stop $\widetilde{t}_2$, decaying either to $Z\widetilde{t}_1$, $h\widetilde{t}_1$ or $t\widetilde{\chi}_1^0$, are also presented, see Figs. 9 and 10.Interpretations in the pMSSM are also discussed, see Figs 13–15.

[76] AAD 15J interpreted the measurement of spin correlations in $t\bar{t}$ production using 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV in exclusion limits on the pair production of light $\widetilde{t}_1$ squarks with masses similar to the top quark mass. The $\widetilde{t}_1$ is assumed to decay through $\widetilde{t}_1 \to t\widetilde{\chi}_1^0$ with predominantly right-handed top and a 100% branching ratio. The data are found to be consistent with the Standard Model expectations and masses between the top quark mass and 191 GeV are excluded, see their Fig. 2

[77] KHACHATRYAN 15AF searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least two energetic jets and significant $\not{E}_T$, using the transverse mass variable

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

M_{T2} to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in simplified models where the decay $\tilde{t} \to t\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 12. See also Table 5. Exclusions in the CMSSM, assuming $\tan\beta = 30$, $A_0 = -2\max(m_0, m_{1/2})$ and $\mu > 0$, are also presented, see Fig. 15.

[78] KHACHATRYAN 15AH searched in 19.4 or 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing either a fully reconstructed top quark, or events containing dijets requiring one or both jets to originate from b-quarks, or events containing a mono-jet. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in simplified models where the decay $\tilde{t} \to t\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 9. Limits are also set in simplified models where the decays $\tilde{t} \to t\tilde{\chi}_1^0$ and $\tilde{t} \to b\tilde{\chi}_1^\pm$, with $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 5$ GeV, each take place with a branching ratio of 50%, see Fig. 10, or with other fractions, see Fig. 11. Finally, limits are set in a simplified model where the decay $\tilde{t} \to c\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Figs. 9, 10 and 11.

[79] KHACHATRYAN 15AH searched in 19.4 or 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing either a fully reconstructed top quark, or events containing dijets requiring one or both jets to originate from b-quarks, or events containing a mono-jet. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in simplified models where the decay $\tilde{t} \to t\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 9. Limits are also set in simplified models where the decays $\tilde{t} \to t\tilde{\chi}_1^0$ and $\tilde{t} \to b\tilde{\chi}_1^\pm$, with $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 5$ GeV, each take place with a branching ratio of 50%, see Fig. 10, or with other fractions, see Fig. 11. Finally, limits are set in a simplified model where the decay $\tilde{t} \to c\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Figs. 9, 10, and 11.

[80] KHACHATRYAN 15X searched in 19.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least two energetic jets, at least one of which is required to originate from a b quark, possibly a lepton, and significant $\not{E}_T$, using the razor variables (M_R and R^2) to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in simplified models where the decay $\tilde{t} \to t\tilde{\chi}_1^0$ and the decay $\tilde{t} \to b\tilde{\chi}_1^\pm$, with $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 5$ GeV, take place with branching ratios varying between 0 and 100%, see Figs. 15, 16 and 17.

[81] AAD 14AJ searched in 20.1 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing four or more jets and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks in simplified models which either assume that the decay $\tilde{t}_1 \to t\tilde{\chi}_1^0$ takes place 100% of the time, see Fig. 8, or that this decay takes place 50% of the time, while the decay $\tilde{t}_1 \to b\tilde{\chi}_1^\pm$ takes place the other 50% of the time, see Fig. 9.

[82] AAD 14BD searched in 20 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing one isolated lepton, jets and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks in simplified models which either assume that the decay $\tilde{t}_1 \to t\tilde{\chi}_1^0$ takes place 100% of the time, see Fig. 15, or the decay $\tilde{t}_1 \to b\tilde{\chi}_1^\pm$ takes place 100% of the time, see Fig. 16–22. For the mixed decay scenario, see Fig. 23.

[83] AAD 14F searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing two leptons (e or μ), and possibly jets and missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks in simplified models which either assume that the decay $\tilde{t}_1 \to b\tilde{\chi}_1^\pm$ takes place 100% of the time, see Figs. 14–17 and 20, or that the decay $\tilde{t}_1 \to t\tilde{\chi}_1^0$ takes place 100% of the time, see Figs. 18 and 19.

[84] AAD 14T searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for monojet-like and c-tagged events. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks in simplified models which assume that the decay $\tilde{t}_1 \to c\tilde{\chi}_1^0$ takes place 100% of the time, see Fig. 9 and 10. The results of the monojet-like analysis are also interpreted in terms of stop pair production in the four-body decay $\tilde{t}_1 \to bff'\tilde{\chi}_1^0$, see Fig. 11.

[85] CHATRCHYAN 14AH searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with at least two energetic jets and significant $\not{E}_T$, using the razor variables (M_R and R^2) to discriminate between signal and background processes. A second analysis requires at least one of the jets to be originating from a b-quark. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay $\tilde{t} \to t\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Figs. 28 and 29. Exclusions in the CMSSM, assuming $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, are also presented, see Fig. 26.

[86] CHATRCHYAN 14R searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in a natural higgsino NLSP simplified model (GMSB) where the decay $\tilde{t} \to b\tilde{\chi}_1^\pm$, with $\tilde{\chi}_1^\pm \to (qq'/\ell\nu)H$, $Z\tilde{G}$, takes place with a branching ratio of 100% (the particles between brackets have a soft p_T spectrum), see Figs. 4–6.

[87] AABOUD 17AF searched in 36 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of top squarks in events containing 2 leptons, jets, b-jets and $\not{E}_T$. In Tstop6 model, assuming $m_{\tilde{\chi}_1^0} = 0$ GeV, $\tilde{t}_1$ masses up to 850 GeV are excluded for $m_{\tilde{\chi}_2^0} > 200$ GeV.

[88] AABOUD 17AF searched in 36 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of $\tilde{t}_2$ in events containing 2 leptons, jets, b-jets and $\not{E}_T$. In Tstop7 model, assuming $m_{\tilde{\chi}_1^0} = 50$ GeV and 100% decays via Z boson, $\tilde{t}_2$ masses up to 800 GeV are excluded. Exclusion limits are also shown as a function of the $\tilde{t}_2$ branching ratios in their Figure 7.

[89] AABOUD 17AF searched in 36 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of $\tilde{t}_2$ in events containing 2 leptons, jets, b-jets and $\not{E}_T$. In Tstop7 model, assuming $m_{\tilde{\chi}_1^0} = 50$ GeV and 100% decays via higgs boson, $\tilde{t}_2$ masses up to 880 GeV are excluded. Exclusion limits are also shown as a function of the $\tilde{t}_2$ branching ratios in their Figure 7.

[90] AABOUD 17AY searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least four jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the top squark mass assuming three pMSSM-inspired models. The first one, referred to as Higgsino LSP model, assumes $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 5$ GeV and $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0} = 10$ GeV, with a mixture of decay modes as in Tstop1, Tstop2 and Tstop6. See their Figure 10. The second and third models are referred to as Wino NLSP and well-tempered pMSSM models, respectively. See their Figure 11 and Figure 12, and text for details on assumptions.

[91] AAD 14B searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing a Z boson, with or without additional leptons, plus jets originating from b-quarks and significant missing transverse momentum. No excess over the expected SM background is observed. Limits are derived in simplified models featuring $\tilde{t}_2$ production, with $\tilde{t}_2 \to Z\tilde{t}_1$, $\tilde{t}_1 \to t\tilde{\chi}_1^0$ with a 100% branching ratio, see Fig. 4, and in the framework of natural GMSB, see Fig. 6.

[92] CHATRCHYAN 14U searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for evidence of direct pair production of top squarks, with Higgs bosons in the decay chain. The search is performed using a selection of events containing two Higgs bosons, each decaying to a photon pair, missing transverse energy and possibly b-quark jets. No significant excesses over the expected SM backgrounds are observed. The results are interpreted in the context of a "natural SUSY" simplified model where the decays $\tilde{t}_1 \to b\tilde{\chi}_1^\pm$, with $\tilde{\chi}_1^\pm \to ff'\tilde{\chi}_1^0$, and $\tilde{\chi}_1^0 \to H\tilde{G}$, all happen with 100% branching ratio, see Fig. 4.

[93] KHACHATRYAN 14C searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for evidence of direct pair production of top squarks, with Higgs or Z-bosons in the decay chain. The search is performed using a selection of events containing leptons and b-quark jets. No significant excesses over the expected SM backgrounds are observed. The results are interpreted in the context of a simplified model with pair production of a heavier top-squark mass eigenstate $\tilde{t}_2$ decaying to a lighter top-squark eigenstate $\tilde{t}_1$ via either $\tilde{t}_2 \to H\tilde{t}_1$ or $\tilde{t}_2 \to Z\tilde{t}_1$, followed in both cases by $\tilde{t}_1 \to t\tilde{\chi}_1^0$. The interpretation is performed in the region where the mass difference between the $\tilde{t}_1$ and $\tilde{\chi}_1^0$ is approximately equal to the top-quark mass, which is not probed by searches for direct $\tilde{t}_1$ pair production, see Figs. 5 and 6. The analysis excludes top squarks with masses $m_{\tilde{t}_2} < 575$ GeV and $m_{\tilde{t}_1} < 400$ GeV at 95% C.L.

[1] CHEKHOVSKY 25K searched in 138 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for evidence of top squark pair production in events with 0, 1, or 2 electrons or muons and at least six jets. No significant excess above the Standard Model expectations is observed. Limits are set in the frameworks of RPV and stealth SUSY models, see their figure 7. In the RPV model Tstop6RPV, each top squark decays to a top quark and a neutralino $\tilde{\chi}^0_1$, followed by an RPV decay of the $\tilde{\chi}^0_1$ to three light-flavor jets. The stealth SUSY model $SY\overline{Y}$ assumes a new hidden sector containing a scalar particle S with even R-parity and its superpartner $\widetilde{S}$, both of which are singlets under all SM interactions. SUSY is approximately conserved in the hidden sector for this model, resulting in nearly mass-degenerate $\widetilde{S}$ and S masses. The stealth sector couples in this model through a gauge singlet MSSM operator $Y\overline{Y}$ within the SU(5) GUT group. In this model, the top squark decays as follows: $\tilde{t} \to g\widetilde{S}$, with $\widetilde{S} \to gg\widetilde{G}$.

[2] AAD 24BT searched in 140 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for pair production of stops decaying RPV to a lepton and a b-quark. The final state consists of two resonant $\ell - b$ pairs. No excess over the SM prediction is observed. Limits are set on the mass of the $\tilde{t}$ assuming decays in a single lepton flavour, or into the three lepton flavours with BR of 1/3, see their Figure 9. Limits are also extracted as a function of the branching fraction into each lepton flavour, assuming that the $\tilde{t}$ decays only via $\tilde{t} \to b\ell$, see their Figure 8.

[3] HAYRAPETYAN 24AP searched in 128 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for evidence of pair-produced multijet signatures probing fully hadronic final states. No significant excess above the Standard Model expectations is observed. Limits are set in three RPV SUSY models: higgsino pair production with decay to merged trijets, stop pair production with decay to merged dijets, and pair-produced gluinos decaying to resolved trijets, see their Fig. 4.

[4] TUMASYAN 23L searched in 138 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for pairs of dijet resonances with the same mass in final states with at least four jets, for the case where the four-jet production proceeds via an intermediate resonant state and for nonresonant production. No significant excess above the Standard Model expectations is observed. Limits are set in the nonresonant search on the top squark mass in the simplified model Tstop1aRPV with λ_{312} coupling, assuming B(ds) = 1, see their figure 12. Limits are also set on resonant pair production of dijet resonances via high mass intermediate states and compared to a signal model of diquarks that decay into pairs of vector-like quarks, see their figures 10 and 11.

[5] TUMASYAN 22AF searched for evidence of new long-lived particles decaying to leptons in pp collisions at $\sqrt{s}$ = 13 TeV, corresponding to 118 (113) fb^{-1} in the ee channel ($e\mu$ and $\mu\mu$) channels. The leptons are required to have transverse impact parameter values between 0.01 and 10 cm and are not required to form a common vertex. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of the top squark in RPV models with top squark pair production and $\tilde{t} \to b\overline{\ell}$ and $\tilde{t} \to d\overline{\ell}$, see their Figure 4, which contains a wider range of lifetime limits. Limits are also set on a gauge-mediated SUSY breaking model, where the next-to-lightest SUSY particle is a slepton and the lightest SUSY particle a gravitino $\widetilde{G}$, see their Figure 5, which also contains a wider range of lifetime limits. Limits are also set in a model that produces BSM Higgs bosons (H) with a mass of 125 GeV through gluongluon fusion, where the H decays to two long-lived scalars S, each of which decays to two oppositely charged and same-flavor leptons.

[6] AAD 21BF searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for pair production of gluinos, stops, electroweakinos decaying RPV either directly or indirectly via the LSP. The final state in all cases is one or two leptons, many jets (up to fifteen) and b-jets. Different models with different branching fractions of the gluino or stop follow from the assumptions on the nature of the electroweakinos. No significant excess above the Standard Model predictions is observed. Limits are set on the *gluino*, $\tilde{t}_1$, electroweakino masses as a function of the $\tilde{\chi}^0_1$ mass in several scenarios of gluino, stop and electroweakino pair production.

[7] SIRUNYAN 21AF searched in 140 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with with two displaced vertices from long-lived particles decaying into multijet or dijet final states. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu2RPV with λ''_{323} coupling, on the $\tilde{\chi}^0_1$ mass in an RPV model with $\tilde{\chi}^0_1$ pair production and the RPV decay $\tilde{\chi}^0_1 \to tbs$ with λ''_{323} coupling and on the $\tilde{t}$ mass in an RPV model with top squark pair production and the RPV decay $\tilde{t} \to \overline{d}_i\,\overline{d}_j$ with λ''_{3ij} coupling, see their Figure 7.

[8] SIRUNYAN 21U searched in 132 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with displaced tracks and displaced vertices associated with a dijet system. No significant excess above the Standard Model expectations is observed. Limits are set on long-lived gluinos in an RPC GMSB SUSY model of gluino pair production, with $\tilde{g} \to g\widetilde{G}$, see their Figure 9, in Tglu1A in a mini-split model, see their Figure 10, and in an RPV model of gluino pair production, with $\tilde{g} \to tbs$ with coupling λ''_{323}, see their Figure 11. Limits are also set on long-lived top squarks in Tstop2RPV, see their Figure 12, in an RPV model with $\tilde{t} \to \overline{d\ell}$ and λ'_{x31} coupling, see their Figure 13, and in a dynamical RPV model with $\tilde{t} \to \overline{d}\,\overline{d}$ via a nonholomorphic RPV coupling η''_{311}, see their Figure 14. The best mass limit is achieved in all cases at $c\tau$ = 30 mm.

[9] SIRUNYAN 21V searched in 137 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with one charged lepton ($e^{\pm}$ or $\mu^{\pm}$) and $\geq$ 7 jets. No significant excess above the Standard Model expectations is observed. Limits are set on an RPV SUSY model like Tstop1 with the additional decay $\tilde{\chi}^0_1 \to qqq$ with coupling λ''_{abc}, with a,b,c $\in$ 1,2, and on a stealth SUSY model called SYY, with one scalar particle S with even R-parity and its superpartner $\widetilde{S}$, both singlets under all SM interactions, and with a portal mediated by loop interactions involving a new vectorlike messenger field (Y), where pair produced top squarks decay as $\tilde{t} \to tg\widetilde{S}$, and $\widetilde{S} \to \widetilde{G}S$, and $S \to gg$, see their Figure 6 and 7.

[10] AAD 20M searched for long-lived particles decaying into hadrons and at least one muon in events containing a displaced muon track and a displaced vertex. The analysis uses a dataset of pp collisions at $\sqrt{s}$ = 13 TeV corresponding to an integrated luminosity of 136 fb^{-1}. Using the Tstop3RPV simplified model, top squarks with masses up to 1.7 TeV are excluded for a lifetime of 0.1 ns, and masses below 1.3 TeV are excluded for lifetimes between 0.01 ns and 30 ns, see their Fig. 7. The dependence on the RPV coupling λ_{23k} multiplied by cosθ_t, with θ_t the mixing angle between the left- and right-handed $\tilde{t}$ squarks, is also shown, see their Fig. 7.

[11] SIRUNYAN 19BI searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV in final states with two muons and two jets, or with one muon, two jets, and missing transverse momentum. Limits are set in a model of pair-produced, prompt or long-lived top squarks with R-parity violating decays to a b-quark and a lepton (Tstop2RPV), branching fraction of $\tilde{t} \to b\mu$ equal to 1/3 and $c\tau$ between 0.1 cm and 10 cm in the case of long-lived top squarks. See their Fig. 10.

[12] SIRUNYAN 19BJ searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV in final states with two electrons and two jets, or with one electron, two jets, and missing transverse momentum. Limits are set in a model of pair-produced, prompt top squarks with R-parity violating decays to a b-quark and a lepton (Tstop2RPV), assuming branching fraction of $\tilde{t} \to be$ equal to 1/3 and $c\tau$ = 0 cm. See their Fig.10.

[13] AABOUD 18BB searched in 36.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for massive colored resonances which are pair-produced and decay into two jets. No significant deviation from the background prediction is observed. Results are interpreted in a SUSY simplified model as Tstop1RPV with $\tilde{t} \to ds$. Top squarks with masses in the range 100–410 GeV are excluded, see their Figure 9(a). The λ''_{312} coupling is assumed to be sufficiently large for the decays to be prompt, but small enough to neglect the single-top-squark resonant production through RPV couplings.

[14] AABOUD 18BB searched in 36.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for massive coloured resonances which are pair-produced and decay into two jets. No significant deviation from the background prediction is observed. Results are interpreted in Tstop1RPV. Top squarks with masses in the range 100–470 GeV or 480–610 GeV are excluded, see their Figure 9(b). The λ''_{323} coupling is assumed to be sufficiently large for the decays to be prompt, but small enough to neglect the single-top-squark resonant production through RPV couplings.

[15] AABOUD 18P searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for pair-produced top squarks that decay through RPV λ'_{i33} (i = 1, 2, 3) couplings to a final state with two leptons and two jets, at least one of which is identified as a b-jet. No significant excess is observed over the SM background. In the Tstop2RPV model, lower limits on the top squark masses between 600 and 1500 GeV are set depending on the branching fraction to be, $b\mu$, and $b\tau$ final states. See their Figs 6 and 7.

[16] SIRUNYAN 18AD searched in 2.6 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for long-lived particles by exploiting the multiplicity of displaced jets to search for the presence of signal decays occurring at distances between 1 and 1000 mm. Limits are set in a model of pair-produced, long-lived top squarks with R-parity violating decays to a b-quark and a lepton, see their Figure 3.

[17] SIRUNYAN 18DV searched in 38.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for long-lived particles in events with multiple jets and two displaced vertices composed of many tracks. No events with two well-separated high-track-multiplicity vertices were observed. Limits are set on the stop and the gluino mass in RPV models of supersymmetry where the stop (gluino) is decaying solely into dijet (multijet) final states, see their Figures 6 and 7.

[18] SIRUNYAN 18DY searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for the pair production of resonances, each decaying to two quarks. The search is conducted separately in a boosted (two-jet) and resolved (four-jet) jet topology. The mass spectra are found to be consistent with the Standard Model expectations. Limits are set on the stop mass in the Tstop3RPV and Tstop1RPV simplified models, see their Figure 11.

[19] AABOUD 17AI searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with one or more isolated lepton, at least eight jets, either zero or many b-jets, for evidence of R-parity violating decays of the top squark. No significant excess above the Standard Model expectations is observed. Limits up to 1.25 (1.10) TeV are set on the top squark mass in R-parity-violating supersymmetry models where $\tilde{t}_1$ decays for a bino LSP as: $\tilde{t} \to t\tilde{\chi}^0_1$ and for a higgsino LSP as $\tilde{t} \to t\tilde{\chi}^0_{1,2}/b\tilde{\chi}^+_1$. These is followed by the decays through the non-zero λ''_{323} coupling $\tilde{\chi}^0_{1,2} \to tbs$, $\tilde{\chi}^{\pm}_1 \to bbs$. See their Figure 10 and text for details on model assumptions.

[20] AAD 16AM searched in 17.4 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing two large-radius hadronic jets. No deviation from the background prediction is observed. Top squarks with masses between 100 and 315 GeV are excluded at 95% C.L. in the

hypothesis that they both decay via R-parity violating coupling λ''_{323} to b- and s-quarks. See their Fig. 10.

[21] KHACHATRYAN 15L searched in 19.4 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for pair production of heavy resonances decaying to pairs of jets in four jet events. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in R-parity-violating supersymmetry models where $\tilde{t} \to qq$ ($\lambda''_{312} \neq 0$), see Fig. 6 (top) and $\tilde{t} \to qb$ ($\lambda''_{323} \neq 0$), see Fig. 6 (bottom).

[22] KHACHATRYAN 14T searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with τ-leptons and b-quark jets, possibly with extra light-flavour jets. No excess above the Standard Model expectations is observed. Limits are set on stop masses in RPV SUSY models with $LQ\overline{D}$ couplings, in two simplified models. In the first model, the decay $\tilde{t} \to \tau b$ is considered, with $\lambda'_{333} \neq 0$, see Fig. 3. In the second model, the decay $\tilde{t} \to \tilde{\chi}^{\pm} b$, with the subsequent decay $\tilde{\chi}^{\pm} \to qq\tau^{\pm}$ is considered, with $\lambda'_{3jk} \neq 0$ and the mass splitting between the top squark and the charging chosen to be 100 GeV, see Fig. 4.

[23] AAD 21B searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least eight jets and at least 5 b-jets, for evidence of R-parity violating decays of the top squark. No significant excess above the Standard Model expectations is observed. Limits up to 950 GeV are set on the top squark mass in Tstop4RPV simplified model. See their Figure 7 for more detailed mass bounds.

[24] KHACHATRYAN 16AC searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with low missing transverse momentum, two oppositely charged electrons or muons, and at least five jets, at least one of which is a b-jet, for evidence of R-parity violating, charging-mediated decays of the top squark. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in R-parity-violating supersymmetry models where $\tilde{t} \to b\tilde{\chi}_1^{\pm}$ with $\tilde{\chi}_1^{\pm} \to \ell^{\pm} jj$, $\lambda'_{ijk} \neq 0$ ($i,j,k \leq 2$), and with $m_{\tilde{t}} - m_{\tilde{\chi}_1^{\pm}} = 100$ GeV, see Fig. 3.

[25] KHACHATRYAN 16BX searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing 4 leptons coming from R-parity-violating decays of $\tilde{\chi}_1^0 \to \ell\ell\nu$ with $\lambda_{121} \neq 0$ or $\lambda_{122} \neq 0$. No excess over the expected background is observed. Limits are derived on the gluino, squark and stop masses, see Fig. 23.

[26] KHACHATRYAN 15E searched for long-lived particles decaying to leptons in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV. Events were selected with an electron and muon with opposite charges and each with transverse impact parameter values between 0.02 and 2 cm. Limits are set on SUSY benchmark models with pair production of top squarks decaying into an $e\mu$ final state via RPV interactions. See their Fig. 2

Heavy $\tilde{g}$ (Gluino) mass limit

For $m_{\tilde{g}} > 60$–70 GeV, it is expected that gluinos would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

>1040	95	[116] AAD	14E	ATLS	$\ell^\pm\ell^\pm(\ell^\mp)$ + jets, $\tilde{g} \to q q' \tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^{(*)\pm}\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \to Z^{(*)}\tilde{\chi}_1^0$ simplified model, $m_{\tilde{\chi}_1^0} < 520$ GeV
>1200	95	[116] AAD	14E	ATLS	$\ell^\pm\ell^\pm(\ell^\mp)$ + jets, $\tilde{g} \to q q' \tilde{\chi}_1^\pm/\tilde{\chi}_2^0$, $\tilde{\chi}_1^\pm \to \ell^\pm\nu\tilde{\chi}_1^0$, $\tilde{\chi}_2^0 \to \ell^\pm\ell^\mp(\nu\nu)\tilde{\chi}_1^0$ simplified model
>1050	95	[117] CHATRCHYAN	14H	CMS	same-sign $\ell^\pm\ell^\pm$, $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$ simplified model, massless $\tilde{\chi}_1^0$
> 900	95	[118] CHATRCHYAN	14H	CMS	same-sign $\ell^\pm\ell^\pm$, $\tilde{g} \to q q' \tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$ simplified model, $m_{\tilde{\chi}_1^\pm} = 0.5\ m_{\tilde{g}}$, massless $\tilde{\chi}_1^0$
>1050	95	[119] CHATRCHYAN	14H	CMS	same-sign $\ell^\pm\ell^\pm$, $\tilde{g} \to b\bar{t}\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^\pm\tilde{\chi}_1^0$ simplified model, $m_{\tilde{\chi}_1^\pm} = 300$ GeV, $m_{\tilde{\chi}_1^0} = 50$ GeV

[1] AAD 25BM searched in 140 fb^{-1} (at $\sqrt{s} = 13$ TeV) and 58.6 fb^{-1} (at $\sqrt{s} = 13.6$ TeV) of pp collisions for an excess of events with taus and $\not{E}_T$. Several signal regions are defined requiring one τ and no other leptons, one τ and one e or μ, or two τ, and then using both a BDT or a cut-and-count analysis to target scenarios with different kinematic regimes. No significant excess over the Standard Model expectation is found. Exclusion limits at 95% C.L. are set on the gluino or squark mass, assuming that the squark (other intermediate or pair-produced) decays to intermediate wino-like $\tilde{\chi}_1^\pm$ or $\tilde{\chi}_2^0$, which, in turn, decays to the $\tilde{\chi}_1^0$ LSP via staus or tau sneutrinos, as in model Tglu1F for gluinos (and similar for squarks). See their Figs. 13 and 14.

[2] AAD 24Z searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with exactly two same-sign leptons or at least three leptons. Several signal regions, including a $\not{E}_T$ selection targeting RPC models, and selections based on b-jet multiplicities, targeting RPV models, are considered. No significant excess over the Standard Model expectation is found. Exclusion limits at 95% C.L. are set on the gluino or squark mass, in multi-step RPC decays via charginos, neutralinos or sleptons into quarks, leptons and neutralinos, or RPV decays of either the neutralino LSP or the stop produced in $\tilde{g} \to t\bar{t}$ into quarks. See their Fig. 7.

[3] HAYRAPETYAN 24M searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of wino- and Higgsino-like charginos in final states with one or more disappearing tracks from the decay $\tilde{\chi}_1^\pm \to \pi^\pm\tilde{\chi}_1^0$ where the soft pion is not reconstructed, $\not{E}_T$, and varying numbers of jets, b-tagged jets, electrons, and muons. No significant excess above the Standard Model expectations is observed. Limits are set on the $\tilde{b}$ mass in the model Tbot1LL for various proper decay lengths $c\tau$ of the $\tilde{\chi}_1^\pm$ as well as on the $\tilde{t}$ mass in the model Tstop1LL, see their Fig. 10. Limits are also set in the model Tglu1LL, see their Fig. 11. In addition, limits are set in specific pure wino as well as pure higgsino dark matter models, in which the relationships among the electroweakino masses, the $\tilde{\chi}_1^\pm$ lifetime, and the $\tilde{\chi}_1^\pm$ decay width are constrained by radiative corrections that account for a large difference between the LSP mass and the SUSY-breaking scale, see their Fig. 12.

[4] HAYRAPETYAN 24P searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of gluino pair production in events with long-lived particles with mean proper decay lengths between 0.1 and 1000 mm, whose decay products produce a final state with at least one displaced vertex and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the $\tilde{g}$ mass in a model for split SUSY, shown in Fig. 8, where the SUSY breaking scale is assumed to be $\gg 10^6$ TeV, and all scalar masses are set to that scale, except for a single, fine-tuned, Higgs boson mass. The decay is as in the model Tglu1A, but the $\tilde{g}$ is long-lived because of its decay through a high-mass, virtual squark. Limits are also set in a GMSB model, where the pair-produced $\tilde{g}$ decays to a gluon and a nearly massless gravitino $\tilde{G}$, see their Fig. 9.

[5] HAYRAPETYAN 24Q searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of stealth supersymmetry in final states with two photons and jets, and low $\not{E}_T$. No significant excess above the Standard Model expectations is observed. The investigated models include a singlet scalar boson S, and its SUSY fermion $\tilde{S}$. In the investigated models, either gluinos or squarks are pair produced and then each decay to a $\tilde{\chi}_1^0$ and a gluon or squark, respectively, followed by the decays $\tilde{\chi}_1^0 \to \gamma\tilde{S}$, $\tilde{S} \to \tilde{G}S$ and $S \to gg$. Limits are set on the $\tilde{g}$ and the $\tilde{q}$ mass, see their Fig. 4.

[6] AAD 23AB searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for an excess of events with one photon, jets and $\not{E}_T$. No significant excess above the Standard Model predictions is observed. Limits are set on the mass of pair produced gluinos decaying to $\tilde{g} \to q q\tilde{\chi}_1^0$ followed by $\tilde{\chi}_1^0 \to \gamma\tilde{G}$ or $\tilde{\chi}_1^0 \to X\tilde{G}$ with equal probability, see Figure 4. X can be Z (left figure) or h (right figure).

[7] AAD 23AE searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 2 ℓ with same flavour and opposite sign, plus jets and $\not{E}_T$, defining signal region with the dilepton invariant mass both on- and off-shell with respect to the Z boson. No significant excess above the Standard Model predictions is observed. Limits are set on models of strong and electroweak production. In this case, limits are placed on the mass of pair-produced gluinos, assuming a scenario like in Tglu1G, see figure 16.

[8] AAD 23AE searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 2 ℓ with same flavour and opposite sign, plus jets and $\not{E}_T$, defining signal region with the dilepton invariant mass both on- and off-shell with respect to the Z boson. No significant excess above the Standard Model predictions is observed. Limits are set on models of strong and electroweak production. In this case, limits are placed on the gluino mass assuming gluino pair production, assuming a scenario like in Tglu1H, see figure 16.

[9] AAD 23AL searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 0 or 1 lepton and at least three b-tagged jets. No significant excess above the Standard Model prediction is observed. Results are interpreted in terms of gluino pair production followed by the decay of gluinos into off-shell third generation squarks, yielding final states with top and bottom quarks, and missing transverse momentum from a $\tilde{\chi}_1^0$ LSP. Limits are set on the mass of the gluino as a function of the $\tilde{\chi}_1^0$ assuming B($\tilde{g} \to \bar{t}t$) = 100% or B($\tilde{g} \to \bar{b}b$) = 100%, see figure 10.

[10] AAD 23AL searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 0 or 1 lepton and at least three b-tagged jets. No significant excess above the Standard Model prediction is observed. Results are interpreted in terms of gluino pair production followed by the decay of gluinos into off-shell third generation squarks, yielding final states with top and bottom quarks, and missing transverse momentum from a $\tilde{\chi}_1^0$ LSP. Limits are set on the mass of the gluino as a function of $m_{\tilde{\chi}_1^0}$, assuming B($\tilde{g} \to \bar{t}t$) + B($\tilde{g} \to \bar{b}b$) + B($\tilde{g} \to t b\tilde{\chi}_1^\pm$) = 100%, and $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 2$ GeV, see figures 11–13.

[11] HAYRAPETYAN 23E searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of gluino, top squark and electroweakino pair production in events with at least one photon, multiple jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set in models for strong production, Tglu4D, Tglu4E, Tglu4F and Tstop13, see their figure 9. They also interpret the results in the models for electroweak production, shown in their figure 10. Tchi1n1A assumes wino-like $\tilde{\chi}_1^\pm\tilde{\chi}_1^0$ production, while Tchi1chi1A assumes higgsino-like cross sections and includes $\tilde{\chi}_1^\pm\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^0\tilde{\chi}_2^0$ and $\tilde{\chi}_{1,2}^0\tilde{\chi}_1^\pm$ production. For $\tilde{\chi}_1^0\tilde{\chi}_2^0$ alone no mass point can be excluded in the model Tchi1chi1A, but in another model for $\tilde{\chi}_1^0\tilde{\chi}_2^0$ production, Tn1n2A.

[12] TUMASYAN 23AY searched in 138 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of gluino pair production in events with a single electron or muon and multiple hadronic jets. No significant excess above the Standard Model expectations is observed. Limits are set in the models Tglu3A and Tglu1B, see their figure 11. For Tglu1B, the chargino mass is set to $m_{\tilde{\chi}_1^\pm} = 0.5\ (m_{\tilde{g}} + m_{\tilde{\chi}_1^0})$.

[13] AAD 22U searched for the signature of disappearing track from a long-lived chargino in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV. Long-lived charginos decay into quasi-degenerate neutralino emitting a low-momentum particle whose identification is not attempted. The signal is identified by requiring short tracklets in the four pixel layers with no continuation in the SCT (strip) detector. The main background from fake tracklets is estimated directly with the data. No significant excess above the background prediction is found. The results are interpreted in an AMSB scenario (win LSP), on $pp \to \tilde{\chi}^\pm\tilde{\chi}^\pm$ and $pp \to \tilde{\chi}^\pm\tilde{\chi}_1^0$, assuming B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0\pi^\pm$) = 100%, see their figure 7. Results are also interpreted in a higgsino-LSP model, with $pp \to \tilde{\chi}^\pm\tilde{\chi}^\mp$, and $pp \to \tilde{\chi}^\pm\tilde{\chi}_{1,2}^0$, assuming B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0\pi^\pm$) = 95.5%, B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0 e^\pm$) = 3%, B($\tilde{\chi}^\pm \to \tilde{\chi}_1^0\mu^\pm$) = 1.5%, see their figure 8. Finally, results are interpreted in a simplified model of gluino pair production, with $pp \to \tilde{g}\tilde{g}$ and B($\tilde{g} \to q q\tilde{\chi}_1^0$) = B($\tilde{g} \to q q\tilde{\chi}^+$) = B($\tilde{g} \to q q\tilde{\chi}^-$) = 1/3, see their figure 9.

[14] TUMASYAN 22V searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of electroweakino pair production with decay to two Higgs bosons H, with $H \to b\bar{b}$, resulting either in 4 resolved b-jets or two large-radius jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ in the models Tn1n1A, see their Figures 11 and 12, or in a model where higgsino-like nearly mass degenerate $\tilde{\chi}_2^0$ and $\tilde{\chi}_3^0$ are pair produced and each decay to H and a bino-like $\tilde{\chi}_1^0$, see their Figure 13. Limits are also set on the gluino mass in the model Tglu1l, see their Figure 14.

[15] AAD 21AK searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of gluinos and squarks in events with a single isolated electron or muon, originating from the decay of a W boson, multiple jets and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1B simplified model and on the squark mass in the Tsqk3 simplified model, see their Figure 8.

[16] AAD 21L searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of gluinos and squarks in events with jets, large missing transverse momentum but no electrons or muons. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A and Tglu1B simplified models, on the squark mass in the Tsqk1 and Tsqk3 simplified models and in a simplified model for gluino-squark production, see their Figures 13-17.

[17] AAD 21X searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for the decay of long-lived R-hadrons stopped by the calorimeter, producing high-momentum jets resulting in large out-of-time energy deposits in the calorimeters. These decays are detected using data collected during periods in the LHC bunch structure when collisions are absent. No significant excess above the predicted background is observed. Limits are set on the R-hadron mass in the Tglu1A simplified model ad a function of the R-hadron lifetime, for different $m_{\tilde{\chi}_1^0}$. See Figures 9, 10.

[18] SIRUNYAN 21AD searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for supersymmetry in events with multiple jets, no leptons, and large $\not{E}_T$. No significant excess above the simplified models Tstop1, Tstop2 with $m_{\tilde{\chi}_1^\pm} = (m_{\tilde{t}} + m_{\tilde{\chi}_1^0})/2$, and a 50:50 mixture of these with $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 5$ GeV, see their Figure 8. Limits are also set on the top squark mass for 10 GeV $< m_{\tilde{t}} - m_{\tilde{\chi}_1^\pm} < 80$ GeV in the simplified models Tstop2, Tstop 3, and Tstop4, see their Figure 9. For indirect top squark production, limits are set on the gluino mass in the simplified models Tglu3A, Tglu3C with $m_{\tilde{t}} - m_{\tilde{\chi}_1^0} = 20$ GeV, and Tglu3D with $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 5$ GeV, see their Figure 10.

[19] SIRUNYAN 21M searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for supersymmetry in events with two opposite-sign same-flavor leptons (electrons, muons) and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu4C, see their Figure 10, on the $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ mass in Tchi1n2Fa, see their Figure 11, on the $\tilde{\chi}_1^0$ mass in Tn1n1C and Tn1n1B for $m_{\tilde{\chi}_2^0} = m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_1^0}$, see their Figure 12. Limits are also set on the light squark mass for the simplified model Tsqk2A, on the sbottom mass in Tsbot3, see their Figure 13, and on the slepton mass in direct electroweak pair production of mass-degenerate left- and right-handed sleptons (selectrons and smuons), see their Figure 14.

[20] AAD 20AL searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 8 or more jets and moderate missing transverse momentum. The selection makes requirements

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

according to the number of b-tagged jets and the scalar sum of masses of large-radius jets. No significant excess above the Standard Model expectations is observed. Limits up to about 2 TeV are set on the gluino mass in Tglu1E simplified model. Limits up to about 1.8 TeV are set on the gluino mass in Tglu3A simplified model. See their Fig. 10(a).

[21] AAD 20V searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in final states with same-sign charged leptons (electrons or muons) and jets. No significant excess over the Standard Model expectation is observed. In the Tglu1E model, considering off-shell intermediate W and Z bosons in the decay chains, gluino masses are excluded at 95% C.L. up to 1600 GeV for neutralino masses of 100 GeV or above (up to 1000 GeV). See their Fig. 7(a).

[22] SIRUNYAN 20B searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one photon and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on chargino masses in a general gauge-mediated SUSY breaking (GGM) scenario Tchi1n12-GGM, see Figure 4. Limits are also set on the NLSP mass in the Tchi1chi1F and Tchi1chi1G simplified models, see their Figure 5. Finally, limits are set on the gluino mass in the Tglu4A simplified model, see Figure 6.

[23] SIRUNYAN 20BJ searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing two hadronically decaying, highly energetic Z bosons and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1H simplified model, see their Figure 9.

[24] SIRUNYAN 20E searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with a single electron or muon and multiple jets, including at least one identified as originating from a b-quark, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A simplified model, see their Fig. 10, and the Tglu3C simplified model, see their Fig. 11.

[25] SIRUNYAN 20T searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least two jets, and two isolated same-sign or three or more charged leptons (electrons or muons). No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A, Tglu3B, Tglu3C and Tglu3D simplified models, see their Figure 7, and in the Tglu1C and Tglu1B simplified models, see their Figures 8 and 9. Limits are also set on the sbottom mass in the Tsbot2 simplified model, see their Figure 10, and on the stop mass in the Tstop7 simplified model, see their Figure 11. Finally, limits are set on the gluino mass in RPV simplified models where the gluino decays either via $\tilde{g} \to q\bar{q}\bar{q} + e/\mu/\tau$ or via $\tilde{g} \to tbs$, see Figure 12.

[26] AABOUD 19I searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in final states with hadronic jets, 1 or two hadronically decaying τ and $\not{E}_T$. In Tglu1F, gluino masses are excluded at 95% C.L. up to 2000 GeV for neutralino masses of 100 GeV or below. Neutralino masses up to 1000 GeV are excluded for all gluino masses below 1400 GeV. See their Fig. 9. Limits are also presented in the context of Gauge-Mediated Symmetry Breaking models: in this case, values of Λ below 110 TeV are excluded at the 95% CL for all values of $\tan\beta$ in the range $2 < \tan\beta < 60$, see their Fig 10.

[27] SIRUNYAN 19AG searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two photons and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu4B simplified model and on the squark mass in the Tsqk4B simplified model, see their Figure 3.

[28] SIRUNYAN 19AU searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at last one photon, jets, some of which are identified as originating from b-quarks, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. In the framework of GMSB, limits are set on the gluino mass in the Tglu4C, Tglu4D and Tglu4E simplified models, and on the top squark mass in the Tstop13 simplified model, see their Figure 5.

[29] SIRUNYAN 19CE searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for new particles decaying to a photon and two gluons in events with at least three large-radius jets of which two have substructure and are composed of a photon and two gluons. No statistically significant excess is observed above the SM background expectation. Upper limits at 95% confidence level on the cross section for gluino pair production are set, using a simplified Tglu1A-like stealth SUSY model. Gluino masses up to 1500–1700 GeV are excluded, depending on the neutralino mass, with the highest exclusion set for $m_{\tilde{\chi}_1^0} = 200$ GeV. See their Fig 4.

[30] SIRUNYAN 19CH searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing multiple jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu1C, Tglu2A and Tglu3A simplified models, see their Figure 13. Limits are also set on squark, sbottom and stop masses in the Tsqk1, Tsbot1, Tstop1 simplified models, see their Figure 14.

[31] SIRUNYAN 19K searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with a photon, an electron or muon, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. In the framework of GMSB, limits are set on the chargino and neutralino mass in the Tchi1n1A simplified model, see their Figure 6. Limits are also set on the gluino mass in the Tglu4A simplified model, and on the squark mass in the Tsqk4A simplified model, see their Figure 7.

[32] SIRUNYAN 19S searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with zero or one charged leptons, jets and $\not{E}_T$. The razor variables (M_R and R^2) are used to categorize the events. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A and Tglu3C simplified models, see Figures 22 and 23, and on the stop mass in the Tstop1 simplified model, see their Figure 24.

[33] AABOUD 18AR searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for gluino pair production in events containing large missing transverse momentum and several energetic jets, at least three of which must be identified as originating from b-quarks. No excess is found above the predicted background. In Tglu3A models, gluino masses of less than 1.97 TeV are excluded for $m_{\tilde{\chi}_1^0}$ below 300 GeV, see their Fig. 10(a). Interpretations are also provided for scenarios where Tglu3A modes mix with Tglu2A and Tglu3D, see their Fig 11.

[34] AABOUD 18AR searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for gluino pair production in events containing large missing transverse momentum and several energetic jets, at least three of which must be identified as originating from b-quarks. No excess is found above the predicted background. In Tglu2A models, gluino masses of less than 1.92 TeV are excluded for $m_{\tilde{\chi}_1^0}$ below 600 GeV, see their Fig. 10(b). Interpretations are also provided for scenarios where Tglu2A modes mix with Tglu3A and Tglu3D, see their Fig 11.

[35] AABOUD 18AS searched for in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for gluino pair production in the context of AMSB or phenomenological MSSM scenarios with wino-like LSP and long-lived charginos. Events with a disappearing track due to a low-momentum pion accompanied by at least four jets are considered. No significant excess above the Standard Model expectations is observed. Exclusion limits are set at 95% confidence level on the mass of gluinos for different chargino lifetimes. Gluino masses up to 1.65 TeV are excluded assuming a chargino mass of 460 GeV and lifetime of 0.2 ns, corresponding to a mass-splitting between the charged and neutral wino of around 160 MeV. See their Fig. 9.

[36] AABOUD 18BJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with two opposite-sign charged leptons (electrons and muons), jets and missing transverse momentum, with various requirements to be sensitive to signals with different kinematic endpoint values in the dilepton invariant mass distribution. The data are found to be consistent with the SM expectation. Results are interpreted in the Tglu1G model: gluino masses below 1850 GeV are excluded for $m_{\tilde{\chi}_1^0} = 100$ GeV, see their Fig. 12(a).

[37] AABOUD 18BJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with two opposite-sign charged leptons (electrons and muons), jets and missing transverse momentum, with various requirements to be sensitive to signals with different kinematic endpoint values in the dilepton invariant mass distribution. The data are found to be consistent with the SM expectation. Results are interpreted in the Tglu1H model: gluino masses below 1650 GeV are excluded for $m_{\tilde{\chi}_1^0} = 100$ GeV, see their Fig. 13(a).

[38] AABOUD 18U searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with at least one isolated photon, possibly jets and significant transverse momentum targeting generalised models of gauge-mediated SUSY breaking. No significant excess of events is observed above the SM prediction. Results for the di-photon channel are interpreted in terms of lower limits on the masses of gluinos in Tglu4B models, which reach as high as 2.3 TeV. Gluinos with masses below 2.15 TeV are excluded for any NLSP mass, see their Fig. 8.

[39] AABOUD 18U searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with at least one isolated photon, possibly jets and significant transverse momentum targeting generalised models of gauge-mediated SUSY breaking. No significant excess of events is observed above the SM prediction. Results of the γ + jets + $\not{E}_T$ channel are interpreted in terms of lower limits on the masses of gluinos in GGM higgsino-bino models (mix of Tglu4B and Tglu4C), which reach as high as 2050 GeV. Gluino masses below 1600 GeV are excluded for any NLSP mass provided that $m_{\tilde{g}} - m_{\tilde{\chi}_1^0} > 50$ GeV. See their Fig. 11.

[40] AABOUD 18V searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with no charged leptons, jets and missing transverse momentum. The data are found to be consistent with the SM expectation. Results are interpreted in the Tglu1A model: gluino masses below 2030 GeV are excluded for massless LSP, see their Fig. 13(b).

[41] AABOUD 18V searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with no charged leptons, jets and missing transverse momentum. The data are found to be consistent with the SM expectation. Results are interpreted in the Tglu1B model. Assuming that $m_{\tilde{\chi}_1^\pm} = 0.5\ (m_{\tilde{g}} + m_{\tilde{\chi}_1^0})$, gluino masses below 1980 GeV are excluded for massless LSP, see their Fig. 14(c). Exclusions are also shown assuming $m_{\tilde{\chi}_1^0} = 60$ GeV, see their Fig. 14(d).

[42] AABOUD 18V searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with no charged leptons, jets and missing transverse momentum. The data are found to be consistent with the SM expectation. Results are interpreted in the Tglu1E model: gluino masses below 1750 GeV are excluded for $m_{\tilde{\chi}_1^0} = 1$ GeV and any $m_{\tilde{\chi}_2^0}$ above 100 GeV, see their Fig. 15. Gluino mass exclusion up to 2 TeV is found for $m_{\tilde{\chi}_2^0} = 1$ TeV.

[43] SIRUNYAN 18AA searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one photon and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on wino masses in a general gauge-mediated SUSY breaking (GGM) scenario with bino-like $\tilde{\chi}_1^0$ and wino-like $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$, see Figure 7. Limits are also set on the NLSP mass in the Tchi1n1A and Tchi1chi1A simplified models, see their Figure 8. Finally, limits are set on the gluino mass in the Tglu4A and Tglu4B simplified models, see their Figure 9, and on the squark mass in the Tskq4A and Tsqk4B simplified models, see their Figure 10.

[44] SIRUNYAN 18AC searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with a single electron or muon and multiple jets. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A and Tglu1B simplified models, see their Figure 5.

[45] SIRUNYAN 18AL searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least three charged leptons, in any combination of electrons and muons, jets and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A and Tglu1C simplified models, see their Figure 5. Limits are also set on the sbottom mass in the Tsbot2 simplified model, see their Figure 6, and on the stop mass in the Tstop7 simplified model, see their Figure 7.

[46] SIRUNYAN 18AR searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing two opposite-charge, same-flavour leptons (electrons or muons), jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu4C simplified model, see their Figure 7. Limits are also set on the chargino/neutralino mass in the Tchi1n2F simplified models, see their Figure 8, and on the higgsino mass in the Tn1n1B and Tn1n1C simplified models, see their Figure 9. Finally, limits are set on the sbottom mass in the Tsbot3 simplified model, see their Figure 10.

[47] SIRUNYAN 18AY searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing one or more jets and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A and Tglu3A simplified models, see their Figure 3. Limits are also set on squark, sbottom and stop masses in the Tsqk1, Tsbot1, Tstop1 and Tstop4 simplified models, see their Figure 3. Finally, limits are set on long-lived gluino masses in a Tglu1A simplified model where the gluino is metastable or long-lived with proper decay lengths in the range 10^{-3} mm $< c\tau < 10^5$ mm, see their Figure 4.

[48] SIRUNYAN 18D searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing identified hadronically decaying top quarks, no leptons, and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1 simplified model, see their Figure 8, and on the gluino mass in the Tglu3A, Tglu3B, Tglu3C and Tglu3E simplified models, see their Figure 9.

[49] SIRUNYAN 18M searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more high-momentum Higgs bosons, decaying to pairs of b-quarks, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1I and Tglu1J simplified models, see their Figure 3.

[50] AABOUD 17AJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign or three leptons, jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 1.75 TeV are

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

set on the gluino mass in Tglu3A simplified models in case of off-shell top squarks and for $m_{\widetilde{\chi}_1^0} = 100$ GeV. See their Figure 4(a).

[51] AABOUD 17AJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign or three leptons, jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 1.57 TeV are set on the gluino mass in Tglu1E simplified models (2-step models) for $m_{\widetilde{\chi}_1^0} = 100$ GeV. See their Figure 4(b).

[52] AABOUD 17AJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign or three leptons, jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 1.86 TeV are set on the gluino mass in Tglu1G simplified models for $m_{\widetilde{\chi}_1^0} = 200$ GeV. See their Figure 4(c).

[53] AABOUD 17AR searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one isolated lepton, at least two jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 2.1 TeV are set on the gluino mass in Tglu1B simplified models, with $x = (m_{\widetilde{\chi}_1^\pm} - m_{\widetilde{\chi}_1^0}) / (m_{\widetilde{g}} - m_{\widetilde{\chi}_1^0}) = 1/2$.Similar limits are obtained for variable x and fixed neutralino mass, $m_{\widetilde{\chi}_1^0} = 60$ GeV. See their Figure 13.

[54] AABOUD 17AR searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one isolated lepton, at least two jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 1.74 TeV are set on the gluino mass in Tglu1E simplified model. Limits up to 1.7 TeV are also set on pMSSM models leading to similar signal event topologies. See their Figure 13.

[55] AABOUD 17AY searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least four jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 1.8 TeV are set on the gluino mass in Tglu3A simplified models assuming $m_{\widetilde{t}_1} - m_{\widetilde{\chi}_1^0} = 5$ GeV. See their Figure 13.

[56] AABOUD 17AZ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least seven jets and large missing transverse momentum. Selected events are further classified based on the presence of large R-jets or b-jets and no leptons. No significant excess above the Standard Model expectations is observed. Limits up to 1.8 TeV are set on the gluino mass in Tglu1E simplified models. See their Figure 6b.

[57] AABOUD 17AZ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least seven jets and large missing transverse momentum. Selected events are further classified based on the presence of large R-jets or b-jets and no leptons. No significant excess above the Standard Model expectations is observed. Limits up to 1.54 TeV are set on the gluino mass in Tglu3A simplified models. See their Figure 7a.

[58] AABOUD 17N searched in 14.7 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in final states with 2 same-flavor, opposite-sign leptons (electrons or muons), jets and large missing transverse momentum. In Tglu1J models, gluino masses are excluded at 95% C.L. up to 1300 GeV for $m_{\widetilde{\chi}_1^0} = 0$ GeV and $m_{\widetilde{\chi}_2^0} = 1100$ GeV. See their Fig. 12 for exclusion limits as a function of $m_{\widetilde{\chi}_2^0}$. Limits are also presented assuming $m_{\widetilde{\chi}_2^0} = m_{\widetilde{\chi}_1^0} + 100$ GeV, see their Fig. 13.

[59] AABOUD 17N searched in 14.7 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in final states with 2 same-flavor, opposite-sign leptons (electrons or muons), jets and large missing transverse momentum. In Tglu1H models, gluino masses are excluded at 95% C.L. up to 1310 GeV for $m_{\widetilde{\chi}_1^0} < 400$ GeV and assuming $m_{\widetilde{\chi}_2^0} = (m_{\widetilde{g}} + m_{\widetilde{\chi}_1^0})/2$. See their Fig. 15.

[60] AABOUD 17N searched in 14.7 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in final states with 2 same-flavor, opposite-sign leptons (electrons or muons), jets and large missing transverse momentum. In Tglu1G models, gluino masses are excluded at 95% C.L. up to 1700 GeV for small $m_{\widetilde{\chi}_1^0}$. The results probe kinematic endpoints as small as $m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0} = (m_{\widetilde{g}} - m_{\widetilde{\chi}_1^0})/2 = 50$ GeV. See their Fig. 14.

[61] KHACHATRYAN 17 searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing four or more jets, no more than one lepton, and missing transverse momentum, using the razor variables (M_R and R^2) to discriminate between signal and background processes. No evidence for an excess over the expected background is observed. Limits are derived on the gluino mass in the Tglu1A, Tglu2A and Tglu3A simplified models, see Figs. 16 and 17. Also, assuming gluinos decay only via three-body processes involving third-generation quarks plus a neutralino/chargino, and assuming $m_{\widetilde{\chi}_1^\pm} = m_{\widetilde{\chi}_1^0} + 5$ GeV, a branching ratio-independent limit on the gluino mass is given, see Fig. 16.

[62] KHACHATRYAN 17AD searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing at least four jets (including b-jets), missing transverse momentum and tagged top quarks. No evidence for an excess over the expected background is observed. Gluino masses up to 1550 GeV and neutralino masses up to 900 GeV are excluded at 95% C.L. See Fig. 13.

[63] KHACHATRYAN 17AD searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing at least four jets (including b-jets), missing transverse momentum and tagged top quarks. No evidence for an excess over the expected background is observed. Gluino masses up to 1450 GeV and neutralino masses up to 820 GeV are excluded at 95% C.L. See Fig. 13.

[64] KHACHATRYAN 17AS searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with a single electron or muon and multiple jets. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A and Tglu1B simplified models, see their Fig. 7.

[65] KHACHATRYAN 17AW searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least three charged leptons, in any combination of electrons and muons, and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A and Tglu1C simplified models, and on the sbottom mass in the Tsbot2 simplified model, see their Figure 4.

[66] KHACHATRYAN 17P searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A, Tglu3A, Tglu3B, Tglu3C and Tglu3D simplified models, see their Figures 7 and 8. Limits are also set on the squark mass in the Tsqk1 simplified model, see their Fig. 7, and on the sbottom mass in the Tsbot1 simplified model, see Fig. 8. Finally, limits are set on the stop mass in the Tstop1, Tstop3, Tstop4, Tstop6 and Tstop7 simplified models, see Fig. 8.

[67] KHACHATRYAN 17V searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two photons and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino and squark mass in the context of general gauge mediation models Tglu4B and Tsqk4, see their Fig. 4.

[68] SIRUNYAN 17AF searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with a single lepton (electron or muon), jets, including at least one jet originating from a b-quark, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A and Tglu3B simplified models, see their Figure 2.

[69] SIRUNYAN 17AY searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one photon, jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu4A and Tglu4B simplified models, and on the squark mass in the Tskq4A and Tsqk4B simplified models, see their Figure 6.

[70] SIRUNYAN 17AZ searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A, Tglu3A simplified models, see their Figures 6. Limits are also set on the squark mass in the Tsqk1 simplified model (for single light squark and for 8 degenerate light squarks), on the sbottom mass in the Tsbot1 simplified model and on the stop mass in the Tstop1 simplified model, see their Fig. 7. Finally, limits are set on the stop mass in the Tstop2, Tstop4 and Tstop8 simplified models, see Fig. 8.

[71] SIRUNYAN 17P searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with multiple jets and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu1C, Tglu2A, Tglu3A and Tglu3D simplified models, see their Fig. 12. Limits are also set on the squark mass in the Tsqk1 simplified model, on the stop mass in the Tstop1 simplified model, and on the sbottom mass in the Tsbot1 simplified model, see Fig. 13.

[72] SIRUNYAN 17S searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two isolated same-sign leptons, jets, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the mass of the gluino mass in the Tglu3A, Tglu3B, Tglu3C, Tglu3D and Tglu1B simplified models, see their Figures 5 and 6, and on the sbottom mass in the Tsbot2 simplified model, see their Figure 6.

[73] AABOUD 16AC searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in final states with hadronic jets, 1 or two hadronically decaying τ and $\not{E}_T$. In Tglu1F, gluino masses are excluded at 95% C.L. up to 1570 GeV for neutralino masses of 100 GeV or below. Neutralino masses up to 700 GeV are excluded for all gluino masses between 800 GeV and 1500 GeV, while the strongest neutralino-mass exclusion of 750 GeV is achieved for gluino masses around 1400 GeV. See their Fig. 8. Limits are also presented in the context of Gauge-Mediated Symmetry Breaking models: in this case, values of Λ below 92 TeV are excluded at the 95% CL, corresponding to gluino masses below 2000 GeV. See their Fig. 9.

[74] AABOUD 16J searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in final states with one isolated electron or muon, hadronic jets, and $\not{E}_T$. Gluino-mediated pair production of stops with a nearly mass-degenerate stop and neutralino are targeted and gluino masses are excluded at 95% C.L. up to 1460 GeV. A 100% of stops decaying via charm + neutralino is assumed. The results are also valid in case of 4-body decays $\widetilde{t}_1 \to f f' b \widetilde{\chi}_1^0$. See their Fig. 8.

[75] AABOUD 16M searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two photons, hadronic jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Exclusion limits at 95% C.L. are set on gluino masses in the general gauge-mediated SUSY breaking model (GGM), for bino-like NLSP. See their Fig. 3.

[76] AABOUD 16N searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing hadronic jets, large $\not{E}_T$, and no electrons or muons. No significant excess above the Standard Model expectations is observed. Gluino masses below 1510 GeV are excluded at the 95% C.L. in a simplified model with only gluinos and the lightest neutralino. See their Fig. 7b.

[77] AABOUD 16N searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing hadronic jets, large $\not{E}_T$, and no electrons or muons. No significant excess above the Standard Model expectations is observed. Gluino masses below 1500 GeV are excluded at the 95% C.L. in a simplified model with gluinos decaying via an intermediate $\widetilde{\chi}_1^\pm$ to two quarks, a W boson and a $\widetilde{\chi}_1^0$, for $m_{\widetilde{\chi}_1^0} = 200$ GeV. See their Fig 8.

[78] AAD 16AD searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing several energetic jets, of which at least three must be identified as b-jets, large $\not{E}_T$ and no electrons or muons. No significant excess above the Standard Model expectations is observed. For $\widetilde{\chi}_1^0$ below 800 GeV, gluino masses below 1780 GeV are excluded at 95% C.L. for gluinos decaying via bottom squarks. See their Fig. 7a.

[79] AAD 16AD searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing several energetic jets, of which at least three must be identified as b-jets, large $\not{E}_T$ and one electron or muon. Large-radius jets with a high mass are also used to identify highly boosted top quarks. No significant excess above the Standard Model expectations is observed. For $\widetilde{\chi}_1^0$ below 700 GeV, gluino masses below 1760 GeV are excluded at 95% C.L. for gluinos decaying via top squarks. See their Fig. 7b.

[80] AAD 16BB searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with exactly two same-sign leptons or at least three leptons, multiple hadronic jets, b-jets, and $\not{E}_T$. No significant excess over the Standard Model expectation is found. Exclusion limits at 95% C.L. are set on the gluino mass in various simplified models (Tglu1D, Tglu1E, Tglu3A). See their Figs. 4.a, 4.b, and 4.d.

[81] AAD 16BG searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in final states with one isolated electron or muon, hadronic jets, and $\not{E}_T$. The data agree with the SM background expectation in the six signal selections defined in the search, and the largest deviation is a 2.1 standard deviation excess. Gluinos are excluded at 95% C.L. up to 1600 GeV assuming they decay via the lightest chargino to the lightest neutralino as in the model Tglu1B for $m_{\widetilde{\chi}_1^0}$=100 GeV, assuming $m_{\widetilde{\chi}_1^\pm} = (m_{\widetilde{g}} + m_{\widetilde{\chi}_1^0})/2$. See their Fig. 6.

[82] AAD 16V searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with $\not{E}_T$ various hadronic jet multiplicities from ≥ 7 to ≥ 10 and with various b-jet multiplicity requirements. No significant excess over the Standard Model expectation is found. Exclusion limits at 95% C.L. are set on the gluino mass in one simplified model (Tglu1E) and a pMSSM-inspired model. See their Fig. 5.

[83] KHACHATRYAN 16AM searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with highly boosted W-bosons and b-jets, using the razor variables (M_R and R^2) to discriminate between signal and background processes. No significant excess above the

by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3C and Tglu3B simplified models, see Fig. 12.

[84] KHACHATRYAN 16BJ searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the following simplified models: Tglu3A and Tglu3D, see Fig. 4, Tglu3B and Tglu3C, see Fig. 5, and Tglu1B, see Fig. 7.

[85] KHACHATRYAN 16BS searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least one energetic jet , no isolated leptons, and significant $\not{E}_T$, using the transverse mass variable M_{T2} to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A and Tglu3A simplified models, see Fig. 10 and Table 3.

[86] KHACHATRYAN 16BY searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two opposite-sign, same-flavour leptons, jets, and missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu4C simplified model, see Fig. 4, and on sbottom masses in the Tsbot3 simplified model, see Fig. 5.

[87] KHACHATRYAN 16V searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least four energetic jets and significant $\not{E}_T$, no identified isolated electron or muon or charged track. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu1C, Tglu2A, and Tglu3A simplified models, see Fig. 8.

[88] AAD 15BG searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with jets, missing E_T, and two opposite-sign same flavor isolated leptons featuring either a kinematic edge, or a peak at the Z-boson mass, in the invariant mass spectrum. No evidence for a statistically significant excess over the expected SM backgrounds are observed and 95% C.L. exclusion limits are derived in a GGM simplified model of gluino pair production where the gluino decays into quarks, a Z-boson, and a massless gravitino LSP, see Fig. 12. Also, limits are set in simplified models with slepton /sneutrino intermediate states, see Fig. 13.

[89] AAD 15BV summarized and extended ATLAS searches for gluinos and first- and second-generation squarks in final states containing jets and missing transverse momentum, with or without leptons or b-jets in the $\sqrt{s}$ =8 TeV data set collected in 2012. The paper reports the results of new interpretations and statistical combinations of previously published analyses, as well as new analyses. Exclusion limits at 95% C.L. are set on the gluino mass in several R-parity conserving models, leading to a generalized constraint on gluino masses exceeding 1150 GeV for lightest supersymmetric particle masses below 100 GeV. See their Figs. 10, 19, 20, 21, 23, 25, 26, 29-37.

[90] AAD 15BX interpreted the results of a wide range of ATLAS direct searches for supersymmetry, during the first run of the LHC using the $\sqrt{s}$ =7 TeV and $\sqrt{s}$ = 8 TeV data set collected in 2012, within the wider framework of the phenomenological MSSM (pMSSM). The integrated luminosity was up to 20.3 fb^{-1}. From an initial random sampling of 500 million pMSSM points, generated from the 19-parameter pMSSM, a total of 310,327 model points with $\tilde{\chi}_1^0$ LSP were selected each of which satisfies constraints from previous collider searches, precision measurements, cold dark matter energy density measurements and direct dark matter searches. The impact of the ATLAS Run 1 searches on this space was presented, considering the fraction of model points surviving, after projection into two-dimensional spaces of sparticle masses. Good complementarity is observed between different ATLAS analyses, with almost all showing regions of unique sensitivity. ATLAS searches have good sensitivity at LSP mass below 800 GeV.

[91] AAD 15CA searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with one or more photons, hadronic jets or b-jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on gluino masses in the general gauge-mediated SUSY breaking model (GGM), for bino-like or higgsino-bino admixtures NLSP, see Fig. 8, 10, 11

[92] KHACHATRYAN 15AF searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least two energetic jets and significant $\not{E}_T$, using the transverse mass variable M_{T2} to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay $\tilde{g} \to q\overline{q}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 13(a), or where the decay $\tilde{g} \to b\overline{b}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 13(b), or where the decay $\tilde{g} \to t\overline{t}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 13(c). See also Table 5. Exclusions in the CMSSM, assuming $\tan\beta = 30$, $A_0 = -2$ max(m_0, $m_{1/2}$) and $\mu > 0$, are also presented, see Fig. 15.

[93] KHACHATRYAN 15I searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events in which b-jets and four W-bosons are produced. Five individual search channels are combined (fully hadronic, single lepton, same-sign dilepton, opposite-sign dilepton, multilepton). No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in a simplified model where the decay $\tilde{g} \to t\overline{t}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 5. Also a simplified model with gluinos decaying into on-shell top squarks is considered, see Fig. 6.

[94] KHACHATRYAN 15X searched in 19.3fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least two energetic jets, at least one of which is required to originate from a b quark, and significant $\not{E}_T$, using the razor variables (M_R) and R^2) to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay $\tilde{g} \to b\overline{b}\tilde{\chi}_1^0$ and the decay $\tilde{g} \to t\overline{t}\tilde{\chi}_1^0$ take place with branching ratios varying between 0, 50 and 100%, see Figs. 13 and 14.

[95] AAD 14AE searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for strongly produced supersymmetric particles in events containing jets and large missing transverse momentum, and no electrons or muons. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing gluinos and squarks, see Figures 5, 6 and 7. Limits are also derived in the mSUGRA/CMSSM with parameters $\tan\beta = 30$, $A_0 = -2\ m_0$ and $\mu > 0$, see their Fig. 8.

[96] AAD 14AG searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing one hadronically decaying τ-lepton, zero or one additional light leptons (electrons or muons), jets and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set in several SUSY scenarios. For an interpretation in the minimal GMSB model, see their Fig. 8. For an interpretation in the mSUGRA/CMSSM with parameters $\tan\beta = 30$, $A_0 = -2\ m_0$ and $\mu > 0$, see their Fig. 9. For an interpretation in the framework of natural Gauge Mediation, see Fig. 10. For an interpretation in the bRPV scenario, see their Fig. 11.

[97] AAD 14X searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in a general gauge-mediation model (GGM) where the decay $\tilde{g} \to q\overline{q}\tilde{\chi}_1^0$, with $\tilde{\chi}_1^0 \to \ell^{\pm}\ell^{\mp}\tilde{G}$, takes place with a branching ratio of 100%, for two choices of $\tan\beta = 1.5$ and 30, see Fig. 11. Also some constraints on the higgsino mass parameter μ are discussed.

[98] CHATRCHYAN 14AH searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with at least two energetic jets and significant $\not{E}_T$, using the razor variables (M_R and R^2) to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay $\tilde{g} \to q\overline{q}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 28. Exclusions in the CMSSM, assuming $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, are also presented, see Fig. 26.

[99] CHATRCHYAN 14AH searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with at least two energetic jets and significant $\not{E}_T$, using the razor variables (M_R and R^2) to discriminate between signal and background processes. A second analysis requires at least one of the jets to be originating from a b-quark. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay $\tilde{g} \to b\overline{b}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Figs. 28 and 29. Exclusions in the CMSSM, assuming $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, are also presented, see Fig. 26.

[100] CHATRCHYAN 14AH searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with at least two energetic jets and significant $\not{E}_T$, using the razor variables (M_R and R^2) to discriminate between signal and background processes. A second analysis requires at least one of the jets to be originating from a b-quark. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay $\tilde{g} \to t\overline{t}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Figs. 28 and 29. Exclusions in the CMSSM, assuming $\tan\beta = 10$, $A_0 = 0$ and $\mu > 0$, are also presented, see Fig. 26.

[101] CHATRCHYAN 14I searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing multijets and large $\not{E}_T$. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing gluinos that decay via $\tilde{g} \to q\overline{q}\tilde{\chi}_1^0$ with a 100% branching ratio, see Fig. 7b, or via $\tilde{g} \to t\overline{t}\tilde{\chi}_1^0$ with a 100% branching ratio, see Fig. 7c, or via $\tilde{g} \to q\overline{q}W/Z\tilde{\chi}_1^0$, see Fig. 7d.

[102] CHATRCHYAN 14N searched in 19.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing a single isolated electron or muon and multiple jets, at least two of which are identified as originating from a b-quark. No significant excesses over the expected SM backgrounds are observed. The results are interpreted in three simplified models of gluino pair production with subsequent decay into virtual or on-shell top squarks, where each of the top squarks decays in turn into a top quark and a $\tilde{\chi}_1^0$, see Fig. 4. The models differ in which masses are allowed to vary.

[103] CHATRCHYAN 14R searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in a slepton co-NLSP simplified model (GMSB) where the decay $\tilde{g} \to q\ell^{\pm}\ell^{\mp}\tilde{G}$ takes place with a branching ratio of 100%, see Fig. 8.

[104] CHATRCHYAN 14R searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in a simplified model where the decay $\tilde{g} \to t\overline{t}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 11.

[105] AABOUD 18BJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with two opposite-sign charged leptons (electrons and muons), jets and missing transverse momentum, with various requirements to be sensitive to signals with different kinematic endpoint values in the dilepton invariant mass distribution. The data are found to be consistent with the SM expectation. Results are interpreted in the Tglu1H model in case of $m_{\tilde{\chi}_1^0} = 1$ GeV: for any $m_{\tilde{\chi}_2^0}$, gluino masses below 1500 GeV are excluded, see their Fig. 14(a).

[106] AABOUD 18V searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV in events with no charged leptons, jets and missing transverse momentum. The data are found to be consistent with the SM expectation. Results are interpreted in a Tglu1C-like model, assuming 50% BR for each gluino decay mode. Gluino masses below 1770 GeV are excluded for any $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$ and $m_{\tilde{\chi}_1^0} = 60$ GeV, see their Fig. 16(b).

[107] AABOUD 17AZ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least seven jets and large missing transverse momentum. Selected events are further classified based on the presence of large R-jets or b-jets and no leptons. No significant excess above the Standard Model expectations is observed. Limits are set for pMSSM models with $M_1 = 60$ GeV, $\tan(\beta) = 10$, $\mu < 0$ varying the soft-breaking parameters M_3 and μ. Gluino masses up to 1600 GeV are excluded for $m_{\tilde{\chi}_1^{\pm}} = 200$ GeV. See their Figure 6a and text for details on the model.

[108] KHACHATRYAN 16AY searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one isolated high transverse momentum lepton (e or μ), hadronic jets of which at least one is identified as coming from a b-quark, and large $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A simplified model, see Fig. 10, and in the Tglu3B model, see Fig. 11.

[109] KHACHATRYAN 16BT performed a global Bayesian analysis of a wide range of CMS results obtained with data samples corresponding to 5.0 fb^{-1} of pp collisions at $\sqrt{s} =$ 7 TeV and in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV. The set of searches considered, both individually and in combination, includes those with all-hadronic final states, same-sign and opposite-sign dileptons, and multi-lepton final states. An interpretation was given in a scan of the 19-parameter pMSSM. No scan points with a gluino mass less than 500 GeV survived and 98% of models with a squark mass less than 300 GeV were excluded.

[110] AAD 15AB searched for the decay of neutral, weakly interacting, long-lived particles in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV. Signal events require at least two reconstructed vertices possibly originating from long-lived particles decaying to jets in the inner tracking detector and muon spectrometer. No significant excess of events over the expected background was found. Results were interpreted in Stealth SUSY benchmark models where a pair of gluinos decay to long-lived singlinos, $\tilde{S}$, which in turn each decay to a low-mass gravitino and a pair of jets. The 95% confidence-level limits are set on the cross section $\times$ branching ratio for the decay $\tilde{g} \to \tilde{S}g$, as a function of the singlino proper lifetime ($c\tau$). See their Fig. 10(f)

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[111] AAD 15AI searched in 20 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing at least one isolated lepton (electron or muon), jets, and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the gluino mass in the CMSSM/mSUGRA, see Fig. 15, in the NUHMG, see Fig. 16, and in various simplified models, see Figs. 18–22.

[112] AAD 15CB searched for events containing at least one long-lived particle that decays at a significant distance from its production point (displaced vertex, DV) into two leptons or into five or more charged particles in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV. The dilepton signature is characterised by DV formed from at least two lepton candidates. Four different final states were considered for the multitrak signature, in which the DV must be accompanied by a high-transverse momentum muon or electron candidate that originates from the DV, jets or missing transverse momentum. No events were observed in any of the signal regions. Results were interpreted in SUSY scenarios involving R-parity violation, split supersymmetry, and gauge mediation. See their Fig. 12–20.

[113] KHACHATRYAN 15AD searched in 19.4 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with two opposite-sign same flavor isolated leptons featuring either a kinematic edge, or a peak at the Z-boson mass, in the invariant mass spectrum. No evidence for a statistically significant excess over the expected SM backgrounds is observed and 95% C.L. exclusion limits are derived in a simplified model of gluino pair production where the gluino decays into quarks, a Z-boson, and a massless gravitino LSP, see Fig. 9.

[114] KHACHATRYAN 15AZ searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with either at least one photon, hadronic jets and $\not{E}_T$ (single photon channel) or with at least two photons and at least one jet and using the razor variables. No significant excess above the Standard Model expectations is observed. Limits are set on gluino masses in the general gauge-mediated SUSY breaking model (GGM), for both a bino-like and wino-like neutralino NLSP scenario, see Fig. 8 and 9.

[115] AAD 14AX searched in 20.1 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for the strong production of supersymmetric particles in events containing either zero or at last one high-p_T lepton, large missing transverse momentum, high jet multiplicity and at least three jets identified as originating from b-quarks. No excess over the expected SM background is observed. Limits are derived in mSUGRA/CMSSM models with $\tan\beta = 30$, $A_0 = -2m_0$ and $\mu > 0$, see their Fig. 14. Also, exclusion limits in simplified models containing gluinos and scalar top and bottom quarks are set, see their Figures 12, 13.

[116] AAD 14E searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for strongly produced supersymmetric particles in events containing jets and two same-sign leptons or three leptons. The search also utilises jets originating from b-quarks, missing transverse momentum and other variables. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing gluinos and squarks, see Figures 5 and 6. In the $\tilde{g} \to qq'\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^{\pm} \to W^{(*)\pm}\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \to Z^{(*)}\tilde{\chi}_1^0$ simplified model, the following assumptions have been made: $m_{\tilde{\chi}_1^{\pm}} = 0.5\ m_{\tilde{\chi}_1^0} + m_{\tilde{g}}$, $m_{\tilde{\chi}_2^0} = 0.5\ (m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_1^{\pm}})$, $m_{\tilde{\chi}_1^0} < 520$ GeV. In the $\tilde{g} \to qq'\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^{\pm} \to \ell^{\pm}\nu\tilde{\chi}_1^0$ or $\tilde{g} \to qq'\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \to \ell^{\pm}\ell^{\mp}(\nu\nu)\tilde{\chi}_1^0$ simplified model, the following assumptions have been made: $m_{\tilde{\chi}_1^{\pm}} = m_{\tilde{\chi}_2^0} = 0.5\ (m_{\tilde{\chi}_1^0} + m_{\tilde{g}})$, $m_{\tilde{\chi}_1^0} < 660$ GeV. Limits are also derived in the mSUGRA/CMSSM, bRPV and GMSB models, see their Fig. 8.

[117] CHATRCHYAN 14H searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, or where the decay $\tilde{g} \to \tilde{t}t$, $\tilde{t} \to t\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, with varying mass of the $\tilde{\chi}_1^0$, or where the decay $\tilde{g} \to \tilde{b}b$, $\tilde{b} \to t\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^{\pm} \to W^{\pm}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, with varying mass of the $\tilde{\chi}_1^{\pm}$, see Fig. 5.

[118] CHATRCHYAN 14H searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay $\tilde{g} \to qq'\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^{\pm} \to W^{\pm}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, with varying mass of the $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_1^0$, see Fig. 7.

[119] CHATRCHYAN 14H searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay $\tilde{g} \to b\bar{t}\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^{\pm} \to W^{\pm}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, for two choices of $m_{\tilde{\chi}_1^{\pm}}$ and fixed $m_{\tilde{\chi}_1^0}$, see Fig. 6.

[1] AAD 24AF searched in 140 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for evidence of gluino pair production followed by direct RPV gluino decays into three jets or $\tilde{g} \to qq\tilde{\chi}^0_1$ followed by the decay of $\tilde{\chi}^0_1$ into three jets. No excess above the Standard Model prediction is observed, and the results are interpreted in models with non-vanishing λ''_{112} or λ''_{113}, Tglu1RPV and Tglu1A with $\tilde{\chi}^0_1$ RPV decay, see their Figures 9 and 10.

[2] AAD 21BF searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for pair production of gluinos, stops, electroweakinos decaying RPV either directly or indirectly via the LSP. The final state in all cases is one or two leptons, many jets (up to fifteen) and b-jets. Different models with different branching fractions of the gluino or stop follow from the assumptions on the nature of the electroweakinos. No significant excess above the Standard Model predictions is observed. Limits are set on the *gluino*, $\tilde{t}_1$, electroweakino masses as a function of the $\tilde{\chi}^0_1$ mass in several scenarios of gluino, stop and electroweakino pair production.

[3] AAD 21Y searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for supersymmetry in events with four or more leptons (electrons, muons and tau-leptons). No significant excess above the Standard Model expectations is observed. Limits are set on Tchi1n12-GGM, and RPV models similar to Tchi1n2l, Tglu1A (with $q = u$, d, s, c, b, with equal branching fractions), and $\tilde{\ell}_L/\tilde{\nu} \to \ell/\nu\tilde{\chi}^0_1$ (mass-degenerate $\tilde{\ell}_L$ and $\tilde{\nu}$ of all 3 generations), all with $\tilde{\chi}^0_1 \to \ell^{\pm}\ell^{\mp}\nu$ via λ_{12k} or λ_{i33} (where $i,k \in 1,2$), see their Figure 11.

[4] AAD 20AL searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with 8 or more jets and moderate missing transverse momentum. The selection makes requirements according to the number of b-tagged jets and the scalar sum of masses of large-radius jets. No significant excess above the Standard Model expectations is observed. Exclusion limits at 95% C.L. are set on the gluino mass in RPV simplified models where the gluino decays via $\tilde{g} \to tbd$ or $\tilde{g} \to tbs$. They extend up to almost 1.6 TeV for a $\tilde{t}_1$ mass of 900 GeV. See their Fig. 10(c).

[5] AAD 20V searched in 139 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign charged leptons (electrons or muons) and jets. No significant excess above the Standard Model expectations is observed. Exclusion limits at 95% C.L. are set on the gluino mass in RPV simplified models where the gluino decays via $\tilde{g} \to tbd$, see Figure 7(b).

[6] SIRUNYAN 20T searched in 137 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least two jets, and two isolated same-sign or three or more charged leptons (electrons or muons). No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu3A, Tglu3B, Tglu3C and Tglu3D simplified models, see their Figure 7, and in the Tglu1C and Tglu1B simplified models, see their Figures 8 and 9. Limits are also set on the sbottom mass in the Tsbot2 simplified model, see their Figure 10, and on the stop mass in the Tstop7 simplified model, see their Figure 11. Finally, limits are set on the gluino mass in RPV simplified models where the gluino decays either via $\tilde{g} \to qq\bar{q}\bar{q} + e/\mu/\tau$ or via $\tilde{g} \to tbs$, see Figure 12.

[7] SIRUNYAN 19F searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for three-jet resonances produced in the decay of a gluino in R-parity violating supersymmetric models. The mass range from 200 to 2000GeV is explored in four separate mass regions. The observations show agreement with standard model expectations. The results are interpreted within the framework of R-parity violating SUSY, where pair-produced gluinos decay to a six quark final state. Gluino masses below 1500GeV are excluded at 95% C.L. See their Fig.5.

[8] AABOUD 18Z searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing four or more charged leptons (electrons, muons and up to two hadronically decaying taus). No significant deviation from the expected SM background is observed. Limits are set on the Higgsino mass in simplified models of general gauge mediated supersymmetry Tn1n1A/Tn1n1B/Tn1n1C, see their Figure 9. Limits are also set on the wino, slepton, sneutrino and gluino mass in a simplified model of NLSP pair production with R-parity violating decays of the LSP via λ_{12k} or λ_{i33} to charged leptons, see their Figures 7, 8.

[9] SIRUNYAN 18AK searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing a single lepton, large jet and b-quark jet multiplicities, coming from R-parity-violating decays of gluinos. No excess over the expected background is observed. Limits are derived on the gluino mass, assuming the RPV $\tilde{g} \to tbs$ decay, see their Figure 9.

[10] SIRUNYAN 18D searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events containing identified hadronically decaying top quarks, no leptons, and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in the Tstop1 simplified model, see their Figure 8, and on the gluino mass in the Tglu3A, Tglu3B, Tglu3C and Tglu3E simplified models, see their Figure 9.

[11] SIRUNYAN 18EA searched in 38.2 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for the pair production of resonances, each decaying to at least four quarks. Reconstructed particles are clustered into two large jets of similar mass, each consistent with four-parton substructure. No statistically significant excess over the Standard Model expectation is observed. Limits are set on the squark and gluino mass in RPV supersymmetry models where squarks (gluinos) decay, through intermediate higgsinos, to four (five) quarks, see their Figure 4.

[12] AABOUD 17AI searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more isolated lepton, at least eight jets, either zero or many b-jets, for evidence of R-parity violating decays of the gluino. No significant excess above the Standard Model expectations is observed. Limits up to 2.1 TeV are set on the gluino mass in R-parity-violating supersymmetry models as Tglu3A with LSP decay through the non-zero λ''_{112} coupling as $\tilde{\chi}^0_1 \to uds$. See their Figure 9.

[13] AABOUD 17AI searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more isolated lepton, at least eight jets, either zero or many b-jets, for evidence of R-parity violating decays of the gluino. No significant excess above the Standard Model expectations is observed. Limits up to 1.65 TeV are set on the gluino mass in R-parity-violating supersymmetry models with $\tilde{g} \to t\bar{t}$, $\bar{t} \to bs$ through the non-zero λ''_{323} coupling. See their Figure 9.

[14] AABOUD 17AI searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with one or more isolated lepton, at least eight jets, either zero or many b-jets, for evidence of R-parity violating decays of the gluino. No significant excess above the Standard Model expectations is observed. Limits up to 1.8 TeV are set on the gluino mass in R-parity-violating supersymmetry models as Tglu1A with the LSP decay through the non-zero λ' coupling as $\tilde{\chi}^0_1 \to qq\ell$. See their Figure 9.

[15] AABOUD 17AJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign or three leptons, jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 1.8 TeV are set on the gluino mass in R-parity-violating supersymmetry models as Tglu3A with LSP decaying through the non-zero λ''_{112} coupling as $\tilde{\chi}^0_1 \to uds$. See their Figure 5(d).

[16] AABOUD 17AJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign or three leptons, jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 1.75 TeV are set on the gluino mass in R-parity-violating supersymmetry models as Tglu1A with LSP decaying through the non-zero λ' coupling as $\tilde{\chi}^0_1 \to qq\ell$. See their Figure 5(c).

[17] AABOUD 17AJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign or three leptons, jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 1.45 TeV are set on the gluino mass in R-parity-violating supersymmetry models where $\tilde{g} \to t\tilde{t}_1$ and $\tilde{t}_1 \to sd$ through the non-zero λ''_{321} coupling. See their Figure 5(b).

[18] AABOUD 17AJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign or three leptons, jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 1.45 TeV are set on the gluino mass in R-parity-violating supersymmetry models where $\tilde{g} \to t\tilde{t}_1$ and $\tilde{t}_1 \to bd$ through the non-zero λ''_{313} coupling. See their Figure 5(a).

[19] AABOUD 17AJ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two same-sign or three leptons, jets and large missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits up to 400 GeV are set on the down type squark ($\tilde{d}_R$ mass in R-parity-violating supersymmetry models where $\tilde{d}_R \to tb$ through the non-zero λ''_{313} coupling or $\tilde{d}_R \to ts$ through the non-zero λ''_{321}. See their Figure 5(e) and 5(f).

[20] AABOUD 17AZ searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with at least seven jets and large missing transverse momentum. Selected events are further classified based on the presence of large R-jets or b-jets and no leptons. No significant excess above the Standard Model expectations is observed. Limits are set for R-parity violating decays of the gluino assuming $\tilde{g} \to t\bar{t}_1$ and $\bar{t}_1 \to bs$ through the non-zero λ''_{323} couplings. The range 625–1375 GeV is excluded for $m_{\tilde{t}_1} = 400$ GeV. See their Figure 7b.

[21] KHACHATRYAN 17Y searched in 19.7 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing at least 8 or 10 jets, possibly b-tagged, coming from R-parity-violating decays of supersymmetric particles. No excess over the expected background is observed. Limits are derived on the gluino mass, assuming various RPV decay modes, see Fig. 7.

[22] KHACHATRYAN 16BJ searched in 2.3 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the following simplified models: Tglu3A and Tglu3D, see Fig. 4, Tglu3B and Tglu3C, see Fig. 5, and Tglu1B, see Fig. 7.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[23] KHACHATRYAN 16BX searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing 0 or 1 leptons and b-tagged jets, coming from R-parity-violating decays of supersymmetric particles. No excess over the expected background is observed. Limits are derived on the gluino mass, assuming the RPV $\tilde{g} \to t\,b\,s$ decay, see Fig. 7 and 10.

[24] AAD 15BV summarized and extended ATLAS searches for gluinos and first- and second-generation squarks in final states containing jets and missing transverse momentum, with or without leptons or b-jets in the $\sqrt{s}$ =8 TeV data set collected in 2012. The paper reports the results of new interpretations and statistical combinations of previously published analyses, as well as new analyses. Exclusion limits at 95% C.L. are set on the gluino mass in several R-parity conserving models, leading to a generalized constraint on gluino masses exceeding 1150 GeV for lightest supersymmetric particle masses below 100 GeV. See their Figs. 10, 19, 20, 21, 23, 25, 26, 29-37.

[25] AAD 14X searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in an R-parity violating simplified model where the decay $\tilde{g} \to q\overline{q}\tilde{\chi}_1^0$, with $\tilde{\chi}_1^0 \to \ell^\pm\ell^\mp\nu$, takes place with a branching ratio of 100%, see Fig. 8.

[26] CHATRCHYAN 14P searched in 19.4 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for three-jet resonances produced in the decay of a gluino in R-parity violating supersymmetric models. No excess over the expected SM background is observed. Assuming a 100% branching ratio for the gluino decay into three light-flavour jets, limits are set on the cross section of gluino pair production, see Fig. 7, and gluino masses below 650 GeV are excluded at 95% C.L. Assuming a 100% branching ratio for the gluino decaying to one b-quark jet and two light-flavour jets, gluino masses between 200 GeV and 835 GeV are excluded at 95% C L.

[27] AABOUD 18CF searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s} = 13$ TeV for events with several jets, possibly b-jets, and large-radius jets for evidence of R-parity violating decays of the gluino. No significant excess above the Standard Model expectations is observed. Limits between 1000 and 1875 GeV are set on the gluino mass in R-parity-violating supersymmetry models as Tglu2RPV with the LSP decay through the non-zero λ'' coupling as $\tilde{\chi}_1^0 \to q\,q\,q$. The most stringent limit is obtained for $m_{\tilde{\chi}_1^0} = 1000$ GeV, the weakest for $m_{\tilde{\chi}_1^0} = 50$ GeV. See their Figure 7(b). Figure 7(a) presents results for gluinos directly decaying into 3 quarks, Tglu1RPV.

[28] KHACHATRYAN 16BX searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing 4 leptons coming from R-parity-violating decays of $\tilde{\chi}_1^0 \to \ell\ell\nu$ with $\lambda_{121} \neq 0$ or $\lambda_{122} \neq 0$. No excess over the expected background is observed. Limits are derived on the gluino, squark and stop masses, see Fig. 23.

[29] AAD 15CB searched for events containing at least one long-lived particle that decays at a significant distance from its production point (displaced vertex, DV) into two leptons or into five or more charged particles in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV. The dilepton signature is characterised by DV formed from at least two lepton candidates. Four different final states were considered for the multitrak signature, in which the DV must be accompanied by a high-transverse momentum muon or electron candidate that originates from the DV, jets or missing transverse momentum. No events were observed in any of the signal regions. Results were interpreted in SUSY scenarios involving R-parity violation, split supersymmetry, and gauge mediation. See their Fig. 12–20.

[30] AAD 15X searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events containing large number of jets, no requirements on missing transverse momentum and no isolated electrons or muons. The sensitivity of the search is enhanced by considering the number of b-tagged jets and the scalar sum of masses of large-radius jets in an event. No evidence was found for excesses above the expected level of Standard Model background. Exclusion limits at 95% C.L. are set on the gluino mass assuming the gluino decays to various quark flavors, and for various neutralino masses. See their Fig. 11–16.

[31] AAD 14AX searched in 20.1 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for the strong production of supersymmetric particles in events containing either zero or at last one high-p_T lepton, large missing transverse momentum, high jet multiplicity and at least three jets identified as originating from b-quarks. No excess over the expected SM background is observed. Limits are derived in mSUGRA/CMSSM models with $\tan\beta = 30$, $A_0 = -2m_0$ and $\mu > 0$, see their Fig. 14. Also, exclusion limits in simplified models containing gluinos and scalar top and bottom quarks are set, see their Figures 12, 13.

[32] AAD 14E searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for strongly produced supersymmetric particles in events containing jets and two same-sign leptons or three leptons. The search also utilises jets originating from b-quarks, missing transverse momentum and other variables. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing gluinos and squarks, see Figures 5 and 6. In the $\tilde{g} \to q\,q'\,\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^{(*)\pm}\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \to Z^{(*)}\tilde{\chi}_1^0$ simplified model, the following assumptions have been made: $m_{\tilde{\chi}_1^\pm} = 0.5\ m_{\tilde{\chi}_1^0} + m_{\tilde{g}}$, $m_{\tilde{\chi}_2^0} = 0.5\ (m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_1^\pm})$, $m_{\tilde{\chi}_1^0} < 520$ GeV. In the $\tilde{g} \to q\,q'\,\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to \ell^\pm\nu\tilde{\chi}_1^0$ or $\tilde{g} \to q\,q'\,\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \to \ell^\pm\ell^\mp(\nu\nu)\tilde{\chi}_1^0$ simplified model, the following assumptions have been made: $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0} = 0.5\ (m_{\tilde{\chi}_1^0} + m_{\tilde{g}})$, $m_{\tilde{\chi}_1^0} < 660$ GeV. Limits are also derived in the mSUGRA/CMSSM, bRPV and GMSB models, see their Fig. 8.

[33] CHATRCHYAN 14H searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the R-parity violating decay $\tilde{g} \to t\,b\,s$ takes place with a branching ratio of 100%, see Fig. 8.

Long-lived $\tilde{g}$ (Gluino) mass limit

Limits on light gluinos ($m_{\tilde{g}} < 5$ GeV) were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 25AE searched for massive, charged long-lived particles in 140 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV. Two analyses are conducted: one looking for a single track, with high specific ionisation losses in the pixel detector and long time of flight to the hadron calorimeter, and one looking for two tracks, both with high specific ionisation in the pixel detector. No excess above the expected background is found. Limits are set in scenarios of long-lived R-hadrons (gluino) production, chargino production or stau pair production, see their figures 13 and 14.

[2] HAYRAPETYAN 25V searched in 101 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for heavy, long-lived, charged particles with large ionization energy loss within the silicon tracker of the CMS experiment. No significant excess above the Standard Model expectations is observed. Limits are set on the pair production of gluino R-hadrons, top squark R-hadrons, and detector-stable $\tilde{\tau}_{R,L}$, see their figure 6. Limits are also set in a model predicting a pair of single- and double-charged τ' fermions from a Z' boson decay, see their figure 7.

[3] HAYRAPETYAN 24AP searched in 128 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for evidence of pair-produced multijet signatures probing fully hadronic final states. No significant excess above the Standard Model expectations is observed. Limits are set in three RPV SUSY models: higgsino pair production with decay to merged trijets, stop pair production with decay to merged dijets, and pair-produced gluinos decaying to resolved trijets, see their Fig. 4.

[4] AAD 23G searched in 139 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for R-hadron pair production in events with high-pt tracks with large ionisation in the pixel detector. No significant excess above the Standard Model predictions is observed. Limits are set on the R-hadron mass for different masses of the LSP and for different R-hadron lifetimes, see Figure 18.

[5] SIRUNYAN 21AF searched in 140 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with with two displaced vertices from long-lived particles decaying into multijet or dijet final states. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the simplified model Tglu2RPV with λ''_{323} coupling, on the $\tilde{\chi}_1^0$ mass in an RPV model with $\tilde{\chi}_1^0$ pair production and the RPV decay $\tilde{\chi}_1^0 \to tbs$ with λ''_{323} coupling and on the $\tilde{t}$ mass in an RPV model with top squark pair production and the RPV decay $\tilde{t} \to \overline{d}_i\overline{d}_j$ with λ''_{3ij} coupling, see their Figure 7.

[6] SIRUNYAN 21U searched in 132 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for supersymmetry in events with displaced tracks and displaced vertices associated with a dijet system. No significant excess above the Standard Model expectations is observed. Limits are set on long-lived gluinos in an RPC GMSB SUSY model of gluino pair production, with $\tilde{g} \to g\tilde{G}$, see their Figure 9, in Tglu1A in a mini-split model, see their Figure 10, and in an RPV model of gluino pair production, with $\tilde{g} \to tbs$ with coupling λ''_{323}, see their Figure 11. Limits are also set on long-lived top squarks in Tstop2RPV, see their Figure 12, in an RPV model with $\tilde{t} \to d\overline{t}$ and λ'_{x31} coupling, see their Figure 13, and in a dynamical RPV model with $\tilde{t} \to \overline{d}\overline{d}$ via a nonholomorphic RPV coupling η''_{311}, see their Figure 14. The best mass limit is achieved in all cases at cτ = 30 mm.

[7] AABOUD 19AT searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for metastable and stable R-hadrons. Multiple search strategies for a wide range of lifetimes, corresponding to path lengths of a few meters, are defined. No significant deviations from the expected Standard Model background are observed. Gluino R-hadrons with lifetimes of the order of 50 ns are excluded at 95% C.L. for masses below 1980 GeV using the muon-spectrometer agnostic analysis. Using the full-detector search, the observed lower limits on the mass are 2000 GeV. See their Figure 9 (top).

[8] AABOUD 19C searched in 36.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for metastable and stable R-hadrons arising as excesses in the mass distribution of reconstructed tracks with high transverse momentum and large dE/dx. Gluino R-hadrons with lifetimes above 10 ns are excluded at 95% C.L. with lower mass limit range between 1000 GeV and 2060 GeV, see their Figure 5(a). Masses smaller than 1290 GeV are excluded for a lifetime of 1 ns, see their Figure 6. In the case of stable R-hadrons, the lower mass limit is 1890 GeV, see their Figure 5(b).

[9] SIRUNYAN 19BH searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for long-lived particles decaying into jets, with each long-lived particle having a decay vertex well displaced from the production vertex. The selected events are found to be consistent with standard model predictions. Limits are set on the gluino mass in a GMSB model where the gluino is decaying via $\tilde{g} \to g\tilde{G}$, see their Figure 4 and in an RPV model of supersymmetry where the gluino is decaying via $\tilde{g} \to t\overline{b}\overline{s}$, see their Figures 5. Limits are also set on the stop mass in two RPV models, see their Figure 6 (for $\tilde{t} \to b\ell$ decays) and Figure 7 (for $\tilde{t} \to \overline{d}\overline{d}$ decays).

[10] SIRUNYAN 19BT searched in 137 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for long-lived particles decaying to displaced, nonprompt jets and missing transverse momentum. Candidate signal events are identified using the timing capabilities of the CMS electromagnetic calorimeter. The results of the search are found to be consistent with the background predictions. Limits are set on the gluino mass in a GMSB model where long-lived gluinos are pair produced and decaying via $\tilde{g} \to g\tilde{G}$, see their Figures 4 and 5.

[11] AABOUD 18S searched in 32.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for long-lived gluinos in final states with large missing transverse momentum and at least one high-mass displaced vertex with five or more tracks. The observed yield is consistent with the expected background. Exclusion limits are derived for Tglu1A models predicting the existence of long-lived gluinos reaching roughly m($\tilde{g}$) = 2000 GeV to 2370 GeV for m($\tilde{\chi}_1^0$) = 100 GeV and gluino lifetimes between 0.02 and 10 ns, see their Fig. 8. Limits are presented also as a function of the lifetime (for a fixed gluino-neutralino mass difference of 100 GeV) and of the gluino and neutralino masses (for a fixed lifetime of 1 ns). See their Fig. 9 and 10 respectively.

[12] SIRUNYAN 18AY searched in 35.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events containing one or more jets and significant $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in the Tglu1A, Tglu2A and Tglu3A simplified models, see their Figure 3. Limits are also set on squark, sbottom and stop masses in the Tsqk1, Tsbot1, Tstop1 and Tstop4 simplified models, see their Figure 3. Finally, limits are set on long-lived gluino masses in a Tglu1A simplified model where the gluino is metastable or long-lived with proper decay lengths in the range 10^{-3} mm < cτ < 10^5 mm, see their Figure 4.

[13] SIRUNYAN 18DV searched in 38.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for long-lived particles in events with multiple jets and two displaced vertices composed of many tracks. No events with two well-separated high-track-multiplicity vertices were observed. Limits are set on the stop and the gluino mass in RPV models of supersymmetry where the stop (gluino) is decaying solely into dijet (multijet) final states, see their Figures 6 and 7.

[14] KHACHATRYAN 17AR searched in 17.6 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for R-parity-violating SUSY in which long-lived neutralinos or gluinos decay into multijet final states. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass for a range of mean proper decay lengths (cτ), see their Fig. 7. The upper limits on the production cross section times branching ratio squared (Fig. 7) are also applicable to long-lived neutralinos.

[15] AABOUD 16B searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for long-lived R-hadrons using observables related to large ionization losses and slow propagation velocities, which are signatures of heavy charged particles traveling significantly slower than the speed of light. Exclusion limits at 95% C.L. are set on the long-lived gluino masses exceeding 1580 GeV. See their Fig. 5.

[16] AABOUD 16C searched in 3.2 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for long-lived and stable R-hadrons identified by anomalous specific ionization energy loss in the ATLAS Pixel detector. Gluino R-hadrons with lifetimes above 0.4 ns are excluded at 95% C.L. with lower mass limit range between 740 GeV and 1590 GeV. In the case of stable R-hadrons, the lower mass limit is 1570 GeV. See their Figs. 5 and 6.

[17] KHACHATRYAN 16BW searched in 2.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 13 TeV for events with heavy stable charged particles, identified by their anomalously high energy deposits in the silicon tracker and/or long time-of-flight measurements by the muon system. No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass, depending on the interaction model and on the fraction f, of produced gluinos hadronizing into a $\tilde{g}$ - gluon state, see Fig. 4 and Table 7.

[18] AAD 15AE searched in 19.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for heavy long-lived charged particles, measured through their specific ionization energy loss in the ATLAS pixel detector or their time-of-flight in the ALTAS muon system. In the absence of an excess of events above the expected backgrounds, limits are set R-hadrons in various scenarios, see Fig. 11. Limits are also set in LeptoSUSY models where the gluino decays to stable 300 GeV leptons, see Fig. 9.

[19] AAD 15BM searched in 18.4 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for stable and metastable non-relativistic charged particles through their anomalous specific ionization energy loss in the ATLAS pixel detector. In absence of an excess of events above the expected backgrounds, limits are set within a generic R-hadron model, on stable gluino R-hadrons (see Table 5) and on metastable gluino R-hadrons decaying to $(g/q\overline{q})$ plus a light $\tilde{\chi}_1^0$ (see Fig. 7) and decaying to $t\overline{t}$ plus a light $\tilde{\chi}_1^0$ (see Fig. 9).

[20] KHACHATRYAN 15AK looked in a data set corresponding to 18.6 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV, and a search interval corresponding to 281 h of trigger lifetime, for long-lived particles that have stopped in the CMS detector. No evidence for an excess over the expected background in a cloud interaction model is observed. Assuming the decay $\tilde{g} \to g\tilde{\chi}_1^0$ and lifetimes between 1 μ and 1000 s, limits are derived on $\tilde{g}$ production as a function of $m_{\tilde{\chi}_1^0}$, see Figs. 4 and 6. The exclusions require that $m_{\tilde{\chi}_1^0}$ is kinematically consistent with the minimum values of the jet energy thresholds used.

[21] AAD 13AA searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing colored long-lived particles that hadronize forming R-hadrons. No significant excess above the expected background was found. Long-lived R-hadrons containing a $\tilde{g}$ are excluded for masses up to 985 GeV at 95% C.L in a general interaction model. Also, limits independent of the fraction of R-hadrons that arrive charged in the muon system were derived, see Fig. 6.

[22] AAD 13BC searched in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV and in 22.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for bottom squark R-hadrons that have come to rest within the

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

ATLAS calorimeter and decay at some later time to hadronic jets and a neutralino. In absence of an excess of events above the expected backgrounds, limits are set on gluino masses for different decays, lifetimes, and neutralino masses, see their Table 6 and Fig. 10.

[23] CHATRCHYAN 13AB looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV and in 18.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{g}$'s. No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 8 and Table 5), depending on the fraction, f, of formation of $\tilde{g}-$g (R-gluonball) states. The quoted limit is for f = 0.1, while for f = 0.5 it degrades to 1276 GeV. In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 928 GeV for f = 0.1.

[24] AAD 12P looked in 31 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with pair production of long-lived gluinos. The hadronization of the gluinos leads to R-hadrons which may stop inside the detector and later decay via $\tilde{g} \to g\tilde{\chi}_1^0$ during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section as a function of $m_{\tilde{g}}$ is derived for $m_{\tilde{\chi}_1^0}$ = 100 GeV, see Fig. 4. The limit is valid for lifetimes between 10^{-5} and 10^3 seconds and assumes the *Generic* matter interaction model for the production cross section.

[25] CHATRCHYAN 12AN looked in 4.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with pair production of long-lived gluinos. The hadronization of the gluinos leads to R-hadrons which may stop inside the detector and later decay via $\tilde{g} \to g\tilde{\chi}_1^0$ during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section as a function of $m_{\tilde{g}}$ is derived, see Fig. 3. The mass limit is valid for lifetimes between 10^{-5} and 10^3 seconds, for what they call "the daughter gluon energy E_g >" 100 GeV and assuming the *cloud* interaction model for R-hadrons. Supersedes KHACHATRYAN 11.

[26] CHATRCHYAN 12L looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{g}$'s. No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 3), depending on the fraction, f, of formation of $\tilde{g}-$g (R-glueball) states. The quoted limit is for f = 0.1, while for f = 0.5 it degrades to 1046 GeV. In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 928 GeV for f=0.1. Supersedes KHACHATRYAN 11C.

[27] AAD 11K looked in 34 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the tile calorimeter, from pair production of $\tilde{g}$. No evidence for an excess over the SM expectation is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 4), for a fraction, f = 10%, of formation of $\tilde{g}-g$ (R-gluonball). If instead of a phase space driven approach for the hadronic scattering of the R-hadrons, a triple-Regge model or a bag-model is used, the limit degrades to 566 and 562 GeV, respectively.

[28] AAD 11P looked in 37 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with heavy stable particles, reconstructed and identified by their time of flight in the Muon System. There is no requirement on their observation in the tracker to increase the sensitivity to cases where gluinos have a large fraction, f, of formation of neutral $\tilde{g}-g$ (R-gluonball). No evidence for an excess over the SM expectation is observed. Limits are derived as a function of mass (see Fig. 4), for f=0.1. For fractions f = 0.5 and 1.0 the limit degrades to 537 and 530 GeV, respectively.

[29] KHACHATRYAN 11 looked in 10 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with pair production of long-lived gluinos. The hadronization of the gluinos leads to R-hadrons which may stop inside the detector and later decay via $\tilde{g} \to g\tilde{\chi}_1^0$ during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section times branching ratio is derived for $m_{\tilde{g}} - m_{\tilde{\chi}_1^0} > 100$ GeV, see their Fig. 2. Assuming 100% branching ratio, lifetimes between 75 ns and 3×10^5 s are excluded for $m_{\tilde{g}}$ = 300 GeV. The $\tilde{g}$ mass exclusion is obtained with the same assumptions for lifetimes between 10 μs and 1000 s, but shows some dependence on the model for R-hadron interactions with matter, illustrated in Fig. 3. From a time-profile analysis, the mass exclusion is 382 GeV for a lifetime of 10 μs under the same assumptions as above.

[30] KHACHATRYAN 11C looked in 3.1 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{g}$. No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 3), depending on the fraction, f, of formation of $\tilde{g}-g$ (R-gluonball). The quoted limit is for f=0.1, while for f=0.5 it degrades to 357 GeV. In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 311 GeV for f=0.1.

Light $\tilde{G}$ (Gravitino) mass limits from collider experiments

The following are bounds on light ($\ll$ 1 eV) gravitino indirectly inferred from its coupling to matter suppressed by the gravitino decay constant.

Unless otherwise stated, all limits assume that other supersymmetric particles besides the gravitino are too heavy to be produced. The gravitino is assumed to be undetected and to give rise to a missing energy ($\not{E}$) signature.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 15BH searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for associated production of a light gravitino and a squark or gluino. The squark (gluino) is assumed to decay exclusively to a quark (gluon) and a gravitino. No evidence was found for an excess above the expected level of Standard Model background and 95% C.L. lower limits were set on the gravitino mass as a function of the squark/gluino mass, both in the case of degenerate and non-degenerate squark/gluino masses, see Figs. 14 and 15.

[2] ABDALLAH 05B use data from $\sqrt{s}$ = 180–208 GeV. They look for events with a single photon + $\not{E}$ final states from which a cross section limit of $\sigma < 0.18$ pb at 208 GeV is obtained, allowing a limit on the mass to be set. Supersedes the results of ABREU 00Z.

[3] ACHARD 04E use data from $\sqrt{s}$ = 189–209 GeV. They look for events with a single photon + $\not{E}$ final states from which a limit on the Gravitino mass is set corresponding to $\sqrt{F} > 238$ GeV. Supersedes the results of ACCIARRI 99R.

[4] HEISTER 03C use the data from $\sqrt{s}$ = 189–209 GeV to search for $\gamma\not{E}_T$ final states.

[5] ACOSTA 02H looked in 87 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with a high-E_T photon and $\not{E}_T$. They compared the data with a GMSB model where the final state could arise from $q\overline{q} \to \tilde{G}\tilde{G}\gamma$. Since the cross section for this process scales as $1/|F|^4$, a limit at 95% CL is derived on $|F|^{1/2} > 221$ GeV. A model independent limit for the above topology is also given in the paper.

[6] ABBIENDI,G 00D searches for $\gamma\not{E}$ final states from $\sqrt{s}$=189 GeV.

Supersymmetry miscellaneous results

Results that do not appear under other headings or that make nonminimal assumptions.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics **C38** 070001 (2014) (http://pdg.lbl.gov).

[1] AAD 24AH combined a number of ATLAS analyses to use them and interpret in a series of models derived from a flat-prior scan to pMSSM parameter space. Limits are provided in terms of fraction of models excluded as a function of one or two parameters, while marginalising over the others.

[2] AAD 20C uses a statistical combination of six final states $b\overline{b}b\overline{b}$, $b\overline{b}WW$, $b\overline{b}\tau\tau$, $WWWW$, $b\overline{b}\gamma\gamma$, and $WW\gamma\gamma$ to search for non-resonant and resonant production of Higgs boson pairs. The search uses 36.1 fb^{-1} of pp collisions data at $\sqrt{s}$ = 13 TeV. Constraints in the habemus Minimal Supersymmetric Standard Model in the (m_A, $\tan\beta$) parameter space are placed, see their Figure 7(b).

[3] AAD 20L used 27.8 fb^{-1} of pp collision data at $\sqrt{s}$ = 13 TeV to search for heavy neutral Higgs bosons produced in association with at least one b-quark and decaying into a pair of b-quarks. The data are compatible with SM expectations, yielding no significant excess of events in the mass range 450–1400 GeV, see their Fig. 11. Exclusion limits at 95% C.L. were derived in hMSSM scenarios as a function of m_A and $\tan\beta$, see their Fig. 9 and 10.

[4] AABOUD 16AF uses a selection of searches by ATLAS for the electroweak production of SUSY particles studying resulting constraints on dark matter candidates. They use 20 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV. A likelihood-driven scan of an effective model focusing on the gaugino-higgsino and Higgs sector of the pMSSM is performed. The ATLAS searches impact models where $m_{\chi_1^0} < 65$ GeV, excluding 86% of them. See their Figs. 2, 4, and 6.

[5] AAD 16AG searches for prompt lepton-jets using 20 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV collected with the ATLAS detector. Lepton-jets are expected from decays of low-mass dark photons in SUSY-portal and Higgs-portal models. No significant excess of events is observed and 95% CL upper limits are computed on the production cross section times branching ratio for two prompt lepton-jets in models predicting 2 or 4 γ_d via SUSY-portal topologies, for γ_d mass values between 0 and 2 GeV. See their Figs 9 and 10. The results are also interpreted in terms of a 90% CL exclusion region in kinetic mixing and dark-photon mass parameter space. See their Fig. 13.

[6] AAD 13P searched in 5 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for single lepton-jets with at least four muons; pairs of lepton-jets, each with two or more muons; and pairs of lepton-jets with two or more electrons. All of these could be signatures of Hidden Valley supersymmetric models. No statistically significant deviations from the Standard Model expectations are found. 95% C.L. limits are placed on the production cross section times branching ratio of dark photons for several parameter sets of a Hidden Valley model.

[7] AALTONEN 12AB looked in 5.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for anomalous production of multiple low-energy leptons in association with a W or Z boson. Such events may occur in hidden valley models in which a supersymmetric Higgs boson is produced in association with a W or Z boson, with $H \to \tilde{\chi}_1^0\tilde{\chi}_1^0$ pair and with the $\tilde{\chi}_1^0$ further decaying into a dark photon (γ_D) and the unobservable lightest SUSY particle of the hidden sector. As the γ_D is expected to be light, it may decay into a lepton pair.

No significant excess over the SM expectation is observed and a limit at 95% C.L. is set on the cross section for a benchmark model of supersymmetric hidden-valley Higgs production.

[8] AAD 11AA looked in 34 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with ≥ 4 jets originating from pair production of scalar gluons, each decaying to two gluons. No two-jet resonances are observed over the SM background. Limits are derived on the cross section times branching ratio (see Fig. 3). Assuming 100% branching ratio for the decay to two gluons, the quoted exclusion range is obtained, except for a 5 GeV mass window around 140 GeV.

[9] CHATRCHYAN 11E looked in 35 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with collimated μ pairs (leptonic jets) from the decay of hidden sector states. No evidence for new resonance production is found. Limits are derived and compared to various SUSY models (see Fig. 4) where the LSP, either the $\widetilde{\chi}_1^0$ or a $\widetilde{q}$, decays to dark sector particles.

[10] ABAZOV 10N looked in 5.8 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events from hidden valley models in which a $\widetilde{\chi}_1^0$ decays into a dark photon, γ_D, and the unobservable lightest SUSY particle of the hidden sector. As the γ_D is expected to be light, it may decay into a tightly collimated lepton pair, called lepton jet. They searched for events with $\not\!\!E_T$ and two isolated lepton jets observable by an opposite charged lepton pair ee, $e\mu$ or $\mu\mu$. No significant excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section times branching ratio is derived, see their Table I. They also examined the invariant mass of the lepton jets for a narrow resonance, see their Fig. 4, but found no evidence for a signal.

[1] AAD 20AM search for a top-color Z' decaying to $t\overline{t}$ in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for $\Gamma_{Z'}/M_{Z'}$ = 0.01. The limit becomes $M_{Z'}$ > 4700 GeV for $\Gamma_{Z'}/M_{Z'}$ = 0.03.

[2] AAD 20W search for techni-ρ decaying to $\pi_T W$ in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 5a for limits on $\sigma \cdot B$.

[3] AAD 16W search for color octet vector resonance decaying to bB in pp collisions at $\sqrt{s}$ = 8 TeV. The vector like quark B is assumed to decay to bH. See their Fig.3 and Fig.4 for limits on $\sigma \cdot B$.

[4] KHACHATRYAN 16E search for top-color Z' decaying to $t\overline{t}$. The quoted limit is for $\Gamma_{Z'}/m_{Z'}$ = 0.012. Also exclude $m_{Z'}$ < 2.9 TeV for wider topcolor Z' with $\Gamma_{Z'}/m_{Z'}$ = 0.1.

[5] AAD 15AB search for long-lived hidden valley π_V particles which are produced in pairs by the decay of a scalar boson. π_V is assumed to decay into dijets. See their Fig. 10 for the limit on σB.

[6] AAD 15AO search for top-color Z' decaying to $t\overline{t}$. The quoted limit is for $\Gamma_{Z'}/m_{Z'}$ = 0.012.

[7] AAD 15BB search for minimal walking technicolor (MWT) isotriplet vector and axial-vector resonances decaying to Wh or Zh. See their Fig. 3 for the exclusion limit in the MWT parameter space.

[8] AAD 15Q search for long-lived hidden valley π_V particles which are produced in pairs by the decay of scalar boson. π_V is assumed to decay into dijets. See their Fig. 5 and Fig. 6 for the limit on σB.

[9] AAIJ 15AN search for long-lived hidden valley π_V particles which are produced in pairs by the decay of scalar boson with a mass of 120GeV. π_V is assumed to decay into dijets. See their Fig. 4 for the limit on σB.

[10] KHACHATRYAN 15C search for a vector techni-resonance decaying to WZ. The limit assumes M_{π_T} = (3/4) M_{ρ_T} − 25 GeV. See their Fig.3 for the limit in $M_{\pi_T} - M_{\rho_T}$ plane of the low scale technicolor model.

[11] KHACHATRYAN 15W search for long-lived hidden valley π_V particles which are produced in pairs in the decay of heavy higgs boson H. π_V is assumed to decay into $\ell^+\ell^-$. See their Fig. 7 and Fig. 8 for the limits on σB.

[12] AAD 14AT search for techni-ω and techni-a resonances decaying to $V\gamma$ with $V = W(\to \ell\nu)$ or $Z(\to \ell^+\ell^-)$.

[13] AAD 14V search for vector techni-resonances decaying into electron or muon pairs in pp collisions at $\sqrt{s}$ = 8 TeV. See their table IX for exclusion limits with various assumptions.

[14] AAD 13AN search for vector techni-resonance a_T decaying into $W\gamma$.

[15] AAD 13AN search for vector techni-resonance ω_T decaying into $Z\gamma$.

[16] Search for top-color Z' decaying to $t\overline{t}$. The quoted limit is for $\Gamma_{Z'}/m_{Z'}$ = 0.012.

[17] CHATRCHYAN 13AP search for top-color leptophobic Z' decaying to $t\overline{t}$. The quoted limit is for $\Gamma_{Z'}/m_{Z'}$ = 0.012.

[18] BAAK 12 give electroweak oblique parameter constraints on the QCD-like technicolor models. See their Fig. 28.

[19] CHATRCHYAN 12AF search for a vector techni-resonance decaying to WZ. The limit assumes M_{π_T} = (3/4) M_{ρ_T} − 25 GeV. See their Fig. 3 for the limit in $M_{\pi_T} - M_{\rho_T}$ plane of the low scale technicolor model.

[20] Using the LHC limit on the Higgs boson production cross section, CHIVUKULA 11 obtain a limit on the top-Higgs mass > 300 GeV at 95% CL assuming 150 GeV top-pion mass.

[21] Using the LHC limit on the Higgs boson production cross section, CHIVUKULA 11A obtain a limit on the techinipion mass ruling out the region 110 GeV < m_P < $2m_t$. Existence of color techni-fermions, top-color mechanism, and $N_{TC} \geq 3$ are assumed.

[22] AALTONEN 10I search for the vector techni-resonances (ρ_T, ω_T) decaying into $W\pi_T$ with $W \to \ell\nu$ and $\pi_T \to b\overline{b}$, $b\overline{c}$, or $b\overline{u}$. See their Fig. 3 for the exclusion plot in $M_{\pi_T} - M_{\rho_T}$ plane.

[23] ABAZOV 10A search for a vector techni-resonance decaying into WZ. The limit assumes $M_{\rho_T} < M_{\pi_T} + M_W$.

[24] ABAZOV 07I search for the vector techni-resonances (ρ_T, ω_T) decaying into $W\pi_T$ with $W \to e\nu$ and $\pi_T \to b\overline{b}$ or $b\overline{c}$. See their Fig. 2 for the exclusion plot in $M_{\pi_T} - M_{\rho_T}$ plane.

[25] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions. at $\sqrt{s}$ = 1.96 TeV. The limit assumes Technicolor-scale mass parameters M_V = M_A = 500 GeV.

[26] CHEKANOV 02B search for color octet techni-π P decaying into dijets in ep collisions. See their Fig. 5 for the limit on $\sigma(ep \to ePX)\cdot B(P \to 2j)$.

[27] ABAZOV 01B searches for vector techni-resonances (ρ_T, ω_T) decaying to e^+e^-. The limit assumes $M_{\rho_T} = M_{\omega_T} < M_{\pi_T} + M_W$.

[28] The limit is independent of the π_T mass. See their Fig. 9 and Fig. 10 for the exclusion plot in the $M_{\rho_T} - M_{\pi_T}$ plane. ABDALLAH 01 limit on the techni-pion mass is M_{π_T} > 79.8 GeV for N_D=2, assuming its point-like coupling to gauge bosons.

[29] AFFOLDER 00F search for ρ_T decaying into $W\pi_T$ or $\pi_T\pi_T$ with $W \to \ell\nu$ and $\pi_T \to \overline{b}b$, $\overline{b}c$. See Fig. 1 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the $M_{\rho_T} - M_{\pi_T}$ plane.

[30] AFFOLDER 00K search for the ρ_{T8} decaying into $\pi_{LQ}\pi_{LQ}$ with $\pi_{LQ} \to b\nu$. For $\pi_{LQ} \to c\nu$, the limit is $M_{\rho_{T8}}$ >510 GeV. See their Fig. 2 and Fig. 3 for the exclusion plot in the $M_{\rho_{T8}} - M_{\pi_{LQ}}$ plane.

[31] ABE 99F search for a new particle X decaying into $b\overline{b}$ in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. See Fig. 7 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\overline{p} \to X)\times B(X \to b\overline{b})$. ABE 99F also exclude top gluons of width Γ=0.3M in the mass interval 280 <M< 670 GeV, of width Γ=0.5M in the mass interval 340 <M< 640 GeV, and of width Γ=0.7M in the mass interval 375 <M< 560 GeV.

[32] ABE 99N search for the techni-ω decaying into $\gamma\pi_T$. The technipion is assumed to decay $\pi_T \to b\overline{b}$. See Fig. 2 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the $M_{\omega_T} - M_{\pi_T}$ plane.

[33] ABE 97G search for a new particle X decaying into dijets in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. See Fig. 5 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\overline{p} \to X)\times B(X \to 2j)$.

[1] AABOUD 17AT limits are from pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit uses a uniform positive prior in $1/\Lambda^2$.
[2] ABDALLAH 09 and SCHAEL 07A limits are from R_b, A^b_{FB}.
[3] SCHAEL 07A limits are from R_c, Q^{depl}_{FB}, and hadronic cross section measurements.
[4] CHEUNG 01B is an update of BARGER 98E.
[5] AAD 21AU search for new phenomena in final states with e^+e^- and one or no b-tagged jets in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limits assume $g^2_* = 4\pi$.
[6] AAD 21Q limits are from pp collisions at $\sqrt{s}$ = 13 TeV. A frequentist statistical framework is used to remove the prior dependence.
[7] SIRUNYAN 21N limits are from e^+e^- mass distribution in pp collisions at $\sqrt{s}$ = 13 TeV.
[8] AAD 20AP limits are from e^+e^- mass distribution in pp collisions at $\sqrt{s}$ = 13 TeV.
[9] ABRAMOWICZ 19 limits are from Q^2 spectrum measurements of $e^{\pm}p \to e^{\pm}X$.
[10] SIRUNYAN 19AC limits are from e^+e^- mass distribution in pp collisions at $\sqrt{s}$ = 13 TeV.
[11] AABOUD 16U limits are from pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit uses a uniform positive prior in $1/\Lambda^2$.
[12] KHACHATRYAN 15AE limit is from e^+e^- mass distribution in pp collisions at E_{cm} = 8 TeV.
[13] AAD 14BE limits are from pp collisions at $\sqrt{s}$ = 8 TeV. The quoted limit uses a uniform positive prior in $1/\Lambda^2$.
[14] AAD 13E limis are from e^+e^- mass distribution in pp collisions at E_{cm} = 7 TeV.
[15] AAD 12AB limis are from e^+e^- mass distribution in pp collisions at E_{cm} = 7 TeV.
[16] AARON 11C limits are from Q^2 spectrum measurements of $e^{\pm}p \to e^{\pm}X$.
[17] ABDALLAH 11 limit is from $e^+e^- \to t\bar{c}$ cross section. $\Lambda_{LL} = \Lambda_{LR} = \Lambda_{RL} = \Lambda_{RR}$ is assumed.
[18] SCHAEL 07A limit assumes quark flavor universality of the contact interactions.
[19] ABULENCIA 06L limits are from $p\bar{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

>6.5		[3] DIAZCRUZ	94	RVUE	$\Lambda^-_{LL}(\tau\nu_\tau\mu\nu_\mu)$

[1] JODIDIO 86 limit is from $\mu^+ \to \overline{\nu}_\mu e^+\nu_e$. Chirality invariant interactions $L = (g^2/\Lambda^2)$ $[\eta_{LL}\ (\overline{\nu}_{\mu L}\gamma^\alpha\mu_L)\ (\overline{e}_L\gamma_\alpha\nu_{eL}) + \eta_{LR}\ (\overline{\nu}_{\mu L}\gamma^\alpha\nu_{eL}\ (\overline{e}_R\gamma_\alpha\mu_R)]$ with $g^2/4\pi = 1$ and $(\eta_{LL},\eta_{LR}) = (0,\pm1)$ are taken. No limits are given for $\Lambda^{\pm}_{LL}$ with $(\eta_{LL},\eta_{LR}) = (\pm1,0)$. For more general constraints with right-handed neutrinos and chirality nonconserving contact interactions, see their text.
[2] DIAZCRUZ 94 limits are from $\Gamma(\tau \to e\nu\nu)$ and assume flavor-dependent contact interactions with $\Lambda(\tau\nu_\tau e\nu_e) \ll \Lambda(\mu\nu_\mu e\nu_e)$.
[3] DIAZCRUZ 94 limits are from $\Gamma(\tau \to \mu\nu\nu)$ and assume flavor-dependent contact interactions with $\Lambda(\tau\nu_\tau\mu\nu_\mu) \ll \Lambda(\mu\nu_\mu e\nu_e)$.

[1] AABOUD 17AK limit is from dijet angular distribution in pp collisions at $\sqrt{s} = 13$ TeV. u, d, and s quarks are assumed to be composite.
[2] AABOUD 18AV obtain limit on t_R compositeness $2\pi/\Lambda^2_{RR} < 1.6$ TeV^{-2} at 95% CL from $t\overline{t}t\overline{t}$ production in the pp collisions at $E_{cm} = 13$ TeV.
[3] SIRUNYAN 18DD limit is from dijet angular distribution in pp collisions at $\sqrt{s} = 13$ TeV.
[4] SIRUNYAN 17F limit is from dijet angular cross sections in pp collisions at $E_{cm} = 13$ TeV. All quarks are assumed to be composite.
[5] AAD 16S limit is from dijet angular selections in pp collisions at $E_{cm} = 13$ TeV. u, d, and s quarks are assumed to be composite.
[6] AAD 15AR obtain limit on the t_R compositeness $2\pi/\Lambda^2_{RR} < 6.6$ TeV^{-2} at 95% CL from the $t\overline{t}t\overline{t}$ production in the pp collisions at $E_{cm} = 8$ TeV.
[7] AAD 15BY obtain limit on the t_R compositeness $2\pi/\Lambda^2_{RR} < 15.1$ TeV^{-2} at 95% CL from the $t\overline{t}t\overline{t}$ production in the pp collisions at $E_{cm} = 8$ TeV.
[8] AAD 15L limit is from dijet angular distribution in pp collisions at $E_{cm} = 8$ TeV. u, d, and s quarks are assumed to be composite.
[9] KHACHATRYAN 15J limit is from dijet angular distribution in pp collisions at $E_{cm} = 8$ TeV. u, d, s, c, and b quarks are assumed to be composite.
[10] FABBRICHESI 14 obtain bounds on chromoelectric and chromomagnetic form factors of the top-quark using $pp \to t\overline{t}$ and $p\overline{p} \to t\overline{t}$ cross sections. The quoted limit on the $q\overline{q}\,t\overline{t}$ contact interaction is derived from their bound on the chromoelectric form factor.

SCALE LIMITS for Contact Interactions: $\Lambda(\nu\nu qq)$

Limits are for $\Lambda^{\pm}_{LL}$ only. For other cases, see each reference.

Λ^+_{LL}(TeV)	Λ^-_{LL}(TeV)	CL%	DOCUMENT ID		TECN	COMMENT
>2.23	>2.13	95	[1] AAD	24AC	ATLS	$t\overline{t}\nu\overline{\nu}$
>5.0	**>5.4**	95	[2] MCFARLAND	98	CCFR	νN scattering

[1] AAD 24AC limit is from the measurement of the $t\overline{t}$ production cross section with large missing E_T in pp collisions at $\sqrt{s} = 13$ TeV.
[2] MCFARLAND 98 assumed a flavor universal interaction. Neutrinos were mostly of muon type.

MASS LIMITS for Excited e (e^*)

Most e^+e^- experiments assume one-photon or Z exchange. The limits from some e^+e^- experiments which depend on λ have assumed transition couplings which are chirality violating ($\eta_L = \eta_R$). However they can be interpreted as limits for chirality-conserving interactions after multiplying the coupling value λ by $\sqrt{2}$; see Note.

Excited leptons have the same quantum numbers as other ortholeptons. See also the searches for ortholeptons in the "Searches for Heavy Leptons" section.

Limits for Excited e (e^*) from Pair Production

These limits are obtained from $e^+e^- \to e^{*+}e^{*-}$ and thus rely only on the (electroweak) charge of e^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the e^* coupling is assumed to be of sequential type. Possible t channel contribution from transition magnetic coupling is neglected. All limits assume a dominant $e^* \to e\gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

	[1] DORENBOS...	89	CHRM	$\overline{\nu}_\mu e \to \overline{\nu}_\mu e$, $\nu_\mu e \to \nu_\mu e$
	[2] GRIFOLS	86	THEO	$\nu_\mu e \to \nu_\mu e$
	[3] RENARD	82	THEO	$g-2$ of electron

[1] DORENBOSCH 89 obtain the limit $\lambda_\gamma^2 \Lambda_{\rm cut}^2 / m_{e^*}^2 < 2.6$ (95% CL), where $\Lambda_{\rm cut}$ is the cutoff scale, based on the one-loop calculation by GRIFOLS 86. If one assumes that $\Lambda_{\rm cut} = 1$ TeV and $\lambda_\gamma = 1$, one obtains $m_{e^*} > 620$ GeV. However, one generally expects $\lambda_\gamma \approx m_{e^*}/\Lambda_{\rm cut}$ in composite models.

[2] GRIFOLS 86 uses $\nu_\mu e \to \nu_\mu e$ and $\overline{\nu}_\mu e \to \overline{\nu}_\mu e$ data from CHARM Collaboration to derive mass limits which depend on the scale of compositeness.

[3] RENARD 82 derived from $g-2$ data limits on mass and couplings of e^* and μ^*. See figures 2 and 3 of the paper.

MASS LIMITS for Excited μ (μ^*)

Limits for Excited μ (μ^*) from Pair Production

These limits are obtained from $e^+e^- \to \mu^{*+}\mu^{*-}$ and thus rely only on the (electroweak) charge of μ^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the μ^* coupling is assumed to be of sequential type. All limits assume a dominant $\mu^* \to \mu\gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

[1] TUMASYAN 23AF limit quoted above assumes $bg \to b^*$ production. The limit becomes $m_{b^*} > 4$ TeV if contact interaction is included in the b^* production cross section. See their Fig. 5 for limits on $\sigma \cdot B$.

[2] TUMASYAN 23BC search for excited light flavor quark q^* in pp collisions at $\sqrt{s} = 13$ TeV. $f = 1.0$ is assumed.

[3] TUMASYAN 23BC search for excited b quark b^* in pp collisions at $\sqrt{s} = 13$ TeV. b^* production via gauge interactions and $f = 1.0$ are assumed. The limit becomes $m_{b^*} > 3.8$TeV if contact interaction is included in the b^* production cross section.

[4] AAD 20T search for resonances decaying into dijets in pp collisions at $\sqrt{s} = 13$ TeV. Assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$.

[5] SIRUNYAN 20AI search for resonances decaying into dijets in pp collisions at $\sqrt{s} = 13$ TeV. Assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$.

[6] AABOUD 18AB assume $\Lambda = m_{b^*}$, $f_s = f = f' = 1$. The contact interactions are not included in b^* production and decay amplitudes.

[7] AABOUD 18BA search for first-generation excited quarks (u^* and d^*) with degenerate mass, assuming $\Lambda = m_{q^*}$, $f_s = f = f' = 1$. The contact interactions are not included in q^* production and decay amplitudes.

[8] SIRUNYAN 18AG search for first-generation excited quarks (u^* and d^*) with degenerate mass, assuming $\Lambda = m_{q^*}$, $f_s = f = f' = 1$.

[9] SIRUNYAN 18AG search for excited b quark assuming $\Lambda = m_{q^*}$, $f_s = f = f' = 1$.

[10] SIRUNYAN 18BO assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$. The contact interactions are not included in q^* production and decay amplitudes.

[11] SIRUNYAN 18P use the hadronic decay of W or Z, assuming $\Lambda = m_{q^*}$, $f_s = f = f' = 1$.

[12] AABOUD 17AK assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$. The contact interactions are not included in q^* production and decay amplitudes. Only the decay of $q^* \to gu$ and $q^* \to gd$ is simulated as the benchmark signals in the analysis.

[13] HAYRAPETYAN 24G search for singly produced narrow resonances decaying to jjj in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 3 for limits on $\sigma \cdot B$.

[14] TUMASYAN 22O search for b^* decaying to tW in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above assumes $\kappa^b_L = g_L = 1$, $\kappa^b_R = g_R = 0$. The limit becomes $m_{b^*} >$

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

3.0 TeV (>3.2 TeV) if we assume $\kappa^b_L = g_L = 0$, $\kappa^b_R = g_R = 1$ ($\kappa^b_L = g_L = 1$, $\kappa^b_R = g_R = 1$). See their Fig. 3 for limits on $\sigma \cdot B$.

[15] SIRUNYAN 21AG search for b^* decaying to tW in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above assumes $\kappa^b_L = g_L = 1$, $\kappa^b_R = g_R = 0$. The limit becomes $m_{b^*} > 2.8$ TeV (> 3.1 TeV) if we assume $\kappa^b_L = g_L = 0$, $\kappa^b_R = g_R = 1$ ($\kappa^b_L = g_L = \kappa^b_R = g_R = 1$). See their Fig. 5 for limits on $\sigma \cdot B$.

[16] KHACHATRYAN 17W assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$. The contact interactions are not included in q^* production and decay amplitudes.

[17] AABOUD 16 assume $\Lambda = m_{b^*}$, $f_s = f = f' = 1$. The contact interactions are not included in the b^* production and decay amplitudes.

[18] AAD 16AH search for b^* decaying to tW in pp collisions at $\sqrt{s} = 8$ TeV. $f_g = f_L = f_R = 1$ are assumed. See their Fig. 12b for limits on $\sigma \cdot B$.

[19] AAD 16AI assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$.

[20] AAD 16AV search for single production of vector-like quarks decaying to Wb in pp collisions. See their Fig. 8 for the limits on couplings and mixings.

[21] AAD 16S assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$. The contact interactions are not included in q^* production and decay amplitudes.

[22] KHACHATRYAN 16I search for b^* decaying to tW in pp collisions at $\sqrt{s} = 8$ TeV. $\kappa^b_L = g_L = 1$, $\kappa^b_R = g_R = 0$ are assumed. See their Fig. 8 for limits on $\sigma \cdot B$.

[23] KHACHATRYAN 16K assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$. The contact interactions are not included in q^* production and decay amplitudes.

[24] KHACHATRYAN 16L search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV using the data scouting technique which increases the sensitivity to the low mass resonances.

[25] AAD 15V assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$. The contact interactions are not included in q^* production and decay amplitudes.

[26] KHACHATRYAN 15V assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$. The contact interactions are not included in q^* production and decay amplitudes.

[27] AAD 14A assume $\Lambda = m_{q^*}$, $f_s = f = f' = 1$.

[28] KHACHATRYAN 14 use the hadronic decay of W, assuming $\Lambda = m_{q^*}$, $f_s = f = f' = 1$.

[29] KHACHATRYAN 14 use the hadronic decay of Z, assuming $\Lambda = m_{q^*}$, $f_s = f = f' = 1$.

[30] KHACHATRYAN 14J assume $f_s = f = f' = \Lambda / m_{q^*}$.

[31] CHATRCHYAN 13AJ use the hadronic decay of W.

[32] CHATRCHYAN 13AJ use the hadronic decay of Z.

MASS LIMITS for Color Sextet Quarks (q_6)

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>84	95	[1] ABE	89D	CDF	$p\overline{p} \rightarrow q_6\overline{q}_6$

[1] ABE 89D look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color sextet quark is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. A limit of 121 GeV is obtained for a color decuplet.

MASS LIMITS for Color Octet Charged Leptons (ℓ_8)

$\lambda \equiv m_{\ell_8}/\Lambda$

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>86	95	[1] ABE	89D	CDF	Stable ℓ_8: $p\overline{p} \rightarrow \ell_8\overline{\ell}_8$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
		[2] ABT	93	H1	e_8: $ep \rightarrow e_8 X$

[1] ABE 89D look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color octet lepton is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. The limit improves to 99 GeV if it always fragments into a unit-charged hadron.

[2] ABT 93 search for e_8 production via e-gluon fusion in ep collisions with $e_8 \rightarrow eg$. See their Fig. 3 for exclusion plot in the m_{e_8}–Λ plane for $m_{e_8} = 35$–220 GeV.

MASS LIMITS for Color Octet Neutrinos (ν_8)

$\lambda \equiv m_{\ell_8}/\Lambda$

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>110	90	[1] BARGER	89	RVUE	ν_8: $p\overline{p} \rightarrow \nu_8\overline{\nu}_8$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
none 3.8–29.8	95	[2] KIM	90	AMY	ν_8: $e^+e^- \rightarrow$ acoplanar jets
none 9–21.9	95	[3] BARTEL	87B	JADE	ν_8: $e^+e^- \rightarrow$ acoplanar jets

[1] BARGER 89 used ABE 89B limit for events with large missing transverse momentum. Two-body decay $\nu_8 \rightarrow \nu g$ is assumed.

[2] KIM 90 is at $E_{cm} = 50$–60.8 GeV. The same assumptions as in BARTEL 87B are used.

[3] BARTEL 87B is at $E_{cm} = 46.3$–46.78 GeV. The limit assumes the ν_8 pair production cross section to be eight times larger than that of the corresponding heavy neutrino pair production. This assumption is not valid in general for the weak couplings, and the limit can be sensitive to its $SU(2)_L \times U(1)_Y$ quantum numbers.

MASS LIMITS for W_8 (Color Octet W Boson)

VALUE (GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[1] ALBAJAR	89	UA1	$p\overline{p} \rightarrow W_8 X$, $W_8 \rightarrow Wg$

[1] ALBAJAR 89 give $\sigma(W_8 \rightarrow W + \text{jet})/\sigma(W) < 0.019$ (90% CL) for $m_{W_8} > 220$ GeV.

Limits on R from Deviations in Gravitational Force Law

This section includes limits on the size of extra dimensions from deviations in the Newtonian ($1/r^2$) gravitational force law at short distances. Deviations are parametrized by a gravitational potential of the form $V = -(G\ m\ m'/r)\ [1 + \alpha \exp(-r/R)]$. For δ toroidal extra dimensions of equal size, $\alpha = 8\delta/3$. Quoted bounds are for $\delta = 2$ unless otherwise noted.

[1] FIORILLO 25 use neutron star cooling to search for new forces probing a range of $|\alpha| \simeq 4\times10^{10}$–$1\times10^{19}$ and length scales $R \simeq 1$–1×10^{-6} μm. See their Fig. 1 for details on the bound.

[2] BLAKEMORE 21 obtain constraints on non-Newtonian forces with strengths $|\alpha| \gtrsim 10^8$ and length scales $R > 10$ μm. See their Fig. 4 for more details including comparison with previous searches.

[3] HEACOCK 21 obtain constraints on non-Newtonian forces with strengths $10^{18} \lesssim |\alpha| \lesssim 10^{25}$ and length scales $R \simeq$ 0.02–10 nm. See their Figure 3 for more details. This improves the results of HADDOCK 18. These constraints do not place limits on the size of extra flat dimensions.

[4] LEE 20 search for new forces probing a range of $|\alpha| \simeq 0.1$–10^5 and length scales $R \simeq$ 7–90 μm. For $\delta = 1$ the bound on R is 30 μm. See their Fig. 5 for details on the bound.

[5] TAN 20A search for new forces probing a range of $|\alpha| \simeq 4\times10^{-3}$–$1\times10^2$ and length scales $R \simeq$ 40–350 μm. See their Fig. 6 for details on the bound.

[6] BERGE 18 uses results from the MICROSCOPE experiment to obtain constraints on non-Newtonian forces with strengths $10^{-11} \lesssim |\alpha| \lesssim 10^{-7}$ and length scales $R \gtrsim 10^5$ m. See their Figure 1 for more details. These constraints do not place limits on the size of extra flat dimensions.

[7] FAYET 18A uses results from the MICROSCOPE experiment to obtain constraints on an EP-violating force possibly arising from a new U(1) gauge boson. For $R \gtrsim 10^7$ m the limits are $|\alpha| \lesssim$ a few 10^{-13} to a few 10^{-11} depending on the coupling, corresponding to $|\epsilon| \lesssim 10^{-24}$ for the coupling of the new spin-1 or spin-0 mediator. These constraints do not place limits on the size of extra flat dimensions. This extends the results of FAYET 18.

[8] KLIMCHITSKAYA 17A uses an experiment that measures the difference of Casimir forces to obtain bounds on non-Newtonian forces with strengths $|\alpha| \simeq 10^5$–10^{17} and length scales $R = 0.03$–10 μm. See their Fig. 3. These constraints do not place limits on the size of extra flat dimensions.

[9] XU 13 obtain constraints on non-Newtonian forces with strengths $|\alpha| \simeq 10^{34}$–10^{36} and length scales $R \simeq$ 1–10 fm. See their Fig. 4 for more details. These constraints do not place limits on the size of extra flat dimensions.

[10] BEZERRA 11 obtain constraints on non-Newtonian forces with strengths $10^{11} \lesssim |\alpha| \lesssim 10^{18}$ and length scales $R =$ 30–1260 nm. See their Fig. 2 for more details. These constraints do not place limits on the size of extra flat dimensions.

[11] SUSHKOV 11 obtain improved limits on non-Newtonian forces with strengths $10^7 \lesssim |\alpha| \lesssim 10^{11}$ and length scales 0.4 μm $< R <$ 4 μm (95% CL). See their Fig. 2. These bounds do not place limits on the size of extra flat dimensions. However, a model dependent bound of $M_* > 70$ TeV is obtained assuming gauge bosons that couple to baryon number also propagate in $(4 + \delta)$ dimensions.

[12] BEZERRA 10 obtain improved constraints on non-Newtonian forces with strengths $10^{19} \lesssim |\alpha| \lesssim 10^{29}$ and length scales $R =$ 1.6–14 nm (95% CL). See their Fig. 1. This bound does not place limits on the size of extra flat dimensions.

[13] MASUDA 09 obtain improved constraints on non-Newtonian forces with strengths $10^9 \lesssim |\alpha| \lesssim 10^{11}$ and length scales $R =$ 1.0–2.9 μm (95% CL). See their Fig. 3. This bound does not place limits on the size of extra flat dimensions.

[14] GERACI 08 obtain improved constraints on non-Newtonian forces with strengths $|\alpha| >$ 14,000 and length scales $R =$ 5–15 μm. See their Fig. 9. This bound does not place limits on the size of extra flat dimensions.

[15] TRENKEL 08 uses two independent measurements of Newton's constant G to constrain new forces with strength $|\alpha| \simeq 10^{-4}$ and length scales $R =$ 0.02–1 m. See their Fig. 1. This bound does not place limits on the size of extra flat dimensions.

[16] DECCA 07A search for new forces and obtain bounds in the region with strengths $|\alpha| \simeq 10^{13}$–10^{18} and length scales $R =$ 20–86 nm. See their Fig. 6. This bound does not place limits on the size of extra flat dimensions.

[17] KAPNER 07 search for new forces, probing a range of $|\alpha| \simeq 10^{-3}$–10^5 and length scales $R \simeq$ 10–1000 μm. For $\delta = 1$ the bound on R is 44 μm. For $\delta = 2$, the bound is expressed in terms of M_*, here translated to a bound on the radius. See their Fig. 6 for details on the bound.

[18] TU 07 search for new forces probing a range of $|\alpha| \simeq 10^{-1}$–10^5 and length scales $R \simeq$ 20–1000 μm. For $\delta = 1$ the bound on R is 53 μm. See their Fig. 3 for details on the bound.

[19] SMULLIN 05 search for new forces, and obtain bounds in the region with strengths $\alpha \simeq 10^3$–10^8 and length scales $R =$ 6–20 μm. See their Figs. 1 and 16 for details on the bound. This work does not place limits on the size of extra flat dimensions.

[20] HOYLE 04 search for new forces, probing α down to 10^{-2} and distances down to 10μm. Quoted bound on R is for $\delta = 2$. For $\delta = 1$, bound goes to 160 μm. See their Fig. 34 for details on the bound.

[21] CHIAVERINI 03 search for new forces, probing α above 10^4 and λ down to 3μm, finding no signal. See their Fig. 4 for details on the bound. This bound does not place limits on the size of extra flat dimensions.

[22] LONG 03 search for new forces, probing α down to 3, and distances down to about 10μm. See their Fig. 4 for details on the bound.

[23] HOYLE 01 search for new forces, probing α down to 10^{-2} and distances down to 20μm. See their Fig. 4 for details on the bound. The quoted bound is for $\alpha \geq 3$.

[24] HOSKINS 85 search for new forces, probing distances down to 4 mm. See their Fig. 13 for details on the bound. This bound does not place limits on the size of extra flat dimensions.

Limits on R from On-Shell Production of Gravitons: $\delta = 2$

This section includes limits on on-shell production of gravitons in collider and astrophysical processes. Bounds quoted are on R, the assumed common radius of the flat extra dimensions, for $\delta = 2$ extra dimensions. Studies often quote bounds in terms of derived parameter; experiments are actually sensitive to the masses of the KK gravitons: $m_{\vec{n}} = |\vec{n}|/R$. See the Review on "Extra Dimensions" for details. Bounds are given in μm for $\delta = 2$.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[2] HANNESTAD 03 obtain a limit on R from the heating of old neutron stars by the surrounding cloud of trapped KK gravitons. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.

[3] SIRUNYAN 21A search for $pp \to ZG$, using 137 fb^{-1} of data at $\sqrt{s} = 13$ TeV to place lower limits on M_D for two to seven extra dimensions (see their Figure 12), from which this bound on R is derived. These limits supersede those obtained in SIRUNYAN 18BV.

[4] TUMASYAN 21D search for $pp \to jG$, using 137 fb^{-1} of data at $\sqrt{s} = 13$ TeV to place lower limits on M_D for two to seven extra dimensions (see their Table 3), from which this bound on R is derived. This limit supersedes that in SIRUNYAN 18S.

[5] SIRUNYAN 17AQ search for $pp \to \gamma G$, using 12.9 fb^{-1} of data at $\sqrt{s} = 13$ TeV to place limits on M_D for three to six extra dimensions (see their Table 3).

[6] AABOUD 16F search for $pp \to \gamma G$, using 3.2 fb^{-1} of data at $\sqrt{s} = 13$ TeV to place limits on M_D for two to six extra dimensions (see their Figure 9), from which this bound on R is derived.

[7] KHACHATRYAN 16N search for $pp \to \gamma G$, using 19.6 fb^{-1} of data at $\sqrt{s} = 8$ TeV to place limits on M_D for three to six extra dimensions (see their Table 5).

[8] AAD 15CS search for $pp \to \gamma G$, using 20.3 fb^{-1} of data at $\sqrt{s} = 8$ TeV to place lower limits on M_D for two to six extra dimensions (see their Fig. 18).

[9] AAD 13C search for $pp \to \gamma G$, using 4.6 fb^{-1} of data at $\sqrt{s} = 7$ TeV to place bounds on M_D for two to six extra dimensions, from which this bound on R is derived.

[10] AAD 13D search for the dijet decay of quantum black holes in 4.8 fb^{-1} of data produced in pp collisions at $\sqrt{s} = 7$ TeV to place bounds on M_D for two to seven extra dimensions, from which these bounds on R are derived. Limits on M_D for all $\delta \leq 7$ are given in their Table 3.

[11] AJELLO 12 obtain a limit on R from the gamma-ray emission of point γ sources that arise from the photon decay of KK gravitons which are gravitationally bound around neutron stars. Limits for all $\delta \leq 7$ are given in their Table 7.

[12] AALTONEN 08AC search for $p\overline{p} \to \gamma G$ and $p\overline{p} \to jG$ at $\sqrt{s} = 1.96$ TeV with 2.0 fb^{-1} and 1.1 fb^{-1} respectively, in order to place bounds on the fundamental scale and size of the extra dimensions. See their Table III for limits on all $\delta \leq 6$.

[13] ABAZOV 08S search for $p\overline{p} \to \gamma G$, using 1 fb^{-1} of data at $\sqrt{s} = 1.96$ TeV to place bounds on M_D for two to eight extra dimensions, from which these bounds on R are derived. See their paper for intermediate values of δ.

[14] DAS 08 obtain a limit on R from Kaluza-Klein graviton cooling of SN1987A due to plasmon-plasmon annihilation.

[15] ABULENCIA,A 06 search for $p\overline{p} \to jG$ using 368 pb^{-1} of data at $\sqrt{s} = 1.96$ TeV. See their Table II for bounds for all $\delta \leq 6$.

[16] ABDALLAH 05B search for $e^+e^- \to \gamma G$ at $\sqrt{s} = 180$–209 GeV to place bounds on the size of extra dimensions and the fundamental scale. Limits for all $\delta \leq 6$ are given in their Table 6. These limits supersede those in ABREU 00Z.

[17] ACHARD 04E search for $e^+e^- \to \gamma G$ at $\sqrt{s} = 189$–209 GeV to place bounds on the size of extra dimensions and the fundamental scale. See their Table 8 for limits with $\delta \leq 8$. These limits supersede those in ACCIARRI 99R.

[18] ACOSTA 04C search for $\overline{p}p \to jG$ at $\sqrt{s} = 1.8$ TeV to place bounds on the size of extra dimensions and the fundamental scale. See their paper for bounds on $\delta = 4, 6$.

[19] CASSE 04 obtain a limit on R from the gamma-ray emission of point γ sources that arises from the photon decay of gravitons around newly born neutron stars, applying the technique of HANNESTAD 03 to neutron stars in the galactic bulge. Limits for all $\delta \leq 7$ are given in their Table I.

[20] ABAZOV 03 search for $p\overline{p} \to jG$ at $\sqrt{s}$=1.8 TeV to place bounds on M_D for 2 to 7 extra dimensions, from which these bounds on R are derived. See their paper for bounds on intermediate values of δ. We quote results without the approximate NLO scaling introduced in the paper.

[21] HANNESTAD 03 obtain a limit on R from graviton cooling of supernova SN1987a. Limits for all $\delta \leq 7$ are given in their Tables V and VI.

[22] HANNESTAD 03 obtain a limit on R from gravitons emitted in supernovae and which subsequently decay, contaminating the diffuse cosmic γ background. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.

[23] HANNESTAD 03 obtain a limit on R from gravitons emitted in two recent supernovae and which subsequently decay, creating point γ sources. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits are corrected in the published erratum.

[24] HEISTER 03C use the process $e^+e^- \to \gamma G$ at $\sqrt{s} = 189$–209 GeV to place bounds on the size of extra dimensions and the scale of gravity. See their Table 4 for limits with $\delta \leq 6$ for derived limits on M_D.

[25] FAIRBAIRN 01 obtains bounds on R from over production of KK gravitons in the early universe. Bounds are quoted in paper in terms of fundamental scale of gravity. Bounds depend strongly on temperature of QCD phase transition and range from $R < 0.13\ \mu$m to 0.001 μm for δ=2; bounds for δ=3,4 can be derived from Table 1 in the paper.

[26] HANHART 01 obtain bounds on R from limits on graviton cooling of supernova SN 1987a using numerical simulations of proto-neutron star neutrino emission.

[27] CASSISI 00 obtain rough bounds on M_D (and thus R) from red giant cooling for δ=2,3. See their paper for details.

[28] ACCIARRI 99S search for $e^+e^- \to ZG$ at $\sqrt{s}$=189 GeV. Limits on the gravity scale are found in their Table 2, for $\delta \leq 4$.

Mass Limits on M_{TT}

This section includes limits on the cut-off mass scale, M_{TT}, of dimension-8 operators from KK graviton exchange in models of large extra dimensions. Ambiguities in the UV-divergent summation are absorbed into the parameter λ, which is taken to be $\lambda = \pm 1$ in the following analyses. Bounds for $\lambda = -1$ are shown in parenthesis after the bound for $\lambda = +1$, if appropriate. Different papers use slightly different definitions of the mass scale. The definition used here is related to another popular convention by $M_{TT}^4 = (2/\pi)\ \Lambda_T^4$, as discussed in the above Review on "Extra Dimensions."

[1] SIRUNYAN 18DD use dijet angular distributions in 35.9 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to place a lower bound on Λ_T, here converted to M_{TT}. This updates the results of SIRUNYAN 17F.

[2] GIUDICE 03 place bounds on Λ_6, the coefficient of the gravitationally-induced dimension-6 operator $(2\pi\lambda/\Lambda_6^2)(\sum \overline{f}\gamma_\mu\gamma^5 f)(\sum \overline{f}\gamma^\mu\gamma^5 f)$, using data from a variety of experiments. Results are quoted for $\lambda = \pm 1$ and are independent of δ.

[3] HAYRAPETYAN 24AJ use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to place lower limits on M_{TT} (equivalent to their M_S). This updates the results of SIRUNYAN 18DU.

[4] SIRUNYAN 21N use 137 (140) fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV in the dielectron (dimuon) channels to place a lower limit on Λ_T, here converted to M_{TT}. Bounds on individual channels can be found in their Table 7.

[5] SIRUNYAN 19AC use 35.9 (36.3) fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV in the dielectron (dimuon) channels to place a lower limit on Λ_T, here converted to M_{TT}. The dielectron and dimuon channels are combined with previous results in the diphoton channel to set the best limit. Bounds on individual channels and different priors can be found in their Table 2. This updates the results in KHACHATRYAN 15AE.

[6] AABOUD 17AP use 36.7 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to place lower limits on M_{TT} (equivalent to their M_S). This updates the results of AAD 13AS.

[7] AAD 14BE use 20 fb^{-1} of data from pp collisions at $\sqrt{s} = 8$ TeV in the dilepton channel to place lower limits on M_{TT} (equivalent to their M_S).

[8] AAD 13E use 4.9 and 5.0 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV in the dielectron and dimuon channels, respectively, to place lower limits on M_{TT} (equivalent to their M_S). The dielectron and dimuon channels are combined with previous results in the diphoton channel to set the best limit. Bounds on individual channels and different priors can be found in their Table VIII.

[9] BAAK 12 use electroweak precision observables to place bounds on the ratio Λ_T/M_D as a function of M_D. See their Fig. 22 for constraints with a Higgs mass of 120 GeV.

[10] AARON 11C search for deviations in the differential cross section of $e^\pm p \to e^\pm X$ in 446 pb^{-1} of data taken at $\sqrt{s} = 301$ and 319 GeV to place a bound on M_{TT}.

[11] ABAZOV 09AE use dijet angular distributions in 0.7 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to place lower bounds on Λ_T (equivalent to their M_S), here converted to M_{TT}.

[12] ABAZOV 09D use 1.05 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to place lower bounds on Λ_T (equivalent to their M_s), here converted to M_{TT}.

[13] SCHAEL 07A use e^+e^- collisions at $\sqrt{s} = 189$–209 GeV to place lower limits on Λ_T, here converted to limits on M_{TT}.

[14] ABDALLAH 06C use e^+e^- collisions at $\sqrt{s} \sim 130$–207 GeV to place lower limits on M_{TT}, which is equivalent to their definition of M_s. Bound shown includes all possible final state leptons, $\ell = e, \mu, \tau$. Bounds on individual leptonic final states can be found in their Table 31.

[15] GERDES 06 use 100 to 110 pb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.8$ TeV, as recorded by the CDF Collaboration during Run I of the Tevatron. Bound shown includes a K-factor of 1.3. Bounds on individual e^+e^- and $\gamma\gamma$ final states are found in their Table I.

[16] ABAZOV 05V use 246 pb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for deviations in the differential cross section to $\mu^+\mu^-$ from graviton exchange.

[17] CHEKANOV 04B search for deviations in the differential cross section of $e^\pm p \to e^\pm X$ with 130 pb^{-1} of combined data and Q^2 values up to 40,000 GeV^2 to place a bound on M_{TT}.

[18] ABBIENDI 03D use e^+e^- collisions at $\sqrt{s}$=181–209 GeV to place bounds on the ultraviolet scale M_{TT}, which is equivalent to their definition of M_s.

[19] ACHARD 03D look for deviations in the cross section for $e^+e^- \to ZZ$ from $\sqrt{s} =$ 200–209 GeV to place a bound on M_{TT}.

[20] ADLOFF 03 search for deviations in the differential cross section of $e^\pm p \to e^\pm X$ at $\sqrt{s}$=301 and 319 GeV to place bounds on M_{TT}.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[21] GIUDICE 03 review existing experimental bounds on M_{TT} and derive a combined limit.

[22] HEISTER 03C use e^+e^- collisions at $\sqrt{s}$= 189–209 GeV to place bounds on the scale of dim-8 gravitational interactions. Their M_S^+ is equivalent to our M_{TT} with $\lambda=\pm1$.

[23] ACHARD 02 search for s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$ at E_{cm} = 192–209 GeV.

[24] ABBOTT 01 search for variations in differential cross sections to e^+e^- and $\gamma\gamma$ final states at the Tevatron.

[25] ABBIENDI 00R uses e^+e^- collisions at $\sqrt{s}$= 189 GeV.

[26] ABREU 00A search for s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$ at E_{cm}= 189–202 GeV.

[27] ABREU 00S uses e^+e^- collisions at $\sqrt{s}$=183 and 189 GeV. Bounds on μ and τ individual final states given in paper.

[28] CHANG 00B derive 3σ limit on M_{TT} of (28,19,15) TeV for δ=(2,4,6) respectively assuming the presence of a torsional coupling in the gravitational action. Highly model dependent.

[29] CHEUNG 00 obtains limits from anomalous diphoton production at OPAL due to graviton exchange. Original limit for δ=4. However, unknown UV theory renders δ dependence unreliable. Original paper works in HLZ convention.

[30] GRAESSER 00 obtains a bound from graviton contributions to $g-2$ of the muon through loops of 0.29 TeV for δ=2 and 0.38 TeV for δ=4,6. Limits scale as $\lambda^{1/2}$. However calculational scheme not well-defined without specification of high-scale theory. See the "Extra Dimensions Review."

[31] HAN 00 calculates corrections to gauge boson self-energies from KK graviton loops and constrain them using S and T. Bounds on M_{TT} range from 0.5 TeV (δ=6) to 1.1 TeV (δ=2); see text. Limits have strong dependence, $\lambda^{\delta+2}$, on unknown λ coefficient.

[32] MATHEWS 00 search for evidence of graviton exchange in CDF and DØ dijet production data. See their Table 2 for slightly stronger δ-dependent bounds. Limits expressed in terms of $\widetilde{M}_S^4 = M_{TT}^4/8$.

[33] MELE 00 obtains bound from KK graviton contributions to $e^+e^- \to VV$ (V=γ,W,Z) at LEP. Authors use Hewett conventions.

[34] ABBIENDI 99P search for s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$ at E_{cm}=189 GeV. The limits $G_+ > 660$ GeV and $G_- > 634$ GeV are obtained from combined E_{cm}=183 and 189 GeV data, where $G_\pm$ is a scale related to the fundamental gravity scale.

[35] ACCIARRI 99M search for the reaction $e^+e^- \to \gamma G$ and s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$, W^+W^-, ZZ, e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, $q\overline{q}$ at E_{cm}=183 GeV. Limits on the gravity scale are listed in their Tables 1 and 2.

[36] ACCIARRI 99S search for the reaction $e^+e^- \to ZG$ and s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$, W^+W^-, ZZ, e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, $q\overline{q}$ at E_{cm}=189 GeV. Limits on the gravity scale are listed in their Tables 1 and 2.

[37] BOURILKOV 99 performs global analysis of LEP data on e^+e^- collisions at $\sqrt{s}$=183 and 189 GeV. Bound is on Λ_T.

Limits on $1/R = M_C$

This section includes limits on $1/R = M_C$, the compactification scale in models with one TeV-sized extra dimension, due to exchange of Standard Model KK excitations. Bounds assume fermions are not in the bulk, unless stated otherwise. See the "Extra Dimensions" review for discussion of model dependence.

[1] AAD 12CC use 4.9 and 5.0 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest KK Z/γ boson (equivalent to $1/R = M_C$). The limit quoted here assumes a flat prior corresponding to when the pure Z/γ KK cross section term dominates. See their Section 15 for more details.

[2] BARBIERI 04 use electroweak precision observables to place a lower bound on the compactification scale $1/R$. Both the gauge bosons and the Higgs boson are assumed to propagate in the bulk.

[3] FLORES 23 use a number of 13 TeV Run 2 searches at the LHC to place constraints on the compactification scale $1/R$ and cutoff scale Λ in the minimal universal extra dimension model with Standard Model fields propagating in the bulk (see their Fig.6).

[4] AVNISH 21 perform a study on the ATLAS collaboration search for multiple jets plus missing transverse energy from pp collisions at $\sqrt{s}$ = 13 TeV and integrated luminosity of 139 fb^{-1}, to place constraints on the compactification scale and cutoff scale Λ in universal extra dimension models with Standard Model fields propagating in the bulk.

[5] AABOUD 18AV use 36.1 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 13 TeV in final states with multiple b-jets, to place a lower bound on the compactification scale in a model with two universal extra dimensions. Assuming the radii of the two extra dimensions are equal, a lower limit of 1.8 TeV for the Kaluza-Klein mass is obtained.

[6] AABOUD 18CE use 36.1 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 13 TeV in final states with same-charge leptons and b-jets, to place a lower bound on the compactification scale in a model with two universal extra dimensions. Assuming the radii of the two extra dimensions are equal, a lower limit of 1.45 TeV for the Kaluza-Klein mass is obtained.

[7] ACCOMANDO 15 use electroweak precision observables to place a lower bound on the compactification scale $1/R$. See their Fig. 2 for the bound as a function of sinβ, which parametrizes the VEV contribution from brane and bulk Higgs fields. The quoted value is for the minimum bound which occurs at sinβ = 0.45.

[8] KHACHATRYAN 15T use 19.7 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 8 TeV to place a lower bound on the compactification scale $1/R$.

[9] CHATRCHYAN 13AQ use 5.0 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV and a further 3.7 fb^{-1} of data at $\sqrt{s}$ = 8 TeV to place a lower bound on the compactification scale $1/R$, in models with universal extra dimensions and Standard Model fields propagating in the bulk. See their Fig. 5 for the bound as a function of the universal bulk fermion mass parameter μ.

[10] CHATRCHYAN 13W use diphoton events with large missing transverse momentum in 4.93 fb^{-1} of data produced from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies Λ/M_C = 20. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.

[11] EDELHAUSER 13 use 19.6 and 20.6 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 8 TeV analyzed by the CMS Collaboration in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the second lightest Kaluza-Klein Z/γ boson (converted to a limit on $1/R = M_C$). The bound assumes Standard Model fields propagating in the bulk and that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies Λ/M_C = 20.

[12] AAD 12CP use diphoton events with large missing transverse momentum in 4.8 fb^{-1} of data produced from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies Λ/M_C = 20. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.

[13] AAD 12X use diphoton events with large missing transverse momentum in 1.07 fb^{-1} of data produced from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies Λ/M_C = 20. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.

[14] ABAZOV 12M use same-sign dimuon events in 7.3 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to place a lower bound on the compactification scale $1/R$, in models with universal extra dimensions where all Standard Model fields propagate in the bulk.

[15] BAAK 12 use electroweak precision observables to place a lower bound on the compactification scale $1/R$, in models with universal extra dimensions and Standard Model fields propagating in the bulk. Bound assumes a 125 GeV Higgs mass. See their Fig. 25 for the bound as a function of the Higgs mass.

[16] FLACKE 12 use electroweak precision observables to place a lower bound on the compactification scale $1/R$, in models with universal extra dimensions and Standard Model fields propagating in the bulk. See their Fig. 1 for the bound as a function of the universal bulk fermion mass parameter μ.

[17] NISHIWAKI 12 use up to 2 fb^{-1} of data from the ATLAS and CMS experiments that constrains the production cross section of a Higgs-like particle to place a lower bound on the compactification scale $1/R$ in universal extra dimension models. The quoted bound assumes Standard Model fields propagating in the bulk and a 125 GeV Higgs mass. See their Fig. 1 for the bound as a function of the Higgs mass.

[18] AAD 11F use diphoton events with large missing transverse energy in 3.1 pb^{-1} of data produced from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies Λ/M_C = 20. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.

[19] AAD 11X use diphoton events with large missing transverse energy in 36 pb^{-1} of data produced from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies Λ/M_C = 20. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.

[20] ABAZOV 10P use diphoton events with large missing transverse energy in 6.3 fb^{-1} of data produced from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies Λ/M_C=20. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.

[21] ABAZOV 09AE use dijet angular distributions in 0.7 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to place a lower bound on the compactification scale.

[22] HAISCH 07 use inclusive $\overline{B}$-meson decays to place a Higgs mass independent bound on the compactification scale $1/R$ in the minimal universal extra dimension model.

[23] GOGOLADZE 06 use electroweak precision observables to place a lower bound on the compactification scale in models with universal extra dimensions. Bound assumes a 115 GeV Higgs mass. See their Fig. 3 for the bound as a function of the Higgs mass.

[24] CORNET 00 translates a bound on the coefficient of the 4-fermion operator $(\overline{\ell}\gamma_\mu\tau^a\ell)(\overline{\ell}\gamma^\mu\tau^a\ell)$ derived by Hagiwara and Matsumoto into a limit on the mass scale of KK W bosons.

[25] RIZZO 00 obtains limits from global electroweak fits in models with a Higgs in the bulk (3.8 TeV) or on the standard brane (3.3 TeV).

Limits on Kaluza-Klein Gravitons in Warped Extra Dimensions

This section places limits on the mass of the first Kaluza-Klein (KK) excitation of the graviton in the warped extra dimension model of Randall and Sundrum. Bounds in parenthesis assume Standard Model fields propagate in the bulk. Experimental bounds depend strongly on the warp parameter, k. See the "Extra Dimensions" review for a full discussion.

Here we list limits for the value of the warp parameter $k/\overline{M}_P = 0.1$.

[1] SIRUNYAN 21N use 137 (140) fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for dilepton resonances in the dielectron (dimuon) channel. See Table 6 for other limits with warp parameter values $k/\overline{M}_P = 0.01$ and 0.05. This updates the results of SIRUNYAN 18BB.

[2] TUMASYAN 25 use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production in the $b\overline{b}b\overline{b}$ final state. See their Figure 5 for limits on the cross section times branching fraction as a function of the KK graviton mass, corresponding to $k/\overline{M}_P = 0.5$. This updates the results of SIRUNYAN 18AF and SIRUNYAN 18CW.

[3] HAYRAPETYAN 24AE use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production in the $b\overline{b}WW$ final state. See their Figure 19 for limits on the cross section times branching fraction as a function of the KK graviton mass for $k/\overline{M}_P = 0.3$, 0.5 and 1.

[4] HAYRAPETYAN 24AJ use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV, in the diphoton channel to place a lower limit on the mass of the lightest KK graviton. See their paper for limits with other warp parameter values $k/\overline{M}_P = 0.01$ and 0.2. This updates the results of SIRUNYAN 18DU.

[5] TUMASYAN 24B use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production in the $\gamma\gamma b\overline{b}$ final state. See their Figure 6 for limits on the cross section times branching fraction as a function of the KK graviton mass assuming $k/\overline{M}_P = 0.5$ and 1. This updates the result of SIRUNYAN 19.

[6] TUMASYAN 23AP use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for WW, ZZ diboson resonances in $q\overline{q}q\overline{q}$ final states. See their Figure 7 for the limit on the cross section times branching fraction as a function of the KK graviton mass. Assuming $k/\overline{M}_P = 0.5$, a graviton mass is excluded below 1400 GeV. This updates the result of SIRUNYAN 20Q.

[7] AAD 22F use 126–139 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production in the $b\overline{b}b\overline{b}$ final state. See their Figure 14 for limits on the cross section times branching fraction as a function of the KK graviton mass. Assuming $k/\overline{M}_P = 1$, gravitons in the mass range 298–1460 GeV are excluded. This updates the results of AABOUD 19A.

[8] TUMASYAN 22D use 137 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for WW resonances in $\ell\nu qq$ final states ($\ell = e, \mu$). See their Figure 6 for the limit on the KK graviton mass as a function of the cross section times branching fraction, including theoretical values for $k/\overline{M}_P = 0.5$. This updates the results of SIRUNYAN 18AX.

[9] TUMASYAN 22J use 137 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for ZZ resonances in the $\nu\overline{\nu}q\overline{q}$ final state. See their Figure 10 for the limit on the KK graviton mass as a function of the cross section times branching fraction, assuming $k/\overline{M}_P = 0.5$. This updates the result of SIRUNYAN 18BK.

[10] TUMASYAN 22R use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for ZZ resonances in $2\ell 2q$ final states ($\ell = e, \mu$). See their Figure 8 for the limit on the KK graviton mass as a function of the cross section times branching fraction. Assuming $k/\overline{M}_P = 0.5$, a graviton mass is excluded below 1200 GeV. This updates the result of SIRUNYAN 18DJ.

[11] TUMASYAN 22U use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production in the $b\overline{b}q\overline{q}'\ell\nu$, $b\overline{b}\ell\nu\ell\nu$ and $b\overline{b}\ell\nu\nu\ell\nu\nu$ final states ($\ell = e, \mu$). See their Figure 7 for limits on the cross section times branching fraction as a function of the KK graviton mass, including theoretical values for $k/\overline{M}_P = 0.3$ and 0.5. This updates the results of SIRUNYAN 19CF and SIRUNYAN 18F.

[12] AAD 21AF use 139 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for ZZ resonances in the $\ell\ell\ell\ell$ and $\ell\ell\nu\overline{\nu}$ final states (ℓ=e, μ). See their Figure 8 for the limit on the cross section times branching fraction as a function of the KK graviton mass, including theoretical values for $k/\overline{M}_P = 1$. This updates the results of AAD 15AU and AABOUD 18BF.

[13] AAD 21AY use 139 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV in the diphoton channel to place a lower limit on the mass of the lightest KK graviton. This updates the results of AABOUD 17AP.

[14] AAD 20AT use 139 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for diboson resonances in semileptonic final states ($\ell\nu qq$,$\ell\ell qq$, $\nu\nu qq$). See their Figure 15 for the limit on the cross section times branching fraction as a function of the KK graviton mass. Lower limits on the graviton mass are also given for $k/\overline{M}_P = 1$. This updates the results of AABOUD 18AK and AABOUD 18AL.

[15] AAD 20C use 36.1 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production in the $b\overline{b}b\overline{b}$, $b\overline{b}W^+W^-$, and $b\overline{b}\tau^+\tau^-$ final states. See their Figure 5(b)(c) for limits on the cross section as a function of the KK graviton mass. In the case of $k/\overline{M}_P = 1$ and 2, gravitons are excluded in the mass range 260–3000 GeV and 260–1760 GeV, respectively.

[16] AAD 20T use 139 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for narrow resonances decaying to bottom quark pairs. See their Figure 7 for the limit on the product of the cross section, branching fraction, acceptance and b-tagging efficiency as a function of the KK graviton mass. In the case of $k/\overline{M}_P = 0.2$, KK gravitons in the mass range 1.25–2.8 TeV are excluded.

[17] SIRUNYAN 20AI use 137 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for dijet resonances. See their Figure 6 for the limit on the product of the cross section, branching fraction and acceptance as a function of the KK graviton mass. This updates the results of SIRUNYAN 18BO.

[18] SIRUNYAN 20F use 35.9 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production in the $b\overline{b}ZZ$ final state. See their Figure 4 for limits on the cross section times branching fraction as a function of the KK graviton mass, and Figure 5 for limits as a function of $k/\overline{M}_P$.

[19] AABOUD 19O use 36.1 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production in the $b\overline{b}WW$ final state. See their Figure 12 for limits on the cross section times branching fraction as a function of the KK graviton mass for $k/\overline{M}_P = 1$ and $k/\overline{M}_P = 2$.

[20] AAD 19D use 139 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for diboson resonances in the all-hadronic final state. See their Figure 9(b) for the limit on the cross section times branching fraction as a function of the KK graviton mass, including theoretical values for $k/\overline{M}_P = 1$. This updates the results of AABOUD 18F.

[21] SIRUNYAN 19BE use 35.9 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production by combining the results from four final states: $b\overline{b}\gamma\gamma$, $b\overline{b}\tau\overline{\tau}$, $b\overline{b}b\overline{b}$, and $b\overline{b}VV$. See their Figure 7 for limits on the cross section times branching fraction as a function of the KK graviton mass.

[22] AABOUD 18BI use 36.1 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for top-quark pairs decaying into the lepton-plus jets topology. See their Figure 16 for the limit on the KK graviton mass as a function of the cross section times branching fraction, including theoretical values for $k/\overline{M}_P = 1$.

[23] AABOUD 18CJ combine the searches for heavy resonances decaying into bosonic and leptonic final states from 36.1 fb^{-1} of pp collision data at $\sqrt{s} = 13$ TeV. The lower limit on the KK graviton mass, with $k/\overline{M}_P = 1$, is 2.3 TeV.

[24] AABOUD 18CQ use 36.1 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production in the $b\overline{b}\tau^+\tau^-$ final state. See their Figure 2 for limits on the cross section times branching fraction as a function of the KK graviton mass. Assuming $k/\overline{M}_P = 1$, gravitons in the mass range 325–885 GeV are excluded.

[25] AABOUD 18CW use 36.1 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for Higgs boson pair production in the $\gamma\gamma b\overline{b}$ final state. See their Figure 7 for limits on the cross section times branching fraction as a function of the KK graviton mass.

[26] SIRUNYAN 18AS use 35.9 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for ZZ resonances in the $\ell\ell\nu\overline{\nu}$ final state (ℓ=e, μ). See their Figure 5 for the limit on the KK graviton mass as a function of the cross section times branching fraction, including theoretical values for $k/\overline{M}_P = 0.1$, 0.5, and 1.0.

[27] SIRUNYAN 18I use 19.7 fb^{-1} of data from pp collisions at $\sqrt{s} = 8$ TeV to search for narrow resonances decaying to bottom quark pairs. See their Figure 3 for the limit on the KK graviton mass as a function of the cross section times branching fraction in the mass range of 325–1200 GeV.

[28] AAD 16R use 20.3 fb^{-1} of data from pp collisions at $\sqrt{s} = 8$ TeV to place a lower bound on the mass of the lightest KK graviton. See their Figure 4 for the limit on the KK graviton mass as a function of the cross section times branching fraction.

[29] AAD 15AZ use 20.3 fb^{-1} of data from pp collisions at $\sqrt{s} = 8$ TeV to place a lower bound on the mass of the lightest KK graviton. See their Figure 2 for limits on the KK graviton mass as a function of the cross section times branching ratio.

[30] AAD 15CP use 20.3 fb^{-1} of data from pp collisions at $\sqrt{s} = 8$ TeV to place a lower bound on the mass of the lightest KK graviton. See their Figures 6b and 6c for the limit on the KK graviton mass as a function of the cross section times branching fraction.

[31] AAD 14V use 20.3 (20.5) fb^{-1} of data from pp collisions at $\sqrt{s} = 8$ TeV in the dielectron (dimuon) channels to place a lower bound on the mass of the lightest KK graviton. This updates the results of AAD 12CC .

[32] AAD 13A use 4.7 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV in the $\ell\nu\ell\nu$ channel, to place a lower bound on the mass of the lightest KK graviton.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[33] AAD 13AO use 4.7 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV in the $\ell\nu jj$ channel, to place a lower bound on the mass of the lightest KK graviton.

[34] AAD 13AS use 4.9 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV in the diphoton channel to place lower limits on the mass of the lightest KK graviton. The diphoton channel is combined with previous results in the dielectron and dimuon channels to set the best limit. See their Table 2 for warp parameter values $k/\overline{M}_P$ between 0.01 and 0.1. This updates the results of AAD 12Y .

[35] AAD 12AD use 1.02 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV to search for KK gravitons in a warped extra dimension decaying to ZZ dibosons in the $lljj$ and $llll$ channels (ℓ=e, μ). The limit is quoted for the combined $lljj + llll$ channels. See their Figure 5 for limits on the cross section $\sigma(G \to ZZ)$ as a function of the graviton mass.

[36] AALTONEN 12V use 6 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for KK gravitons in a warped extra dimension decaying to ZZ dibosons in the $lljj$ and $llll$ channels (ℓ=e, μ). It provides improved limits over the previous analysis in AALTONEN 11G. See their Figure 16 for limits from all channels combined on the cross section times branching ratio $\sigma(p\overline{p} \to G^* \to ZZ)$ as a function of the graviton mass.

[37] BAAK 12 use electroweak precision observables to place a lower bound on the compactification scale $k\, e^{-\pi k R}$, assuming Standard Model fields propagate in the bulk and the Higgs is confined to the IR brane. See their Fig. 27 for more details.

[38] AALTONEN 11G use 2.5–2.9 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for KK gravitons in a warped extra dimension decaying to ZZ dibosons via the $eeee$, $ee\mu\mu$, $\mu\mu\mu\mu$, $eejj$, and $\mu\mu jj$ channels. See their Fig. 20 for limits on the cross section $\sigma(G \to ZZ)$ as a function of the graviton mass.

[39] AALTONEN 11R uses 5.7 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV in the dielectron channel to place a lower bound on the mass of the lightest graviton. It provides combined limits with the diphoton channel analysis of AALTONEN 11U. For warp parameter values $k/\overline{M}_P$ between 0.01 to 0.1 the lower limit on the mass of the lightest graviton is between 612 and 1058 GeV. See their Table I for more details.

[40] ABAZOV 11H use 5.4 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to place a lower bound on the mass of the lightest graviton. Their 95% C.L. exclusion limit does not include masses less than 300 GeV.

[41] AALTONEN 10N use 2.9 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to place a lower bound on the mass of the lightest graviton.

[42] ABAZOV 10F use 5.4 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to place a lower bound on the mass of the lightest graviton. For warp parameter values of $k/\overline{M}_P$ between 0.01 and 0.1 the lower limit on the mass of the lightest graviton is between 560 and 1050 GeV. See their Fig. 3 for more details.

[43] AALTONEN 08S use $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to four electrons via two Z bosons using 1.1 fb^{-1} of data. See their Fig. 8 for limits on $\sigma \cdot B(G \to ZZ)$ versus the graviton mass.

[44] ABAZOV 08J use $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to electrons and photons using 1 fb^{-1} of data. For warp parameter values of $k/\overline{M}_P$ between 0.01 and 0.1 the lower limit on the mass of the lightest excitation is between 300 and 900 GeV. See their Fig. 4 for more details.

[45] AALTONEN 07G use $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to photons using 1.2 fb^{-1} of data. For warp parameter values of $k/\overline{M}_P = 0.1$, 0.05, and 0.01 the bounds on the graviton mass are 850, 694, and 230 GeV, respectively. See their Fig. 3 for more details. See also AALTONEN 07H.

[46] AALTONEN 07H use $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to electrons using 1.3 fb^{-1} of data. For a warp parameter value of $k/\overline{M}_P = 0.1$ the bound on the graviton mass is 807 GeV. See their Fig. 4 for more details. A combined analysis with the diphoton data of AALTONEN 07G yields for $k/\overline{M}_P = 0.1$ a graviton mass lower bound of 889 GeV.

[47] ABAZOV 05N use $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to muons, electrons or photons, using 260 pb^{-1} of data. For warp parameter values of $k/\overline{M}_P = 0.1$, 0.05, and 0.01, the bounds on the graviton mass are 785, 650 and 250 GeV respectively. See their Fig. 3 for more details.

[48] ABULENCIA 05A use $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to muons or electrons, using 200 pb^{-1} of data. For warp parameter values of $k/\overline{M}_P = 0.1$, 0.05, and 0.01, the bounds on the graviton mass are 710, 510 and 170 GeV respectively.

Limits on Kaluza-Klein Gluons in Warped Extra Dimensions

This section places limits on the mass of the first Kaluza-Klein (KK) excitation of the gluon in warped extra dimension models with Standard Model fields propagating in the bulk. Bounds are given for a specific benchmark model with $\Gamma/m = 15.3\%$ where Γ is the width and m the mass of the KK gluon. See the "Extra Dimensions" review for more discussion.

[1] AABOUD 18BI use 36.1 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV. This result updates AAD 13AQ.

[2] HAYRAPETYAN 25T use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to place limits on a KK gluon decaying to W bosons via a spin-0 radion, R. See their Figure 6 for limits on the cross section times branching fraction as a function of the KK gluon and radion mass.

[3] HAYRAPETYAN 24G use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to place limits on a KK gluon decaying to gluons via a spin-0 radion, R. See their Figure 3 for limits on the cross section times branching fraction as a function of the KK gluon mass and various values of the radion mass. This updates the results of TUMASYAN 22C.

[4] AABOUD 19AS use 36.1 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV. An upper bound of 3.4 TeV is placed on the KK gluon mass for $\Gamma/m = 30\%$.

[5] SIRUNYAN 19AL use 35.9 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to place limits on a KK gluon decaying to a top quark and a heavy vector-like fermion, T. KK gluon masses between 1.5 and 2.3 TeV and between 2.0 and 2.4 TeV are excluded for T masses of 1.2 and 1.5 TeV, respectively.

[6] CHATRCHYAN 13BM use 19.7 fb^{-1} of data from pp collisions at $\sqrt{s} = 8$ TeV. Bound is for a width of approximately 15–20% of the KK gluon mass.

[7] CHEN 13A place limits on the KK mass scale for a specific warped model with custodial symmetry and bulk fermions. See their Figures 4 and 5.

[8] AAD 12BV use 2.05 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV.

Black Hole Production Limits

Semiclassical Black Holes

VALUE (GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[1] SIRUNYAN	18DA	CMS	$pp \to$ multijet

	[4] AAD	13AW	ATLS	$pp \to \mu\mu$

[1] SIRUNYAN 18DA use 35.9 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for semiclassical black holes decaying to multijet final states. No excess of events above the expected level of standard model background was observed. Exclusions at 95% CL are set on the mass threshold for black hole production as a function of the higher-dimensional Planck scale for rotating and nonrotating black holes under several model assumptions (ADD, 2, 4, 6 extra dimensions model) in the 7.1–10.3 TeV range. These limits supersede those in SIRUNYAN 17CP.

[2] AAD 16N use 3.6 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for semiclassical black hole decays to multijet final states. No excess of events above the expected level of Standard Model background was observed. Exclusion contours at 95% C.L. are set on the mass threshold for black hole production versus higher-dimensional Planck scale for rotating black holes (ADD, 6 extra dimensions model).

[3] AAD 16O use 3.2 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for semiclassical black hole decays to high-mass final states with leptons and jets. No excess of events above the expected level of Standard Model background was observed. Exclusion contours at 95% C.L. are set on the mass threshold for black hole production versus higher-dimensional Planck scale for rotating black holes (ADD, 2 to 6 extra dimensions).

[4] AAD 13AW use 20.3 fb^{-1} of data from pp collisions at $\sqrt{s} = 8$ TeV to search for semiclassical black hole decays to like-sign dimuon final states using large track multiplicity. No excess of events above the expected level of Standard Model background was observed. Exclusion contours at 95% C.L. are set on the mass threshold for black hole production versus higher-dimensional Planck scale in various extra dimensions, rotating and non-rotating models.

[1] AAD 24S use 140 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for quantum black hole decays to final states with high-invariant-mass lepton + jet. No excess of events above the expected level of Standard Model background was observed. Exclusion limits at 95% C.L. are set on mass thresholds for black hole production in an ADD (6 extra dimensions) model and the Randall-Sundrum (one extra dimension) model. The resulting lower mass threshold limits in the ADD (RS) models are 9.2 (6.8) TeV. The ADD limit supersedes that in AAD 14AL.

[2] AAD 23CB use 139 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for quantum black hole decays with different-flavor high-mass dilepton final states. No excess of events above the expected level of Standard Model background was observed. Exclusion limits at 95% C.L. are set on mass thresholds for black hole production in ADD (6 extra dimensions) and RS1 models. Assuming the black hole mass threshold is equal to the higher-dimensional Planck scale, mass thresholds below 5.9 (3.8), 5.2 (3.0), and 5.1 (3.0) TeV are excluded in the $e\mu$, $e\tau$ and $\mu\tau$ channels for the ADD (RS1) models, respectively. These limits supersede those in AABOUD 18CM.

[3] TUMASYAN 23AW use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for quantum black hole decays in the tau lepton plus missing transverse momentum final state. Assuming the black hole mass threshold is equal to the higher-dimensional Planck scale, threshold masses below 6.6 TeV are excluded in the ADD model with four extra dimensions (see their Figure 8).

[4] TUMASYAN 23BC use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for quantum black hole decays to final states with a photon and a jet. No excess of events above the expected level of Standard Model background was observed. Exclusion limits at 95% C.L. are set on mass thresholds for black hole production in ADD (6 extra dimensions) and RS1 models. Assuming the black hole mass threshold is equal to the higher-dimensional Planck scale, mass thresholds below 7.5 TeV and 5.2 TeV are excluded for the ADD and RS1 models, respectively (see their Figure 9).

[5] TUMASYAN 23H use 138 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for quantum black hole decays with different-flavor high-mass dilepton final states. No excess of events above the expected level of Standard Model background was observed.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

Exclusion limits at 95% C.L. are set on mass thresholds for black hole production in the ADD model (with 4 extra dimensions). Assuming the black hole mass threshold is equal to the higher-dimensional Planck scale, mass thresholds below 5.6, 5.2, and 5.0 TeV are excluded in the $e\mu$, $e\tau$ and $\mu\tau$ channels, respectively.

[6] AAD 20T use 139 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for quantum black hole decays to final states with dijets. No excess of events above the expected level of Standard Model background was observed. Exclusion limits at 95% C.L. are set on mass thresholds for black hole production in an ADD (6 extra dimensions) model. Assuming the black hole mass threshold is equal to the higher-dimensional Planck scale, mass thresholds below 9.4 TeV are excluded. This limit supersedes AABOUD 17AK.

[7] AABOUD 18BA use 36.7 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for quantum black hole decays to final states with a photon and a jet. No excess of events above the expected level of Standard Model background was observed. Exclusion limits at 95% C.L. are set on mass thresholds for black hole production in ADD (6 extra dimensions) and RS1 models. Assuming the black hole mass threshold is equal to the Planck scale, mass thresholds below 7.1 TeV and 4.4 TeV are excluded for the ADD and RS1 models, respectively. These limits supersede those in AAD 16AI.

[8] SIRUNYAN 18AT use 35.9 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for quantum black hole decays to $e\mu$ final states. In Figure 4, lower mass limits of 5.3, 5.5 and 5.6 TeV are placed in a model with 4, 5 and 6 extra dimensions, respectively, and a lower mass limit of 3.6 TeV is found for a single warped dimension.

[9] SIRUNYAN 18DD use 35.9 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for quantum black hole decays in dijet angular distributions. A lower mass limit of 5.9 (8.2) TeV is placed in the RS (ADD) model with one (six) extra dimension(s).

[10] SIRUNYAN 17CP use 2.3 fb^{-1} of data from pp collisions at $\sqrt{s} = 13$ TeV to search for quantum black holes decaying to dijet final states. No excess of events above the expected level of standard model background was observed. Limits on the quantum black hole mass threshold are set as a function of the higher-dimensional Planck scale, under the assumption that the mass threshold must exceed the above Planck scale. Depending on the model, mass thresholds in the range up to 5.1–9.0 TeV are excluded.

[11] KHACHATRYAN 16BE use 19.7 fb^{-1} of data from pp collisions at $\sqrt{s} = 8$ TeV to search for quantum black holes undergoing lepton flavor violating decay to the $e\mu$ final state. No excess of events above the expected level of standard model background was observed. Exclusion limits at 95% CL are set on mass thresholds for black hole production in the ADD (2–6 flat extra dimensions), RS1 (1 warped extra dimension), and a model with a Planck scale at the TeV scale from a renormalization of the gravitational constant (no extra dimensions). Limits on the black hole mass threshold are set assuming that it is equal to the higher-dimensional Planck scale. Mass thresholds for quantum black holes in the range up to 3.15–3.63 TeV are excluded in the ADD model. In the RS1 model, mass thresholds below 2.81 TeV are excluded in the PDG convention for the Schwarzschild radius. In the model with no extra dimensions, mass thresholds below 1.99 TeV are excluded.

[12] KHACHATRYAN 15V use 19.7 fb^{-1} of data from pp collisions at $\sqrt{s} = 8$ TeV to search for quantum black holes decaying to dijet final states. No excess of events above the expected level of standard model background was observed. Exclusion limits at 95% CL are set on mass thresholds for black hole production in the ADD (2–6 flat extra dimensions) and RS1 (1 warped extra dimension) model. Limits on the black hole mass threshold are set as a function of the higher-dimensional Planck scale, under the assumption that the mass threshold must exceed the above Planck scale. Depending on the model, mass thresholds in the range up to 5.0–6.3 TeV are excluded. This paper supersedes CHATRCHYAN 13AD.

[13] AAD 14V use 20.3 (20.5) fb^{-1} of data in the dielectron (dimuon) channels from pp collisions at $\sqrt{s} = 8$ TeV to search for quantum black hole decays involving high-mass dilepton resonances. No excess of events above the expected level of Standard Model background was observed. Exclusion limits at 95% C.L. are set on mass thresholds for black hole production in ADD (6 extra dimensions) and RS1 models. Assuming the black hole mass threshold is equal to the higher-dimensional Planck scale, mass thresholds below 3.65 TeV and 2.24 TeV are excluded for the ADD and RS1 models, respectively.

[14] CHATRCHYAN 13A use 5 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV to search for quantum black holes decaying to dijet final states. No excess of events above the expected level of standard model background was observed. Exclusion limits at 95% CL are set on mass thresholds for black hole production in the ADD (2–6 flat extra dimensions) and RS (1 warped extra dimension) model. Limits on the black hole mass threshold are set as a function of the higher-dimensional Planck scale, under assumption that the mass threshold must exceed the above Planck scale. Depending on the model, mass thresholds in the range up to 4.0–5.3 TeV are excluded.

WIMP and Dark Matter Searches

We omit papers on CHAMP's, millicharged particles, and other exotic particles.

GALACTIC WIMP SEARCHES

These limits are for weakly-interacting stable particles that may constitute the invisible mass in the galaxy. Unless otherwise noted, a local mass density of 0.3 GeV/cm^3 is assumed; see each paper for velocity distribution assumptions. In the papers the limit is given as a function of the X^0 mass. Here we list limits only for typical mass values of sub-GeV, GeV, 20 GeV, 100 GeV, and 1 TeV. Specific limits on supersymmetric dark matter particles may be found in the Supersymmetry section.

Spin-Independent Cross Section Limits for Dark Matter Particle (X^0) on Nucleon

For m_{X^0} in GeV range

We provide here limits fo $m_{X^0} < 5$ GeV

[1] AALBERS 25A search for sub-GeV cosmic-ray boosted wimps at LZ. No signal observed. Limits placed in m(DM): 1×10^{-4}–1 GeV range vs. σ^{SI} plane. Quoted limit for m(DM) = 1 MeV.

[2] ADAMS 25 report on fermionic DM in MeV range search via DM absorption at PICO-60. No signal observed. Limits placed on absorption cross section for EFT operator O_4 vs. m(DM) .

[3] APRILE 25 report light DM search near edge of neutrino fog using XENONnT. No signal observed. Require $\sigma^{SI}(\chi N) < 2.5 \times 10^{-9}$ pb for m(χ) = 6 GeV.

[4] APRILE 25A search for light MeV-scale DM using XENONnT. No signal observed. Limits placed in various planes. Quoted limit for Halo light DM with heavy mediator Fig. 5b with m(χ) = 1 GeV.

[5] BUI 25 report search for light DM via phonons in TESSERACT detector. No signal observed. Limits placed in m(χ) vs. σ^{SI} plane for MeV-scale DM. Quoted limit is for m(χ) = 87 MeV.

[6] ZHANG 25B search for light GeV-scale wimps using run 0 and run 1 PandaX-4T data. No signal observed. Quoted limit is for m(χ) = 3 GeV.

[7] ANGLOHER 24 search for spin-independent light WIMP (mass between 0.16 and 6 GeV) scatter on diamond target. No signal observed. Limits placed in σ^{SI} vs mass plane for sub-GeV WIMPs. Quoted limit is for m(WIMP) = 0.2 GeV.

[8] ANGLOHER 24B search for low mass m(wimp) ~ 100 MeV. No signal observed. Limits placed in cross section vs. mass plane. Quoted limit for m(wimp) = 100 MeV.

[9] AALBERS 23A search for e recoil events from GeV scale WIMP scatter on Xe. No signal observed. Limits placed on 6 different models including $\sigma^{SI} < 3\times10^{-3}$ for m(χ) ~ 1 GeV via Migdal scattering.

[10] AGNES 23 for for light DM via e recoil/Migdal effect. No signal observed. $\sigma^{SI}(\chi N) < 4\times10^{-7}$ pb for m(χ) = 3 GeV.

[11] AGNES 23B search for GeV-scale DM scatter on nucleons in Ar. No signal observed. Limit $\sigma^{SI}(\chi N) < 6\times10^{-7}$ pb for m(χ) = 3 GeV.

[12] ALBAKRY 23 search for light DM via Migdal effect. No signal observed. Allow $\sigma^{SI} < 0.5$ pb for m(χ)=1 GeV (see e.g. Fig. 7).

[13] AMBROSONE 23 derive limits on $\sigma(\chi p)$ due to possible DM distortion of cosmic ray spectra in starburst galaxies. Limits placed in σ vs. mass (10^{-3}–10 MeV) plane, the most stringent given above being at 1 keV.

[14] ANGLOHER 23 search for light DM using Si target. No signal observed. Require $\sigma^{SI} <$ 70 pb for m(χ) = 0.3 GeV (see e.g. Fig. 5).

[15] LI 23F searches for SI light DM scatter from Xe. No signal observed. The quoted limit for m(χ) = 4 GeV.

[16] MA 23A search for GeV-scale DM using PandaX-4T. No signal observed. $\sigma(\chi p) < 5\times10^{-10}$ pb for m(χ) = 10 GeV.

[17] ADHIKARI 22B search for sub-GeV WIMPs via SI and SD detection; no signal detected; limits placed in m(χ) vs. σ plane for m(χ): 0.2–3 GeV; quoted limit is for m(χ) = 1 GeV.

[18] ARMENGAUD 22 search for GeV-scale DM scatter on Ge at EDELWEISS via Migdal effect; no signal observed; limits placed in $\sigma^{SI}(\chi N)$ vs. m(DM) plane; quoted limit is for m(DM) = 100 MeV.

[19] CUI 22 search for sub-GeV boosted DM at PandaX-II at CJPL; no signal detected; limits set in $\sigma^{SI}(\chi p)$ vs. m(χ) plane; quoted limit for m(χ) = 0.1 GeV.

[20] XU 22 search for sub-GeV boosted DM in CDEX; no signal observed; limits placed in $\sigma(\chi N)$ vs. m(DM) plane; quoted limit is for m(DM) = 0.1 GeV.
[21] AKERIB 21A present new technique for low mass WIMP detection. Require $\sigma^{SI}(p\chi) < 2\times10^{-7}$ pb for m(WIMP) 10 GeV.
[22] ALKHATIB 21 search for light DM using SuperCDMS; require $\sigma^{SI}(p\chi) < 5\times10^{6}$ for m(DM) = 0.1 GeV.
[23] ANDRIAMIRADO 21A search for upscattered (boosted) sub-GeV DM interacting with proton in PROSPECT detector. No signal observed. Limits placed in $\sigma(\chi N)$ vs. m(DM) plane for m(DM) $\sim$ 1 keV $-$ 0.5 GeV. The listed limit is for m(DM) = 1 keV.
[24] APRILE 21 search for low recoil energy GeV-scale DM in XENON1T with 1.6 keV threshold. No signal in 0.6 t y exposure. Limits placed in $\sigma^{SI}(\chi N)$ vs. m(DM) plane for m(DM) between 3–12 GeV. The listed limit is for m(DM) = 5 GeV.
[25] AGUILAR-AREVALO 20C search for WIMP SI scatter on Si using DAMIC at SNOLab; some excess; limits placed in σ vs m(DM) for m(DM) in 1.2–10 GeV; quoted limit for m(WIMP) = 2 GeV.
[26] AKERIB 20A search for GeV-scale WIMPs via WIMP-nucleon scatter with single photon emission; no signal; limits placed in m(WIMP) vs σ^{SI} plane: for example $\sigma^{SI}(\chi n) < 8\times10^{-4}$ pb for m(WIMP) = 2.5 GeV.
[27] ABDELHAMEED 19A search for GeV scale dark matter SI scatter on $CaWO_4$; no signal, limits placed in σ vs. mass plane for m(DM) $\sim$ 0.1–10 GeV. The listed limit is for m(DM) = 1 GeV.
[28] AGNESE 19A search for 1.5–10 GeV WIMP scatter on Ge in CDMSlite dataset. Limits set in a likelihood analysis. No signal was observed. Limit reported for m(χ) = 5 GeV.
[29] AKERIB 19 search for 0.4–5 GeV DM using bremsstrahlung photons and "Migdal" electrons; 1.4×10^{4} kg d exposure of liquid Xe; constraint $\sigma^{SI}(\chi N) < 1$ pb for m(χ) = 5 GeV in light scalar mediator model.
[30] AMOLE 19 search for SI WIMP scatter on C_3F_8 in PICO-60 bubble chamber; no signal: set limit for spin independent coupling $\sigma^{SI}(\chi N) < 1\times10^{-6}$ pb for m(χ) = 5 GeV.
[31] APRILE 19C search for light DM scatter on Xe via atomic excitation, ionization (Migdal effect) or bremsstrahlung; no signal, limits placed in σ vs. m(DM) plane for m(DM) $\sim$ 0.085–2 GeV. The listed limit is for m(DM) = 1 GeV.
[32] APRILE 19D search for light DM scatter on Xe via ionization to probe SI, SD, and χe cross sections; with 22 t d exposure, limits placed in various σ vs. m(DM) planes. Quoted limit is for m(DM) = 5 GeV.
[33] ARMENGAUD 19search for GeV scale WIMP scatter on Ge; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 0.045–10 GeV; quoted limit is for m(χ) = 5 GeV.
[34] KOBAYASHI 19 search for sub-GeV WIMP annual modulation in Xe via brems; no signal; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m $\sim$ 0.3–1 GeV; quoted limit is for m(χ) = 0.5 GeV.
[35] LIU 19B seach for sub-GeV DM using Migdal effect on Ge at CDEX-IB; no signal, require $\sigma^{SI}(\chi N) < 7\times10^{2}$ pb for m(χ) = 0.1 GeV.
[36] AGNES 18 search for 1.8–20 GeV WIMP SI scatter on Ar; quoted limit is for m(χ) = 5 GeV.
[37] AGNESE 18 search for GeV scale WIMPs using CDMSlite; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m $\sim$ 1.5–20 GeV; quoted limit is for m(χ) = 5 GeV.
[38] APRILE 18 search for WIMP scatter on 1 t yr Xe; no signal, limits set in $\sigma(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 6–1000 GeV; quoted limit is for m = 6 GeV.
[39] ARNAUD 18 search for low mass WIMP scatter on Ne via SPC at NEWS-G; limits set in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m $\sim$ 0.5–20 GeV; quoted limit is for m = 5 GeV.
[40] JIANG 18 search for GeV scale WIMP scatter on Ge; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 3–10 GeV; quoted limit is for m(χ) = 5 GeV.
[41] YANG 18 search for WIMP scatter on Ge; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 2–10 GeV; quoted limit is for m(χ) = 5 GeV.
[42] AKERIB 17 search for WIMP scatter on Xe; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 5–1×10^{5} GeV; quoted limit is for m(χ) = 5 GeV.
[43] ANGLOHER 17A search for GeV scale WIMP scatter on Al_2O_3 crystal; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 0.15–10 GeV; quoted limit is for m(χ) = 5 GeV.
[44] ANGLOHER 16 search for GeV scale WIMP scatter on $CaWO_4$; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 0.5–30 GeV; quoted limit is for m(χ) = 5 GeV.
[45] APRILE 16 search for low mass WIMPs via ionization at XENON100; limits placed in $\sigma^{SI}(\chi N)$ vs m(χ) plane for m $\sim$ 3.5–20 GeV; quoted limit is for m(χ) = 5 GeV.
[46] ARMENGAUD 16 search for GeV scale WIMP scatter on Ge; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 4–30 GeV; quoted limit is for m(χ) = 5 GeV.
[47] HEHN 16 search for low mass WIMPs via SI scatter on Ge target using profile likelihood analysis; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 4–30 GeV; quoted limit is for m(χ) = 5 GeV.
[48] ZHAO 16 search for GeV-scale WIMP scatter on Ge; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 4–30 GeV; quoted limit is for m(χ) = 5 GeV.
[49] AMOLE 15 search for WIMP scatter on C_3F_8 in PICO-2L; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 4–25 GeV; quoted limit is for m(χ) = 5 GeV.
[50] XIAO 15 search for WIMP scatter on Xe with PandaX-I; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 5–100 GeV; quoted limit is for m(χ) = 5 GeV.
[51] AGNESE 14 search for GeV scale WIMPs SI scatter at SuperCDMS; no signal, limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 3.5–30 GeV; quoted limit is for m(χ) = 5 GeV.
[52] AKERIB 14 search for WIMP scatter on Xe; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 5–5000 GeV. Limit given for m(χ) = 5 GeV.
[53] LI 13B search for WIMP scatter on Ge; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 4–100 GeV; quoted limit is for m(χ) = 5 GeV.
[54] ARCHAMBAULT 12 search for low mass WIMP scatter on C_4F_{10}; limits set in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m $\sim$ 4–12 GeV; quoted limit is for m = 5 GeV.
[55] AALSETH 11 search for GeV-scale SI WIMP scatter on Ge; limits placed on $\sigma^{SI}(\chi N)$ for m(χ) $\sim$ 3.5–100 GeV; quoted limit is for m(χ) = 5 GeV.
[56] AHMED 11B search for GeV scale WIMP scatter on Ge in CDMS II; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m $\sim$ 4–12 GeV.
[57] ANGLE 11 search for GeV scale WIMPs in Xenon-10; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 4–20 GeV; quoted limit is for m(χ) = 5 GeV.
[58] AKERIB 10 search for WIMP scatter on Ge/Si in CDMS II; limits place in $\sigma_{SI}(\chi N)$ vs. m(χ) plane for m $\sim$ 3–100 GeV. Limit given for m(DM) = 5 GeV.

For m_{χ^0} = 20 GeV

For limits from χ^0 annihilation in the Sun, the assumed annihilation final state is shown in parenthesis in the comment.

[1] AALBERS 25 report search for SI WIMP interaction at LZ using 4.2 ton-years exposure. No signal observed. Limits placed in m(DM) vs. $\sigma^{SI}(\chi N)$ plane.

[2] APRILE 25B search for wimps using 3.1 ton-years of data. No signal observed. Limits placed in σ^{SI} vs m(χ) plane.

[3] BO 25 search for wimp dark matter with PandaX-4T. No signal detected. Limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane.

[4] DAS 25 report WIMP DM search with InDEx detector. No signal observed. Limits placed in σ vs. m plane.

[5] UMEMOTO 25 report on directional DM search using nano-imaging tracking (NIT) emulsion device. No signal observed. Limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane.

[6] YU 25 report on COSINE-100 wimp search in 3-year data. No signal observed. Limits placed in σ^{SI} vs m(χ) plane.

[7] ANGLOHER 24A search for WIMP scatter on NaI target. No signal observed. Limits placed in σ^{SI} vs m plane.

[8] AALBERS 23 present first limits for WIMP scatter on Xe. $\sigma^{SI}(\chi p) < 1\times10^{-11}$ pb for m(χ) = 20 GeV.

[9] ABE 23E search for WIMP scatter on Xe in XMASS. No signal observed. Require $\sigma^{SI} < 2\times10^{-7}$ pb for m(χ) = 20 GeV.

[10] APRILE 23A present first results from Xe-nton SI WIMP search. No signal observed. Quoted limit is for m(χ) = 20 GeV.

[11] MENG 21B search for SI WIMP interaction with 3.7 t Xe and 0.63 t yr exposure. No signal observed. Limits placed in m(DM) vs. σ^{SI} plane.

[12] FELIZARDO 20 presents 2014 SIMPLE bounds on WIMP DM using C_2ClF_5 target.

[13] WANG 20G search for SI WIMP scatter on Xe with 132 t d exposure of PANDAX-II.

[14] ANGLOHER 19 search for low mass WIMP scatter on $CaWO_4$; no signal; limits placed on Wilson coefficients for m(χ) = 0.6–60 GeV.

[15] KIM 19A search for WIMP scatter in NaI KIMS experiment; no signal: require $\sigma^{SI}(\chi n) < 7\times10^{-5}$ pb for m(χ) = 20 GeV.

[16] KOBAYASHI 19 search for WIMP scatter in XMASS single-phase liquid Xe detector; no signal; require $\sigma^{SI}(\chi N) < 3\times10^{-7}$ pb for m(χ) = 20 GeV.

[17] SEONG 19 search for $\Upsilon \to \gamma A$, $A \to \chi\chi$ via CP-odd Higgs; no signal; limits on BF set; model dependent conversion to WIMP-nucleon scattering cross section limits $\sigma^{SI} < 10^{-36}$ cm^2 for m(χ) = 0.01–1 GeV.

[18] YANG 19 search for low mass wimps via annual modulation in Ge; no signal; require $\sigma^{SI}(\chi N) < 3.5\times10^{-5}$ pb for m(χ) = 20 GeV.

[19] ABE 18C search for WIMP annual modulation signal for m(WIMP): 6–20 GeV; limits set on SI WIMP-nucleon cross section: see Fig. 6.

[20] ADHIKARI 18 search for WIMP scatter on NaI; no signal; require $\sigma^{SI} < 1.44\times10^{-5}$ pb for m(WIMP) = 20 GeV; inconsistent with DAMA/LIBRA result.

[21] AGNES 18 search low mass m(WIMP): 1.8–20 GeV scatter on Ar; limits on SI WIMP-nucleon cross section set in Fig. 8.

[22] AGNESE 18 give limits for $\sigma^{SI}(\chi N)$ for m(WIMP) between 1.5 and 20 GeV using CDMSlite mode data.

[23] AGNESE 18A search for WIMP scatter on Ge at SuperCDMS; 1 event, consistent with expected background; set limit in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m ~ 10–250 GeV.

[24] APRILE 18 search for WIMP scatter on 1 t yr Xe; no signal, limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) ~ 6–1000 GeV.

[25] ARNAUD 18 search for low mass WIMP scatter on Ne via SPC at NEWS-G; limits set in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m ~ 0.5–20 GeV.

[26] AARTSEN 17 obtain σ(SI) < 6×10^{-6} pb for m(wimp) = 20 GeV from ν from earth.

[27] AKERIB 17 search for WIMP scatter on Xe; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) ~ 5–1 $\times 10^5$ GeV.

[28] BARBOSA-DE-SOUZA 17 search for annual modulation of WIMP scatter on NaI using an exposure of 61 kg yr of DM-Ice17 for recoil energy in the 4–20 keV range (DAMA found modulation for recoil energy < 5 keV). No modulation seen. Sensitivity insufficient to distinguish DAMA signal from null.

[29] CUI 17A search for SI WIMP scatter; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m ~ 10–1 $\times 10^4$ GeV using 54 ton-day exposure of Xe.

[30] AGNESE 16 CDMSlite excludes low mass WIMPs 1.6–5.5 GeV and SI scattering cross section depending on m(WIMP); see Fig. 4.

[31] AGUILAR-AREVALO 16 search low mass 1–10 GeV WIMP scatter on Si CCDs; set limits Fig. 11.

[32] ANGLOHER 16 search for GeV scale WIMP scatter on $CaWO_4$; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) ~ 0.5–30 GeV.

[33] APRILE 16 search for low mass WIMPs via ionization at XENON100; limits placed in $\sigma^{SI}(\chi N)$ vs m(χ) plane for m ~ 3.5–20 GeV.

[34] ARMENGAUD 16 search for GeV scale WIMP scatter on Ge; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) ~ 4–30 GeV.

[35] HEHN 16 search for low mass WIMPs via SI scatter on Ge target using profile likelihood analysis; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) ~ 4–30 GeV.

[36] ZHAO 16 search for GeV-scale WIMP scatter on Ge; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) ~ 4–30 GeV.

[37] AGNESE 15A reanalyse AHMED 11B low threshold data. See their Fig. 12 (left) for improved limits extending down to 5 GeV.

[38] AGNESE 15B reanalyse AHMED 10 data.

[39] See their Fig. 7 for limits extending down to 4 GeV.

[40] XIAO 15 search for WIMP scatter on Xe with PandaX-I; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) ~ 5–100 GeV.

[41] This limit value is provided by the authors. See their Fig. 4 for limits extending down to m_{X^0} = 3.5 GeV.

[42] This limit value is provided by the authors. AGNESE 14A result is from CDMSlite mode operation with enhanced sensitivity to low mass m_{X^0}. See their Fig. 3 for limits extending down to m_{X^0} = 3.5 GeV (see also Fig. 4 in AGNESE 14).

[43] See their Fig. 5 for limits extending down to m_{X^0} = 5.5 GeV.

[44] See their Fig. 5 for limits extending down to m_{X^0} = 1 GeV.

[45] See their Fig. 5 for limits extending down to m_{X^0} = 5 GeV.

[46] LIU 14A result is based on prototype CDEX-0 detector. See their Fig. 13 for limits extending down to m_{X^0} = 2 GeV.

[47] See their Fig. 4 for limits extending down to m_{X^0} = 4.5 GeV.

[48] AARTSEN 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken between June 2010 and May 2011.

[49] See their Fig. 8 for limits extending down to m_{X^0} = 7 GeV.

[50] This limit value is provided by the authors. AGNESE 13 use data taken between Oct. 2006 and July 2007. See their Fig. 4 for limits extending down to m_{X^0} = 7 GeV.

[51] This limit value is provided by the authors. AGNESE 13A use data taken between July 2007 and Sep. 2008. Three candidate events are seen. Assuming these events are real, the best fit parameters are m_{X^0} = 8.6 GeV and $\sigma = 1.9\times10^{-5}$ pb.

[52] This limit value is provided by the authors. Limit from combined data of AGNESE 13 and AGNESE 13A. See their Fig. 4 for limits extending down to m_{X^0} = 5.5 GeV.

[53] BERNABEI 13A search for annual modulation of counting rate in the 2–6 keV recoil energy interval, in a 14 yr live time exposure of 1.33 t yr. Find a modulation of 0.0112 ± 0.0012 counts/(day kg keV) with 9.3 sigma C.L. Find period and phase in agreement with expectations from DM particles.

[54] LI 13B search for WIMP scatter on Ge; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) ~ 4–100 GeV.

[55] See their Fig. 5 for limits for m_{X^0} = 4–12 GeV.

[56] ANGLOHER 12 observe excess events above the expected background which are consistent with X^0 with mass ~ 25 GeV (or 12 GeV) and spin-independent X^0-nucleon cross section of 2×10^{-6} pb (or 4×10^{-5} pb).

[57] Reanalysis of ANGLOHER 09 data with all three nuclides. See also BROWN 12.

[58] See also APRILE 14A.

[59] See their Fig. 4 for limits extending down to m_{X^0} = 7 GeV.

[60] See their Fig. 13 for cross section limits for m_{X^0} between 1.2 and 10 GeV.

[61] See also DAHL 12 for a criticism.

[62] See their Fig. 4 for limits extending to m_{X^0} = 3.5 GeV.

[63] AALSETH 11A find indications of annual modulation of the data, the energy spectrum being compatible with X^0 mass around 8 GeV. See also AALSETH 13.

[64] AHMED 11 search for X^0 inelastic scattering. See their Fig. 8–10 for limits. The inelastic cross section reduces to the elastic cross section at the limit of zero mass splitting (Fig. 8, left).

[65] AHMED 11A combine CDMS II and EDELWEISS data.

[66] ANGLE 11 show limits down to m_{X^0} = 4 GeV on Fig. 3.

[67] APRILE 11 reanalyze APRILE 10 data.

[68] APRILE 11A search for X^0 inelastic scattering. See their Fig. 2 and 3 for limits. See also APRILE 14A.

[69] HORN 11 perform detector calibration by neutrons. Earlier results are only marginally affected.

[70] See their Fig. 10 and 12 for limits extending to X^0 mass of 1 GeV.

[71] Superseded by AHMED 10.

[72] See their Fig. 6(a) for cross section limits for m_{X^0} extending down to 2 GeV.

[73] See their Fig. 2 for cross section limits for m_{X^0} between 4 and 10 GeV.

For m_{X^0} = 100 GeV

For limits from X^0 annihilation in the Sun, the assumed annihilation final state is shown in parenthesis in the comment.

[1] AALBERS 25 search for WIMP DM using 4.2 ton-year LZ exposure. No signal observed. Limits placed in m(DM) vs. $\sigma^{SI}(\chi N)$ plane.

[2] APRILE 25B search for wimps using 3.1 ton-years of data. No signal observed. Limits placed in σ^{SI} vs m(χ) plane.

[3] BO 25 search for wimp dark matter with PandaX-4T. No signal detected. Limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane.

[4] UMEMOTO 25 use directional DM search in nano-imaging tracking (NIT) emulsion device. No signal observed. Limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane.

[5] YU 25 report on COSINE-100 wimp search in 3-year data. No signal observed. Limits placed in σ^{SI} vs m(χ) plane.

[6] ANGLOHER 24A search for WIMP scatter on NaI target. No signal observed. Limits placed in σ^{SI} vs m plane.

[7] AALBERS 23 present first LZ limits on SI WIMP-nucleon scatter from Xe. $\sigma^{SI}(\chi p) < 2.5\times10^{-11}$ pb for m(χ) = 100 GeV.

[8] ABE 23E search for WIMP scatter on Xe in XMASS. No signal observed. Require $\sigma^{SI} < 2\times10^{-7}$ pb for m(χ) = 100 GeV.

[9] APRILE 23A present first results from Xe-nton SI WIMP search. No signal observed. Quoted limit is for m(χ) = 100 GeV.

[10] MENG 21B search for SI WIMP interaction with 3.7 t Xe and 0.63 t yr exposure. No signal observed. Limits placed in m(DM) vs. σ^{SI} plane.

[11] ADHIKARI 20 search for SI WIMP scatter from Ar in AJAJ 19 data. No signal observed. Limits placed on σ^p vs. m(WIMP) for various assumed operators and models.

[12] FELIZARDO 20 presents 2014 SIMPLE bounds on WIMP DM using C_2ClF_5 target.

[13] WANG 20G search for SI WIMP scatter on Xe with 132 t d exposure of PANDAX-II.

[14] ABE 19 search for SI DD in single phase Xe; no signal; require $\sigma^{SI}(\chi p) < 4\times10^{-8}$ pb for m(χ) $\sim$ 100 GeV.

[15] AJAJ 19 search for SI WIMP-nucleon scatter with 758 tonne day exposure of single phase liquid Ar; no signal: require $\sigma^{SI}(\chi N) < 3.9\times10^{-9}$ pb for m(χ) = 100 GeV.

[16] ADHIKARI 18 search for WIMP scatter on NaI;limit set $\sigma^{SI}(\chi p) < 2.3\times10^{-6}$ pb for m(χ) = 100 GeV.

[17] AGNES 18A search for WIMP scatter on 46.4 kg Ar; no signal; require $\sigma^{SI}(\chi N) < 1.14\times10^{-8}$ pb for m(χ) = 100 GeV.

[18] AGNESE 18A set limit $\sigma^{SI}(\chi N) < 2\times10^{-8}$ pb for m(WIMP) = 100 GeV.

[19] AMAUDRUZ 18 search for WIMP scatter on Ar with DEAP-3600; limits set: $\sigma^{SI}(\chi p) < 1.2\times10^{-8}$ pb for m(WIMP) = 100 GeV.

[20] APRILE 18 search for WIMP scatter on 1.3 t liquid Xe; no signal; require $\sigma^{SI}(\chi p) < 9.12\times10^{-11}$ pb for m(χ) = 100 GeV.

[21] REN 18 search for self-interacting DM at Panda-X-II with a total exposure of 54 ton day; limits set in m(DM) vs. m(mediator) plane.

[22] AKERIB 17 exclude SI cross section $> 1.7\times10^{-10}$ pb for m(WIMP) = 100 GeV. Uses complete LUX data set.

[23] APRILE 17G set limit $\sigma^{SI}(\chi p) < 1.2\ 10^{-10}$ pb for m(WIMP) = 100 GeV using 1 ton fiducial mass Xe TPC. Exposure is 34.2 live days.

[24] CUI 17A search for SI WIMP scatter; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m $\sim$ 10–1 $\times 10^4$ GeV using 54 ton-day exposure of Xe.

[25] AKERIB 16 re-analysis of 2013 data exclude SI cross section $> 1\times10^{-9}$ pb for m(WIMP) = 100 GeV on Xe target.

[26] APRILE 16B combined 447 live days using Xe target exclude σ(SI) $> 1.1\times10^{-9}$ pb for m(WIMP) = 50 GeV.

[27] TAN 16 search for WIMP scatter off Xe target; see SI exclusion plot Fig. 6.

[28] TAN 16B search for WIMP-p scatter off Xe target; see Fig. 5 for SI exclusion.

[29] AGNESE 15B reanalyse AHMED 10 data.

[30] XIAO 15 search for WIMP scatter on Xe with PandaX-I; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 5–100 GeV.

[31] AVRORIN 14 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the Sun in data taken between 1998 and 2003. See their Table 1 for limits assuming annihilation into neutrino pairs.

[32] AARTSEN 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken between June 2010 and May 2011.

[33] ADRIAN-MARTINEZ 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken between Jan. 2007 and Dec. 2008.

[34] AGNESE 13 use data taken between Oct. 2006 and July 2007.

[35] BOLIEV 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken from 1978 to 2009. See also SUVOROVA 13 for an older analysis of the same data.

[36] LI 13B search for WIMP scatter on Ge; limits placed in $\sigma^{SI}(\chi N)$ vs. m(χ) plane for m(χ) $\sim$ 4–100 GeV.

[37] ABBASI 12 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the Sun. The amount of X^0 depends on the X^0-proton cross section.

[38] Reanalysis of ANGLOHER 09 data with all three nuclides. See also BROWN 12.

[39] See also APRILE 14A.

[40] See their Fig. 6 for a limit on inelastically scattering X^0 for $m_{X^0} = 70$ GeV.

[41] AHMED 11 search for X^0 inelastic scattering. See their Fig. 8–10 for limits.

[42] AHMED 11A combine CDMS and EDELWEISS data.

[43] AJELLO 11 search for $e^{\pm}$ flux from X^0 annihilations in the Sun. Models in which X^0 annihilates into an intermediate long-lived weakly interacting particles or X^0 scatters inelastically are constrained. See their Fig. 6–8 for limits.

[44] APRILE 11 reanalyze APRILE 10 data.

[45] APRILE 11A search for X^0 inelastic scattering. See their Fig. 2 and 3 for limits. See also APRILE 14A.

[46] Supersedes ARMENGAUD 10. A limit on inelastic cross section is also given.

[47] HORN 11 perform detector calibration by neutrons. Earlier results are only marginally affected.

[48] AKIMOV 10 give cross section limits for inelastically scattering dark matter. See their Fig. 4.

[49] Superseded by AHMED 10.

[50] ANGLE 09 search for X^0 inelastic scattering. See their Fig. 4 for limits.

[51] GIULIANI 05 analyzes the spin-independent X^0–nucleon cross section limits with both isoscalar and isovector couplings. See their Fig. 3 and 4 for limits on the couplings.

For $m_{X^0} = 1$ TeV

For limits from X^0 annihilation in the Sun, the assumed annihilation final state is shown in parenthesis in the comment.

[1] ADAMS 25 report on fermionic DM in MeV range search via nuclear absorption at PICO-60. No signal observed. Limits placed on m(DM) vs. absorption cross section for EFT operator O_4.
[2] ARORA 25 report search for light DM at NEWS-G. No signal observed. Limits placed in $\sigma^{SD}(\chi p)$ vs m(χ) plane. Quoted limit is for m(χ) = 0.76 GeV.
[3] YU 25 report on COSINE-100 wimp search in 3-year data. No signal observed. Limits placed in $\sigma^{SD}(\chi p)$ vs m(χ) plane. Quoted limit for m(χ) = 3 GeV.
[4] ZHANG 25B search for light GeV-scale wimps using run 0 and run 1 PandaX-4T data. No signal observed. Quoted limit is for m(χ) = 3 GeV.
[5] ANGLOHER 24B search for low mass wimps. No signal observed. Limits placed in σ vs. m plane. Quoted limit for m = 100 MeV.
[6] AALBERS 23A search for GeV-scale WIMP scatter on Xe. No signal observed. Limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane. Quoted limit is for m(χ) = 1 GeV via Migdal scattering.
[7] ADHIKARI 22B search for sub-GeV WIMPs via SI and SD detection; no signal detected; limits placed in m(χ) vs. σ plane for m(χ): 0.2–3 GeV; quoted limit is for SD m(χ) = 1 GeV.
[8] ANGLOHER 22 search for SD WIMP-proton scatter from Li target; no signal detected; limits placed in σ vs. m(WIMP) plane; limit quoted for m(WIMP) = 1 GeV.
[9] ANGLOHER 22A search for spin-dependent DM scatter on Li and Al for m(DM) $\sim$ 0.2–6 GeV; no signal observed; limits set in $\sigma(\chi p)$ vs. m(DM) plane; quoted limit is for m(DM) = 1 GeV.
[10] ABDELHAMEED 20A use $LiAlO_2$ target in CRESST to search for SD WIMP scatter on p; no signal; quoted limit is for m(DM) = 1 GeV.
[11] ABDELHAMEED 19 search for SD WIMP scatter on ^{7}Li; limits placed on $\sigma^{SD}(\chi p)$ for m(χ) $\sim$ 0.8–20 GeV; quoted limit is for m(χ) = 1 GeV.
[12] AMOLE 19 search for SD WIMP scatter on C_3F_8 in PICO-60 bubble chamber; no signal: set limit for spin dependent coupling $\sigma^{SD}(\chi p) < 2\times10^{-4}$ pb for m(χ) = 5 GeV.
[13] APRILE 19C search for light DM on Xe via Migdal/brem effect; no signal, require $\sigma^{SD}(\chi p) < 1.7\times10^4$ pb for m(χ) = 1 GeV.
[14] ARMENGAUD 19 search for GeV scale WIMP scatter on Ge; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 0.5–10 GeV; quoted limit is for m(χ) = 5 GeV.
[15] XIA 19A search for WIMP scatter on Xe in PandaX-II; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 5–1 $\times 10^5$ GeV; quoted limit is for m(χ) = 5 GeV.
[16] AGNESE 18 search for GeV scale WIMPs with CDMSlite; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 1.5–20 GeV; quoted limit is for m(χ) = 5 GeV.
[17] AKERIB 17A search for SD WIMP scatter on Xe using 129.5 kg yr exposure; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 6–1 $\times 10^5$ GeV.
[18] FU 17 search for SD WIMP scatter on Xe; limits set in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 4–1 $\times 10^3$ GeV.; quoted limit is for m(χ) = 5 GeV.
[19] AMOLE 15 search for WIMP scatter on C_3F_8 in PICO-2L; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 4–1 $\times 10^4$ GeV; quoted limit is for m(χ) = 5 GeV.
[20] ARCHAMBAULT 12 search for SD WIMP scatter in ^{19}F with PICASSO; limits set in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m $\sim$ 4–500 GeV; quoted limit is for m(χ) = 5 GeV.

For $m_{X^0} = 20$ GeV

For limits from X^0 annihilation in the Sun, the assumed annihilation final state is shown in parenthesis in the comment.

[1] DAS 25 search for WIMP DM with InDEx detector. No signal observed. Limits placed in σ vs. m plane.

[2] AALBERS 23 yield first SD LZ limits on WIMP-p scatter using Xe. $\sigma^{SD}(\chi p) < 6 \times 10^{-5}$ pb for m(χ) = 20 GeV.

[3] ABBASI 22B search for WIMP annihilation to $b\overline{b}$, $\tau\overline{\tau}$, $\nu\overline{\nu}$ in Sun with 7 years data; no signal; limits set in m(χ) vs. $\sigma^{SD}(\chi p)$ plane for m(χ): 10–100 GeV; quoted limit for $\nu\overline{\nu}$ channel.

[4] ANGLOHER 22 search for SD WIMP-proton scatter from Li target; no signal detected; limits placed in σ vs. m(WIMP) plane.

[5] HUANG 22 search for SD DM scatter on Xe; no signal observed; limits placed in $\sigma(\chi n)$ vs. m(DM) plane; quoted limit is for m(DM) = 20 GeV.

[6] AARTSEN 20C place combined IceCube and Pico-60 velocity-independent limits on spin-dependent WIMP-p scatter $\sigma^{SD}(\chi p) <$ 9–5 pb for m(WIMP) = 20 GeV assuming dominant annihilation to $\tau\overline{\tau}$.

[7] ABDELHAMEED 20A use $LiAlO_2$ target in CRESST to search for spin-dependent WIMP scatter on p; limits set for m(WIMP): 0.3–30 GeV in Fig. 8. Quoted limit is for M(WIMP) = 30 GeV.

[8] FELIZARDO 20 presents 2014 SIMPLE bounds on WIMP DM using C_2ClF_5 target.

[9] ABDELHAMEED 19 uses Li_2MoO_4 target to set limit for spin dependent coupling $\sigma^{SD}(\chi p) < 3. \times 10^5$ pb for m(χ) = 20 GeV.

[10] AMOLE 19 search for SD WIMP scatter on C_3F_8 in PICO-60 bubble chamber; no signal: set limit for spin dependent coupling $\sigma^{SD}(\chi p) < 2.5 \times 10^{-5}$ pb for m(χ) = 20 GeV.

[11] APRILE 19A search for SD WIMP scatter on 1 t yr Xe; no signal, limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m $\sim$ 6–1000 GeV.

[12] XIA 19A search for WIMP scatter on Xe in PandaX-II; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 5–1 $\times 10^5$ GeV.

[13] AGNESE 18 give limits for $\sigma^{SD}(p\chi)$ for m(WIMP) between 1.5 and 20 GeV using CDMSlite mode data.

[14] AKERIB 17A search for SD WIMP scatter on Xe using 129.5 kg yr exposure; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 6–1 $\times 10^5$ GeV.

[15] BEHNKE 17 show final Picasso results based on 231.4 kg d exposure at SNOLab for WIMP scatter on C_4F_{10} search via superheated droplet; require σ(SD) $< 1.32 \times 10^{-2}$ pb for m(WIMP) = 20 GeV.

[16] FU 17 search for SD WIMP scatter on Xe; limits set in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 4–1 $\times 10^3$ GeV.

[17] AMOLE 16A require SD WIMP-p scattering $< 5 \times 10^{-4}$ pb for m(WIMP) = 20 GeV; bubbles from C_3F_8 target.

[18] KHACHATRYAN 16AJ require SD WIMP-p $< 2 \times 10^{-6}$ pb for m(WIMP) = 20 GeV from $pp \to Z + \not{E}_T$; $Z \to \ell\overline{\ell}$ signal.

[19] AARTSEN 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken between June 2010 and May 2011.

[20] The value has been provided by the authors. APRILE 13 note that the proton limits on Xe are highly sensitive to the theoretical model used. See also APRILE 14A.

[21] ARCHAMBAULT 12 search for WIMP scatter on C_4F_{10}; limits set in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m $\sim$ 4–500 GeV.

[22] Use a direction-sensitive detector.

[23] TANAKA 11 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the Sun. The amount of X^0 depends on the X^0-proton cross section.

[24] See also AKERIB 05.

For m_{X^0} = 100 GeV

For limits from X^0 annihilation in the Sun, the assumed annihilation final state is shown in parenthesis in the comment.

[1] AALBERS 23 yield first SD LZ limits on WIMP-p scatter using Xe. $\sigma^{SD}(\chi p) < 1.5 \times 10^{-4}$ pb for m(χ) = 100 GeV.

[2] ADHIKARI 23C search for SD WIMP scatter on I. No signal observed. Require $\sigma^{SD}(\chi p) < 1$ pb for m(χ) = 100 GeV.

[3] SHIMADA 23 search for WIMPs in NEWAGE directional detector. No signal observed. Limits placed in $\sigma^{SD}(\chi p)$ vs. mass plane. Quoted limit for m(χ) = 150 GeV.

[4] ABBASI 22B search for WIMP annihilation to $b\overline{b}$, $\tau\overline{\tau}$, $\nu\overline{\nu}$ in Sun with 7 years data; no signal; limits set in m(χ) vs. $\sigma^{SD}(\chi p)$ plane for m(χ): 10–100 GeV; quoted limit for $\nu\overline{\nu}$ channel.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[5] HUANG 22 search for SD DM scatter on Xe; no signal observed; limits placed in $\sigma(\chi n)$ vs. m(DM) plane; quoted limit is for m(DM) = 100 GeV.

[6] IKEDA 21 use direction sensitive TPC NEWAGE to search for SD WIMPs. No signal observed. Limits set in $\sigma^{SD}(\chi p)$ vs. m plane; $\sigma^{SD}(\chi p) < 50$ pb for m(DM) = 100 GeV.

[7] AARTSEN 20C place combined IceCube and Pico-60 velocity-independent limits on spin-dependent WIMP-p scatter $\sigma^{SD}(\chi p) < 3.34 \times 10^{-4}$ pb for m(WIMP) = 100 GeV assuming dominant annihilation to $\tau\overline{\tau}$.

[8] FELIZARDO 20 presents 2014 SIMPLE bounds on WIMP DM using C_2ClF_5 target.

[9] AMOLE 19 search for SD WIMP scatter on C_3F_8 in PICO-60 bubble chamber; no signal: set limit for spin dependent coupling $\sigma^{SD}(\chi p) < 4 \times 10^{-5}$ pb for m(χ) = 100 GeV.

[10] APRILE 19A search for SD WIMP scatter on 1 t yr Xe; no signal, limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m $\sim$ 6–1000 GeV.

[11] XIA 19A search for WIMP scatter on Xe in PandaX-II; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 5–1 $\times 10^5$ GeV.

[12] AKERIB 17A search for SD WIMP scatter on Xe using 129.5 kg yr exposure; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 6–1 $\times 10^5$ GeV.

[13] AMOLE 17 require σ(WIMP-p)$^{SD} < 5 \times 10^{-5}$ pb for m(WIMP) = 100 GeV using PICO-60 1167 kg-days exposure at SNOLab.

[14] APRILE 17A require require σ(WIMP-p)(inelastic)$^{SD} < 3.3 \times 10^{-2}$ pb for m(WIMP) = 100 GeV, based on 7640 kg day exposure at LNGS.

[15] BATTAT 17 use directional detection of CS_2 ions to require σ(SD) $< 2.8 \times 10^{-1}$ pb for 100 GeV WIMP with a 55 days exposure at the Boulby Underground Science Facility.

[16] FU 17 from a 33000 kg d exposure at CJPL, PANDAX II derive for m(DM) = 100 GeV, σ^{SD}(WIMP-p) $< 2 \times 10^{-3}$ pb.

[17] AABOUD 16D use ATLAS 13 TeV 3.2 fb^{-1} of data to search for monojet plus missing E_T; agree with SM rates; present limits on large extra dimensions, compressed SUSY spectra and wimp pair production.

[18] AABOUD 16F search for monophoton plus missing E_T events at ATLAS with 13 Tev and 3.2 fb^{-1}; signal agrees with SM background; place limits on SD WIMP-proton scattering vs. mediator mass and large extra dimension models.

[19] AARTSEN 16C search for high energy ν from WIMP annihilation in solar core; limits set on SD WIMP-p scattering (Fig. 8).

[20] ADRIAN-MARTINEZ 16 search for WIMP annihilation into ν from solar core; exclude SD cross section < few 10^{-4} depending on m(WIMP).

[21] AKERIB 16A using 2013 data exclude SD WIMP-proton scattering $> 3 \times 10^{-3}$ pb for m(WIMP) = 100 GeV.

[22] AMOLE 16 use bubble technique on CF_3I target to exclude SD WIMP-p scattering $> 5 \times 10^{-4}$ pb for m(WIMP) = 100 GeV.

[23] Use a direction-sensitive detector.

[24] AVRORIN 14 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the Sun in data taken between 1998 and 2003. See their Table 1 for limits assuming annihilation into neutrino pairs.

[25] AARTSEN 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken between June 2010 and May 2011.

[26] ADRIAN-MARTINEZ 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken between Jan. 2007 and Dec. 2008.

[27] The value has been provided by the authors. APRILE 13 note that the proton limits on Xe are highly sensitive to the theoretical model used. See also APRILE 14A.

[28] BOLIEV 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken from 1978 to 2009. See also SUVOROVA 13 for an older analysis of the same data.

[29] ABBASI 12 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the Sun. The amount of X^0 depends on the X^0-proton cross section.

[30] ARCHAMBAULT 12 search for WIMP scatter on C_4F_{10}; limits set in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m $\sim$ 4–500 GeV.

[31] TANAKA 11 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the Sun. The amount of X^0 depends on the X^0-proton cross section.

[32] See their Fig. 3 for limits on spin-dependent proton couplings for X^0 mass of 50 GeV.

[33] See also AKERIB 05.

[34] GIULIANI 05A analyze available data and give combined limits.

[35] GIULIANI 04 reanalyze COLLAR 00 data and give limits for spin-dependent X^0-proton coupling.

[36] GIULIANI 04A give limits for spin-dependent X^0-proton couplings from existing data.

For m_{X^0} = 1 TeV

For limits from X^0 annihilation in the Sun, the assumed annihilation final state is shown in parenthesis in the comment.

[1] AALBERS 23 yield first SD LZ limits on WIMP-p scatter using Xe. $\sigma^{SD}(\chi p) < 2 \times 10^{-3}$ pb for m(χ) = 1 TeV.

[2] ADHIKARI 23C search for SD WIMP scatter on I. No signal observed. Require $\sigma^{SD}(\chi p) < 0.2$ pb for m(χ) = 1 TeV.

[3] HUANG 22 search for SD DM scatter on Xe; no signal observed; limits placed in $\sigma(\chi n)$ vs. m(DM) plane; quoted limit is for m(DM) = 1 TeV.

[4] IKEDA 21 use direction sensitive TPC NEWAGE to search for SD WIMPs. No signal observed. Limits set in $\sigma^{SD}(\chi p)$ vs. m plane; $\sigma^{SD}(\chi p) < 200$ pb for m(DM) = 1000 GeV.

[5] AARTSEN 20C place combined IceCube and Pico-60 velocity-independent limits on spin-dependent WIMP-p scatter $\sigma^{SD}(\chi p) < 3 \times 10^{-3}$ pb for m(WIMP) = 1 TeV assuming dominant annihilation to WW.

[6] AMOLE 19 search for SD WIMP scatter on C_3F_8 in PICO-60 bubble chamber; no signal: set limit for spin dependent coupling $\sigma^{SD}(\chi p) < 3 \times 10^{-4}$ pb for m(χ) = 1000 GeV.

[7] APRILE 19A search for SD WIMP scatter on 1 t yr Xe; no signal, limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m $\sim$ 6–1000 GeV.

[8] XIA 19A search for WIMP scatter on Xe in PandaX-II; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 5–1 $\times 10^5$ GeV.

[9] ALBERT 18C search for DM annihilation in Sun to long-lived mediator (LLM) which decays outside Sun, for DM masses above 1 TeV; assuming LLM, limits set on $\sigma^{SD}(\chi p)$.

[10] AARTSEN 17A search for neutrinos from solar WIMP annihilation into $\tau^+\tau^-$ in 532 days of live time.

[11] AKERIB 17A search for SD WIMP scatter on Xe using 129.5 kg yr exposure; limits placed in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 6–1 $\times 10^5$ GeV.

[12] FU 17 search for SD WIMP scatter on Xe; limits set in $\sigma^{SD}(\chi p)$ vs. m(χ) plane for m(χ) $\sim$ 4–1 $\times 10^3$ GeV.

[13] ADRIAN-MARTINEZ 16B search for secluded DM via WIMP annihilation in solar core into light mediator which later decays to μ or ν; limits presented in Figures 3 and 4.

[14] AVRORIN 14 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the Sun in data taken between 1998 and 2003. See their Table 1 for limits assuming annihilation into neutrino pairs.

[15] AARTSEN 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken between June 2010 and May 2011.

[16] ADRIAN-MARTINEZ 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken between Jan. 2007 and Dec. 2008.

[17] The value has been provided by the authors. APRILE 13 note that the proton limits on Xe are highly sensitive to the theoretical model used. See also APRILE 14A.

[18] BOLIEV 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken from 1978 to 2009. See also SUVOROVA 13 for an older analysis of the same data.

[19] ABBASI 12 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the Sun. The amount of X^0 depends on the X^0-proton cross section.

[20] Use a direction-sensitive detector.

[21] TANAKA 11 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the Sun. The amount of X^0 depends on the X^0-proton cross section.

[22] ABBASI 10 search for ν_μ from annihilations of Kaluza-Klein photon dark matter in the Sun.

[23] See also AKERIB 05.

[1] APRILE 25 report GeV-scale DM search near edge of neutrino fog using XENONnT. No signal observed. Limits set in $\sigma^{SD}(\chi N)$ vs. m(χ) plane. Quoted limit is for m(χ) = 6 GeV.

[2] ZHANG 25B search for light GeV-scale wimps using run 0 and run 1 PandaX-4T data. No signal observed. Quoted limit is for m(χ) = 3 GeV.

[3] ANGLOHER 24B search for low mass wimps. No signal observed. Limits placed in σ vs. m plane. Quoted limit for m = 100 MeV.

[4] AALBERS 23A search for GeV-scale WIMP scatter on Xe. No signal observed. Limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane. Quoted limit is for m(χ) = 1 GeV via Migdal scattering.

[5] ANGLOHER 22 search for SD WIMP scatter on Li target; no signal detected; limits placed on WIMP-neutron SD scatter versus m(WIMP); limit quoted for m(WIMP) = 1 GeV.

[6] ANGLOHER 22A search for spin-dependent DM scatter on Li and Al for m(DM) ~ 0.2–6 GeV; no signal observed; limits set in $\sigma(\chi n)$ vs. m(DM) plane; quoted limit is for m(DM) = 1 GeV.

[7] ABDELHAMEED 20A use $LiAlO_2$ target in CRESST to search for SD WIMP scatter; no signal; quoted limit is for m(DM) = 1 GeV.

[8] ABDELHAMEED 19 search for GeV-scale WIMP SD scatter on ^{7}Li crystal; set limit $\sigma^{SD}(\chi n)$ for m(χ) ~ 0.8–20 GeV; quoted limit for m(χ) = 1 GeV.

[9] APRILE 19C search for light DM on Xe via Migdal/bremsstrahlung effect; no signal, require $\sigma^{SD}(\chi n)$ <230 pb for m(χ) = 1 GeV.

[10] APRILE 19D search for light DM scatter on Xe via ionization; no signal, limits placed in σ vs. m(DM) ~ 3–6 GeV; quoted limit is for m(DM) = 5 GeV.

[11] ARMENGAUD 19 search for GeV scale WIMP scatter on Ge; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 0.5–10 GeV; quoted limit is for m(χ) = 5 GeV.

[12] XIA 19A search for WIMP scatter on Xe in PandaX-II; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 5–1 × 10^5 GeV; quoted limit is for m(χ) = 5 GeV.

[13] AGNESE 18 search for GeV scale WIMPs scatter at CDMSlite; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m ~ 1.5–20 GeV; quoted limit is for m(χ) = 5 GeV.

[14] JIANG 18 search for GeV scale WIMP scatter on Ge; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 3–10 GeV; quoted limit is for m(χ) = 5 GeV.

[15] YANG 18 search for WIMP scatter on Ge; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 2–10 GeV; quoted limit is for m(χ) = 5 GeV.

[16] AKERIB 17A search for SD WIMP scatter on Xe with 129.5 kg yr exposure; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 5–1 × 10^5 GeV; quoted limit is for m(χ) = 5 GeV.

[17] FU 17 search for SD WIMP scatter on Xe; limits set in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 4–1 × 10^3 GeV.; quoted limit is for m(χ) = 5 GeV.

[18] ZHAO 16 search for GeV-scale WIMP scatter on Ge; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 4–30 GeV; quoted limit is for m(χ) = 5 GeV.

[19] AHMED 11B search for GeV scale WIMP scatter on Ge in CDMS II; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m ~ 4–12 GeV. Limit given for m(χ) = 5 GeV.

For m_{X^0} = 20 GeV

[1] AALBERS 23 yield first LZ limits on SD WIMP-n scatter using Xe. $\sigma^{SD}(\chi n) < 2 \times 10^{-6}$ pb for m(χ) = 20 GeV.

[2] ANGLOHER 22 search for SD WIMP-neutron scatter from Li target; no signal detected; limits placed in σ vs. m(WIMP) plane.

[3] HUANG 22 search for SD DM scatter on Xe; no signal observed; limits placed in $\sigma(\chi n)$ vs. m(DM) plane; quoted limit is for m(DM) = 20 GeV.

[4] ABDELHAMEED 20A use $LiAlO_2$ target in CRESST to search for SD WIMP scatter on n; limits placed for m(WIMP): 0.3–30 GeV in Fig. 8. Quoted limit is for M(WIMP) = 30 GeV.

[5] FELIZARDO 20 presents 2014 SIMPLE bounds on WIMP DM using C_2ClF_5 target.

[6] APRILE 19A search for SD WIMP scatter on 1 t yr Xe; no signal: limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m ~ 6–1000 GeV.

[7] XIA 19A search for WIMP scatter on Xe in PandaX-II; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 5–1 × 10^5 GeV.

[8] AGNESE 18 give limits for $\sigma^{SD}(n\chi)$ for m(WIMP) between 1.5 and 20 GeV using CDMSlite mode data.

[9] AKERIB 17A search for SD WIMP scatter on Xe with 129.5 kg yr exposure; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 5–1 × 10^5 GeV.

[10] FU 17 search for SD WIMP scatter on Xe; limits set in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 4–1 × 10^3 GeV.

[11] ZHAO 16 search for GeV-scale WIMP scatter on Ge; limits placed in $\sigma^{SD}(\chi n)$ vs. m(χ) plane for m(χ) ~ 4–30 GeV.

[12] Derived limit from search for inelastic scattering $X^0 + {}^{129}\text{Xe} \rightarrow X^0 + {}^{129}\text{Xe}^*(39.58\ \text{keV})$.

[13] The value has been provided by the authors. See also APRILE 14A.

[14] See their Fig. 6(b) for cross section limits for m_{X^0} extending down to 2 GeV.

[15] See also AKERIB 05.

For m_{X^0} = 100 GeV

[1] ADARI 25 search for MeV-scale DM using SENSEI at SNOLab. No signal observed. Limits placed in σ_e vs. mass plane for light and heavy mediator models.

[2] AGGARWAL 25A search for MeV-scale DM scattering on *e* at DAMIC-M. No signal observed. Limits placed in m(DM) vs. σ_e plane for light and heavy mediator models. Quoted limit is for m(DM) = 10 MeV for heavy mediator model with $F_{DM} = 1$.

[3] ALBAKRY 25 report on search for MeV-scale DM using HVeV detectors at SuperCDMS. No signal observed. Limits placed in various planes for different DM hypotheses. Quoted limit is for σ_e for light WIMP interacting via heavy mediator with $F_{DM} = 1$ and m(DM) = 10 MeV.

[4] BAUDIS 25 search for MeV-scale DM via microwire-based superconducting nanowire single-photon detector (SNSPD) as a target and sensor for dark matter scattering and absorption in QROCODILE experiment. No signal observed. Limits placed in m(DM): 1–5000 MeV vs. σ plane for MeV-scale dark photon scattering from *e* or nucleon via light or heavy mediator.

[5] BLOCH 25 report search for MeV-scale DM at SENSEI at SnoLab. No signal observed. Limits place in σ_e vs. m(χ) plane. Quoted limit is for m(χ) = 1 MeV assuming light mediator.

[6] CHOI 25 search for keV range DM produced from dark photon decay in NEON experiment. No signal observed. Limits placed in σ_e vs. m(χ) plane. Quoted limit is for m(χ) = 100 keV.

[7] DU 25 place bounds on strongly interacting DM scatter on *e* using JWST images. No signal observed. Limits placed in σ_e vs. m plane for assumed light mediator and fraction DM abundance.

[8] LIANG 25 reexamine SENSEI data using plasmon effect and considers that DM can be boosted scattering with cosmic rays.They place new limits on sub-MeV DM in m(χ) vs. σ_e plane for light and heavy mediator. Quoted limit is from SENSEI light mediator reanalysis with m(χ) = 0.01 MeV.

[9] SHEN 25 search for MeV-scale solar boosted DM scatter on *e*. No signal observed. Limits placed in σ_e vs m(χ) plane. Quoted limit is for m(χ) = 1 MeV.

[10] ZHANG 25B search for light GeV-scale wimps using run 0 and run 1 PandaX-4T data. No signal observed. Limits placed on σ_e vs. m(χ) depending on assumed light/heavy mediator model.

[11] SHANG 24 report on search for electron cosmic-ray boosted DM in keV range or below with PandaX-4T. No signal observed. Limits plotted in $\sigma(\chi e)$ vs m plane for m $\sim$ 10^{-2}–10^3 keV.

[12] ZHANG 24A examine detection of accelerated MeV-scale DM on *e* in Ge semiconductor. Limits placed in σ_e vs. m plane depending on various mediator assumptions.

[13] ZHANG 24E search for dark matter from evaporating primordial black holes (PBH) scattering on electrons in Ge with CDEX10 experiment conducted in the China Jinping Underground Laboratory. No signal observed. Limits placed in $\sigma(\chi e)$ vs. m(χ) and other planes for assumed PBH mass and fractional abundance.

[14] AGNES 23A search for MeV-scale DM scatter from *e* using Ar. No signal observed. $\sigma(\chi e) < 3 \times 10^{-3}$ pb for m(χ) = 30 MeV.

[15] ARNQUIST 23A search for LDM scatter on *e* using CCDs. No signal observed. Require $\sigma(\chi e) < 0.3$ pb for m(χ) = 10 MeV and $F_{DM} = 1$ (Fig. 3b).

[16] LI 23F search for light DM in MeV range via scatter from *e*. No signal observed. Limits set. The quoted limit is for m(χ) = 0.2 GeV with $F_{DM} = 1$.

[17] AGOSTINI 22 search for superWIMP particles using GERDA detector; no signal observed; limits placed in mass vs coupling plane for m(DM) 0.06–1 MeV.

[18] APRILE 22 place new limits on WIMP-*e* scatter for dark photon and various multipole moments vs. WIMP mass for various DM models; quoted limit for m(WIMP) = 1 GeV in light mediator model.

[19] BATTAGLIERI 22 search for light MeV scale DM particles produced in JLAB beam dump; no signal observed; limits set in kinetic mixing vs. m(DM) plane for m(DM) $\sim$ 1–200 MeV .

[20] BOSE 22 theoretically derive limits on WIMP-*e* scatter from solar gamma rays using data of Fermi-LAT; limit quoted for m(WIMP) = 5 GeV.

[21] GHOSH 22 derive limits on sub-GeV boosted DM scatter from *e* or ν using SuperK/XENON1T data; quoted limit for m(χ) = 1 MeV.

[22] HOCHBERG 22 search for sub-eV or sub-MeV scale DM scatter/absorption on *e* in superconducting nanowire; no signal observed; limits set in m(DM) vs. cross section plane for sub-MeV-scale DM and in m(DM) vs. kinetic mixing plane for sub-eV-scale DM.

[23] ZHANG 22A search for DM scatter on *e* using CDEX-10; no signal observed; limits placed on $\sigma(\chi e)$ vs. m(DM) plane for m(DM) $\sim$ 0.07–10 GeV for various simplified models.

[24] CHENG 21 search for MeV-scale DM scatter from *e* in PANDAX-II. No signal detected. Limits set in $\sigma(\chi e)$ vs. m(DM) plane for two choices of form factors; $\sigma(\chi e) < 10$ pb for m(χ) = 10 MeV and $F_{DM} = 1$.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[25] AKERIB 20 search for mirror DM with LUX 95 d × 118 kg data for mirror e scatter from Xe; no signal, limits placed in kinetic mixing parameter vs. mirror e temperature T ∼ 0.1–0.9 keV plane.
[26] AMARAL 20 search SuperCDMS data for low mass DM scatter from e in Si; no signal; quoted limit $\sigma_e < 8.7 \times 10^2$ pb for m(DM) = 10 MeV with form factor $F_{DM} = 1$.
[27] APRILE 20 report excess at electron recoil around 2–3 keV in Xe; data compared to unforeseen tritium background, and various signal models (bosonic DM, solar axion, and neutrino magnetic moment).
[28] ARNAUD 20 search for MeV DM scattering from e in Ge; no signal; quoted limit is for m(DM) = 10 MeV with form factor $F_{DM} = 1$.
[29] BARAK 20 report search for MeV scale DM scatter from e in Si; limits placed in σ_e vs. m(DM) plane; quoted limit is for m(DM) = 10 MeV and form factor $F_{DM} = 1$.
[30] ABRAMOFF 19 search for MeV-scale WIMP scatter from Si skipper-CCD; limits placed on $\sigma(\chi e)$ for m(χ) ∼ 0.5–100 MeV depending on DM form factors. Limit given for m(DM) = 1 MeV.
[31] AGUILAR-AREVALO 19A search for MeV scale DM scatter from e in Si CCDs at SNOLAB; no signal, limits placed in σ(e) vs. m(DM) plane for m(DM) ∼ 0.6–100 MeV.
[32] APRILE 19D search for light DM scatter on Xe via ionization; no signal, limits placed in σ on nucleus vs. m(DM) plane for m(DM) ∼ 0.02–10 GeV; quoted limit is for m(DM) = 0.2 GeV.
[33] AGNES 18B search for MeV scale WIMP scatter from e in Ar; no signal, limits set in σ_e vs. m(χ) plane for m ∼ 20–1000 MeV and two choices of form factor F(DM); quoted limit for m(χ) = 100 MeV and F = 1.
[34] AGNESE 18B search for $e\chi$ scatter in SuperCDMS; limits placed in $\sigma(e\chi)$ vs. m(χ) plane for m ∼ 0.3–1 × 10^4 MeV for two assumed form factors and also in m(dark photon) vs. kinetic mixing plane. Limit given for m(χ) = 1 GeV and F=1.
[35] CRISLER 18 search for $\chi e \to \chi e$ scatter in Si CCD; place limits on MeV DM in σ_e vs. m(χ) plane for m ∼ 0.5–1000 MeV for different form factors; quoted limit is for F(DM) = 1 and m(χ) = 10 MeV.
[36] APRILE 17 search for WIMP-e annual modulation signal for recoil energy in the 2.0–5.8 keV interval using 4 years data with Xe. No significant effect seen.

Cross-Section Limits for Dark Matter Particles (X^0) on Nuclei

For m_{X^0} in GeV range

We provide here limits fo $m_{X^0} < 5$ GeV

[1] UCHIDA 14 limit is for inelastic scattering $X^0 + {}^{129}\text{Xe}^* \to X^0 + {}^{129}\text{Xe}^*$ (39.58 keV).
[2] ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
[3] BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.
[4] KLIMENKO 98 limit is for inelastic scattering $X^0\,{}^{73}\text{Ge} \to X^0\,{}^{73}\text{Ge}^*$ (13.26 keV).
[5] BELLI 96 limit for inelastic scattering $X^0\,{}^{129}\text{Xe} \to X^0\,{}^{129}\text{Xe}^*$(39.58 keV).
[6] BELLI 96C use background subtraction and obtain $\sigma < 150$ pb (< 1.5 fb) (90% CL) for spin-dependent (independent) X^0-proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
[7] BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
[8] SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
[9] SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.
[10] GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
[11] SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
[12] REUSSER 91 limit here is changed from published (0.04) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For m_{X^0} = 100 GeV

[1] APRILE 21A search for inelastic DM scatter off ^{129}Xe nuclei with 0.83 t yr exposure. No signal obseved. Limits placed in $\sigma(\chi\text{Xe})$ vs. m(DM) plane for WIMP mass between 20 GeV and 10 TeV.
[2] UCHIDA 14 limit is for inelastic scattering $X^0 + {}^{129}\text{Xe}^* \to X^0 + {}^{129}\text{Xe}^*$(39.58 keV).
[3] ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
[4] BELLI 02 discuss dependence of the extracted WIMP cross section on the assumptions of the galactic halo structure.
[5] BERNABEI 02C analyze the DAMA data in the scenario in which X^0 scatters into a slightly heavier state as discussed by SMITH 01.
[6] GREEN 02 discusses dependence of extracted WIMP cross section limits on the assumptions of the galactic halo structure.
[7] ULLIO 01 disfavor the possibility that the BERNABEI 99 signal is due to spin-dependent WIMP coupling.
[8] BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.
[9] BERNABEI 00D limit is for inelastic scattering $X^0\,{}^{129}\text{Xe} \to X^0\,{}^{129}\text{Xe}$ (39.58 keV).
[10] AMBROSIO 99 search for upgoing muon events induced by neutrinos originating from WIMP annihilations in the Sun and Earth.
[11] BRHLIK 99 discuss the effect of astrophysical uncertainties on the WIMP interpretation of the BERNABEI 99 signal.
[12] KLIMENKO 98 limit is for inelastic scattering $X^0\,{}^{73}\text{Ge} \to X^0\,{}^{73}\text{Ge}^*$ (13.26 keV).
[13] KLIMENKO 98 limit is for inelastic scattering $X^0\,{}^{73}\text{Ge} \to X^0\,{}^{73}\text{Ge}^*$ (66.73 keV).
[14] BELLI 96 limit for inelastic scattering $X^0\,{}^{129}\text{Xe} \to X^0\,{}^{129}\text{Xe}^*$(39.58 keV).
[15] BELLI 96C use background subtraction and obtain $\sigma < 0.35$ pb (< 0.15 fb) (90% CL) for spin-dependent (independent) X^0-proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
[16] BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
[17] SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
[18] SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.
[19] GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
[20] SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
[21] BECK 94 uses enriched ^{76}Ge (86% purity).
[22] REUSSER 91 limit here is changed from published (0.3) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For m_{X^0} = 1 TeV

[1] UCHIDA 14 limit is for inelastic scattering $X^0 + {}^{129}\text{Xe}^* \rightarrow X^0 + {}^{129}\text{Xe}^*$ (39.58 keV).

[2] ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.

[3] BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.

[4] BERNABEI 99D search for SIMPs (Strongly Interacting Massive Particles) in the mass range 10^3–10^{16} GeV. See their Fig. 3 for cross-section limits.

[5] DERBIN 99 search for SIMPs (Strongly Interacting Massive Particles) in the mass range 10^2–10^{14} GeV. See their Fig. 3 for cross-section limits.

[6] KLIMENKO 98 limit is for inelastic scattering $X^0\,{}^{73}\text{Ge} \rightarrow X^0\,{}^{73}\text{Ge}^*$ (13.26 keV).

[7] KLIMENKO 98 limit is for inelastic scattering $X^0\,{}^{73}\text{Ge} \rightarrow X^0\,{}^{73}\text{Ge}^*$ (66.73 keV).

[8] BELLI 96 limit for inelastic scattering $X^0\,{}^{129}\text{Xe} \rightarrow X^0\,{}^{129}\text{Xe}^*$(39.58 keV).

[9] BELLI 96 limit for inelastic scattering $X^0\,{}^{129}\text{Xe} \rightarrow X^0\,{}^{129}\text{Xe}^*$(236.14 keV).

[10] BELLI 96C use background subtraction and obtain $\sigma < 0.7$ pb (< 0.7 fb) (90% CL) for spin-dependent (independent) X^0-proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.

[11] BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.

[12] SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.

[13] SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.

[14] GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.

[15] SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.

[16] BECK 94 uses enriched ^{76}Ge (86% purity).

[17] REUSSER 91 limit here is changed from published (5) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

Miscellaneous Results from Underground Dark Matter Searches

[1] AGNES 25 report on search for MeV-scale boosted dark matter arising form primordial black hole (PBH) evaporation using DarkSide-50 detector with a 12202 ± 180 kg·d exposure. No signal observed. Limits depend on PBH mass and abundance: see Fig. 4 in m(χ) vs. σ^{SI} plane.

[2] AMARE 25 reports on annual modulation modulation search in NaI target at ANAIS-112 in the Canfranc underground laboratory. No signal observed. Results incompatible with DAMA/LIBRA results at 4σ.

[3] BERGHAUS 25 derive limits on ultra-heavy decaying DM in m(DM): 10^{10}–10^{16} GeV range. Limits placed in lifetime τ vs. mass plane for various assumed decay modes from gamma ray searches at Fermi-LAT and neutrino searches at IceCube.

[4] CARLIN 25 reports combined Cosine-100 and Anais-112 annual modulation for DM scatter on NaI. No annual modulation found. Incompatible with DAMA/LIBRA results at 4.7σ.

[5] LIANG 25A report on inelastic WIMP search using CDEX-1B. No signal observed. Limits placed in σ^{SI} vs. δ (mass difference) plane for various inelastic wimp mass values m(χ), see Fig. 8.

[6] NING 25B search for leptonic-mediator dark matter at PandaX-4T. No signal observed. Limits placed in mediator mass m(ϕ) vs. DM mass m(χ) plane for both Dirac and Majorana DM particles with coupling $\lambda = 1$.

[7] WANG 25A report on search for boosted dark matter at CDEX-10. No signal observed. Exclusion limits presented for boosted DM model in m(χ) vs. non-relativistic effective field theory (NREFT) operator couplings for various NREFT operators.

[8] ABE 24A report Kamland-Zen search for de-excitation of WIMP DM bound to nucleus due to small mass splitting with charged WIMP partner. No signal observed. Limits placed in several parameter planes such as charged WIMP decay width vs. mass splitting (e.g. Fig. 7).

[9] AGNES 24 search for annual modulation signal from wimp interactions in Ar. No signal observed.

[10] ARNQUIST 24A report DAMIC-M search for MeV-scale DM scatter on e via mediator. No signal observed. Limits placed in σ(e) vs m plane.

[11] ABE 23A search for boosted sub-GeV DM using 0.37 Mt·y exposure of SuperK data. No signal observed. Model dependent limits set, see Fig. 3 corrected in ABE 23G erratum.

[12] ADAMS 23 search for inelastic DM scatter in fluorocarbons. No signal observed. Limits placed in σ vs. m(χ) mass splitting plane.

[13] ADHIKARI 23B search for boosted heavy photon DM in MeV range using Cosine-100. No signal observed. Limits placed in coupling vs. mass plane for masses 1–100 MeV.

[14] AL-KHARUSI 23 search for absorption of MeV-scale DM with 234.1 kg·y exposure of ^{136}Xe, triggering beta decay. No signal observed. Limit placed in cross section vs. mass plane for m(χ) = 1.7–11.6 MeV (see Fig. 5).

[15] APRILE 23 search for multiple scatter events from Planck scale-DM particles. No signal observed. Limits set on σ^{SI} and σ^{SD} on n and p.

[16] HUANG 23 search for MeV-scale scalar DM interacting via GeV-scale dark mediator. Limits placed on cross section vs. mass plane.

[17] NING 23A search for boosted LDM arising from η decays which are produced in CR events with 0.63 t·y exposure. No signal observed. Limits placed in $\sigma(\chi N)$ vs. m(χ) plane for various mediator models and branching fraction assumptions (see Fig. 2).

[18] ADHIKARI 22 search for multiple scatter of Planck scale DM on Ar using DEAP detector. No signal observed. Limits placed in mass vs. cross section plane for m(DM): 10^7–10^{19} GeV.

[19] ADHIKARI 22D report search for annual modulation signal of DM in a 173 kg·yr exposure of NaI; result consistent with both the modulation amplitude reported by DAMA/LIBRA and no-modulation .

[20] DAI 22A search for MeV-scale exotic DM interaction with Ge; no signal observed; limits set in m(DM) vs. cross section plane for m(DM) ∼ 5–60 MeV in simplified model.

[21] GU 22 use PANDAX to search for absorption of fermionic DM in MeV range in Xe; no signal observed; limits set in m(DM) vs. cross section plane for m(DM) ∼ 30–125 MeV.

[22] ZHANG 22 search for light DM scatter on e; no signal observed; limits placed in $\sigma \cdot v$ vs. m(DM) plane for m(DM) ∼ 10–180 keV.

[23] AKERIB 21B place limits on 15 WIMP non-relativistic EFT couplings for m(DM): 10–4000 GeV using 3.14 kg d exposure.

[24] AMARE 21 search for WIMP annual modulation signal on NaI target in the Canfranc Underground Laboratory (LSC). With an effective exposure of 313.95 kg y, and a sensitivity of 2.5 σ no signal is observed. Incompatible with DAMA/LIBRA at 3.3 σ level.

[25] WANG 21K use CDEX detector to search for WIMP dark matter scatter on Ge; no signal observed; limits placed on 14 non-relativistic effective operators along with WIMP-pion coupling for m(WIMP) ∼ 3–20 GeV.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[26] AGOSTINI 20 search for keV–MeV scale super-WIMP absorption in Ge in GERDA; no signal; limits placed on keV–MeV scale bosonic superWIMPs in coupling vs. mass plane.
[27] ANDRIANAVALOMAHEFA 20 search for hidden photon DM in eV range; place limits in m(DM) vs ln(χ) plane: exclude coupling $\chi \lesssim 1\times10^{-12}$ for m(DM) $\sim$ 2.5–7 eV.
[28] CLARK 20 use Majorana and Xe-1-ton data to constrain superheavy multply interacting dark matter (MIMP) in range m$\sim 10^8$–10^{17} GeV depending on interaction cross section.
[29] ABRAMOFF 19 search for MeV scale DM via DM–e scattering and dark photon DM via absorption in Si; limits set in coupling vs. m(χ) plane and on dark photon in m(A) vs. kinetic mixing parameter plane.
[30] ADHIKARI 19 search for annual modulation signal from WIMP scatter on NaI with 1.7 yr exposure; result consistent with both DAMA/LIBRA and null hypothesis.
[31] AMARE 19 is ANAIS-112 search for WIMP scatter annual modulation on NaI; 157.55 kg yr exposure; result compatible with null hypothesis; confirm goal of reaching sensitivity at 3σ to DAMA/LIBRA result in 5 years.
[32] APRILE 19 search for WIMP-pion scattering in Xe; no signal: require $\sigma(\chi\pi) < 6.4\times10^{-10}$ pb for m(χ) = 30 GeV.
[33] BRINGMANN 19 derive theoretically limits on GeV and sub-GeV mass dark matter, in its high energy component generated by interaction with cosmic rays; place limits on σ^{SI} and $\sigma^{SD} < 10^5$ pb.
[34] BRUNE 19 examine possibility of Majoron dark matter; limits placed on Majoron mass vs. coupling from SN1987a and ν-less double beta decay.
[35] CHOI 19 from multimessenger observation finds limit on $\sigma(\nu\chi)$/m(DM) $< 5.1\times10^{-23}$ cm^2/GeV based on 290 TeV IceCube neutrino event.
[36] HA 19 search for inelastic boosted MeV scale dark photon using COSINE-100 data; limits placed in m vs. epsilon plane for various mediators.
[37] KLOPF 19 search for DM via $n \to \chi e^+ e^-$; no signal: limits placed in branching fraction vs. m(e^+e^-) plane.
[38] AARTSEN 18D search for long-lived DM particles decaying $\chi \to \nu X$; no excess seen; for DM masses above 10 TeV, excluding lifetimes shorter than 10^{28} s.
[39] ABE 18F search for keV mass ALPs and hidden photons (HP) scatter on electrons; limits set on mass vs. coupling.
[40] AGNES 18B search for MeV-scale DM scatter on electrons in Ar; no signal; require $\sigma(\chi e) < 9\times10^{-3}$ pb for DM form factor F(DM) = 1 and < 300 pb for F(DM) proportional to 1/q^2 for m(χ) = 100 MeV.
[41] AGNESE 18B search for MeV scale DM via DM-e scattering and dark photon DM via absorption in Si; limits set on MeV DM in coupling vs. m(χ) plane and on dark photon in m(A') vs. kinetic mixing plane.
[42] AKERIB 18A search for annual and diurnal modulation of DM scattering rate on electrons for recoil energy between 2 and 6 keVee; no signal found.
[43] ARMENGAUD 18 search for ALP from the Sun and galactic bosonic DM, interacting in Ge; no signal; limits set for 0.8–500 keV DM particles.
[44] KACHULIS 18 search for an excess of elastically scattered electrons above the atmospheric neutrino background in Super-K; limits placed for simple annihilation or decay in the Sun or galactic center producing "boosted" dark matter.
[45] AGUILAR-AREVALO 17 search for hidden photon DM scatter on Si target CCD; limit kinetic mixing $\kappa < 1\times10^{-12}$ for m = 10 eV.
[46] APRILE 17 search for WIMP-e annual modulation signal for recoil energy in the 2.0–5.8 keV interval using 4 years data with Xe. No significant effect seen.
[47] APRILE 17D set limits on 14 WIMP-nucleon different interaction operators. No deviations found using 225 live days in the 6.6–240 keV recoil energy range.
[48] APRILE 17H search for keV bosonic DM via $e\chi \to e$, looking for electronic recoils with 224.6 live days of data and 34 kg of LXe. Limits set on $\chi e e$ coupling for m(χ) = 8–125 keV.
[49] APRILE 17K search for magnetic inelastic DM via $\chi N \to \chi^* \to \chi\gamma$. Limits set in DM magnetic moment vs. mass splitting plane for two DM masses corresponding to the DAMA/LIBRA best fit values.
[50] ANGLOHER 16A require q^2 dependent scattering $< 8\times10^{-3}$ pb for asymmetric DM m(WIMP) = 3 GeV on $CaWO_4$ target. It uses a local dark matter density of 0.38 GeV/cm^3.
[51] APRILE 15 search for periodic variation of electronic recoil event rate in the data between Feb. 2011 and Mar. 2012. No significant modulation is found for periods up to 500 days.
[52] APRILE 15A search for X^0 scattering off electrons. See their Fig. 4 for limits on cross section through axial-vector coupling for m_{X^0} between 0.6 GeV and 1 TeV. For m_{X^0} = 2 GeV, $\sigma < 60$ pb (90%CL) is obtained.

X^0 Annihilation Cross Section

Limits are on σv for X^0 pair annihilation for the X^0 mass specified in the footnote when needed.

[1] ABBASI 25A search for WIMP annihilation to ν_μ in center of earth. No signal observed. Limits placed in mass vs. σ^{SI} plane for various WIMP-WIMP annihilation channels.

[2] ABE 25A search for branon DM annihilation to γ-rays in dwarf spheroidals. No signal observed. Limits placed in m(branon) vs. $\langle\sigma\cdot v\rangle$ plane. The quoted limit is for m(branon) = 1.5 TeV.

[3] AIELLO 25B search for ν from DM annihilation in galactic center and sun with KM3NeT. No signal observed. Limits placed in various planes for different DM annihilation channels. Quoted limit is for DM annihlation to ν (direct channel, no intermediate states) in galactic center which limits $\langle\sigma\cdot v\rangle$ for m(DM) = 1 TeV.

[4] CRNOGORCEVIC 25 examine DM annihilation from cusps in galactic clusters. No signal observed. Results depend on galactic cluster DM profile. Quoted limit comes from m(χ) = 100 GeV for annihilation into $b\overline{b}$ and excludes claimed DM annihilation signal from Milky Way center.

[5] FERNANDEZ-SUAREZ 25 search for gamma ray signal in Fermi-LAT data arising from wimp annihilation in stellar streams. No signal observed. Limits placed in $\langle\sigma\cdot v\rangle$ vs. m(χ) plane for different annihilation final states.

[6] ZAKHAROV 25 report search for keV-scale DM annihilation to x-rays using 11 years NuSTAR data. No signal observed. Limts placed on $\langle\sigma\cdot v\rangle$. Quoted limit is for m($\chi$) = 10 keV.

[7] ACHARYYA 24 search for TeV-scale wimp annihilation in dwarf spheroidals. No signal observed. Limits placed on $\langle\sigma\cdot v\rangle$ vs. m(wimp) in various annihilation channels. Quoted limit for $\chi\chi \rightarrow WW$.

[8] CAO 24 search for superheavy WIMP annihilation in dwarf spheroidals to $b\overline{b}$ or $\tau\overline{\tau}$. No signal observed. Limits set in $\langle\sigma\cdot v\rangle$ vs. m(WIMP) plane. Quoted limit for $b\overline{b}$ with m(WIMP) = 1 TeV.

[9] CHOLIS 24 derive limits on wimp annihilation contribution to Fermi-LAT observation of isotropic gamma ray background. Limits set in $\langle\sigma\cdot v\rangle$ vs m plane for various $\chi\chi$ annihilation channel.

[10] CRNOGORCEVIC 24 interpret published Fermi-LAT data aimed at Ursa-Major III to derive limits on WIMP annihilation in high J-factor dwarf spheroidal. Fermi-LAT limits are recast in $\langle\sigma\cdot v\rangle$ vs m plane depend on J and on assumed annihilation channel.

[11] DE-LA-TORRE-LUQUE 24 analyze 15 years Fermi-LAT data for m(WIMP) 10–300 GeV annihilation to photons. No signal observed. Limits placed in $\langle\sigma\cdot v\rangle$ vs m plane for several models motivated by galactic center excess.

[12] MANNA 24 analyze SPT-SZ survay for 1–300 GeV gamma rays from wimp annihilation in galaxy clusters. Some slight signals observed in conflict with dwarf spheroidal searches. Limits in $\langle\sigma\cdot v\rangle$ vs m plane; quoted limit is for m(wimp) = 10 GeV in $b\overline{b}$ annihilation channel.

[13] MCDANIEL 24 combined 14.3 years Fermi-LAT data from multiple dwarf spheroidals to gain updated bounds on WIMP annihilation rates with some 2σ excesses claimed. Reported limit is for 100 GeV WIMP mass.

[14] MCDANIEL 24 perform combined 14 year Fermi-LAT analysis of gammas from dwarf spheroidals. New limits obtained from Fig. 6. Quoted value for m(WIMP) = 100 GeV in $b\overline{b}$ and $\tau\overline{\tau}$ annihilation channels.

[15] SONG 24 use Fermi-LAT data to constrain heavy 10^3–10^{11} GeV DM annihilation and decay. Limits placed in $\langle\sigma\cdot v\rangle$ vs. m and lifetime vs. m planes.

[16] SONG 24A examine Fermi-LAT gamma ray data from superheavy WIMP annihilation/decay in galaxy clusters. Limits placed in $\langle\sigma\cdot v\rangle$ vs m and lifetime vs m planes for a variety of annihilation/decay modes.

[17] ZAKHAROV 24A derive limits DM annihilation to X-rays in the 4–15 keV particle mass range via SRG/ART-XC telescope. Limits placed in $\langle\sigma\cdot v\rangle$ vs m plane. Quoted limit is from MW halo for m = 10 keV, see Fig. 10.

[18] ABBASI 23A search for WIMP-WIMP annihilation to ν's. No signal observed. Require $\langle\sigma\cdot v\rangle < 10^{-24}$ cm^3/s for m(χ) $\sim$ 10–10 $\times 10^4$ GeV for various halo profiles.

[19] ABBASI 23B search for PeV-scale WIMP-WIMP annihilation to μ or b pairs. No signal observed. Require $\langle\sigma\cdot v\rangle < 10^{-22}$ cm^3/s for $\chi\chi \rightarrow b\overline{b}$ with m(χ) about 1 PeV or $\langle\sigma\cdot v\rangle < 10^{-23}$ cm^3/s for $\chi\chi \rightarrow \mu^+\mu^-$ with m(χ) about 1 PeV.

[20] ABE 23B search for WMP-WIMP annihilation to γ in GC. No signal observed. Require $\langle\sigma\cdot v\rangle < 5\times10^{-28}$ cm^3/s for m(χ) = 1 TeV or $\langle\sigma\cdot v\rangle < 1\times10^{-25}$ cm^3/s for m(χ) = 100 TeV.

[21] ALBERT 23 search for WIMP pair annihilation to γ in galactic halo. No signal observed. Limits placed in $\langle\sigma\cdot v\rangle$ vs. mass (10–100 TeV) plane for various annihilation channels.

[22] CHENG 23A provide updated combined Fermi-LAT/DAMPE search for gamma line from WIMP annihilation. No signal observed. Limits placed in $\langle\sigma\cdot v\rangle$ vs. mass (6–200 GeV) plane for various halo profiles.

[23] FOSTER 23 search for gamma ray line in Fermi-LAT data. No signal observed. Limits placed in $\langle\sigma\cdot v\rangle$ vs. m(χ) plane. For Higgsino DM limit see Fig. 12.

[24] GUO 23 search with Five-hundred-meter Aperture Spherical Radio Telescope for synchrotron emission radio signal of DM annihilation from dwarf spheroidal galaxy. No signal observed. Limits set in $\langle\sigma\cdot v\rangle$ vs. m(χ) plane for various annihilation final states.

[25] GUO 23A search in public IceCube data for DM annihilation to neutrinos. No signal observed. Limits placed in $\langle\sigma\cdot v\rangle$ vs m(χ) plane for various annihilation assumptions.

[26] LAVIS 23 search for 2HDM+S DM and generic spectra using MeerKAT. No signal observed. Limits placed in $\langle\sigma\cdot v\rangle$ vs. mass (10–1000 GeV) plane for various annihilation channels.

[27] ABDALLA 22 search for WIMP annihilation in galactic center to gamma rays using HESS; no signal observed; limits set in mass vs $\langle\sigma\cdot v\rangle$ plane for dominant annihilation to WW or $\tau\overline{\tau}$. Limit here for $\tau\overline{\tau}$ channel 0.7 TeV mass.

[28] ALBERT 22A search for secluded PeV-scale DM annihilation to four final states; no signal detected; limits placed in $\langle\sigma\cdot v\rangle$ vs. m(χ) plane for m(χ): 6–6000 TeV for m(mediator) = 50, 250, and 1000 GeV.

[29] CHAN 22 derive a variety of limits on DM annihilation to various channels resulting in X-rays from dwarf galaxy Omega Centauri. Limits are very dependent on assumed DM density and diffusion coefficient. Quoted limit is for m(WIMP) = 100 GeV annihilating to WW with parameters as in Fig. 4.

[30] EGOROV 22 derives limits on DM annihlation to $b\overline{b}$ or $\tau\overline{\tau}$ via radio signals from M31; quoted limit from $b\overline{b}$ channel with LOFAR telescope as main data source, using parameters as in Fig. 10 (green curve) for m(χ) = 100 GeV.

[31] MANCONI 22 use polarized synchrotron emission data from Planck to constrain WIMP annihilation cross section in Galaxy; limits set in $\langle\sigma\cdot v\rangle$ vs. m(DM) plane.

[32] ABDALLAH 21 search for WIMP-WIMP annihilation into 2 monoenergetic γ rays in WLM dwarf irregular galaxy using HESS data. No signal. Limits placed in $\langle\sigma\cdot v\rangle$ vs. m(WIMP) plane for a mass of 370 GeV.

[33] CIRELLI 21 derive limits on light DM annihilation to ee, $\mu\mu$, $\pi\pi$ that then produce X-rays using data published by INTEGRAL telescope. Limits placed in $\langle\sigma\cdot v\rangle$ vs. m(DM) plane for m(DM) = 1–5000 MeV.

[34] JOHN 21 derive limits on leptophilic DM annihilating to positrons by comparing expected spectra to AMS-02 data. The range m(DM): 60–300 GeV appears excluded for this type of model, see Fig. 3.

[35] ABAZAJIAN 20 derive new limits on WIMP annihilation in galactic center (GC): $\langle\sigma\cdot v\rangle < 2.5\times10^{-27}$ cm^3/s for m(WIMP) = 50 GeV: seems to rule out WIMP explanation for GC γ excess, favouring an astrophysics origin.

[36] ABDALLAH 20 search for WIMP annihilation in newly discovered by DES dwarf satellite galaxies using HESS; limits placed in $\langle\sigma\cdot v\rangle$ vs. m(DM) plane depending on annihilation channel and which dwarf satellite.

[37] ABE 20G search Super-Kamiokande data for WIMP annihilation to neutrinos in galactic center/halo; no signal; limits placed in $\langle\sigma\cdot v\rangle$ vs. m(DM) plane depending on annihilation channel and m(WIMP). Reported limit for annihilation to $\nu\overline{\nu}$ at 1 GeV.

[38] ALBERT 20 search for TeV-scale WIMP annihlation to $\gamma\gamma$ in dwarf spheroidal galaxies; no signal; limits placed in $\sigma\cdot v$ vs m(WIMP) plane: e.g. $\sigma\cdot v < 2.2\times10^{-24}$ cm^3/s for m(WIMP) = 1 TeV.

[39] ALBERT 20A search for WIMP annihilation to ν in galactic center using Antares; limits placed in $\sigma\cdot$v vs m(WIMP) plane e.g. $\sigma\cdot$v $< 5\times10^{-24}$ cm^3/s for m(WIMP) = 1 TeV assuming annihilation dominantly to $\tau\overline{\tau}$.

[40] ALBERT 20C report combined Antares + IceCube search for WIMP annihilation to $\tau\overline{\tau}$; for NFW halo profile report $\sigma\cdot v < 1\times10^{-23}$ cm^3/s for m(WIMP) = 100 GeV.

[41] ALVAREZ 20 use profiling over J-factor distributions and background to derive new limits on $\sigma\cdot$v; e.g. $\sigma\cdot$v $< 8\times10^{-26}$ cm^3/s for m(WIMP) = 100 GeV.

[42] HOOF 20 examine γ rays from 27 dwarf spheroidals using Fermi-LAT data; place limits in $\sigma\cdot$v vs m(WIMP) plane using profile likelihood and marginalized posterior techniques for DM annihilation to $\tau\overline{\tau}$ and $b\overline{b}$; quoted limit uses first technique and $b\overline{b}$ channel for m(WIMP) = 100 GeV; results rule out WIMP explanation of galactic center excess.

[43] MAZZIOTTA 20 use Fermi-LAT pointed-at-Sun data to search for DM annihilation in the Sun to long-lived mediators decaying into gamma rays, i.e. $\chi\chi \rightarrow \phi\phi \rightarrow 4\gamma$. Limits placed on the SI and SD DM-nucleon cross sections in the σ–DM mass plane for DM masses in the range 3 GeV – 1.8 TeV. Limits are evaluated in both cases of equilibrium and non-equilibrium.

[44] ABEYSEKARA 19 search for γs from DM annihilation in galactic substructures with HAWC; no signal, limits placed in J$\langle\sigma\cdot v\rangle$ vs. declination plane for m(DM) $\sim$ 1–108 TeV.

[45] ALBERT 19B search for DM signal from M31 galaxy in μ, τ, t, b, W channels using HAWC for m(DM) $\sim$ 1–100 TeV; no signal, limits placed in $\langle\sigma\cdot v\rangle$ vs. m(DM) plane.

[46] CHEUNG 19 derive model-dependent bounds on $\langle\sigma\cdot v\rangle$ from EDGES data: $< 4\times10^{-26}$ cm^3/s for e^+e^- and $b\overline{b}$ for m(χ) = 100 GeV (including boost factor).

[47] DI-MAURO 19 place limits on WIMP annihilation via Fermi-LAT observation of M31 and M33 galaxies: $\langle\sigma\cdot v\rangle < 7\times10^{-27}$cm^3/s for m($\chi$) = 20 GeV from M31.

[48] JOHNSON 19 search for γ-rays, 10–600 GeV energy, from P-wave annihilating DM around SgrA* BH using Fermi-LAT; limits set for various models.

[49] LI 19D search for $\chi\chi \rightarrow \gamma$ in Fermi-LAT data; no signal, require $\langle\sigma\cdot v\rangle < 2\times10^{-26}$ cm^3/s for m(χ) = 100 GeV.

[50] NG 19 search for X-ray line from sterile ν decay/annihilation using NuStar M-31; no signal: limits placed in m(ν) vs mixing angle and $\langle\sigma\cdot v\rangle$ vs m(ν).

[51] QUEIROZ 19 examine $\chi\chi \rightarrow \chi SM$ semi-annihilation of DM reaction; limits placed for various assumed SM particles in $\langle\sigma\cdot v\rangle$ vs. m(χ) plane.

[52] ABDALLAH 18 search for WIMP WIMP $\rightarrow \gamma X$ in central galactic halo, 10 years of data; limits placed in $\langle\sigma\cdot v\rangle$ vs. m(WIMP) plane for m(WIMP): 0.3–70 TeV.

[53] AHNEN 18 search for WIMP WIMP$\rightarrow \gamma X$ from Ursa Major II; limits set in $\langle\sigma\cdot v\rangle$ vs. m(WIMP) plane for $b\overline{b}$, W^+W^-, $\tau^+\tau^-$, and $\mu^+\mu^-$ annihilation modes.

[54] ALBERT 18B search for TeV-scale WIMPs with WIMP WIMP $\rightarrow \gamma X$ in Andromeda galaxy using HAWC Observatory; limits set in $\langle\sigma\cdot v\rangle$ vs m(WIMP) plane.

[55] CHANG 18A examine $\chi\chi \rightarrow b\overline{b} \rightarrow \gamma$ using Fermi Pass 8 data; no signal; require $\langle\sigma\cdot v\rangle < 10^{-26}$ cm^3/s for m(χ) = 50 GeV.

[56] LISANTI 18 examine Fermi Pass 8 γ-ray data from galaxy groups; report m(WMP) > 30 GeV for annihilation in $b\overline{b}$ channel.

[57] MAZZIOTTA 18 examine Fermi-LAT electron and positron spectra searching for features originating from DM particles annihilation into e^+e^- pairs, from 45 GeV to 2 TeV; no signal found, limits are obtained.

[58] AARTSEN 17C use 1005 days of IceCube data to search for $\chi\chi \rightarrow$ neutrinos via various annihilation channels. Limits set.

[59] ALBERT 17A search for DM annihilation to ν using ANTARES data from 2007–2015. No signal. Limits set in $\langle\sigma\cdot v\rangle$ vs. m(DM) plane for m(DM) $\sim$ 10–10 $\times 10^5$ GeV. The listed limit is for m(DM) = 100 TeV.

[60] ARCHAMBAULT 17 set limits for WIMP mass between 100 GeV and 1 TeV on $\langle\sigma\cdot v\rangle$ for W^+W^-, ZZ, $b\overline{b}$, $s\overline{s}$, $u\overline{u}$, $d\overline{d}$, $t\overline{t}$, e^+e^-, gg, $c\overline{c}$, hh, $\gamma\gamma$, $\mu^+\mu^-$,$\tau^+\tau^-$ annihilation channels.

[61] AVRORIN 17 find upper limits for the annhilation cross section in various channels for DM particle mass between 30 GeV and 10 TeV. Strongest upper limits coming from the two neutrino channel require $\langle\sigma\cdot v\rangle < 6\times10^{-20}$ cm^3/s in dwarf galaxies and $\langle\sigma\cdot v\rangle < 7\times10^{-21}$ cm^3/s in LMC for 5 TeV WIMP mass.

[62] BOUDAUD 17 use data from the spacecraft Voyager 1, beyond the heliopause, and from AMS02 on $\chi\chi \rightarrow e^+e^-$ to require $\langle\sigma\cdot v\rangle < 1.\times10^{-28}$ cm^3/s for m(χ) = 10 MeV.

[63] AARTSEN 16D search for GeV ν from WIMP annihilation in galaxy; limits set on $\langle\sigma\cdot v\rangle$ in Fig. 6, 7.

[64] ABDALLAH 16 require $\langle\sigma\cdot v\rangle < 6\times10^{-26}$ cm^3/s for m(WIMP) = 1.5 TeV from 254 hours observation (WW channel) and $< 2\times10^{-26}$ cm^3/s for m(WIMP) = 1.0 TeV in $\tau^+\tau^-$ channel.

[65] ABDALLAH 16A search for line spectra from WIMP + WIMP $\rightarrow \gamma\gamma$ in 18 hr HESS data; rule out previous 130 GeV WIMP hint from Fermi-LAT data.

[66] AHNEN 16 require $\langle\sigma\cdot v\rangle < 3\times10^{-26}$ cm^3/s for m(WIMP) = 100 GeV (WW channel).

[67] AVRORIN 16 require $\langle$s.v$\rangle < 1.91\times10^{-21}$ cm^3/s from WIMP annihilation to ν via WW channel for m(WIMP) = 1 TeV.

[68] CAPUTO 16 place limits on WIMPs from annihilation to gamma rays in Small Magellanic Cloud using Fermi-LaT data: $\langle\sigma\cdot v\rangle < 3\times10^{-26}$cm^3/s for m(WIMP) = 10 GeV.

[69] FORNASA 16 use anisotropies in the γ-ray diffuse emission detected by Fermi-LAT to bound $\langle\sigma\cdot v\rangle < 10^{-25}$cm^3/s for m(WIMP) = 100 GeV in $b\overline{b}$ channel: see Fig. 28. The limit is driven by dark-matter subhalos in the Milky Way and it refers to their Most Constraining Scenario.

[70] LEITE 16 constrain WIMP annihilation via search for radio emissions from Smith cloud; $\langle\sigma\cdot v\rangle < 5\times10^{-27}$cm^3/s in ee channel for m(WIMP) = 5 GeV.

[71] LI 16 re-analyze Fermi-LAT data on 8 dwarf spheroidals; set limit $\langle\sigma\cdot v\rangle < 2\times10^{-26}$ cm^3/s for m(WIMP) = 100 GeV in $b\overline{b}$ mode with substructures included.

[72] LI 16A constrain $\langle\sigma\cdot v\rangle < 10^{-25}$cm^3/s in $b\overline{b}$ channel for m(WIMP) = 100 GeV using Fermi-LAT data from M31; see Fig. 6.

[73] LIANG 16 search dwarf spheroidal galaxies, Large Magellanic Cloud, and Small Magellanic Cloud for γ-line in Fermi-LAT data.

[74] LU 16 re-analyze Fermi-LAT and AMS-02 data; require $\langle\sigma\cdot v\rangle < 10^{-25}$cm^3/s for m_m(WIMP) = 1 TeV in $b\overline{b}$ channel.

[75] SHIRASAKI 16 re-anayze Fermi-LAT extra-galactic data; require $\langle\sigma\cdot v\rangle < 10^{-23}$cm^3/s for m(WIMP) = 1 TeV in $b\overline{b}$ channel; see Fig. 8.

[76] AARTSEN 15C search for neutrinos from X^0 annihilation in the Galactic halo. See their Figs. 16 and 17, and Table 5 for limits on $\sigma\cdot$v for X^0 mass between 100 GeV and 100 TeV.

[77] AARTSEN 15E search for neutrinos from X^0 annihilation in the Galactic center. See their Figs. 7 and 9, and Table 3 for limits on $\sigma\cdot$v for X^0 mass between 30 GeV and 10 TeV.

[78] ABRAMOWSKI 15 search for γ from X^0 annihilation in the Galactic center. See their Fig. 4 for limits on $\sigma\cdot$v for X^0 mass between 250 GeV and 10 TeV.

[79] ACKERMANN 15 search for monochromatic γ from X^0 annihilation in the Galactic halo. See their Fig. 8 and Tables 2–4 for limits on $\sigma\cdot$v for X^0 mass between 0.2 GeV and 500 GeV.

[80] ACKERMANN 15A search for γ from X^0 annihilation (both Galactic and extragalactic) in the isotropic γ background. See their Fig. 7 for limits on $\sigma\cdot$v for X^0 mass between 10 GeV and 30 TeV.

[81] ACKERMANN 15B search for γ from X^0 annihilation in 15 dwarf spheroidal satellite galaxies of the Milky Way. See their Figs. 1 and 2 for limits on $\sigma\cdot$v for X^0 mass between 2 GeV and 10 TeV.

[82] ADRIAN-MARTINEZ 15 search for neutrinos from X^0 annihilation in the Galactic center. See their Figs. 10 and 11 and Tables 1 and 2 for limits on $\sigma\cdot$v for X^0 mass between 25 GeV and 10 TeV.

[83] ACKERMANN 14 search for γ from X^0 annihilation in 25 dwarf spheroidal satellite galaxies of the Milky Way. See their Tables II–VII for limits assuming annihilation into e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, $u\overline{u}$, $b\overline{b}$, and W^+W^-, for X^0 mass ranging from 2 GeV to 10 TeV.

[84] Limit assuming X^0 pair annihilation into $b\overline{b}$.

[85] Limit assuming X^0 pair annihilation into W^+W^-.

[86] ALEKSIC 14 search for γ from X^0 annihilation in the dwarf spheroidal galaxy Segue 1. The listed limit assumes annihilation into W^+W^-. See their Figs. 6, 7, and 16 for limits on $\sigma\cdot$v for annihilation channels $\mu^+\mu^-$, $\tau^+\tau^-$, $b\overline{b}$, $t\overline{t}$, $\gamma\gamma$, γZ, W^+W^-, ZZ for X^0 mass between 10^2 and 10^4 GeV.

[87] AARTSEN 13C search for neutrinos from X^0 annihilation in nearby galaxies and galaxy clusters. See their Figs. 5–7 for limits on $\sigma\cdot$v for $X^0X^0 \rightarrow \nu\overline{\nu}$, $\mu^+\mu^-$, $\tau^+\tau^-$, and W^+W^- for X^0 mass between 300 GeV and 100 TeV.

[88] ABRAMOWSKI 13 search for monochromatic γ from X^0 annihilation in the Milky Way halo in the central region. Limit on $\sigma\cdot$v between 10^{-28} and 10^{-25} cm^3 s^{-1} (95% CL) is obtained for X^0 mass between 500 GeV and 20 TeV for $X^0X^0 \rightarrow \gamma\gamma$. X^0 density distribution in the Galaxy by Einasto is assumed. See their Fig. 4.

[89] ACKERMANN 13A search for monochromatic γ from X^0 annihilation in the Milky Way. Limit on $\sigma\cdot$v for the process $X^0X^0 \rightarrow \gamma\gamma$ in the range 10^{-29}–10^{-27} cm^3 s^{-1} (95% CL) is obtained for X^0 mass between 5 and 300 GeV. The limit depends slightly on the assumed density profile of X^0 in the Galaxy. See their Tables VII–X and Fig.10. Supersedes ACKERMANN 12.

[90] ABRAMOWSKI 12 search for γ's from X^0 annihilation in the Fornax galaxy cluster. See their Fig. 7 for limits on $\sigma\cdot$v for X^0 mass between 0.1 and 100 TeV for the annihilation channels $\tau^+\tau^-$, $b\overline{b}$, and W^+W^-.

[91] ACKERMANN 12 search for monochromatic γ from X^0 annihilation in the Milky Way. Limit on $\sigma\cdot$v in the range 10^{-28}–10^{-26} cm^{3}s^{-1} (95% CL) is obtained for X^0 mass between 7 and 200 GeV if X^0 annihilates into $\gamma\gamma$. The limit depends slightly on the assumed density profile of X^0 in the Galaxy. See their Table III and Fig. 15.

[92] ACKERMANN 12 search for γ from X^0 annihilation in the Milky Way in the diffuse γ background. Limit on $\sigma\cdot$v of 10^{-24} cm^{3}s^{-1} or larger is obtained for X^0 mass between 5 GeV and 10 TeV for various annihilation channels including W^+W^-, $b\overline{b}$, gg, e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$. The limit depends slightly on the assumed density profile of X^0 in the Galaxy. See their Figs. 17–20.

[93] ALIU 12 search for γ's from X^0 annihilation in the dwarf spheroidal galaxy Segue 1. Limit on $\sigma\cdot$v in the range 10^{-24}–10^{-20} cm^{3}s^{-1} (95% CL) is obtained for X^0 mass between 10 GeV and 2 TeV for annihilation channels e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, $b\overline{b}$, and W^+W^-. See their Fig. 3.

[94] ABBASI 11C search for ν_μ from X^0 annihilation in the outer halo of the Milky Way. The limit assumes annihilation into $\nu\nu$. See their Fig. 9 for limits with other annihilation channels.

[95] ABRAMOWSKI 11 search for γ from X^0 annihilation near the Galactic center. The limit assumes Einasto DM density profile.

[96] ACKERMANN 11 search for γ from X^0 annihilation in ten dwarf spheroidal satellite galaxies of the Milky Way. The limit for $m = 10$ GeV assumes annihilation into $b\overline{b}$, the others W^+W^-. See their Fig. 2 for limits with other final states. See also GERINGER-SAMETH 11 for a different analysis of the same data.

Dark Matter Particle (X^0) Production in Hadron Collisions

Searches for X^0 production in association with observable particles (γ, jets, ...) in high energy hadron collisions. If a specific form of effective interaction Lagrangian is assumed, the limits may be translated into limits on X^0-nucleon scattering cross section.

[1] AAD 25BA reports search for dark Higgs s with dark matter ($\chi\chi$) produced via Z' leading to 3–4 b-jets plus $\not{E}_T$ with 140 fb^{-1} in Run 2. No signal observed. Limits placed in m(s) vs. m(Z') plane.

[2] AAD 25C reports search for dark matter $\chi\chi$ produced in association with dark Higgs s decaying to $b\bar{b}$ with 140 fb^{-1}. No signal observed. Limits placed in m(Z') vs m(s) and other planes for three different dark Higgs scenarios.

[3] CHEKHOVSKY 25D report on search for DM production in association with top quarks. Slight excess of events observed. Limits placed depend on assumed mediator mass and assuming m(χ) = 1 GeV. Limits also placed on ALP simplified model.

[4] CHEKHOVSKY 25H search for dark matter $\chi\chi$ plus single top production via flavor-changing mediator boson M in 138 fb^{-1}. No signal observed. Limits placed in m(M) vs m(χ) plane for flavor-changing mediator model.

[5] HAYRAPETYAN 25P search for DM χ production in association with $b\bar{b}$ at CMS with 138 fb^{-1}. No signal observed. Limits placed in m(χ) vs m(a) and other planes for various choices of 2HDM+a model parameters.

[6] AAD 24AC search for $t\bar{t}$ + mediator, where mediator decays to dark matter, within 140 fb^{-1} of data. No signal observed. Limits placed in σ vs m(mediator) plane.

[7] AAD 24AC search for $t\bar{t}$+MET signal at $\sqrt{s}$=13 TeV and 139 fb^{-1}. No signal observed. Assume DM mediator model coupling to $t\bar{t}$ and limits placed in various m(DM), m(mediator), coupling planes.

[8] AAD 24AH search for SUSY in pMSSM model. No signal observed. Several regions of DM-allowed parameters space now ruled out.

[9] AAD 24AK search for top + MET in various simplified models including mediator decaying to DM. No signal observed. Limits placed in various parameter space planes.

[10] AAD 24CD search for hadronically-decaying W/Z plus MET events in 140 fb^{-1} at 13 TeV. No signal observed. Limits placed in m(χ) vs. mediator mass plane for simplified dark matter model.

[11] HAYRAPETYAN 24B search for inelastic DM production where heavier state decays to displaced muons. No signal observed. Limits placed in signal strength vs mass plane for various choices of mass gap.

[12] HAYRAPETYAN 24W search for dark matter via dark Higgs decay in WW + MET events. No signal observed. Limits placed in m(χ) vs m(mediator) or m(s) plane where s is dark Higgs.

[13] AAD 23A search for $H \to$ invisible. No signal observed. Results interpreted in terms of several DM Higgs portal simplified models.

[14] AAD 23AF search for $\bar{t}t + H \to$ invisible with 139 fb^{-1} of data. No signal observed. Limits placed on branching fractions of H decays etc. for various DM mediator models. Result also included in AAD 23A.

[15] AAD 23AJ search for $tW\chi\chi$ production in mediator-extended 2HDM with 139 fb^{-1} of data. No signal observed. Limits placed in m(H) vs. m(mediator) and tan(β) vs. m(H) planes.

[16] AAD 23BX search for $A \to Ha$ production where $H \to \tau\bar{\tau}$ and $a \to \chi\chi$. No signal observed. Limits placed on 2HDM+a model.

[17] AAD 23W search for DM in dark Higgs model via $WW\chi\chi$ final state with 139 fb^{-1} of data. No signal detected. Limits set in m(dark Higgs) vs. m(Z') plane.

[18] AKIMOV 23 search for light DM via COHERENT CsI detector at SNS. No signal observed. For scalar DM model, limits set for m(χ) = 1–300 MeV. Limit of $\sigma(\chi N) < 1 \times 10^1$ pb set at peak sensitivity m(χ) = 25 MeV.

[19] LIN 23C search for $\chi \to \gamma\gamma$ decay where $p \to \chi\chi$ at KOTO. No signal observed. Limits placed on K_L^0 branching fraction.

[20] AAD 22D search for Z+H production with $Z \to l\bar{l}$ and $H \to \chi\chi$ with 139 fb^{-1} at 13 TeV; no signal found; limits placed in various simplified models depending on Higgs portal and DM mediator.

[21] AAD 22P search for H production via VBF with $H \to \chi\chi$ with 139 fb^{-1} at 13 TeV; no signal found; limits placed for various Higgs DM portal simplified models.

[22] AGUILAR-AREVALO 22A report search for MeV vector portal and leptophobic DM via scatter on liquid Ar at the Lujan stopped pion source at LANL; no signal detected; limits placed on vector portal and leptophobic DM vs. m(χ): 1–40 MeV.

[23] TUMASYAN 22AA search for Z' decay to dark quarks with 138 fb^{-1} at 13 TeV; no signal observed; limits exclude a wide range of strongly coupled hidden sector models.

[24] TUMASYAN 22AG search for strongly interacting dark matter production via scalar mediator, with SIMP decay to trackless jets with 16.1 fb^{-1} at 13 TeV; no signal detected; limits placed in mass vs. cross section plane for simplified models.

[25] TUMASYAN 22G search for VBF production of Higgs with $H \to \chi\chi$ with 101 fb^{-1} at 13 TeV, combined with earlier searches, in total 19.7 fb^{-1} at 8 TeV and 140 fb^{-1} at 13 TeV are used; no signal detected; limits placed in mass vs. cross section plane for various Higgs portal simplified models.

[26] AAD 21AZ search for DM in $H\not{E}_T \to \gamma\gamma\not{E}_T$ events with 139 fb^{-1} at 13 TeV. No signal observed. Limits placed for several simplified models.

[27] AAD 21BB search for DM in $H\not{E}_T \to b\bar{b}\not{E}_T$ events with 139 fb^{-1} at 13 TeV. No signal observed. Limits placed for several simplified models.

[28] AAD 21D search for $VV + \chi\chi$, $V \to q\bar{q}$ with 139 fb^{-1} at 13 TeV LHC. No signal detected. Limits placed in dark Higgs boson mass vs. m(Z') plane. Here VV stand for $W^{\pm}W^{\mp}$, ZZ.

[29] AAD 21F search for monojet recoiling against invisibles with 139 fb^{-1} at 13 TeV LHC. No signal detected. Limits placed in various simplified dark matter models.

[30] AAD 21K search for a photon recoiling against dark matter with 139 fb^{-1} at 13 TeV LHC. No signal detected. Limits placed on parameter space of various simplified models.

[31] AAD 21O search for ℓ + jets + $\not{E}_T$ to search for t-pairs + DM particles with 139 fb^{-1} at LHC 13 TeV LHC. No signal detected. Limits placed in the cross-section vs. mediator mass plane, assuming light DM states.

[32] AAD 21P search for $\ell^+\ell^-$ + jets + $\not{E}_T$ in context of various BSM models with 139 fb^{-1} at 13 TeV LHC. No signal observed. Limits placed in parameter space of dark matter models and SUSY.

[33] AAD 21S search for b-jets + $\not{E}_T$ signal from BSM/DM models with 139 fb^{-1} at 13 TeV LHC. No signal observed. Limits placed on parameter space of DM models.

[34] SIRUNYAN 21A search for DM production in association with leptonically decaying Z boson in 137 fb^{-1} at 13 TeV; no signal; limits set in large variety of simplified DM models.

[35] TUMASYAN 21D search for DM and other exotica at CMS in jets + $\not{E}_T$ events with 137 fb^{-1} at 13 TeV. No signal observed. Limits placed for a variety of simplified models.

[36] SIRUNYAN 20X search for DM in $pp \to Z' \to A(Z')h \to h + \not{E}_T$ in CMS at 13 TeV with 35.9 fb^{-1}; no signal; limits placed in σ^{SI} vs. m(χ), and σ, m(A) and tanβ vs m(Z') for considered DM models.

[37] AABOUD 19AA searches for BSM physics in more than 700 event classes with more than 10^5 regions at 13 TeV with 3.2 fb^{-1}; no significant signal.

[38] AABOUD 19AI searches for vector boson fusion $pp \to Hqq$, $H \to$ invisible at 13 TeV with 36.1 fb^{-1}; no signal: require B($H \to$ invisible) < 0.37 (0.28 expected).

[39] AABOUD 19AL perform search in three different channels for $H \to \chi\chi$ at 7, 8 and 13 TeV; combined result BF($H \to$ invisible) < 0.26 (0.17 expected).

[40] AABOUD 19Q search for single $t + \not{E}_T$ at 13 TeV with 36.1 fb^{-1} of data; no signal; limits set in σ or coupling vs. mass plane for simplified models.

[41] AABOUD 19V review ATLAS results from 7, 8 and 13 TeV searches for mediator-based DM and DE scalar which couples to gravity; no signal: limits set for large variety of simplified models.

[42] BANERJEE 19 search for dark photon via $eN \to eN+\not{E}$ in NA64; no signal, limits placed in kinetic mixing ϵ vs. m(DM) plane for m(DM) $\sim$ 0.001–1 GeV.

[43] SIRUNYAN 19AN search at 13 TeV with 35.9 fb^{-1} for $pp \to H\chi\chi \to b\bar{b}\not{E}_T$; no signal: limits set in the context of a 2HDM + pseudoscalar (a) model and a baryonic Z' model.

[44] SIRUNYAN 19BC search for DM via LeptoQuark pair annihilation LQ LQ $\to \mu j\chi\chi \to \mu j\not{E}_T$ with 77.4 fb^{-1}, 13 TeV; no signal: limits placed in m(χ) vs. m(LQ) plane. Model dependent limits on DM mass up to 600 GeV depending on m(LQ) placed.

[45] SIRUNYAN 19BO search for vector boson fusion $VV \to qqH$ with $H \to \chi\chi$ at 13 TeV with 38.2 fb^{-1}; no signal: limits placed for several models. Also search for $H \to$ invisible at 7, 8, and 13 TeV; no signal: limit placed on BF < 0.19.

[46] SIRUNYAN 19C search for DM via $pp \to t\bar{t}\chi\chi$ at 13 TeV, 35.9 fb^{-1}; no signal; limits placed on coupling vs. mediator mass for various simplified models.

[47] SIRUNYAN 19O search for $pp \to \gamma$ at 13 TeV with 35.9 fb^{-1}; no signal: limits placed on parameters of various models.

[48] SIRUNYAN 19X search for $pp \to t\bar{t}\not{E}_T$ and $pp \to t\not{E}_T$ + ... at 13 TeV with 35.9 fb^{-1}; no signal: limits placed on χ production σ for various simplified models with m(χ) = 1 GeV.

[49] AABOUD 18 search for $pp \to Z + \not{E}_T$ with $Z \to \ell\ell$ at 13 TeV with 36.1 fb^{-1} of data. Limits set for simplified models.

[50] AABOUD 18A search for $pp \to t\bar{t}\not{E}_T$ or $pp \to b\bar{b}\not{E}_T$ at 13 TeV, 36.1 fb^{-1} of data. Limits set for simplified models.

[51] AABOUD 18CA search for $pp \to VX\chi\chi$ with $V \to jj$ at 13 TeV, 36.1 fb^{-1}. No signal observed. Limits set in m(DM) vs m(mediator) simplified model plane.

[52] AABOUD 18I search for $pp \to j + \not{E}_T$ at 13 TeV with 36.1 fb^{-1} of data. Limits set for simplified models with pair-produced weakly interacting dark-matter candidates.

[53] AGUILAR-AREVALO 18B search for WIMP production in MiniBooNE p beam dump; no signal; limits set for m(χ) $\sim$ 5–50 MeV in vector portal DM model.

[54] KHACHATRYAN 18 search for $pp \to Z(\ell\ell) + \not{E}_T$. No signal observed. Llimits set on effective dark matter interactions and other exotic physics models.

[55] SIRUNYAN 18BF search for $pp \to t\not{E}_T$ at 13 TeV and 36 fb^{-1}; no signal; limits placed on DM models involving a flavor changing neutral current, scalar resonance decaying to top quark and DM.

[56] SIRUNYAN 18BO search for high mass dijet resonances at 13 TeV and 36 fb^{-1}; no signal: limits placed on various models, including simplified DM models involving a spin = 1 Z' mediator.

[57] SIRUNYAN 18BV search for $pp \to Z\not{E}_T$ at 13 TeV; no signal, limits placed for various exotic physics models including DM.

[58] SIRUNYAN 18C search for new physics in $pp \to$ final states with two oppositely charged leptons at 13 TeV with 35.9 fb^{-1}. Limits placed on m(mediator) and top squark for various simplified models.

[59] SIRUNYAN 18CU search for $pp \to Z\not{E}_T$ at 13 TeV and 2.3 fb^{-1}. No signal observed. Limits placed for various exotic models including DM.

[60] SIRUNYAN 18DH search for $pp \to \chi\chi h$; $h \to \gamma\gamma$ or $\tau\bar{\tau}$ at 13 TeV, 35.9 fb^{-1}; no signal; limits placed on massive boson mediator Z' in the context of Z'+2HDM and baryonic Z' models. Limits also cast in terms of spin-independent WIMP-nucleon cross section for masses 1–200 GeV.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[61] SIRUNYAN 18S search for $pp \to$ jets $\not{E}_T$ at 13 TeV; no signal: limits placed on simplified dark matter models, on the branching ratio of the Higgs boson to invisible particles, and on several other exotic physics models including fermion portal DM.

[62] AABOUD 17A search for $H \to b\overline{b} + \not{E}_T$. See Fig. 4b for limits set on VB mediator vs WIMP mass.

[63] AABOUD 17AM search for $pp \to Z' \to Ah \to h(b\overline{b}) + \not{E}_T$ at 13 TeV. Limits set in m(Z') vs. m(A) plane and on the visible cross section of $h(b\overline{b}) + \not{E}_T$ events in bins of $\not{E}_T$.

[64] AABOUD 17AQ search for WIMP in $pp \to h(\gamma\gamma) + \not{E}_T$ in 36.1 fb^{-1} of data. Limits on the visible cross section are also provided. Model dependent limits on spin independent DM - Nucleon cross-section are also presented, which are more stringent than those from direct searches for DM mass smaller than 2.5 GeV.

[65] AABOUD 17BD search for $pp \to$ jet(s) + $\not{E}_T$ at 13 TeV with 3.2 fb^{-1} of data. Limits set for simplified models. Observables corrected for detector effects can be used to constrain other models.

[66] AABOUD 17R, for an axial vector mediator in the s-channel, excludes m(mediator) $<$ 750–1200 GeV for m(DM) $<$ 230–480 GeV, depending on the couplings.

[67] AGUILAR-AREVALO 17A search for DM produced in 8 GeV proton collisions with steel beam dump followed by DM-nucleon scattering in MiniBooNE detector. Limit placed on DM cross section parameter $Y < 2 \times 10^{-8}$ for $\alpha_D = 0.5$ and for $0.01 < m(\text{DM}) < 0.3$ GeV.

[68] BANERJEE 17 search for dark photon invisible decay via $e\,N$ scattering; exclude m(γ') $<$ 100 MeV as an explanation of (g_μ−2) muon anomaly.

[69] KHACHATRYAN 17A search for WIMPs in forward jets + $\not{E}_T$ channel with 18.5 fb^{-1} at 8 TeV; limits set in effective theory model, Fig. 3.

[70] KHACHATRYAN 17F search for $H \to$ invisibles in pp collisions at 7, 8, and 13 TeV; place limits on Higgs portal DM.

[71] SIRUNYAN 17 search for $pp \to Z + \not{E}_T$ with 2.3 fb^{-1} at 13 TeV; no signal seen; limits placed on WIMPs and unparticles.

[72] SIRUNYAN 17AP search for $pp \to Z' \to Ah \to h + \not{E}_T$ with $h \to b\overline{b}$ or $\gamma\gamma$ and $A \to \chi\chi$ with 2.3 fb^{-1} at 13 TeV. Limits set in m(Z') vs. m(A) plane.

[73] SIRUNYAN 17AQ search for $pp \to \gamma + \not{E}_T$ at 13 TeV with 12.9 fb^{-1}. Limits derived for simplified DM models, effective electroweak-DM interaction and Extra Dimensions models.

[74] SIRUNYAN 17BB search for WIMPs via $pp \to t\overline{t}$+$\not{E}_T$, $pp \to b\overline{b}$+$\not{E}_T$ at 13 TeV with 2.2 fb^{-1}. Limits derived for various simplified models.

[75] SIRUNYAN 17G search for $pp \to j + \not{E}_T$ with 12.9 fb^{-1} at 13 TeV; limits placed on WIMP mass/mediators in DM simplified models.

[76] SIRUNYAN 17U search for WIMPs/unparticles via $pp \to Z\chi\chi$, $Z \to \ell\overline{\ell}$ at 13 TeV with 2.3 fb^{-1}. Limits derived for various simplified models.

[77] AABOUD 16AD place limits on VVXX effective theory via search for hadronic W or Z plus WIMP pair production. See Fig. 5.

[78] AAD 16AF search for $VV \to (H \to$ WIMP pair) + forward jets with 20.3 fb^{-1} at 8 TeV; set limits in Higgs portal model, Fig. 8.

[79] AAD 16AG search for lepton jets with 20.3 fb^{-1} of data at 8 TeV; Fig. 13 excludes dark photons around 0.1–1 GeV for kinetic mixing 10^{-6}–10^{-2}.

[80] AAD 16M search with 20.3 fb^{-1} of data at 8 TeV pp collisions; limits placed on EFT model (Fig. 7) and simplified Z' model (Fig. 6).

[81] KHACHATRYAN 16BZ search for jet(s) + $\not{E}_T$ in 19.7 fb^{-1} at 8 TeV; limits set for variety of simplified models.

[82] KHACHATRYAN 16CA search for WIMPs via jet(s) + $\not{E}_T$ using razor variable; require mediator scale > 1 TeV for various effective theories.

[83] KHACHATRYAN 16N search for γ + WIMPs in 19.6 fb^{-1} at 8 TeV; limits set on SI and SD WIMP-p scattering in Fig. 3.

[84] AAD 15AS search for events with one or more bottom quark and missing E_T, and also events with a top quark pair and missing E_T in pp collisions at $E_{\text{cm}} = 8$ TeV with $L = 20.3$ fb^{-1}. See their Figs. 5 and 6 for translated limits on X^0–nucleon cross section for $m = 1$–700 GeV.

[85] AAD 15BH search for events with a jet and missing E_T in pp collisions at $E_{\text{cm}} = 8$ TeV with $L = 20.3$ fb^{-1}. See their Fig. 12 for translated limits on X^0–nucleon cross section for $m = 1$–1200 GeV.

[86] AAD 15CF search for events with a H^0 ($\to \gamma\gamma$) and missing E_T in pp collisions at $E_{\text{cm}} = 8$ TeV with $L = 20.3$ fb^{-1}. See paper for limits on the strength of some contact interactions containing X^0 and the Higgs fields.

[87] AAD 15CS search for events with a photon and missing E_T in pp collisions at $E_{\text{cm}} = 8$ TeV with $L = 20.3$ fb^{-1}. See their Fig. 13 (see also erratum) for translated limits on X^0–nucleon cross section for $m = 1$–1000 GeV.

[88] KHACHATRYAN 15AG search for events with a top quark pair and missing E_T in pp collisions at $E_{\text{cm}} = 8$ TeV with $L = 19.7$ fb^{-1}. See their Fig. 8 for translated limits on X^0–nucleon cross section for $m = 1$–200 GeV.

[89] KHACHATRYAN 15AL search for events with a jet and missing E_T in pp collisions at $E_{\text{cm}} = 8$ TeV with $L = 19.7$ fb^{-1}. See their Fig. 5 and Tables 4–6 for translated limits on X^0–nucleon cross section for $m = 1$–1000 GeV.

[90] KHACHATRYAN 15T search for events with a lepton and missing E_T in pp collisions at $E_{\text{cm}} = 8$ TeV with $L = 19.7$ fb^{-1}. See their Fig. 17 for translated limits on X^0–proton cross section for $m = 1$–1000 GeV.

[91] AAD 14AI search for events with a W and missing E_T in pp collisions at $E_{\text{cm}} = 8$ TeV with $L = 20.3$ fb^{-1}. See their Fig. 4 for translated limits on X^0–nucleon cross section for $m = 1$–1500 GeV.

[92] AAD 14BK search for hadronically decaying W, Z in association with $\not{E}_T$ in 20.3 fb^{-1} at 8 TeV pp collisions. Fig. 5 presents exclusion results for SI and SD scattering cross section. In addition, cross section limits on the anomalous production of W or Z bosons with large missing transverse momentum are also set in two fiducial regions.

[93] AAD 14K search for events with a Z and missing E_T in pp collisions at $E_{\text{cm}} = 8$ TeV with $L = 20.3$ fb^{-1}. See their Fig. 5 and 6 for translated limits on X^0–nucleon cross section for $m = 1$–10^3 GeV.

[94] AAD 14O search for ZH^0 production with H^0 decaying to invisible final states. See their Fig. 4 for translated limits on X^0–nucleon cross section for $m = 1$–60 GeV in Higgs-portal X^0 scenario.

[95] AAD 13AD search for events with a jet and missing E_T in pp collisions at $E_{\text{cm}} = 7$ TeV with $L = 4.7$ fb^{-1}. See their Figs. 5 and 6 for translated limits on X^0–nucleon cross section for $m = 1$–1300 GeV.

[96] AAD 13C search for events with a photon and missing E_T in pp collisions at $E_{\text{cm}} = 7$ TeV with $L = 4.6$ fb^{-1}. See their Fig. 3 for translated limits on X^0–nucleon cross section for $m = 1$–1000 GeV.

[97] AALTONEN 12K search for events with a top quark and missing E_T in $p\overline{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV with $L = 7.7$ fb^{-1}. Upper limits on $\sigma(tX^0)$ in the range 0.4–2 pb (95% CL) is given for $m_{X^0} = 0$–150 GeV.

[98] AALTONEN 12M search for events with a jet and missing E_T in $p\overline{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV with $L = 6.7$ fb^{-1}. Upper limits on the cross section in the range 2–10 pb (90% CL) is given for $m_{X^0} = 1$–300 GeV. See their Fig. 2 for translated limits on X^0–nucleon cross section.

[99] CHATRCHYAN 12AP search for events with a jet and missing E_T in pp collisions at $E_{\text{cm}} = 7$ TeV with $L = 5.0$ fb^{-1}. See their Fig. 4 for translated limits on X^0–nucleon cross section for $m_{X^0} = 0.1$–1000 GeV.

[100] CHATRCHYAN 12T search for events with a photon and missing E_T in pp collisions at $E_{\text{cm}} = 7$ TeV with $L = 5.0$ fb^{-1}. Upper limits on the cross section in the range 13–15 fb (90% CL) is given for $m_{X^0} = 1$–1000 GeV. See their Fig. 2 for translated limits on X^0–nucleon cross section.

Dark Matter Particle (X^0) Production in e^+e^- Collisions

Model dependent limits on dark matter parameters.

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
	[1] ADACHI 25U	BEL2	inelastic DM in association with dark photon and dark Higgs

[1] ADACHI 25U report on search for inelastic dark matter wimps produced in e^+e^- collisions in association with dark photon and dark Higgs. No signal observed. Limits placed on GeV-scale DM in m(h') vs. mixing angle and m(χ) vs. kinetic mixing planes.

Other Particle Searches

OMITTED FROM SUMMARY TABLE

OTHER PARTICLE SEARCHES

Revised February 2018 by K. Hikasa (Tohoku University).

We collect here those searches which do not appear in any other search categories. These are listed in the following order:

- Concentration of stable particles in matter
- General new physics searches
- Limits on jet-jet resonance in hadron collisions
- Limits on neutral particle production at accelerators
- Limits on charged particles in e^+e^- collisions
- Limits on charged particles in hadron reactions
- Limits on charged particles in cosmic rays
- Searches for quantum black hole production

Note that searches appear in separate sections elsewhere for Higgs bosons (and technipions), other heavy bosons (including W_R, W', Z', leptoquarks, axigluons), axions (including pseudo-Goldstone bosons, Majorons, familons), WIMPs, heavy leptons, heavy neutrinos, free quarks, monopoles, supersymmetric particles, and compositeness.

We no longer list for limits on tachyons and centauros. See our 1994 edition for these limits.

CONCENTRATION OF STABLE PARTICLES IN MATTER

Concentration of Heavy (Charge +1) Stable Particles in Matter

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$<4\times10^{-17}$	95	[1] YAMAGATA	93	SPEC	Deep sea water, M=5–1600m_p
$<6\times10^{-15}$	95	[2] VERKERK	92	SPEC	Water, M= 10^5 to 3×10^7 GeV
$<7\times10^{-15}$	95	[2] VERKERK	92	SPEC	Water, M= 10^4, 6×10^7 GeV
$<9\times10^{-15}$	95	[2] VERKERK	92	SPEC	Water, M= 10^8 GeV
$<3\times10^{-23}$	90	[3] HEMMICK	90	SPEC	Water, $M=1000m_p$

$<1.\times10^{-29}$		SMITH	82B	SPEC	Water, M=30–400m_p
$<2.\times10^{-28}$		SMITH	82B	SPEC	Water, M=12–1000m_p
$<1.\times10^{-14}$		SMITH	82B	SPEC	Water, $M>1000\ m_p$
$<(0.2\text{–}1.)\times10^{-21}$		SMITH	79	SPEC	Water, M=6–350 m_p

[1] YAMAGATA 93 used deep sea water at 4000 m since the concentration is enhanced in deep sea due to gravity.

[2] VERKERK 92 looked for heavy isotopes in sea water and put a bound on concentration of stable charged massive particle in sea water. The above bound can be translated into into a bound on charged dark matter particle (5×10^6 GeV), assuming the local density, ρ=0.3 GeV/cm^3, and the mean velocity $\langle v\rangle$=300 km/s.

[3] See HEMMICK 90 Fig. 7 for other masses 100–10000 m_p.

Concentration of Heavy Stable Particles Bound to Nuclei

$<1.2\times10^{-12}$/nucleon	68	[5] NORMAN	87	SPEC	^{56,58}FeX^-

[1] AFEK 21 search for millicharged particles bound to matter using an optomechanical device. No signal was observed. Limits placed in the abundance vs. charge plane (Fig. 3). This is translated to the mass versus charge plane by requiring bound states to be stable.

[2] JAVORSEK 01 search for (neutral) SIMPs (strongly interacting massive particles) bound to Au nuclei. Here M is the effective SIMP mass.

[3] JAVORSEK 01B search for (neutral) SIMPs (strongly interacting massive particles) bound to Au and Fe nuclei from various origins with exposures on the earth's surface, in a satellite, heavy ion collisions, etc. Here M is the mass of the anomalous nucleus. See also JAVORSEK 02.

[4] See HEMMICK 90 Fig. 7 for other masses 100–10000 m_p.

[5] Bound valid up to $m_{X^-}\sim100$ TeV.

GENERAL NEW PHYSICS SEARCHES

This subsection lists some of the search experiments which look for general signatures characteristic of new physics, independent of the framework of a specific model.

The observed events are compatible with Standard Model expectation, unless noted otherwise.

[1] HAYRAPETYAN 24AO report on search for soft unclustered energy deposits. No signal observed. Limits placed in mediator mass vs. decay temperature plane.

[2] ALKHATIB 21A search for lightly ionizing fractionally charged relics scattering from Ge. No signal observed. Limits plotted in fractional charge f vs. vertical intensity plane for m $\sim$ 5 MeV to 100 TeV.

[3] AGUILAR-AREVALO 20B search for light BSM mediator effect on ν elastic scatter on nuclei; no signal; limits placed in m(mediator) vs. coupling plane for two models of MeV-scale mediators.

[4] FEDDERKE 20 place limits on cosmic relic charged massive particles (CHAMPs) due to their capture and subsequent disruption of old white dwarf stars; limits placed in the m(CHAMP) vs. relic density parameter plane.

[5] SIRUNYAN 20A search for SUSY and LQ production using mT2 or presence of long-lived charged particle; no signal, limits placed in various mass planes for different BSM scenarios and various assumed lifetimes.

[6] ALCANTARA 19 place limits on m(WIMPzilla=X) vs lifetime from upper bound on ultra high energy cosmic rays at Auger experiment: e.g. $\tau(X)<\ 4\times10^{22}$ yr for m(X) = 10^{16} GeV.

[7] PORAYKO 18 search for deviations in the residuals of pulsar timing data using PPTA. No signal observed. Limits set on fuzzy DM with $3\times10^{-24}\ <$ m(DM) $<2\times10^{-22}$ eV.

[8] AAD 15AT search for events with a top quark and mssing E_T in pp collisions at E_{cm} = 8 TeV with L = 20.3 fb^{-1}.

[9] KHACHATRYAN 15F search for events with a top quark and mssing E_T in pp collisions at E_{cm} = 8 TeV with L = 19.7 fb^{-1}.

[10] AALTONEN 14J examine events with a W and two jets in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 8.9 fb^{-1}. Invariant mass distributions of the two jets are consistent with the Standard Model expectation.

[11] AAD 13A search for resonant WW production in pp collisions at E_{cm} = 7 TeV with L = 4.7 fb^{-1}.

[12] AAD 13C search for events with a photon and missing $\not{E}_T$ in pp collisions at E_{cm} = 7 TeV with L = 4.6 fb^{-1}.

[13] AALTONEN 13I search for events with a photon and missing E_T, where the photon is detected after the expected timing, in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 6.3 fb^{-1}. The data are consistent with the Standard Model expectation.

[14] CHATRCHYAN 13 search for events with an opposite-sign lepton pair, jets, and missing E_T in pp collisions at E_{cm} = 7 TeV with L = 4.98 fb^{-1}.

[15] AAD 12C search for events with a $t\bar{t}$ pair and missing $\not{E}_T$ in pp collisions at E_{cm} = 7 TeV with L = 1.04 fb^{-1}.

[16] AALTONEN 12M search for events with a jet and missing E_T in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 6.7 fb^{-1}.
[17] CHATRCHYAN 12AP search for events with a jet and missing E_T in pp collisions at E_{cm} = 7 TeV with L = 5.0 fb^{-1}.
[18] CHATRCHYAN 12Q search for events with a Z, jets, and missing $\not{E}_T$ in pp collisions at E_{cm} = 7 TeV with L = 4.98 fb^{-1}.
[19] CHATRCHYAN 12T search for events with a photon and missing $\not{E}_T$ in pp collisions at E_{cm} = 7 TeV with L = 5.0 fb^{-1}.
[20] AAD 11S search for events with one jet and missing E_T in pp collisions at E_{cm} = 7 TeV with L = 33 pb^{-1}.
[21] AALTONEN 11AF search for high-p_T like-sign dileptons in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 6.1 fb^{-1}.
[22] CHATRCHYAN 11C search for events with an opposite-sign lepton pair, jets, and missing E_T in pp collisions at E_{cm} = 7 TeV with L = 34 pb^{-1}.
[23] CHATRCHYAN 11U search for events with one jet and missing E_T in pp collisions at E_{cm} = 7 TeV with L = 36 pb^{-1}.
[24] AALTONEN 10AF search for $\gamma\gamma$ events with e, μ, τ, or missing E_T in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 1.1–2.0 fb^{-1}.
[25] AALTONEN 09AF search for $\ell\gamma b$ events with missing E_T in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 1.9 fb^{-1}. The observed events are compatible with Standard Model expectation including $t\overline{t}\gamma$ production.
[26] AALTONEN 09G search for $\mu\mu\mu$ and $\mu\mu e$ events with missing E_T in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 976 pb^{-1}.

LIMITS ON JET-JET RESONANCES

Heavy Particle Production Cross Section

Limits are for a particle decaying to two hadronic jets.

Units(pb)	CL%	Mass(GeV)	DOCUMENT ID		TECN	COMMENT

[1] AAD 25AX report on search for BSM dijet events via $pp \to A \to BC$ using various signal regions and new physics models. Results from Fig. 6 place upper bounds on new physics expected cross sections for different models and signal regions.
[2] AAD 25AZ report on ATLAS dijet resonance search with 132 fb^{-1} using the trigger-level analysis. No signal observed. Limits are set on leptophobic Z' model in m(Z') vs coupling plane.
[3] HAYRAPETYAN 24G search for trijet resonance at CMS with 138 fb^{-1} of data at 13 TeV. No signal observed. Limits placed on various models vs mass(resonance).
[4] TUMASYAN 23L search for dijet resonance in 4-jet events with 138 fb^{-1} fb of data. There are two events in the tails of the distributions, each with a four-jet mass of 8 TeV and an average dijet mass of 2 TeV, resulting in local and global significances of 3.9 and 1.6 standard deviations, respectively, if interpreted as a signal. Limits set for simplified diquark model.
[5] AAD 20AD search for weakly supervised dijet resonance in ATLAS with 139 fb^{-1} at 13 TeV; no signal; various limits placed depending on kinematics and production cross section.
[6] AAD 20T search for dijet resonance with or without b-jets at 13 TeV and 139 fb^{-1}; no signal; limits placed in $\sigma \cdot$ BF vs mass plane for various BSM models.
[7] AAD 20W search for dijet resonance plus lepton with ATLAS at 13 TeV and 139 fb^{-1}; no signal; limits placed in $\sigma \cdot$ BF vs. mass plane for various BSM models.
[8] SIRUNYAN 20AI search for dijet resonance in CMS at 13 TeV with 137 fb^{-1}; no signal; limits set in σ vs. mass plane for various BSM models.
[9] AABOUD 19AJ search for low mass dijet resonance in $pp \to \gamma X$, $X \to jj$ at 13 TeV with 79.8 fb^{-1} of data; no signal found; limits placed on Z' model in coupling vs. m(Z') plane.
[10] SIRUNYAN 19B search for low mass resonance $pp \to jA$, $A \to b\overline{b}$ at 13 TeV using 35.9 fb^{-1}; no signal; exclude resonances 50–350 GeV depending on production and decay.
[11] SIRUNYAN 19CD search for $pp \to Z'\gamma$, $Z' \to jj$ with fat jet (jj); no signal, limits placed in m(Z') vs. coupling plane for Z' masses from 10 to 125 GeV.
[12] AABOUD 18AD search for new heavy particle $Y \to HX \to (bb) + (qq)$. No signal observed. Limits set on m(Y) vs. m(X) in the ranges of m(Y) in 1–4 TeV and m(X) in 50–1000 GeV.
[13] AABOUD 18CK search for SUSY Higgsinos in gauge-mediation via $pp \to bbb + \not{E}_T$ at 13 TeV using two complementary analyses with 24.3/36.1 fb^{-1}; no signal is found and Higgsinos with masses between 130 and 230 GeV and between 290 and 880 GeV are excluded at the 95% confidence level.
[14] AABOUD 18CL search for $pp \to$ vector-like quarks $\to$ jets at 13 TeV with 36 fb^{-1}; no signal seen; limits set on various VLQ scenarios. For pure $B \to Hb$ or $T \to Ht$, set the mass limit m $>$ 1010 GeV.
[15] AABOUD 18N search for dijet resonance at Atlas with 13 TeV and 29.3 fb^{-1}; limits set on m(Z') in the mass range of 450–1800 GeV.
[16] SIRUNYAN 18DJ search for $pp \to ZZ$ or $WZ \to \ell\overline{\ell}jj$ resonance at 13 TeV, 35.9 fb^{-1}; no signal; limits set in the 400–4500 GeV mass range, exclusion of W' up to 2270 GeV in the HVT model A, and up to 2330 GeV for HVT model B. WED bulk graviton exclusion up to 925 GeV.
[17] SIRUNYAN 18DY search for $pp \to RR$; $R \to jj$ two dijet resonances at 13 TeV 35.9 fb^{-1}; no signal; limits placed on RPV top-squark pair production.
[18] KHACHATRYAN 17W search for dijet resonance in 12.9 fb^{-1} data at 13 TeV; see Fig. 2 for limits on axigluons, diquarks, dark matter mediators etc.
[19] KHACHATRYAN 17Y search for $pp \to$ (8–10) j in 19.7 fb^{-1} at 8 TeV. No signal seen. Limits set on colorons, axigluons, RPV, and SUSY.
[20] SIRUNYAN 17F measure $pp \to jj$ angular distribution in 2.6 fb^{-1} at 13 TeV; limits set on LEDs and quantum black holes.
[21] AABOUD 16 search for resonant dijets including one or two b-jets with 3.2 fb^{-1} at 13 TeV; exclude excited b^* quark from 1.1–2.1 TeV; exclude leptophilic Z' with SM couplings from 1.1–1.5 TeV.
[22] AAD 16N search for $\geq$ 3 jets with 3.6 fb^{-1} at 13 TeV; limits placed on micro black holes (Fig. 10) and string balls (Fig. 11).
[23] AAD 16S search for high mass jet-jet resonance with 3.6 fb^{-1} at 13 TeV; exclude portions of excited quarks, W', Z' and contact interaction parameter space.
[24] KHACHATRYAN 16K search for dijet resonance in 2.4 fb^{-1} data at 13 TeV; see Fig. 3 for limits on axigluons, diquarks etc.
[25] KHACHATRYAN 16L use data scouting technique to search for jj resonance on 18.8 fb^{-1} of data at 8 TeV. Limits on the coupling of a leptophobic Z' to quarks are set, improving on the results by other experiments in the mass range between 500–800 GeV.
[26] AAD 13D search for dijet resonances in pp collisions at E_{cm} = 7 TeV with L = 4.8 fb^{-1}. The observed events are compatible with Standard Model expectation. See their Fig. 6 and Table 2 for limits on resonance cross section in the range m = 1.0–4.0 TeV.
[27] AALTONEN 13R search for production of a pair of jet-jet resonances in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 6.6 fb^{-1}. See their Fig. 5 and Tables I, II for cross section limits.
[28] CHATRCHYAN 13A search for qq, qg, and gg resonances in pp collisions at E_{cm} = 7 TeV with L = 4.8 fb^{-1}. See their Fig. 3 and Table 1 for limits on resonance cross section in the range m = 1.0–4.3 TeV.
[29] CHATRCHYAN 13A search for $b\overline{b}$ resonances in pp collisions at E_{cm} = 7 TeV with L = 4.8 fb^{-1}. See their Fig. 8 and Table 4 for limits on resonance cross section in the range m = 1.0–4.0 TeV.
[30] AAD 12S search for dijet resonances in pp collisions at E_{cm} = 7 TeV with L = 1.0 fb^{-1}. See their Fig. 3 and Table 2 for limits on resonance cross section in the range m = 0.9–4.0 TeV.
[31] CHATRCHYAN 12BL search for $t\overline{t}$ resonances in pp collisions at E_{cm} = 7 TeV with L = 4.4 fb^{-1}. See their Fig. 4 for limits on resonance cross section in the range m = 0.5–3.0 TeV.
[32] AAD 11AG search for dijet resonances in pp collisions at E_{cm} = 7 TeV with L = 36 pb^{-1}. Limits on number of events for m = 0.6–4 TeV are given in their Table 3.
[33] AALTONEN 11M find a peak in two jet invariant mass distribution around 140 GeV in W + 2 jet events in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 4.3 fb^{-1}.
[34] ABAZOV 11I search for two-jet resonances in W + 2 jet events in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 4.3 fb^{-1} and give limits $\sigma <$ (2.6–1.3) pb (95% CL) for m = 110–170 GeV. The result is incompatible with AALTONEN 11M.
[35] AAD 10 search for narrow dijet resonances in pp collisions at E_{cm} = 7 TeV with L = 315 nb^{-1}. Limits on the cross section in the range 10–10^3 pb is given for m = 0.3–1.7 TeV.
[36] KHACHATRYAN 10 search for narrow dijet resonances in pp collisions at E_{cm} = 7 TeV with L = 2.9 pb^{-1}. Limits on the cross section in the range 1–300 pb is given for m = 0.5–2.6 TeV separately in the final states qq, qg, and gg.
[37] ABE 99F search for narrow $b\overline{b}$ resonances in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. Limits on $\sigma(p\overline{p} \to X+$ anything)$\times$B($X \to b\overline{b}$) in the range 3–10^3 pb (95%CL) are given for m_X=200–750 GeV. See their Table I.
[38] ABE 97G search for narrow dijet resonances in $p\overline{p}$ collisions with 106 pb^{-1} of data at E_{cm} = 1.8 TeV. Limits on $\sigma(p\overline{p} \to X +$ anything)$\cdot$B($X \to jj$) in the range 10^4–10^{-1} pb (95%CL) are given for dijet mass m=200–1150 GeV with both jets having $|\eta| < 2.0$ and the dijet system having $|\cos\theta^*| < 0.67$. See their Table I for the list of limits. Supersedes ABE 93G.
[39] ABE 93G give cross section times branching ratio into light (d, u, s, c, b) quarks for Γ = 0.02 M. Their Table II gives limits for M = 200–900 GeV and Γ = (0.02–0.2) M.

[1] AAD 24AT search for $h \to$ ALPs with ALP $\to \gamma\gamma$. No signal observed. Limits placed in BF(h) vs. m(ALP) plane.

[2] ALBERT 18C search for WIMP annihilation in Sun to long-lived, radiatively decaying mediator; no signal; limits set on $\sigma^{SD}(\chi p)$ assuming long-lived mediator.

[3] KHACHATRYAN 17D search for new scalar resonance decaying to $Z\gamma$ with $Z \to e^+e^-$, $\mu^+\mu^-$ in pp collisions at 8 and 13 TeV; no signal seen.

[4] AAD 16AI search for excited quarks (EQ) and quantum black holes (QBH) in 3.2 fb^{-1} at 13 TeV of data; exclude EQ below 4.4 TeV and QBH below 3.8 (6.2) TeV for RS1 (ADD) models. The visible cross section limit was obtained for 5 TeV resonance with $\sigma_G/M_G = 2\%$.

[5] KHACHATRYAN 16M search for $\gamma\gamma$ resonance using 19.7 fb^{-1} at 8 TeV and 3.3 fb^{-1} at 13 Tev; slight excess at 750 GeV noted; limit set on RS graviton.

[6] ABBIENDI 00D associated production limit is for m_{X^0}= 90–188 GeV, m_{Y^0}=0 at E_{cm}=189 GeV. See also their Fig. 9.

[7] ABBIENDI 00D pair production limit is for m_{X^0} = 45–94 GeV, m_{Y^0}=0 at E_{cm}=189 GeV. See also their Fig. 12.

[8] ACKERSTAFF 97B associated production limit is for m_{X^0} = 80–160 GeV, m_{Y^0}=0 from 10.0 pb^{-1} at E_{cm} = 161 GeV. See their Fig. 3(a).

[9] ACKERSTAFF 97B pair production limit is for m_{X^0} = 40–80 GeV, m_{Y^0}=0 from 10.0 pb^{-1} at E_{cm} = 161 GeV. See their Fig. 3(b).

[1] AFANACIEV 25 report on search for ^{8}Be* emission of $X \to e^+e^-$ at MEG-II. No signal observed. Limits placed in m(e^+e^-) vs. branching fraction plane.

[2] ALRAHMAN 25 report on search for neutral long-lived particle (S) produced from K decay but decaying $S \to \mu^+\mu^-$ at ICARUS experiment at Fermilab. No signal observed. Limits placed in mass vs.coupling plane for axion and Higgs portal models.

[3] HAYRAPETYAN 25O search for long-lived heavy neutral leptons at CMS with 138 fb^{-1} using displaced lepton plus jet. No signal observed. Limits placed in lepton mixing angle vs mass plane for masses in the range of 1.0–16.5 GeV.

[4] AAD 24AE search for heavy vector triplet production with decay to boson pairs. No signal was observed. Limits placed in σ vs m plane. Limits also placed in various two-dimensional coupling planes (g_F, g_H, g_ℓ, g_ℓ(3rd Gen), g_q, g_q(3rd Gen), g_q(1st/2nd Gen)).

[5] AAD 24BV search for VBF di-Higgs production with decay to boosted 4b state. No signal observed. Limits placed in mass vs. cross section plane for various simplified models.

[6] AAD 24CD search for hadronically-decaying W/Z + MET events from new physics with 140 fb^{-1} at 13 TeV. No signal observed. Limits placed on various simplified new physics models.

[7] AAD 24E uses a new resonance search technique for two-body decays into any pair of ℓ, b, and jet with 140 fb^{-1} of data. No signal was observed. Limits placed in σ vs mass plane for various decay modes.

[8] AAD 24S search for quantum black hole (QBH) decay to lepton + jet in 140 fb^{-1} of data. No signal observed. Limits placed in $\sigma \cdot$BF vs mass plane for ADD and RS models.

[9] HAYRAPETYAN 24AB search for heavy neutral leptons N at CMS with 138 fb^{-1} of data. No signal observed. Limits placed in mixing angle vs m(N) plane.

[10] HAYRAPETYAN 24AC search for heavy long-lived neutrino N produced in B-decays in 41.6 fb^{-1} of data. No signal observed. Limits placed in mixing angle vs m(N) plane.

[11] HAYRAPETYAN 24AZ search for various new bosons via production and decay to four muon states with 41.5 and 59.7 fb^{-1} of data at 13 TeV. No signal observed. Limits placed usually in mass vs. cross section plane for a variety of new physics simplified models.

[12] AAD 23P search in 22 channels for exotica produced in association with $h \to \gamma\gamma$ in 139 fb^{-1} of data. No signal observed. Limits placed on production cross section in various channels.

[13] TUMASYAN 23BC search for γ-jet resonance at CMS with 138 fb^{-1} of data. No signal observed. Limits placed on quantum black hole and excited quark models.

[14] TUMASYAN 23BF search for $pp \to pp + \gamma/Z + X$ search where X is missing particle using CMS-TOTEM with 37.2 fb^{-1} of data. No signal observed. Limits placed on σ vs. m plane.

[15] TUMASYAN 22AG search for strongly interacting neutral massive particles via trackless jets with 16.1 fb^{-1} at 13 TeV; no signal detected; limits placed in mass vs. cross section plane for various simplified models.

[16] AAD 21F search for hard monojet production at ATLAS with 139 $^{-1}$ of 13 TeV data. No signal observed. Limits placed on invisible production cross-section recoiling against ISR and interpreted in variety of BSM models.

[17] AAIJ 20AL search for dimuon resonance from promptly decaying X particle. No signal detected. Limits placed on m(X) up to 60 GeV depending on mixing in 2HDM.

[18] SIRUNYAN 20AY measured Υ(1S) pair production cross section and searched for new states decaying into $\Upsilon(1S)\mu^+\mu^-$ at CMS with 13 TeV with 35.9 fb^{-1}. No signal is found and limits are set in $\sigma \cdot$BF vs. mass plane for tetra-b-quarks with masses between 17.5 and 19 GeV and for generic search for narrow resonances with mass between 16.5 and 27 GeV.

[19] SIRUNYAN 20Z search for BSM physics via multilepton production with CMS at 13 TeV with 137 fb^{-1}; no signal is found and limits are set on type-III seesaw and other BSM models.

[20] AABOUD 19H searches for di-photon-jet resonance at 13 TeV and 36.7 fb^{-1} of data; no signal found and limits placed on $\sigma \cdot$BR vs. mass plane for various simplified models.

[21] AABOUD 19V review ATLAS searches for mediator-based DM at 7, 8, and 13 TeV with up to 37 fb^{-1} of data; no signal found and limits set for wide variety of simplified models of dark matter.

[22] SIRUNYAN 19O search for $pp \to \gamma \not{E}_T$ at 13 TeV with 36.1 fb^{-1}; no signal found and limits set for various simplified models.

[23] AABOUD 18CJ make multichannel search for $pp \to VV/\ell\ell/\ell\nu$, $V = W,Z,h$ at 13 TeV, 36.1 fb^{-1}; no signal found; limits placed for several BSM models.

[24] AABOUD 18CM search for lepton-flavor violating resonance in $pp \to e\mu/e\tau/\mu\tau$ at 13 TeV, 36.1 fb^{-1}; no signal is found and limits placed for various BSM models.

[25] AAIJ 18AJ search for prompt and delayed dark photon decay $A' \to \mu^+\mu^-$ at LHCb detector using 1.6 fb^{-1} of pp collisions at 13 TeV; limits on m(A') vs. kinetic mixing are set.

[26] BANERJEE 18 search for dark photon A'/16.7 MeV boson X at NA64 via $eZ \to eZX(A')$; no signal found and limits set on the X-e^- coupling ϵ_e in the range $1.3 \times 10^{-4} \leq \epsilon_e \leq 4.2 \times 10^{-4}$ excluding part of the allowed parameter space.

[27] BANERJEE 18A search for invisibly decaying dark photons in $eZ \to eZA'$, $A' \to$ invisible; no signal found and limits set on mixing for m(A') < 1 GeV.

[28] MARSICANO 18 search for dark photon $e^+e^- \to A'(\gamma)$ visible decay in SLAC E137 e beam dump data. No signal observed and limits set in ϵ coupling vs m(A') plane, see their figure 7.

[29] SIRUNYAN 18BB search for high mass dilepton resonance; no signal found and exclude portions of p-space of Z', KK graviton models.

[30] SIRUNYAN 18DA search for $pp \to$ Black Hole, string ball, sphaleron via high multiplicity events at 13 TeV, 35.9 fb^{-1}; no signal, require e.g. m(BH) > 10.1 TeV.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[31] SIRUNYAN 18DD search for $pp \to jj$ deviations in dijet angular distribution. No signal observed. Set limits on large extra dimensions, black holes and DM mediators e.g. m(BH) $>$ 5.9–8.2 TeV.
[32] SIRUNYAN 18DR search for dimuon resonance in $pp \to b\mu\overline{\mu}$ at 8 and 13 TeV. Slight excess seen at m($\mu\overline{\mu}$) $\sim$ 28 GeV in some channels.
[33] SIRUNYAN 18DU search for high mass diphoton resonance in $pp \to \gamma\gamma$ at 13 TeV using 35.9 fb^{-1}; no signal; limits placed on RS Graviton, LED, and clockwork.
[34] SIRUNYAN 18ED search for $pp \to V \to Wh$; $h \to b\overline{b}$; $W \to \ell\nu$ at 13 TeV with 35.9 fb^{-1}; no signal; limits set on m(W') $>$ 2.9 TeV.
[35] AABOUD 17B exclude m(W', Z') $<$ 1.49–2.31 TeV depending on the couplings and W'/Z' degeneracy assumptions via WH, ZH search in pp collisions at 13 TeV with 3.2 fb^{-1} of data.
[36] AAIJ 17BR search for long-lived hidden valley pions from Higgs decay. Limits are set on the signal strength as a function of the mass and lifetime of the long-lived particle in their Fig. 4 and Tab. 4.
[37] AAD 16O search for high E_T ℓ + (ℓs or jets) with 3.2 fb^{-1} at 13 TeV; exclude micro black holes mass $<$ 8 TeV (Fig. 3) for models with two extra dimensions.
[38] AAD 16R search for WW, WZ, ZZ resonance in 20.3 fb^{-1} at 8 TeV data; limits placed on massive RS graviton (Fig. 4).
[39] KRASZNAHORKAY 16 report pLi $\to$ Be $\to e\overline{e}N$ 5σ resonance at 16.7 MeV– possible evidence for nuclear interference or new light boson. However, such nuclear interference was ruled out already by ZANG 17.
[40] LEES 15E search for long-lived neutral particles produced in e^+e^- collisions in the Upsilon region, which decays into e^+e^-, $\mu^+\mu^-$, $e^\pm\mu^\mp$, $\pi^+\pi^-$, K^+K^-, or $\pi^\pm K^\mp$. See their Fig. 2 for cross section limits.
[41] ADAMS 97B search for a hadron-like neutral particle produced in pN interactions, which decays into a ρ^0 and a weakly interacting massive particle. Upper limits are given for the ratio to K_L production for the mass range 1.2–5 GeV and lifetime 10^{-9}–10^{-4} s. See also our Light Gluino Section.
[42] GALLAS 95 limit is for a weakly interacting neutral particle produced in 800 GeV/c pN interactions decaying with a lifetime of 10^{-4}–10^{-8} s. See their Figs. 8 and 9. Similar limits are obtained for a stable particle with interaction cross section 10^{-29}–10^{-33} cm^2. See Fig. 10.
[43] AKESSON 91 limit is from weakly interacting neutral long-lived particles produced in pN reaction at 450 GeV/c performed at CERN SPS. Bourquin-Gaillard formula is used as the production model. The above limit is for $\tau > 10^{-7}$ s. For $\tau > 10^{-9}$ s, $\sigma < 10^{-30}$ cm^{-2}/nucleon is obtained.
[44] BADIER 86 looked for long-lived particles at 300 GeV π^- beam dump. The limit applies for nonstrongly interacting neutral or charged particles with mass $>$2 GeV. The limit applies for particle modes, $\mu^+\pi^-$, $\mu^+\mu^-$, $\pi^+\pi^-$X, $\pi^+\pi^-\pi^\pm$ etc. See their figure 5 for the contours of limits in the mass-τ plane for each mode.
[45] GUSTAFSON 76 is a 300 GeV FNAL experiment looking for heavy ($m >$2 GeV) long-lived neutral hadrons in the M4 neutral beam. The above typical value is for m = 3 GeV and assumes an interaction cross section of 1 mb. Values as a function of mass and interaction cross section are given in figure 2.

Production of New Penetrating Non-ν Like States in Beam Dump

[1] BOSSI 25 search for 17 MeV resonance in $e^+e^- \to e^+e^-$ and $\gamma\gamma$ at PADME at Frascati experiment. No signal observed. Limits are placed above approximately 4×10^{-4} exclusion at 90% CL in mass vs. coupling plane in vicinity of 17 MeV. The most significant deviation is found at 16.90 MeV, corresponding to a global significance of approximately 2 standard deviations over the null hypothesis expectation.
[2] ADACHI 23K search for spin-0 LLP called S in B decays. No signal observed. Limits placed in branching fraction vs. m(S) plane.
[3] KILE 18 investigate archived ALEPH $e^+e^- \to$ 4 jets data and see 4–5 σ excess at 110 GeV.
[4] ABLIKIM 17AA search for dark photon $A \to \ell\overline{\ell}$ at 3.773 GeV with 2.93 fb^{-1}. Limits are set in ϵ vs m(A) plane.
[5] ACKERSTAFF 98P search for pair production of long-lived charged particles at E_{cm} between 130 and 183 GeV and give limits $\sigma <$(0.05–0.2) pb (95%CL) for spin-0 and spin-1/2 particles with m=45–89.5 GeV, charge 1 and 2/3. The limit is translated to the cross section at E_{cm}=183 GeV with the s dependence described in the paper. See their Figs. 2–4.
[6] ABREU 97D search for pair production of long-lived particles and give limits $\sigma <$(0.4–2.3) pb (95%CL) for various center-of-mass energies E_{cm}=130–136, 161, and 172 GeV, assuming an almost flat production distribution in cosθ.
[7] BARATE 97K search for pair production of long-lived charged particles at E_{cm} = 130, 136, 161, and 172 GeV and give limits $\sigma <$(0.2–0.4) pb (95%CL) for spin-0 and spin-1/2 particles with m=45–85 GeV. The limit is translated to the cross section at E_{cm}=172 GeV with the E_{cm} dependence described in the paper. See their Figs. 2 and 3 for limits on J = 1/2 and J = 0 cases.
[8] AKERS 95R is a CERN-LEP experiment with $W_{cm} \sim m_Z$. The limit is for the production of a stable particle in multihadron events normalized to $\sigma(e^+e^- \to$ hadrons). Constant phase space distribution is assumed. See their Fig. 3 for bounds for $Q = \pm2/3$, $\pm4/3$.
[9] BUSKULIC 93C is a CERN-LEP experiment with $W_{cm} = m_Z$. The limit is for a pair or single production of heavy particles with unusual ionization loss in TPC. See their Fig. 5 and Table 1.
[10] ADACHI 90C is a KEK-TRISTAN experiment with W_{cm} = 52–60 GeV. The limit is for pair production of a scalar or spin-1/2 particle. See Figs. 3 and 4.
[11] ADACHI 90E is KEK-TRISTAN experiment with W_{cm} = 52–61.4 GeV. The above limit is for inclusive production cross section normalized to $\sigma(e^+e^- \to \mu^+\mu^-)\cdot\beta(3-\beta^2)/2$, where $\beta = (1 - 4m^2/W_{cm}^2)^{1/2}$. See the paper for the assumption about the production mechanism.
[12] KINOSHITA 82 is SLAC PEP experiment at W_{cm} = 29 GeV using lexan and ^{39}Cr plastic sheets sensitive to highly ionizing particles.
[13] BARTEL 80 is DESY-PETRA experiment with W_{cm} = 27–35 GeV. Above limit is for inclusive pair production and ranges between 1. $\times$ 10^{-1} and 1. $\times$ 10^{-2} depending on mass and production momentum distributions. (See their figures 9, 10, 11).

Branching Fraction of Z^0 to a Pair of Stable Charged Heavy Fermions

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$<5 \times 10^{-6}$	95	[1] AKERS	95R	OPAL	m= 40.4–45.6 GeV
$<1 \times 10^{-3}$	95	AKRAWY	90O	OPAL	m = 29–40 GeV

[1] AKERS 95R give the 95% CL limit $\sigma(X\overline{X})/\sigma(\mu\mu) < 1.8\times10^{-4}$ for the pair production of singly- or doubly-charged stable particles. The limit applies for the mass range 40.4–45.6 GeV for $X^\pm$ and $<$ 45.6 GeV for $X^{\pm\pm}$. See the paper for bounds for $Q = \pm2/3$, $\pm4/3$.

LIMITS ON CHARGED PARTICLES IN HADRONIC REACTIONS

MASS LIMITS for Long-Lived Charged Heavy Fermions

Limits are for spin 1/2 particles with no color and SU(2)$_L$ charge. The electric charge Q of the particle (in the unit of e) is therefore equal to its weak hypercharge. Pair production by Drell-Yan like γ and Z exchange is assumed to derive the limits.

[1] AAD 25AA search for vector-like lepton (VLL) pair production at ATLAS with 140 fb^{-1} of data. No signal observed. Limits placed on VLL mass for singlet and doublet models with mxing to e or μ. The resulting mass lower limits are 1220 GeV (1270 GeV) and 320 GeV (400 GeV) for vector-like electrons (muons) in the doublet and singlet scenarios, respectively.

[2] AAD 24AK search for single top + MET in 140 fb^{-1} fb of data. No signal observed. Limits placed in various planes such as σ vs m(mediator) for assumed simplified models.

[3] AAD 24B search for non-resonant jets +MET at $\sqrt{s}$ = 13 TeV with 139 fb^{-1}. No excess observed. Limits placed on dark sector model mediator mass and coupling.

[4] AAD 24CM search for new dark mesons decaying to t/b states with 140 fb^{-1} at 13 TeV. No signal observed. Limits placed in mass vs. σ plane for various new physics simplified models.

[5] AAD 22G search for single vector-like quark T with $T \rightarrow th$ in all hadronic mode with 139 fb^{-1} at 13 TeV; no signal observed; limits placed in mass vs. coupling plane.

[6] TUMASYAN 22H search for new states of matter via non-resonant mutilepton production based on a luminosity of 138 fb^{-1}; no signal observed; limits placed on vector-like leptons, leptoquarks, and new fermions from type-III seesaw model.

[7] SIRUNYAN 21T perform model unspecific search for deviations from SM with CMS at 13 TeV with 35.9^{-1} fb data in numerous signature channels. No deviations from SM found.

[8] SIRUNYAN 20C search for four top-quark production with decay to multileptons at CMS at 13 TeV with 137 fb^{-1}; no signal is found and limits are placed on the Higgs boson oblique parameter in the effective field theory framework (EFT) and the model parameters (tanβ).

[9] AABOUD 19AA search for BSM physics at 13 TeV with 3.2 fb^{-1} in $> 10^5$ regions of $>$ 700 event classes; no significant signal found.

[10] AABOUD 19Q search for single top+MET events at 13 TeV with 36.1 fb^{-1} of data; no signal found and limits set in σ or coupling vs. mass plane for variety of simplified models including DM and vector-like top quark T.

[11] AABOUD 17D search for $WWjj$, $WZjj$ in pp collisions at 8 TeV with 3.2 fb^{-1}; set limits on anomalous couplings.

[12] AABOUD 17L search for the pair production of heavy vector-like T quarks in the $Z(\rightarrow \nu\nu)tX$ final state.

[13] SIRUNYAN 17B search for vector-like quark $pp \rightarrow TX \rightarrow tHX$ in 2.3 fb^{-1} at 13 TeV; no signal seen; limits placed.

[14] SIRUNYAN 17C search for vector-like quark $pp \rightarrow TX \rightarrow Z$ + (t or b) in 2.3 fb^{-1} at 13 TeV; no signal seen; limits placed.

[15] SIRUNYAN 17J search for $pp \rightarrow X_{5/3}X_{5/3} \rightarrow tWtW$ with 2.3 fb^{-1} at 13 TeV. No signal seen: m(X) > 1020 (990) GeV for RH (LH) new charge 5/3 quark.

[16] AAIJ 15BD search for production of long-lived particles in pp collisions at E_{cm} = 7 and 8 TeV. See their Table 6 for cross section limits.

[17] AAD 13AH search for production of long-lived particles with $|q|$=(2–6)e in pp collisions at E_{cm} = 7 TeV with 4.4 fb^{-1}. See their Fig. 8 for cross section limits.

[18] AAD 11I search for production of highly ionizing massive particles in pp collisions at E_{cm} = 7 TeV with L = 3.1 pb^{-1}. See their Table 5 for similar limits for $|q| = 6e$ and 17e, Table 6 for limits on pair production cross section.

[19] AALTONEN 09Z search for long-lived charged particles in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 1.0 fb^{-1}. The limits are on production cross section for a particle of mass above 100 GeV in the region $|\eta| \lesssim 0.7$, $p_T > 40$ GeV, and $0.4 < \beta < 1.0$.

[20] Limit for weakly interacting charge-1 particle.

[21] Limit for up-quark like particle.

[22] ABAZOV 09M search for pair production of long-lived charged particles in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 1.1 fb^{-1}. Limit on the cross section of (0.31–0.04) pb (95% CL) is given for the mass range of 60–300 GeV, assuming the kinematics of stau pair production.

[23] AKTAS 04C look for charged particle photoproduction at HERA with mean c.m. energy of 200 GeV.

[24] ABE 92J look for pair production of unit-charged particles which leave detector before decaying. Limit shown here is for m=50 GeV. See their Fig. 5 for different charges and stronger limits for higher mass.

[25] CARROLL 78 look for neutral, $S = -2$ dihyperon resonance in $pp \rightarrow 2K^+$X. Cross section varies within above limits over mass range and p_{lab} = 5.1–5.9 GeV/c.

[26] LEIPUNER 73 is an NAL 300 GeV p experiment. Would have detected particles with lifetime greater than 200 ns.

[1] AAD 25N search for semi-visible jets arising from dark sector particle production via Z'. No signal observed. Limits placed in m(Z') vs. R, the fraction of invisible particles in a jet.

[2] HAYRAPETYAN 23F search for anomalous top $\rightarrow$ leptons decay via effective operators. No signal observed. Limits placed on EFT operators.

[3] BALDIN 76 is a 70 GeV Serpukhov experiment. Value is per Al nucleus at $\theta = 0$. For other charges in range -0.5 to -3.0, CL = 90% limit is $(2.6 \times 10^{-36})/|(\text{charge})|$ for mass range (2.1–9.4 GeV) $\times |(\text{charge})|$. Assumes stable particle interacting with matter as do antiprotons.

[4] ALBROW 75 is a CERN ISR experiment with E_{cm} = 53 GeV. θ = 40 mr. See figure 5 for mass ranges up to 35 GeV.

[5] JOVANOVICH 75 is a CERN ISR 26+26 and 15+15 GeV pp experiment. Figure 4 covers ranges Q = 1/3 to 2 and m = 3 to 26 GeV. Value is per GeV momentum.

[6] APPEL 74 is NAL 300 GeV pW experiment. Studies forward production of heavy (up to 24 GeV) charged particles with momenta 24–200 GeV (−charge) and 40–150 GeV (+charge). Above typical value is for 75 GeV and is per GeV momentum per nucleon.

[7] ALPER 73 is CERN ISR 26+26 GeV pp experiment. $p >$0.9 GeV, 0.2 < β <0.65.

[8] ANTIPOV 71B is from same 70 GeV p experiment as ANTIPOV 71C and BINON 69.

[9] ANTIPOV 71C limit inferred from flux ratio. 70 GeV p experiment.

[10] DORFAN 65 is a 30 GeV/c p experiment at BNL. Units are per GeV momentum per nucleus.

Long-Lived Heavy Particle Invariant Cross Section

$<3.0 \times 10^{-37}$	90	[6] VIDAL	78	CNTR		m=4.5–6 GeV

[1] BERNSTEIN 88 limits apply at x = 0.2 and p_T = 0. Mass and lifetime dependence of limits are shown in the regions: m = 1.5–7.5 GeV and $\tau = 10^{-8}$–2×10^{-6} s. First number is for hadrons; second is for weakly interacting particles.

[2] THRON 85 is FNAL 400 GeV proton experiment. Mass determined from measured velocity and momentum. Limits are for $\tau > 3 \times 10^{-9}$ s.

[3] ARMITAGE 79 is CERN-ISR experiment at E_{cm} = 53 GeV. Value is for x = 0.1 and p_T = 0.15. Observed particles at m = 1.87 GeV are found all consistent with being antideuterons.

[4] BOZZOLI 79 is CERN-SPS 200 GeV pN experiment. Looks for particle with τ larger than 10^{-8} s. See their figure 11–18 for production cross-section upper limits vs mass.

[5] CUTTS 78 is pBe experiment at FNAL sensitive to particles of $\tau > 5 \times 10^{-8}$ s. Value is for $-0.3 < x < 0$ and p_T = 0.175.

[6] VIDAL 78 is FNAL 400 GeV proton experiment. Value is for x = 0 and p_T = 0. Puts lifetime limit of $< 5 \times 10^{-8}$ s on particle in this mass range.

Long-Lived Heavy Particle Production (σ(Heavy Particle) / $\sigma(\pi)$)

[1] AAD 25AE search for heavy long-lived particles in ATLAS detector. No signal observed. Limits placed in mass vs. lifetime plane for several R-parity violating SUSY models.

[2] AAD 25AY report on long-lived particle (LLP) search at ATLAS with 140 fb^{-1} of pp collisions data at $\sqrt{s}$ = 13 TeV. No signal observed. Limits set on cross-section times LLP branching fraction to hadronic jets with decay in the proper decay length ($c\tau$) range between 0.1–100 m, depending on particle masses from production point for Higgs portal model, baryogenesis model and ALP model.

[3] AAD 25M searches for long-lived sleptons and charginos decaying to displaced leptons in ATLAS Run 2 and a subset of Run 3 data. No signal observed. Limits placed in m(LLP) vs. lifetime τ plane for different LLP hypotheses.

[4] ABRAHAM 25 report search for LLPs produced at LHC but undergo delayed decays to multi-photon final states downstream at FASER detector. 1 event observed. Limits placed in mass vs. coupling plane for a variety of BSM models, including ALPs.

[5] ALCOTT 25 use displaced milliQan detector to search for millicharged particles at CMS with 124.7 fb^{-1} of data at LHC. No signal observed. Limits placed in milli-charge vs. mass plane.

[6] CHEKHOVSKY 25E report on CMS search for vector-like lepton pair production with decay to long-lived boson a which decays to $\gamma\gamma$ in muon chamber. No signal observed. Limits placed in m(VLL) vs τ_a plane.

[7] HAYRAPETYAN 25V search for multi-charged long-lived particles (R-hadrons and other exotica) at CMS with 101 fb^{-1}. No signal observed. Limits placed on production cross section vs. mass.

[8] AAD 24AS search for long-lived dark photons (DP) produced from dark sector. No signal observed. Limits placed in portal coupling vs m(DP) plane.

[9] AAD 24BN report on ATLAS search for hadronically-decaying long-lived particles that decay in the tracking detector. No signal was observed. Limits placed in $c\tau$ vs cross section or branching fraction plane for various simplified new physics models.

[10] AAD 24BZ search for long-lived particle decaying to jets in hadronic calorimeter in association with lepton/jet. No signal observed. Limits placed in $c\tau$ vs. cross section plane for various simplified new physics models.

[11] ABREU 24 report FASER search for long-lived dark photon A' decay to e^+e^- with 27 fb^{-1}. No signal observed. Limits placed in m(A') vs. kinetic mixing plane and also for a B-L extended gauge model.

[12] HAYRAPETYAN 24AI search for long-lived particles (LLPs) using a Muon Detector Shower with a high hit multiplicity in the muon chambers with 138 fb^{-1} of data at 13 TeV. No signal was observed. Limits placed in Higgs BF vs. $c\tau$ (lifetime) plane.

[13] HAYRAPETYAN 24M search for long-lived charginos in SUSY decays with 138 fb^{-1} of data at 13 TeV. No signal observed. Limits placed in mass vs mass difference plane for various simplified models.

[14] HAYRAPETYAN 24P search for long-lived particles in SUSY models via displaced vertices with 138 fb^{-1} of data at 13 TeV. No signal observed. Limits set in split SUSY and gauge mediated SUSY breaking models.

[15] HAYRAPETYAN 24S search for long-lived heavy neutral lepton decaying in muon chambers with 138 fb^{-1} of data at 13 TeV. No signal observed. Limits placed in mass vs. mixing angle plane.

[16] HAYRAPETYAN 24Y search for displaced dimuons in CMS with 36 fb^{-1} of data at 13.6 TeV. No signal observed. Limits placed for various models incldluing Abelian dark Higgs and RPV SUSY.

[17] AAD 23AM search for long-lived higgsinos from gauge-mediation which decay to Z or H. No signal observed. Limits placed in $c\tau$ vs m(χ) plane for various simplified models.

[18] AAD 23AR search for long-lived particles via decay to displaced γ with 139 fb^{-1} of data. No signal observed. Limits placed in m vs. τ and BF vs. τ planes for gauge-mediated SUSY model.

[19] AAD 23BQ search for displaced dimuon events in ATLAS detector. No signal observed. Limits placed in smuon lifetime vs. mass plane for long-lived smuon model.

[20] AAD 23CO search for monopoles and high-electric-charge LLPs in ATLAS with 139 fb^{-1} of data. No signal observed. Limits placed in mass vs. charge plane.

[21] AAD 23G search for heavy highly ionizing long-lived particles with 139 fb^{-1} of data. No signal observed. Limits placed in m vs. τ plane for several SUSY models.

[22] AAD 23I search for light long-lived particles decaying to collimated decay products (e.g. dileptons). No signal observed. Limits placed in BF vs. τ plane.

[23] TUMASYAN 23AO search for trackless jets from LLP production at CMS. No signal observed. Limits placed for SUSY model with long-lived neutralino in m(χ) vs. $c\tau$ plane.

[24] TUMASYAN 23G search for LLP decaying to displaced dimuons at CM with 97.6 fb^{-1} fb of data. No signal observed. Limits placed in $c\tau$ vs. m plane for hidden Abelian Higgs simplified model.

[25] AAD 22H search for scalar mediator decay to two LLPs which decay in muon chambers with 139 fb^{-1} at 13 TeV; no signal detected; limits placed on various simplified models.

[26] AAD 22K search for LLP pair production via scalar mediator with LLP decay in hadron calorimeter; no signal detected; limits placed for various simplified models.

[27] AAD 22U search for chargino LLP via disappearing tracks; no signal observed; limits placed in m(chargino) vs lifetime plane for cases of higgsino- or wino-like chargino.

[28] AAIJ 22U reports search for LLP production at LHCB with 5.4 fb^{-1} at 13 TeV followed by semileptonic decay to muon; no signal detected; limits placed in mass or lifetime vs. cross section plane for several simplified models.

[29] ACHARYA 22A report search for monople and HECO production via DY at 8 TeV LHC with 2.2 fb^{-1} with MoEDAL detector; no signal detected; limits placed in mass vs. cross section plane for various electric/magnetic charge scenarios.

[30] TUMASYAN 22AD search for heavy neutral lepton which decays as LLP to trilepton state with 138 fb^{-1} at 13 TeV; no signal detected; limits placed in mass vs. coupling plane.

[31] TUMASYAN 22AF search for LLPs via displaced lepton vertices. The analysis is performed with an integrated luminosity of 118 (113) fb^{-1} when analyzing the ee ($e\mu$, $\mu\mu$) channel; no signal detected; limits placed for a variety of simplified models.

[32] TUMASYAN 22M search in 117 fb^{-1} of 13 TeV data for ZH production with $H \rightarrow SS$ where S is a LLP; no signal observed; limits placed in decay length vs. branching fraction plane.

[33] TUMASYAN 22N search in 101 fb^{-1} of 13 TeV data for LLP production via decay to dimuons; no signal observed; limits placed on mass vs. coupling or lifetime for a variety of simplified models.

[34] AAD 21AL reports on ATLAS search for long-lived charged particles with 139 fb^{-1} at 13 TeV. No signal observed. Limits placed in lifetime vs. mass plane: e.g. for τ(LLP) $\sim$ 0.1 ns, m(selectron) > 720 GeV.

[35] AAD 21BA search for long-lived particles from ZH production ($H \rightarrow b\overline{b}$) with 2 displaced vertices in 139 fb^{-1} of data at 13 TeV. No signal detected. Limits placed in branching fraction vs. lifetime plane.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[36] AAIJ 21V search for $pp \to$ LLP + LLP with LLP$\to e\mu\nu$ in the lifetime range between 2 and 50 ps at LHCb with 5.4 fb^{-1} at 13 TeV. No signal observed. Limits placed in LLP cross section vs. mass or lifetime plane for m(LLP) $\sim$ 7 to 50 GeV.

[37] SIRUNYAN 21AF search for LLPs at CMS via jets with 2 displaced vertices in 140 fb^{-1} of data at 13 TeV. No signal observed. Limits placed for RPV SUSY models in which a long-lived neutralino or gluino decays into a multijet final state with top, bottom, and strange quarks.

[38] SIRUNYAN 21U search for long-lived particles (LLPs) via displaced jets at CMS with LHC13 and 132 fb^{-1}. No signal detected. Limits placed on simplified model production of LLP $X \to q\overline{q}$ with $\sigma < 0.07$ fb for m(X) $>$ 500 GeV and c$\tau \sim$ 2 to 250 mm.

[39] TUMASYAN 21 search for long-lived particles in CMS muon endcap detector in 137 fb^{-1} of data at 13 TeV. No signal detected. Limits are placed depending on the branching fraction of Higgs boson to LLP decaying to dd, bb, and $\tau^+\tau^-$, depending on proper decay length, and LLP masses.

[40] AAD 20D search for opposite-sign dileptons originating from long-lived particles in pp collisions at 13 Tev with 32.8 fb^{-1}; limits placed in squark cross section vs. cτ plane for RPV SUSY.

[41] AAD 20J search for scalar boson decay to two long-lived particles; no signal; limits placed in BF vs cτ plane for various mass hypotheses. This search is also combined with other ATLAS displaced-jet searches.

[42] AAD 20M search for long-lived top-squarks decay to μ and hadrons; no signal; limits placed in cross section vs. mass and mass vs. lifetime planes.

[43] AAD 20P search for long-lived dark photons produced from the decay of a scalar boson, with each dark photon decaying into displaced collimated leptons or light hadrons at 13 TeV with 36 fb^{-1}; no signal; limits placed in $\sigma \cdot$ BF vs. cτ and other planes.

[44] AAIJ 20AL search for long-lived $X \to \mu^+\mu^-$ decays in 5.1 fb^{-1} of LHCb data at 13 TeV; no signal; limits placed on m(X) up to 3 GeV depending on kinetic mixing.

[45] BALL 20 search for long-lived milli-charged particles produced at LHC; limits placed in charge vs. mass plane (Fig. 8).

[46] AABOUD 19AE search for long-lived particles via displaced jets using 10.8 fb^{-1} or 33.0 fb^{-1} data (depending on a trigger) at 13 TeV; no signal found and limits set in branching ratio vs. decay length plane.

[47] AABOUD 19AK searches for long-lived particle Z_d via $pp \to \Phi \to ZZ_d$ at 13 TeV with 36.1 fb^{-1}; no signal found and limits set in $\sigma\times$BR vs. lifetime plane for simplified model.

[48] AABOUD 19AM search for Drell-Yan (DY) production of long-lived multi-charge particles at 13 TeV with 36.1 fb^{-1} of data; no signal found and exclude 50 GeV $<$ m(LLMCP) $<$ 980–1220 GeV for electric charge $|q| =$ (2–7)e.

[49] AABOUD 19AO search for neutral long-lived particles producing displaced jets at 13 TeV with 36.1 fb^{-1} of data; no signal found and exclude regions of $\sigma \cdot$ BR vs. lifetime plane for various models.

[50] AABOUD 19AT search for heavy, charged long-lived particles at 13 TeV with 36.1 fb^{-1}; no signal found and upper limits set on masses of various hypothetical particles.

[51] AABOUD 19G search for long-lived particle with decay to $\mu^+\mu^-$ at 13 TeV with 32.9 fb^{-1}; no signal found and limits set in combinations of lifetime, mass and coupling planes for various simplified models.

[52] SIRUNYAN 19BH search for long-lived SUSY particles via displaced jets at 13 TeV with 35.9 fb^{-1}; no signal found and limits placed in mass vs lifetime plane for various hypothetical models.

[53] SIRUNYAN 19BT search for displaced jet(s)+$\not{E}_T$ at 13 TeV with 137 fb^{-1}; no signal found and limits placed in mass vs lifetime plane for gauge mediated SUSY breaking models.

[54] SIRUNYAN 19CA search for gluino/squark decay to long-lived neutralino, decay to γ in GMSB; no signal, limits placed in m(χ) vs. lifetime plane for SPS8 GMSB benchmark point.

[55] SIRUNYAN 19Q search for $pp \to j +$ displaced jet via dark quark with 13 TeV at 16.1 fb^{-1}; no signal found and limits set in mass vs lifetime plane for dark quark/dark pion model.

[56] SIRUNYAN 18AW search for very long lived particles (LLPs) decaying hadronically or to $\mu\overline{\mu}$ in CMS detector; none seen/limits set on lifetime vs. cross section.

[57] AAIJ 16AR search for long lived particles from $H \to XX$ with displaced X decay vertex using 0.62 fb^{-1} at 7 TeV; limits set in Fig. 7.

[58] KHACHATRYAN 16BW search for heavy stable charged particles via ToF with 2.5 fb^{-1} at 13 TeV; require stable m(gluinoball) $>$ 1610 GeV.

[59] BADIER 86 looked for long-lived particles at 300 GeV π^- beam dump. The limit applies for nonstrongly interacting neutral or charged particles with mass $>$2 GeV. The limit applies for particle modes, $\mu^+\pi^-$, $\mu^+\mu^-$, $\pi^+\pi^-$X, $\pi^+\pi^-\pi^\pm$ etc. See their figure 5 for the contours of limits in the mass-τ plane for each mode.

$<$75	95	[1] RAM	94	SPEC	920$<m_{X^{++}}<$1025 MeV

[1] RAM 94 search for a long-lived doubly-charged fermion X^{++} with mass between m_N and m_N+m_π and baryon number +1 in the reaction $pp \to X^{++}n$. No candidate is found. The limit is for the cross section at 15° scattering angle at 460 MeV incident energy and applies for $\tau(X^{++}) \gg 0.1$ μs.

LIMITS ON CHARGED PARTICLES IN COSMIC RAYS

[1] AALBERS 25B report results of search for milli-charged particles which are produced in cosmic rays but detected at LZ. No signal observed. Limits placed in mass vs. fractional charge plane.

[2] ALEMANNO 22 search for flux of fractionally charged particles (FCPs) in space; no signal observed; limits set in flux vs charge plane for mass as low as GeV.

[3] CAO 22 search for superheavy DM decaying to gamma rays; no signal observed; limits placed in mass vs. lifetime plane for m $\sim 10^5$–10^9 GeV for DM decays to $b\overline{b}$ or $\tau\overline{\tau}$.

[4] ALVIS 18 search for fractional charged flux of cosmic matter at Majorana demonstrator; no signal observed and limits are set on the flux of lightly ionizing particles for charge as low as e/1000.

[5] See AGNESE 15 Fig. 6 for limits extending down to Q = 1/200.

[6] SAITO 90 candidates carry about 450 MeV/nucleon. Cannot be accounted for by conventional backgrounds. Consistent with strange quark matter hypothesis.

[7] MINCER 85 is high statistics study of calorimeter signals delayed by 20–200 ns. Calibration with AGS beam shows they can be accounted for by rare fluctuations in signals from low-energy hadrons in the shower. Claim that previous delayed signals including BJORNBOE 68, DARDO 72, BHAT 82, SAKUYAMA 83B below may be due to this fake effect.

[8] SAKUYAMA 83B analyzed 6000 extended air shower events. Increase of delayed particles and change of lateral distribution above 10^{17} eV may indicate production of very heavy parent at top of atmosphere.

[9] BHAT 82 observed 12 events with delay $> 2.\times10^{-8}$ s and with more than 40 particles. 1 eV has good hadron shower. However all events are delayed in only one of two detectors in cloud chamber, and could not be due to strongly interacting massive particle.

[10] MARINI 82 applied PEP-counter for TOF. Above limit is for velocity = 0.54 of light. Limit is inconsistent with YOCK 80 YOCK 81 events if isotropic dependence on zenith angle is assumed.

[11] YOCK 81 saw another 3 events with $Q = \pm1$ and m about $4.5m_p$ as well as 2 events with $m >5.3m_p$, $Q = \pm0.75 \pm 0.05$ and $m >2.8m_p$, $Q = \pm0.70 \pm 0.05$ and 1 event with $m = (9.3 \pm 3.)m_p$, $Q = \pm0.89 \pm 0.06$ as possible heavy candidates.

[12] YOCK 80 events are with charge exactly or approximately equal to unity.

[13] BHAT 78 is at Kolar gold fields. Limit is for $\tau > 10^{-6}$ s.

[14] YOCK 74 events could be tritons.

Superheavy Particle (Quark Matter) Flux in Cosmic Rays

[1] ADRIANI 15 search for relatively light quark matter with charge $Z = 1$–8. See their Figs. 2 and 3 for flux upper limits.

[2] AMBROSIO 00B searched for quark matter ("nuclearites") in the velocity range (10^{-5}–1) c. The listed limit is for 2×10^{-3} c.

[3] ASTONE 93 searched for quark matter ("nuclearites") in the velocity range (10^{-3}–1) c. Their Table 1 gives a compilation of searches for nuclearites.

[4] AHLEN 92 searched for quark matter ("nuclearites"). The bound applies to velocity $< 2.5\times10^{-3}$ c. See their Fig. 3 for other velocity/c and heavier mass range.

[5] NAKAMURA 91 searched for quark matter in the velocity range (4×10^{-5}–1) c.

[6] ORITO 91 searched for quark matter. The limit is for the velocity range (10^{-4}–10^{-3}) c.

[7] LIU 88 searched for quark matter ("nuclearites") in the velocity range (2.5×10^{-3}–1)c. A less stringent limit of 5.8×10^{-11} applies for (1–2.5) $\times 10^{-3}c$.

[8] BARISH 87 searched for quark matter ("nuclearites") in the velocity range (2.7×10^{-4}–5×10^{-3})c.

[9] NAKAMURA 85 at KEK searched for quark-matter. These might be lumps of strange quark matter with roughly equal numbers of u, d, s quarks. These lumps or nuclearites were assumed to have velocity of (10^{-4}–10^{-3}) c.

[10] ULLMAN 81 is sensitive for heavy slow singly charge particle reaching earth with vertical velocity 100–350 km/s.
