$\underline{W' \to Tb/Bt}$: W' bosons are predicted to decay to VLQ third generation partners T, B quarks within composite Higgs and warped extra dimensional models [228]. In the benchmark scenarios of this framework, W' decays to Tb or Bt are equally distributed and the subsequent VLQ decays $T \to tH$ and $B \to bH^0$ each are assumed to have a branching fraction of 0.5. The search for $W' \to Tb/bH^0 \to tbH^0$ is performed using a sample of 35.9 fb^{-1} by CMS [229] in the final state with all-hadronic decays of both the Higgs boson ($H^0 \to b\bar{b}$) and the top quark. Both the H^0 boson and the top quark are expected to be boosted in the decay of a heavy W', and hence jet substructure techniques, including subjet b-tagging and double b-tagging are deployed to identify the H^0-tagged and the top-tagged jets. The three particle mass m_{tbH^0}, is used as the signal discriminant to observe the W' resonance. There is no excess observed in data above the expected SM background. This search excludes W' production cross section above 0.01–0.43 pb for masses between 1.5–4.0 TeV.

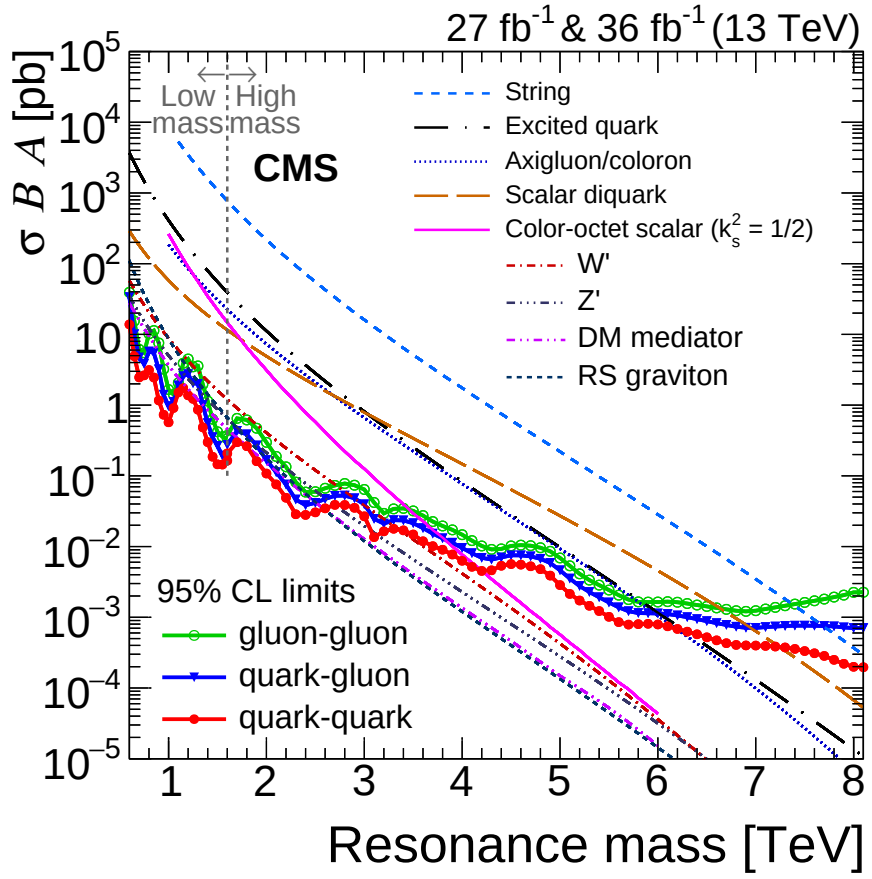

Figure 91.3: Observed 95% C.L. limits on $\sigma \times B \times A$ for string resonances, excited quarks, axigluons, colorons, E6 diquarks, s8 resonances, W' and Z' bosons, and Randall–Sundrum Gravitons g_{KK} from [214].

91.2.5 *Colorons and Colored Scalars*

These particles are associated with top-condensate and top-seesaw models, which involve an enlarged color gauge group. The new particles decay to dijets, $t\bar{t}$, and $b\bar{b}$.

Direct searches for colorons, color-octet scalars and other heavy objects decaying to $q\bar{q}$, qg, qq, or gg have been performed using LHC data from pp collisions at $\sqrt{s}$ =7, 8 and 13 TeV. Based on the analysis of dijet events from a data sample corresponding to a luminosity of 19.6 fb^{-1}, at $\sqrt{s}$ = 8 TeV, the CMS experiment excluded pair production of colorons with mass between 1.20−3.60 and 3.90 − 4.08 TeV [230]. Analyses of inclusive 8- and 10-jet final states with low missing transverse momentum by CMS [231], set limits in several benchmark models. Colorons (axigluons) with masses between 0.6 and 0.75 (up to 1.15) TeV were excluded, and gluinos in R-parity violating supersymmetric scenarios were ruled out from 0.6 up to 1.1 TeV.

A search for pair-produced colorons based on an integrated luminosity of 5.0 fb^{-1} at $\sqrt{s}$ = 7 TeV by CMS excluded colorons with masses between 0.25 TeV and 0.74 TeV, assuming colorons decay 100% into $q\bar{q}$ [232]. This analysis was based on events with at least four jets and two dijet combinations with similar dijet mass. Color-octet scalars (s8) with masses between 1.20−2.79 TeV were excluded by CMS [230], and below 2.7 TeV by ATLAS [233].

These studies have now been extended to take advantage of the increased center-of-mass energy during Run 2 of the LHC. Using 35.9 fb^{-1} of data collected at $\sqrt{s}$ =13 TeV, searches for narrow resonances have been performed by CMS. An analysis of the dijet invariant mass spectrum formed using wide jets [214, 234, 235], separated by $\Delta\eta_{jj} \leq 1.3$, led to limits on new particles decaying to parton pairs (qq, qg, gg). Specific exclusions on the masses of colorons and color-octet scalars were obtained and are shown in Fig. 91.3. Exclusions have been obtained for axigluons and colorons below 6.1 TeV, and color-octet scalars below 3.4 TeV.

Additional searches for dijet resonances have been performed by both ATLAS [236–238] and CMS [239, 240], though they have not been interpreted in the context of coloron production.

91.3 Conclusions

As the above analyses have demonstrated, there is already substantial sensitivity to possible new particles predicted to accompany the H^0 in dynamical frameworks of electroweak symmetry breaking. No significant hints of any deviations from the standard model have been observed, and limits typically at the scale of a few hundred GeV to a few TeV are set.

Given the need to better understand the H^0 and to determine in detail how it behaves, such analyses continue to be a major theme of Run 3 of the LHC, and we look forward to increased sensitivity as a result of the higher luminosity at the increased center of mass energy of collisions.

92. Grand Unified Theories

Revised August 2025 by N. Nagata (UTokyo); written with A. Hebecker (Heidelberg U.) and J. Hisano (Nagoya U.; KMI, Nagoya U).

92.1 The Standard Model

The Standard Model (SM) can be defined as a renormalizable quantum field theory with the gauge group $G_{\rm SM} = {\rm SU}(3)_C \times {\rm SU}(2)_L \times {\rm U}(1)_Y$ and three generations of fermions transforming under the representations

$$(\mathbf{3},\mathbf{2})_{1/3} + (\overline{\mathbf{3}},\mathbf{1})_{-4/3} + (\overline{\mathbf{3}},\mathbf{1})_{2/3} + (\mathbf{1},\mathbf{2})_{-1} + (\mathbf{1},\mathbf{1})_{2}\ , \quad (92.1)$$

along with a scalar Higgs doublet H transforming as $(\mathbf{1},\mathbf{2})_1$. Throughout this review, we use bold numbers to indicate the dimension of representations of non-Abelian gauge groups (fundamental and antifundamental in the present case), while the subscript denotes the ${\rm U}(1)_Y$ hypercharge.[1] The fermion fields in Eq. (92.1) correspond to the familiar set $[Q, u^c, d^c, L, e^c]$, where $Q = (u, d)$ and $L = (\nu, e)$ are the quark and lepton ${\rm SU}(2)_L$ doublets, and u^c, d^c, e^c are the charge-conjugate ${\rm SU}(2)_L$ singlets. Especially after the discovery of the Higgs boson, the SM stands out as a remarkably complete and experimentally consistent framework.

A notable exception to the success of the SM lies in the neutrino sector: although neutrino masses are now known to be non-zero, no such masses arise in the SM, even after the Higgs field acquires a vacuum expectation value (VEV). A minimal extension to account for these non-zero neutrino masses involves the inclusion of a dimension-five operator of the form $(HL)^2$ [1], which induces Majorana masses for neutrinos after electroweak symmetry breaking. This operator can be generated by integrating out heavy gauge-singlet fermions which couple to L and H—commonly referred to as right-handed neutrinos; this is known as the seesaw mechanism [2–8]. Alternatively, if light singlet neutrinos are introduced, neutrinos may instead acquire Dirac masses.

The SM also faces a variety of theoretical and phenomenological challenges. Among the most pressing is the electroweak hierarchy problem, which concerns the stability of the Higgs mass against large quantum corrections. Moreover, we still lack an understanding of the underlying dynamics responsible for spontaneous symmetry breaking in the electroweak sector. The SM also fails to provide a viable dark matter candidate, nor does it offer a mechanism for generating the observed baryon asymmetry of the Universe. In addition, the smallness of the QCD θ parameter, $\theta_{\rm QCD}$—the so-called strong CP problem—remains unexplained. The seemingly intricate pattern of quantum number assignments in Eq. (92.1) is also left without theoretical justification. Taken together with the large number of apparently arbitrary coupling constants, these shortcomings cast doubt on the plausibility of the SM as a truly fundamental theory, even leaving aside the issues expected to arise from quantum gravity at energies near the Planck scale, M_P.

To be precise, the SM contains 19 parameters that must be determined from experimental data. These include the three gauge couplings, g_3, g_2, and g_1;[2] 13 parameters associated with the Yukawa sector (comprising nine charged fermion masses, three mixing angles, and one CP phase in the CKM matrix); the Higgs mass and its quartic coupling; and $\theta_{\rm QCD}$. Majorana neutrinos add 3 mass parameters and 6 mixing and phase parameters. As we will see, grand unified theories (GUTs) can address the values of the three gauge couplings, in addition to the group-theoretic structure of Eq. (92.1). In many concrete realizations, GUTs can also shed light on other features of the SM, such as the family structure and the hierarchical values of fermion masses.

[1] We adopt the convention $Q = T_3 + Y/2$ for electric charge. All spinor fields are taken to be left-handed.

[2] Equivalently, the ${\rm SU}(2)_L$ and ${\rm U}(1)_Y$ gauge couplings are denoted by $g = g_2$ and $g' = \sqrt{3/5}\ g_1$. One often uses $\alpha_s = \alpha_3 = g_3^2/(4\pi)$ and $\alpha_{\rm EM} = e^2/(4\pi)$, with $e = g \sin\theta_W$ and $\sin^2\theta_W = (g')^2/(g^2 + (g')^2)$.

92.2 Basic group theory and charge quantization

92.2.1 ${\rm SU}(4)_C \times {\rm SU}(2)_L \times {\rm SU}(2)_R$

Historically, the first attempt at unification was the Pati–Salam model, based on the gauge group $G_{\rm PS} = {\rm SU}(4)_C \times {\rm SU}(2)_L \times {\rm SU}(2)_R$ [9].[3] In this framework, the SM fermions of one generation, together with an additional SM singlet, are embedded in the representations $(\mathbf{4},\mathbf{2},\mathbf{1})$ and $(\overline{\mathbf{4}},\mathbf{1},\mathbf{2})$ of $G_{\rm PS}$. The quantum numbers in Eq. (92.1) can be reproduced by considering the symmetry breaking pattern ${\rm SU}(4)_C \to {\rm SU}(3)_C \times {\rm U}(1)_{B-L}$, together with the identification of the SM hypercharge as a linear combination of $B-L$ (baryon minus lepton number) and the T_3 generator of ${\rm SU}(2)_R$: $Y/2 = T_{3R} + (B-L)/2$. The model naturally explains charge quantization—that is, why all electric charges in the SM are integer multiples of the smallest one. Specifically, the $\mathbf{4}$ and $\overline{\mathbf{4}}$ representations of ${\rm SU}(4)_C$ treat lepton number as a fourth color, and the traceless nature of the diagonal generator implies that quark charges are fixed as fractional multiples of lepton charges, proportional to $1/N_c$ with $N_c = 3$ the number of colors. However, since $G_{\rm PS}$ is not a simple group—it consists of three simple factors—it does not predict gauge coupling unification.

92.2.2 *SU(5)*

Since $G_{\rm SM}$ has rank four—two from ${\rm SU}(3)_C$, and one each from ${\rm SU}(2)_L$ and ${\rm U}(1)_Y$—the rank-four group SU(5) is the minimal choice for a simple group into which $G_{\rm SM}$ can be embedded [13]. In this framework, the three SM gauge couplings originate from a single unified coupling α_G at the grand unification scale M_G. The embedding of $G_{\rm SM}$ into SU(5) is straightforward. The ${\rm SU}(3)_C$ and ${\rm SU}(2)_L$ subgroups can be identified with the upper-left 3×3 and lower-right 2×2 blocks, respectively, within the traceless 5×5 matrices representing the generators of SU(5) in its fundamental representation. The ${\rm U}(1)_Y$ generator corresponds to the diagonal matrix ${\rm diag}(-2/3,-2/3,-2/3,1,1)$, which commutes with the generators of ${\rm SU}(3)_C \times {\rm SU}(2)_L \subset {\rm SU}(5)$. From this structure, one finds that a single generation of SM fermions is elegantly unified into the $\mathbf{10} \oplus \overline{\mathbf{5}}$ representations of SU(5), where the $\mathbf{10}$ denotes the rank-2 antisymmetric tensor representation:

$$\mathbf{10}: \begin{pmatrix} 0 & u_b^c & -u_g^c & u^r & d^r \\ -u_b^c & 0 & u_r^c & u^g & d^g \\ u_g^c & -u_r^c & 0 & u^b & d^b \\ -u^r & -u^g & -u^b & 0 & e^c \\ -d^r & -d^g & -d^b & -e^c & 0 \end{pmatrix} \quad \text{and} \quad \overline{\mathbf{5}}: \begin{pmatrix} d_r^c \\ d_g^c \\ d_b^c \\ e \\ -\nu_e \end{pmatrix}. \quad (92.2)$$

In addition to explaining charge quantization, this structure accounts for why the left-handed quark and lepton states form ${\rm SU}(2)_L$ doublets, while their right-handed counterparts are ${\rm SU}(2)_L$ singlets.

Since SU(5) has 24 generators, SU(5) GUTs predict 12 additional gauge bosons—known as X bosons (or X/Y bosons)—beyond those of the SM. These X bosons transform as an ${\rm SU}(3)_C$ triplet and an ${\rm SU}(2)_L$ doublet. Their interactions connect quarks and leptons, leading to the violation of both baryon and lepton number, and consequently predicting nucleon decay. Furthermore, the ${\rm U}(1)_Y$ hypercharge is automatically quantized, as it corresponds to a generator of SU(5).

In the minimal SU(5) model, the Higgs field is embedded in either a $\mathbf{5}_H$ or a $\overline{\mathbf{5}}_H$ representation. Each multiplet contains three extra states known as color-triplet Higgs bosons. These triplets couple to matter in a way that violates both baryon and lepton number, thereby inducing nucleon decay. To remain consistent with the experimental non-observation of such decay, the triplet mass must be $\gtrsim 10^{11}$ GeV [14–16].[4]

Supersymmetry (SUSY) is frequently invoked in the context of GUTs. It is a symmetry relating bosons and fermions, and it requires the existence of superpartners for all SM particles. SUSY was originally introduced as a solution to the electroweak hierarchy problem [18–21]. In addition, as discussed in Sec. 92.5, SUSY theories have the appealing feature that gauge coupling unification

[3] See also Refs. [10–12].

[4] This bound can be relaxed through a fine-tuned cancellation between the renormalizable Yukawa interactions and higher-dimensional operators involving the GUT-breaking Higgs field [17].

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

is realized with high precision. In SUSY GUTs [22–27], both $\mathbf{5}_H$ and $\overline{\mathbf{5}}_H$ Higgs multiplets are required—not only to cancel gauge anomalies, but also to provide masses for both up- and down-type quarks. As we will discuss in Sec. 92.6, nucleon decay tends to be more severe in the minimal SUSY SU(5) model, since integrating out the color-triplet Higgs multiplets generates baryon-number-violating dimension-five operators [28, 29], whereas only dimension-six operators are generated in the non-SUSY case. The lower bound on the triplet mass from nucleon decay experiments depends on the SUSY scale but is typically above the unification scale M_G. The mass splitting between the Higgs doublet and triplet components arises from their interactions with the SU(5)-breaking sector, as discussed in Sec. 92.3.

92.2.3 *SO(10)*

While SU(5) provides the minimal framework for grand unification, it does not fully unify the matter content: each SM generation must be split across two distinct representations, **10** and $\overline{\mathbf{5}}$. To incorporate the right-handed neutrinos required for the seesaw mechanism, additional SU(5) singlets must be introduced. In this case, the right-handed neutrino masses are not necessarily tied to the grand unification scale.

By contrast, a single **16**-dimensional spinor representation of SO(10) accommodates an entire SM generation along with a singlet that naturally plays the role of a right-handed neutrino [30, 31]. This structure can be understood via the breaking pattern $\mathrm{SO}(10) \to \mathrm{SU}(5) \times \mathrm{U}(1)_X$ and the associated branching rule: $\mathbf{16} = \mathbf{10}_{-1} + \overline{\mathbf{5}}_3 + \mathbf{1}_{-5}$,[5] where the subscripts denote charges under the $\mathrm{U}(1)_X$ subgroup, which can be written as $2Y - 5(B-L)$. This $\mathrm{U}(1)_X$ is orthogonal to SU(5) and reflects the fact that SO(10) has rank five. Remarkably, all representations of SO(10) are anomaly-free in four dimensions (4d). As a result, the anomaly cancellation observed in SU(5) GUTs—or within each SM generation—can be viewed as a consequence of this broader property of SO(10).

We now describe in more detail how a single family of quarks and leptons is embedded in the **16**. To understand this, recall that the Γ-matrices of the 10-dimensional (10d) Clifford algebra give rise to five independent, anticommuting 'creation-annihilation' operators $\Gamma^{a\pm} = (\Gamma^{2a-1} \pm i\Gamma^{2a})/2$ for $a = 1, \ldots, 5$. These correspond to five fermionic harmonic oscillators, or "spin" 1/2 systems. The 32-dimensional spinor space, constructed as a tensor product of these five "spin" states, is reducible because the 10d rotation generators $M_{mn} = [\Gamma^m, \Gamma^n]/(4i)$ (for $m, n = 1, \ldots, 10$) always flip an even number of "spin" directions. This reducibility gives rise to the **16**-dimensional irreducible chiral spinor representation, as shown in Table 92.1. Next, one also recalls that the natural embedding of SU(5) in SO(10) relies on 'pairing up' the 10 real dimensions to produce 5 complex dimensions, $\mathbb{R}^{10} \equiv \mathbb{C}^5$, similarly to the paring up of Γ^ms used above. Specifically, each $|\pm\rangle$ system corresponds to a complex dimension of SU(5), as indicated by the labeling of the "spin" columns in Table 92.1: The first three and last two "spins" correspond to $\mathrm{SU}(3)_C$ and $\mathrm{SU}(2)_L$, respectively. An $\mathrm{SU}(3)_C$ rotation just raises one color index and lowers another, changing colors $\{r, g, b\}$, or changes relative phases between the three spin states. Similarly, an $\mathrm{SU}(2)_L$ rotation raises one weak index and lowers another, thereby flipping the weak isospin from up to down or vice versa, or changes the relative phase between the two spin states. In this representation $\mathrm{U}(1)_Y$ hypercharge is simply given by $Y = -2/3(\sum \text{color spins}) + (\sum \text{weak spins})$.[6] SU(5) rotations that are orthogonal to $G_{\rm SM}$ act by raising (or lowering) a color index while simultaneously lowering (or raising) a weak index. Such transformations can mix the states within the sets $\{Q, u^c, e^c\}$ and $\{d^c, L\}$, respectively, while ν^c remains a singlet under these rotations. Since SO(10) has 45 generators, it introduces 21 additional generators beyond those of SU(5), including $\mathrm{U}(1)_X$ mentioned above. The $\mathrm{U}(1)_X$ charge, associated with the SU(5)-invariant generator, is given by $X = 2\sum(\text{spins})$. The remaining 20 generators correspond to SO(10) transformations outside of SU(5), and can be realized as operations that simultaneously raise or lower two spin directions. These rotations relate **1** and $\overline{\mathbf{5}}$ to **10**.

Table 92.1: Quantum numbers in the **16** representation of SO(10)

State	$\mathrm{U}(1)_Y$	Color	Weak	SU(5)	$\mathrm{U}(1)_X$	SO(10)
ν^c	0	$---$	$--$	**1**	-5	
e^c	2	$---$	$++$			
u^r	1/3	$+--$	$-+$			
d^r	1/3	$+--$	$+-$			
u^g	1/3	$-+-$	$-+$			
d^g	1/3	$-+-$	$+-$	**10**	-1	
u^b	1/3	$--+$	$-+$			
d^b	1/3	$--+$	$+-$			**16**
u_r^c	$-4/3$	$-++$	$--$			
u_g^c	$-4/3$	$+-+$	$--$			
u_b^c	$-4/3$	$++-$	$--$			
d_r^c	2/3	$-++$	$++$			
d_g^c	2/3	$+-+$	$++$			
d_b^c	2/3	$++-$	$++$	$\overline{\mathbf{5}}$	3	
ν	-1	$+++$	$-+$			
e	-1	$+++$	$+-$			

SO(10) has two inequivalent maximal subgroups—and hence two distinct symmetry breaking patterns: $\mathrm{SO}(10) \to \mathrm{SU}(5) \times \mathrm{U}(1)_X$ and $\mathrm{SO}(10) \to \mathrm{SU}(4)_C \times \mathrm{SU}(2)_L \times \mathrm{SU}(2)_R$. In the first case, one can proceed with symmetry breaking down to $G_{\rm SM} \subset \mathrm{SU}(5)$ exactly as in the minimal SU(5). Alternatively, $\mathrm{U}(1)_Y$ can be identified as a linear combination of $\mathrm{U}(1)_X$ and the U(1) subgroup of SU(5), leading to the flipped SU(5) model [36–39] as an intermediate stage in the breaking of SO(10) to $G_{\rm SM}$. The second path features the Pati–Salam model at the intermediate scale, with the decomposition $\mathbf{16} = (\mathbf{4}, \mathbf{2}, \mathbf{1}) \oplus (\overline{\mathbf{4}}, \mathbf{1}, \mathbf{2})$. Alternatively, SO(10) may break directly to the SM at M_G. In such "direct breaking" scenarios, as well as in those following the chain $\mathrm{SO}(10) \to \mathrm{SU}(5) \to G_{\rm SM}$ with SU(5) broken at M_G, gauge coupling unification remains intact. In contrast, gauge couplings need not unify at the intermediate scale in flipped SU(5) or Pati–Salam models.

In the minimal SO(10) model, the Higgs fields reside in the fundamental representation $\mathbf{10}_H$, which is decomposed as $\mathbf{10}_H = \mathbf{5}_H \oplus \overline{\mathbf{5}}_H$ in SU(5). Notably, SO(10) is unique among the discussed GUTs in that the representation itself distinguishes SM matter from Higgs fields (see Sec. 92.6).

92.2.4 *Beyond SO(10)*

Finally, one may consider larger symmetry groups. A notable example is the exceptional group E_6, which has a maximal subgroup $\mathrm{SO}(10) \times \mathrm{U}(1)$ [40]. Its fundamental representation decomposes as $\mathbf{27} = \mathbf{16}_1 + \mathbf{10}_{-2} + \mathbf{1}_4$. Another maximal subgroup is $\mathrm{SU}(3)_C \times \mathrm{SU}(3)_L \times \mathrm{SU}(3)_R \subset \mathrm{E}_6$, with the branching rule $\mathbf{27} = (\mathbf{3}, \mathbf{3}, \mathbf{1}) + (\overline{\mathbf{3}}, \mathbf{1}, \overline{\mathbf{3}}) + (\mathbf{1}, \overline{\mathbf{3}}, \mathbf{3})$. Even independently of an underlying E_6, the gauge group $[\mathrm{SU}(3)]^3$—augmented by a $\mathbb{Z}_3$ permutation symmetry that interchanges the three SU(3) factors—can be considered. This framework is known as "trinification" [41, 42], where the $\mathbb{Z}_3$ symmetry guarantees gauge coupling unification. The breaking pattern $\mathrm{E}_6 \to [\mathrm{SU}(3)]^3$ has been employed in phenomenological studies of heterotic string theory [43–46]. However, in models based on larger symmetry groups such as E_6, SU(6), etc., the presence of many additional states poses a challenge: these extra states must be decoupled from the low-energy EFT.

Intriguingly, the hierarchical embedding of gauge groups—where $G_{\rm SM}$ is a maximal subgroup of SU(5), which itself, together with $\mathrm{U}(1)_X$, forms a maximal subgroup of SO(10)—continues in a remarkably elegant and systematic fashion, culminating in the largest exceptional group. This leads to the well-known symmetry breaking chain $\mathrm{E}_8 \to \mathrm{E}_7 \to \mathrm{E}_6 \to \mathrm{SO}(10) \to \mathrm{SU}(5) \to G_{\rm SM}$ and,

[5] Useful references on group theory in this context include [32–35], and references therein.

[6] The spin sum is calculated as $(N_+ - N_-)/2$, where N_+ and N_- are the numbers of "+" and "−" entries in the color or weak column of Table 92.1.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

together with the distinguished role of E_8 in both group theory and string theory, offers a tantalizing hint at a deeper unifying structure. However, since all representations of E_8 and E_7 are real and therefore incapable of accommodating chiral fermions in 4d, such constructions necessarily lie outside the scope of conventional 4d GUTs.

92.2.5 *Global structures of the Standard Model gauge group*

While our focus so far has been on the Lie algebra of the gauge symmetry, it is worth recalling that distinct Lie groups can share the same Lie algebra. In the case of the SM, it is known that there are four possible gauge groups that correspond to the same SM Lie algebra [47,48] (see also Ref. [49] for a recent discussion): $G_{\rm SM} = {\rm SU}(3)_C \times {\rm SU}(2)_L \times {\rm U}(1)_Y/\Gamma$ with $\Gamma = 1, \mathbb{Z}_2, \mathbb{Z}_3, \mathbb{Z}_6$.[7] While these gauge groups describe the same perturbative theory, they can differ in their non-perturbative properties, such as the types of topological defects or instanton effects they allow.

If the SM gauge symmetry originates from the spontaneous breaking of a GUT gauge symmetry, which of the above four gauge groups is realized depends on the choice of the GUT gauge group. For example, in the case of SU(5), the SM gauge group can be embedded as

$$\begin{pmatrix} U & 0 \\ 0 & V \end{pmatrix} \in {\rm SU}(5) \ , \tag{92.3}$$

where $U \in {\rm U}(3)$, $V \in {\rm U}(2)$, and $\det U \det V = 1$. Thus, the resulting subgroup is ${\rm S}({\rm U}(3) \times {\rm U}(2))$. Each element can be parametrized as $U = e^{i\theta/3}\widetilde{U}$ and $V = e^{-i\theta/2}\widetilde{V}$ with $\theta \in \mathbb{R}$, $\widetilde{U} \in {\rm SU}(3)$, and $\widetilde{V} \in {\rm SU}(2)$. Then, one finds that the parameters $\theta' = 2\pi n + \theta$, $\widetilde{U}' = e^{-2\pi i n/3}\widetilde{U}$, and $\widetilde{V}' = e^{2\pi i n/2}\widetilde{V}$ with $n = 0, 1, 2, 3, 4, 5$ all correspond to the same group element, indicating that the gauge group is equivalent to $G_{\rm SM} = {\rm SU}(3)_C \times {\rm SU}(2)_L \times {\rm U}(1)_Y/\mathbb{Z}_6$. Similarly, embeddings into other simple GUT groups such as SO(10) and E_6 lead to the same SM gauge group. In contrast, partial unification scenarios yield different global structures: the Pati–Salam group $G_{\rm PS}$ leads to $\Gamma = \mathbb{Z}_3$, whereas the trinification group ${\rm SU}(3)_C \times {\rm SU}(3)_L \times {\rm SU}(3)_R$ gives $\Gamma = \mathbb{Z}_2$.

92.3 GUT breaking and doublet-triplet splitting

In the standard 4d field-theoretic approach to GUTs, the unified gauge group is spontaneously broken by an appropriately chosen GUT Higgs sector. Scalar potentials (or superpotentials in the case of SUSY GUTs) can be constructed whose vacua break the GUT gauge group. While these potentials are somewhat ad hoc—much like the Higgs potential in the SM—the simplest expectation is that all dimensionful parameters in the theory are of $\mathcal{O}(M_G)$. In the minimal SU(5), the GUT-breaking Higgs field is the adjoint representation **24** and acquires a VEV along the $G_{\rm SM}$-singlet direction, $\langle \Phi \rangle \propto {\rm diag}(-2/3, -2/3, -2/3, 1, 1)$. For SO(10) to break to SU(5), a Higgs field in the **16** or **126** representation must acquire a VEV along a direction that is an SU(5) singlet but carries nonzero ${\rm U}(1)_X$ charge.

The masses of the doublet and triplet components in the $\mathbf{5}_H$ (and $\overline{\mathbf{5}}_H$) are generically split due to their couplings to the GUT-breaking Higgs field. In addition, both components receive an equal contribution from an SU(5)-invariant GUT-scale mass term. Without further structure, achieving a light doublet at the electroweak scale requires an extreme fine-tuning between two large contributions. SUSY helps stabilize the doublet mass against large radiative corrections, thanks to the non-renormalization theorem [50]. However, even in SUSY models, fine-tuning is still required at tree level. This constitutes the well-known doublet-triplet splitting problem, which is closely related—within the SUSY context—to the μ-problem, *i.e.*, the puzzle of why the coefficient of the superpotential term $\mu H_u H_d$ is much smaller than the GUT scale.

Several mechanisms for realizing natural doublet-triplet splitting have been proposed within the framework of SUSY. These include the sliding singlet mechanism [51], the missing partner mechanism [52,53], the missing VEV mechanism [54,55], and the pseudo-Nambu–Goldstone boson mechanism [56]. Concrete implementations of these ideas have been studied in various GUT models: the missing partner mechanism in SU(5) [57–61] and in the flipped SU(5) [38, 62], the missing VEV mechanism in SO(10) [63–75], and the pseudo-Nambu–Goldstone boson mechanism [76–84]. These models have been shown to be compatible with gauge coupling unification and nucleon decay constraints. Once a model with vanishing fundamental μ term has been realized, an *effective* μ term of order the SUSY breaking scale can then be induced by, for example, higher-mass-dimension terms in the Kähler potential [85] or superpotential [86]. For a review of the μ problem and some suggested solutions in SUSY GUTs and string theory, see Refs. [87–95] and references therein.

In general, GUT-breaking sectors that resolve the doublet-triplet splitting problem, stabilize all GUT-scale VEVs, and yield realistic neutrino masses and Yukawa couplings—including controlled violations of GUT relations in the latter—require a number of nontrivial ingredients. However, the introduction of large or numerous representations is constrained, as it can drive the theory to a Landau pole below the Planck scale. Moreover, in the 4d field-theoretic approach, GUTs are regarded as EFTs valid only below the Planck scale. Since the GUT scale M_G lies relatively close to this cutoff, the effects of higher-dimensional operators cannot be neglected in general. In particular, operators involving the GUT-breaking Higgs fields can influence low-energy observables, such as quark and lepton masses, and must therefore be taken into account in realistic model building.

Thus, especially in the context of GUT breaking and doublet-triplet splitting, models beyond 4d field theory appear attractive. While this is mainly the subject of the next section, some advantages can already be noted: In models with extra dimensions, in particular string constructions, GUT breaking may occur due to boundary conditions in the compactified dimensions [96–110]. No complicated GUT breaking sector is then required. Moreover, boundary conditions can give mass only to the triplet, leaving the doublet massless. This is similar to the missing partner mechanism since the effective mass term does not 'pair up' the triplets from $\mathbf{5}_H$ and $\overline{\mathbf{5}}_H$ but rather each of them with further fields which are automatically present in the higher-dimensional theory. This can eliminate dimension-five nucleon decay (cf. Sec. 92.6).

92.4 String-theoretic and higher-dimensional unified models

As noted earlier, the GUT scale is dangerously close to the scale of quantum gravity. It may hence be necessary to discuss unified models of particle physics in the latter, more ambitious context. Among the models of quantum gravity, superstring or M-theory stands out as the best-studied and technically most developed proposal, possessing in particular a high level of internal, mathematical consistency. For our purposes, it is sufficient to know that five 10d and one 11d low-energy effective supergravity theories arise in this setting (see Refs. [111–114] and references therein).

Grand unification is realized most naturally in the context of the two heterotic string theories with gauge groups $E_8 \times E_8$ and SO(32) [101, 115] (see Refs. [116–118] for some of the more recent results). Justified in part by the intriguing breaking path $E_8 \to \cdots \to G_{\rm SM}$ mentioned above, the focus has historically largely been on $E_8 \times E_8$. To describe particle physics, solutions of the 10d theory with geometry $\mathbb{R}^{1,3} \times M_6$ are considered, where M_6 is a Calabi–Yau (CY) 3-fold (with 6 real dimensions) [101]. The background solution involves expectation values of higher-dimensional components of the $E_8 \times E_8$ gauge fields. This includes both Wilson lines [96] and non-vanishing field-strength and leads, in general, to a reduced gauge symmetry and to chirality in the resulting 4d effective theory. The 4d fermions arise from 10d gauginos.

Given an appropriate embedding[8] of $G_{\rm SM}$ in $E_8 \times E_8$, gauge coupling unification is automatic at leading order. Corrections arise

[7] The cases with $\Gamma = \mathbb{Z}_2$, $\mathbb{Z}_3$, and $\mathbb{Z}_6$ are also referred to as ${\rm SU}(3) \times {\rm U}(2)$, ${\rm U}(3) \times {\rm SU}(2)$, and ${\rm S}({\rm U}(3) \times {\rm U}(2))$, respectively. The group ${\rm SU}(3) \times {\rm SU}(2) \times {\rm U}(1)$ serves as the covering group of these.

[8] All embeddings of $G_{\rm SM}$ in one E_8 factor which are consistent with a breaking-pattern $E_8 \to {\rm SU}(5) \to G_{\rm SM}$ are suitable. Other embeddings can change the ratios between the three resulting $G_{\rm SM}$ couplings at the GUT scale by group-theoretic factors. Crucially, due to the single 10d gauge coupling, no continuous tuning is possible.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

mainly through (string)-loop effects and are similar to the familiar field-theory thresholds of 4d GUTs [119] discussed in Sec. 92.5. Thus, one may say that coupling unification is a generic prediction in spite of the complete absence[9] of a 4d GUT at any energy scale. This absence is both an advantage and a weakness. On the up side, GUT breaking and doublet-triplet splitting [122] are more naturally realized and dimension-five nucleon decay is relatively easy to avoid. On the down side, there is no reason to expect full GUT representations in the matter sector and flavor model building is much less tied to the GUT structure than in 4d.

Let us pause to explain the beautiful idea behind the advertised solution of the doublet-triplet splitting problem: One starts with a simply connected CY X and mods out the action of a discrete group G (say $\mathbb{Z}_2$). In the absence of fixed points, X/G is smooth and has a non-contractible 1-cycle. Furthermore, let G also act on the gauge bundle, according to an embedding $G \to \mathrm{E}_8$. Now the parallel transport around the 1-cycle is tied to a gauge rotation (one says a non-trivial Wilson-line is present). Moreover, this Wilson line can not be continuously turned off since, *e.g.*, in the case of $\mathbb{Z}_2$, its square is the unit element of the group. The induced 'Wilson-line breaking', which comes on top of the breaking by non-zero field strengths, may remove certain sub-representations (*e.g.*, the triplet of $\mathrm{SU}(5) \to G_{\mathrm{SM}}$) while keeping others exactly massless. A simpler and, due to fixed points, singular version of this will appear below in the context of orbifold GUTs.

One technical problem of heterotic constructions is the dependence on the numerous size and shape parameters of M_6 (the so-called moduli), the stabilization of which is poorly understood (see Refs. [123–125] for recent developments). Another is the sheer mathematical complexity of the analysis, involving in particular the study of (non-Abelian) gauge-bundles on CY spaces [126] (see, however, Refs. [127, 128]).

An interesting aspect of heterotic string constructions is represented by orbifold models [97–100]. Here the internal space is given by a six-torus, modded out by a discrete symmetry group (*e.g.*, $T^6/\mathbb{Z}_n$). More recent progress is reported in Refs. [129–137], including in particular the systematic exploration of the phenomenological advantages of so-called 'non-prime' (referring to n) orbifolds. The symmetry breaking to G_{SM} as well as the survival of Higgs doublets without triplet partners is ensured by the appropriate embedding of the discrete orbifold group in $\mathrm{E}_8 \times \mathrm{E}_8$. String theory on such spaces, which are locally flat but include singularities, is much more calculable than in the CY case. The orbifold geometries can be viewed as singular limits of CYs.

An even simpler approach to unified model building—while still retaining many of the advantages of full-fledged string constructions—is offered by orbifold GUTs [102–110]. These are typically 5d or 6d SUSY field theories with a unified gauge group—such as SU(5) or SO(10)—that is broken through the compactification to 4d. To illustrate the idea with a simple example, consider SU(5) defined on the spacetime $\mathbb{R}^{1,3} \times S^1/(\mathbb{Z}_2 \times \mathbb{Z}_2')$. The compact space in this case is an interval of length $\pi R/2$, and the embedding of $\mathbb{Z}_2'$ in the hypercharge direction of SU(5) leads to the desired breaking to G_{SM}. Concretely, the 5d X bosons are assigned Dirichlet boundary conditions (BCs) at one end of the interval, eliminating their Kaluza–Klein (KK) zero modes. Their lightest modes have masses of $\sim 1/R$, setting the KK scale as the effective GUT scale. A key implication is that the boundary theory lacks full SU(5) invariance. Nevertheless, since the SU(5)-symmetric 5d bulk governs the running of the 4d gauge couplings, gauge coupling unification remains a prediction. Furthermore, many challenges inherent to conventional 4d GUTs can be avoided in this framework. In particular, the doublet-triplet splitting problem is resolved.

With the advent of the string-theory flux landscape [138, 139], which is best understood in 10d type-IIB supergravity, the focus in string model building has shifted to this framework. While type II string theories have no gauge group in 10d, brane-stacks support gauge dynamics. A particularly appealing setting (see, *e.g.*, Ref. [140]) is provided by type IIB models with D7 branes (defining 8d submanifolds). However, in the SO(10) context the **16** is not available and, for SU(5), the top-Yukawa coupling vanishes at leading order [141]. As a crucial insight, this can be overcome on the non-perturbative branch of type IIB, also known as F-theory [142–144]. This setting allows for more general branes, thus avoiding constraints of the Dp-brane framework. GUT breaking can be realized using hypercharge flux (the VEV of the $\mathrm{U}(1)_Y$ field strength), an option not available in heterotic models. The whole framework combines the advantages of the heterotic or higher-dimensional unification approach with the more recent progress in understanding moduli stabilization. It thus represents at this moment the most active and promising branch of theory-driven GUT model building (see, *e.g.*, Refs. [145–149] and references therein).

As a result of the flux-breaking, a characteristic 'type IIB' or 'F-theoretic' tree-level correction to gauge unification arises [150–154]. The fact that this correction can be rather significant numerically is occasionally held against the framework of F-theory GUTs. However, at a parametric level, this correction nevertheless behaves like a 4d threshold, *i.e.*, it provides $\mathcal{O}(1)$ additive contributions to the inverse 4d gauge couplings $\alpha_i^{-1}(M_G)$.

A final important issue in string GUTs is the so-called string-scale/GUT-scale problem [155]. It arises since, in heterotic compactifications, the Planck scale and the high-scale value of the gauge coupling unambiguously fix the string-scale to about 10^{18} GeV. As the compactification radius R is raised above the string length, the GUT scale (identified with $1/R$) goes down and the string coupling goes up. Within the domain of perturbative string theory, a gap of about a factor ~ 20 remains between the lowest GUT scale achievable in this way and the phenomenological goal of 2×10^{16} GeV. The situation can be improved by venturing into the non-perturbative regime [155], by considering 'anisotropic' geometries with hierarchically different radii R [155, 156] or by including GUT scale threshold corrections [157, 158].

In F-theory GUTs, the situation is dramatically improved since the gauge theory lives only in four out of the six compact dimensions. This allows for models with a 'decoupling limit', where the GUT scale is parametrically below the Planck scale [143, 144]. However, moduli stabilization may not be without problems in such constructions, in part due to a tension between the required large volume and the desirable low SUSY breaking scale.

92.5 Gauge coupling unification

The quantitative unification of the three SM gauge couplings at the energy scale M_G is one of the central pillars of the GUT paradigm, and it holds clear phenomenological significance. Gauge coupling unification is well understood within the framework of effective field theory (EFT) [159–161]. In the simplest scenario, the EFT at energy scales $\mu \gg M_G$ has a unified gauge symmetry and a single running gauge coupling $\alpha_G(\mu)$. At lower energies $\mu \ll M_G$, heavy states with masses around M_G—such as X bosons, GUT-breaking Higgs fields, and color-triplet Higgs fields—are integrated out. The resulting low-energy EFT then features three independent gauge couplings and the matter content of the SM or its SUSY extension. One-loop renormalization group equations (RGEs) provide a means of extrapolating the gauge couplings down to the electroweak scale,

$$\alpha_i^{-1}(m_Z) = \alpha_G^{-1}(M_G) + \frac{b_i}{2\pi} \log\left(\frac{M_G}{m_Z}\right) + \delta_i \ , \quad (i = 1, 2, 3) \ , \tag{92.4}$$

where b_i are the one-loop β-function coefficients (with $b_i^{\mathrm{SM}} = \{41/10, -19/6, -7\}$ in the SM and $b_i^{\mathrm{MSSM}} = \{33/5, 1, -3\}$ in the minimal SUSY SM (MSSM)), m_Z is the Z-boson mass, and δ_i encode all subleading effects. These include threshold corrections at or near the weak scale—such as those arising from superpartners and the extended Higgs sector in the MSSM—as well as threshold effects at the GUT scale and higher-order loop corrections.

When SUSY is invoked as a solution to the gauge hierarchy problem—that is, the issue of naturalness or fine-tuning associated with the electroweak scale [18–21]—it predicts that the superpartners of SM particles should lie near the weak scale. Assuming this, and adopting a minimal Higgs sector, gauge coupling unification is achieved with remarkable precision in the

[9] See, however, Refs. [120, 121].

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

MSSM [162–168], whereas it fails in the SM, as illustrated in Fig. 92.1.

The three equations contained in Eq. (92.4) can be used to determine the three 'unknowns' $\alpha_3(m_Z)$, $\alpha_G(M_G)$ and M_G, assuming that all other parameters entering the equations are given. Focusing on the SUSY case and using the $\overline{\rm MS}$ coupling constants $\alpha_{\rm EM}^{-1}(m_Z)$ and $\sin^2\theta_W(m_Z)$ taken from Ref. [170] as input, $\alpha_{\rm EM}^{-1}(m_Z) = 127.930 \pm 0.008$ and $\sin^2\theta_W(m_Z) = 0.23122 \pm 0.00004$, one determines $\alpha_{1,2}^{-1}(m_Z)$, which then gives

$$\alpha_G^{-1}(M_G) \simeq 24.3 \qquad \text{and} \qquad M_G \simeq 2\times 10^{16}\ \text{GeV}\ . \tag{92.5}$$

Here we have set $\delta_i = 0$ for simplicity. Crucially, one in addition obtains a prediction for the low-energy observable α_3,

$$\alpha_3^{-1}(m_Z) = -\frac{5}{7}\alpha_1^{-1}(m_Z) + \frac{12}{7}\alpha_2^{-1}(m_Z) + \Delta_3\ , \tag{92.6}$$

where

$$\Delta_3 = \frac{5}{7}\delta_1 - \frac{12}{7}\delta_2 + \delta_3\ . \tag{92.7}$$

Here we followed the elegant formulation in Ref. [171] of the classical analyses of Refs. [162–168]. Of course, it is a matter of convention which of the three low-energy gauge coupling parameters one 'predicts' and indeed, early works on the subject discussed the prediction of $\sin^2\theta_W$ in terms of $\alpha_{\rm EM}$ and α_3 [172–174]. Remarkably, the leading order result (*i.e.*, Eq. (92.6) with $\Delta_3 = 0$) is in excellent agreement with experiments [170]:

$$\alpha_3^{\rm LO}(m_Z) = 0.117 \quad \text{vs.} \quad \alpha_3^{\rm exp}(m_Z) = 0.1180 \pm 0.0009\ . \tag{92.8}$$

However, this near perfection is to some extent accidental. To see this, we now discuss the various contributions to the subleading corrections δ_i (and hence to Δ_3).

The two-loop running correction from the gauge sector $\Delta_3^{(2)}$ and the low-scale threshold correction $\Delta_3^{(l)}$ from superpartners can be summarized as [171]

$$\Delta_3^{(2)} \simeq -0.82 \qquad \text{and} \qquad \Delta_3^{(l)} \simeq \frac{19}{28\pi}\log\left(\frac{m_{\rm SUSY}}{m_Z}\right)\ . \tag{92.9}$$

The relevant scale $m_{\rm SUSY}$ can be estimated as [168]

$$m_{\rm SUSY} \simeq m_H^{3/19} m_{\widetilde{H}}^{12/19} m_{\widetilde{W}}^{4/19} \times \left(\frac{m_{\widetilde{W}}}{m_{\widetilde{g}}}\right)^{28/19} \left(\frac{m_{\widetilde{l}}}{m_{\widetilde{q}}}\right)^{3/19}\ , \tag{92.10}$$

where m_H stands for the masses of non-SM Higgs states and superpartner masses are given in self-evident notation. Detailed analyses including the above effects are best done using appropriate software packages, such as SOFTSUSY [169] (or alternatively SuSpect [175] or SPheno [176]). See also Ref. [169] for references for the underlying theoretical two-loop analyses.

To gain a rough estimate of these effects, let us assume that all superpartners are degenerate at $m_{\rm SUSY} = 1$ TeV except for gluino, with a mass ratio $m_{\widetilde{W}}/m_{\widetilde{g}} \simeq 1/3$. Under this assumption, one finds $\Delta_3^{(l)} \simeq -0.35 + 0.22\ln(m_{\rm SUSY}/m_Z) \simeq 0.18$. This leads to a predicted value of $\alpha_3(m_Z) \simeq 0.126$, which significantly deviates from the near-perfect one-loop unification observed earlier. Before exploring this discrepancy in more detail, it is useful to introduce another important class of corrections—those arising from high-scale (GUT-scale) thresholds.

To discuss high scale thresholds, let us set all other corrections to zero for the moment and write down a version of Eq. (92.4) that captures the running near and above the GUT scale more correctly. The threshold correction at one-loop level can be evaluated accurately by the simple step-function approximation for the β functions in the $\overline{\rm DR}$ scheme [26, 177],[10]

$$\alpha_i^{-1}(m_Z) = \alpha_G^{-1}(\mu) + \frac{1}{2\pi}\left[b_i \ln\frac{\mu}{m_Z} + b_i^C \ln\frac{\mu}{M_C} + b_i^X \ln\frac{\mu}{M_X} + b_i^\Phi \ln\frac{\mu}{M_\Phi}\right]\ . \tag{92.11}$$

We initiate the RG running at a scale $\mu \gg M_G$, considering the minimal set of states relevant for the transition from the SU(5) GUT to the MSSM. These include the color-triplet Higgs multiplets with mass M_C, the massive vector multiplets of the X-bosons with mass M_X (along with the associated GUT Higgs degrees of freedom), and the remaining GUT Higgs fields and superpartners with mass M_Φ. The corresponding β-function coefficients $b_i^{C,X,\Phi}$ are given in Refs. [182, 183]. Importantly, the combination of b_i coefficients in Eq. (92.11) is such that the RG evolution preserves GUT universality at high scales, rendering the prediction for α_3 independent of the choice of μ.

To relate this to our previous discussion, we can, for example, define $M_G \equiv M_X$ and then choose $\mu = M_G$ in Eq. (92.11). This gives the high-scale threshold corrections

$$\delta_i^{(h)} = \frac{1}{2\pi}\left[b_i^C \ln\frac{M_G}{M_C} + b_i^\Phi \ln\frac{M_G}{M_\Phi}\right]\ , \tag{92.12}$$

and a corresponding correction $\Delta_3^{(h)}$. To get some intuition for the magnitude, one can furthermore assume $M_\Phi = M_G$, finding (with $b_i^C = \{2/5, 0, 1\}$)

$$\Delta_3^{(h)} = \frac{9}{14\pi}\ln\left(\frac{M_G}{M_C}\right)\ . \tag{92.13}$$

To achieve the required effect of $-\Delta_3^{(2)} - \Delta_3^{(l)} \simeq +0.64$, the color-triplet Higgs would need to be roughly a factor of 20 lighter than the GUT scale. Although such a light triplet is excluded in the minimal model by current nucleon decay limits [184]—as will be discussed in Sec. 92.6—this example nonetheless illustrates that threshold corrections of this magnitude can, in principle, be realized through appropriate GUT-scale model building, for instance in specific SU(5) [57–61] or SO(10) [63–72] frameworks. In fact, much larger or even oppositely signed corrections can arise in models that involve extended field content, particularly those employing many higher-dimensional representations, as is often necessary in fully realistic 4d GUTs. Higher-dimensional operators suppressed by M_P^{-1}, involving the GUT gauge fields and the GUT-breaking Higgs field, can also induce threshold corrections of comparable magnitude [185–190]. These corrections can, in particular, be utilized to raise the mass of the color-triplet Higgs. Consequently, there exists substantial freedom in model building.

The analysis above implicitly assumes universal soft SUSY-breaking masses at the GUT scale, which directly affect the spectrum of SUSY particles at the weak scale; in the simplest scenario, motivated by SO(10) unification, one adopts a universal gaugino mass $M_{1/2}$, a common scalar mass m_{16} for squarks and sleptons, and a universal Higgs mass m_{10}. In some cases, threshold corrections to gauge couplings can be traded for threshold effects on the soft SUSY-breaking parameters (see Ref. [191] and references therein). For instance, if gaugino masses are not unified at M_G—in particular, if gluino is lighter than wino at the weak scale (cf. Eq. (92.10))—then weak-scale threshold corrections may allow for a significantly smaller or even slightly negative GUT-scale threshold correction to be consistent with successful gauge coupling unification [192, 193].

It is also noteworthy that precise gauge coupling unification can be achieved without significant GUT-scale threshold corrections simply by increasing $m_{\rm SUSY}$ in Eq. (92.10) [194–196]. This remains possible even if gauginos are kept at the TeV scale, by taking the masses of higgsinos and non-SM Higgs bosons to lie in the multi-TeV range. Such a setup is particularly attractive, as

[10] The $\overline{\rm DR}$ scheme is commonly employed for regularization in SUSY theories [178]. The transformation of gauge couplings from the $\overline{\rm MS}$ to the $\overline{\rm DR}$ scheme is provided in Ref. [177]. For an alternative approach based on holomorphic gauge couplings and the NSVZ β-functions, see, for example, Refs. [179–181].

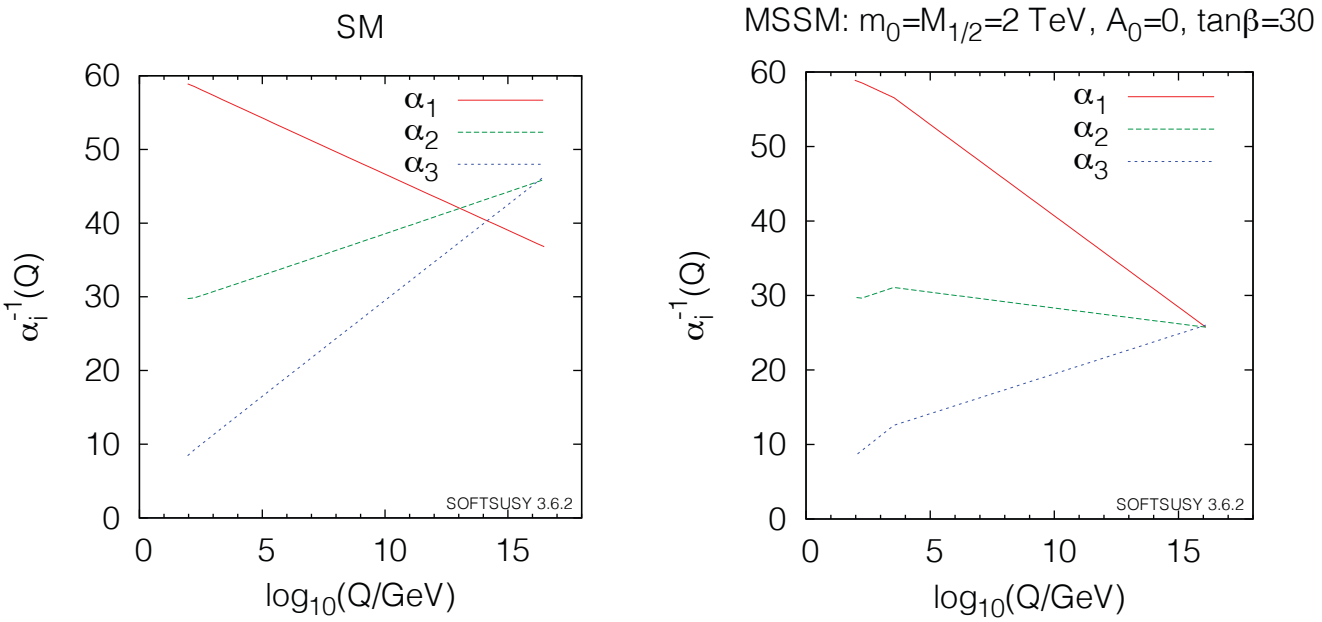

Figure 92.1: Running of the gauge couplings in the SM and MSSM, shown using two-loop RG evolution. The SUSY threshold, set at 2 TeV, is clearly visible on the MSSM side. (We thank Ben Allanach for providing the plots, which were generated using SOFTSUSY [169].)

it preserves a viable dark matter candidate—namely, the lightest neutralino. Hierarchical SUSY mass spectra of this type, often motivated by anomaly mediation [197,198], have been extensively studied in the literature [199–210]. This scenario has the additional merit of accommodating both the observed value of the SM-like Higgs boson mass[11] and the current null results from SUSY searches at the LHC, although it reintroduces a little hierarchy problem associated with the electroweak scale.

In non-SUSY GUTs or in SUSY GUTs with a very high SUSY breaking scale, achieving gauge coupling unification typically requires the presence of new light states in incomplete GUT multiplets or multiple symmetry-breaking scales. For example, in non-SUSY models with the breaking chain $SO(10) \to SU(4)_C \times SU(2)_L \times SU(2)_R \to G_{SM}$, where the second stage of symmetry breaking occurs at an intermediate scale corresponding to the mass scale of right-handed neutrinos, gauge couplings can unify at the SO(10) breaking scale [219], while remaining consistent with current bounds on nucleon decay [220]. Similar unification can also be realized in alternative symmetry-breaking chains or in scenarios with extra light states—such as dark matter candidates—present at low energies [221, 222]. Alternatively, string-theoretic corrections discussed in Sec. 92.4 can be invoked to offset the effects of a high SUSY-breaking scale. This possibility has been explored concretely, for example, in the context of F-theory GUTs [223]. In principle, large threshold corrections arising from large GUT representations may also enable gauge coupling unification [224, 225].

In orbifold GUTs, certain "GUT scale" threshold corrections come from the KK modes between the compactification scale, $M_c \sim 1/R$, and the effective cutoff scale M_*, which is the string scale in string theory. Gauge coupling unification then constrains the values of M_c and M_*. It is interesting to note that a ratio $M_*/M_c \sim 100$, needed for gauge coupling unification to work in orbifold GUTs, is typically the maximum value for this ratio consistent with perturbativity [226]. Often, one finds M_c to be lower than the 4d GUT scale. Since the X-bosons, responsible for nucleon decay, get mass at the compactification scale, this has significant consequences for nucleon decay.

[11] In the MSSM, the tree-level Higgs boson mass is bounded from above by m_Z, but radiative corrections—particularly from heavy stop loops—can raise it to the observed value of ~ 125 GeV [211–218].

Finally, it has been shown that non-SUSY GUTs in warped 5d orbifolds can be consistent with gauge coupling unification. This assumes (in 4d language) that the right-handed top quark and the Higgs doublets are composite-like objects with a compositeness scale in the TeV range [227].

92.6 Nucleon decay

Quarks and leptons are indistinguishable in any 4d GUT, and both the baryon (B) and lepton number (L) are not conserved. This leads to baryon-number-violating nucleon decay. In addition to baryon-number violation, lepton-number violation is also required for nucleon decay since, in the SM, leptons are the only free fermions which are lighter than nucleons. In the SM, the lowest-dimension operators relevant for nucleon decay are $(B+L)$-violating dimension-six four-fermion terms, and all B-violating operators with dimension less than seven preserve $B - L$ [1, 228].

In SU(5) GUTs, the dimension-six baryon-number-violating operators are induced by X boson exchange. These operators are suppressed by $(1/M_X^2)$, where M_X is the X boson mass, and the nucleon lifetime is given by $\tau_N \propto M_X^4/(\alpha_G^2 m_N^5)$, with m_N the nucleon mass. The dominant proton decay mode, as well as the baryon-number-violating decay mode of the neutron, via the X-boson exchange is given by $p \to \pi^0 e^+$ and $n \to \pi^- e^+$, respectively.[12] The present experimental bound on $p \to \pi^0 e^+$ comes from Super-Kamiokande. With 450 kton-years of data they find $\tau_p/\mathrm{Br}(p \to \pi^0 e^+) > 2.4 \times 10^{34}$ years at 90% CL [233].[13] In addition, Hyper-Kamiokande [235] is planned to reach to $\tau_p/\mathrm{Br}(p \to \pi^0 e^+) \sim 10^{35}$ years. For a broader overview of planned experiments and historical developments, the reader is referred to Ref. [236]. The hadronic matrix elements relevant for baryon-number-violating operators are now reliably computed using lattice QCD simulations [237]. In SUSY SU(5) GUTs, the null results from nucleon decay searches place a lower bound on the X boson mass that is approaching 10^{16} GeV [238], which is remarkably close to the GUT scale inferred from gauge coupling unification. In contrast, predictions for nucleon decay rates in non-SUSY GUTs are more uncertain. This is because gauge cou-

[12] Other decay modes, such as $p \to \pi^+ \bar{\nu}$, $p \to \pi^0 \mu^+$, and $n \to \pi^0 \bar{\nu}$, can be dominant in extended GUT frameworks, including flipped SU(5) [229, 230], SO(10), and E_6 [231, 232] models.

[13] For $n \to \pi^- e^+$, the current limit is $\tau_p/\mathrm{Br}(n \to \pi^- e^+) > 5.3 \times 10^{33}$ years [234].

plings do not unify with the SM particle content alone. Once additional states or sizable threshold corrections are introduced to achieve precision unification, a broad range of possible unification scales becomes viable.

In SUSY GUTs, there exist additional sources of baryon- and/or lepton-number violation in the form of dimension-four/five operators [28, 29]. These arise because, in the SUSY SM, quarks and leptons are accompanied by scalar partners—squarks and sleptons. Note that in the SUSY context, fields are understood as chiral superfields, which include both fermionic and bosonic components. In this framework, baryon- and lepton-number-violating operators of dimension four and five appear as F-terms composed of chiral superfields. These operators involve two fermionic components, with the remaining fields being one or two scalar fields; in SU(5), they have the form:

$$\begin{aligned}(\mathbf{10}\,\overline{\mathbf{5}}\,\overline{\mathbf{5}}) &\supset (u^c\,d^c\,d^c) + (Q\,L\,d^c) + (e^c\,L\,L)\ ,\\ (\mathbf{10}\,\mathbf{10}\,\mathbf{10}\,\overline{\mathbf{5}}) &\supset (Q\,Q\,Q\,L) + (u^c\,u^c\,d^c\,e^c) + \\ &\quad B\text{- and } L\text{-conserving terms}\ . \end{aligned} \tag{92.14}$$

The dimension-four operators in $(\mathbf{10}\,\overline{\mathbf{5}}\,\overline{\mathbf{5}})$ violate either B or L. The nucleon lifetime is extremely short if both types of dimension-four operators are present in the SUSY SM since squark or slepton exchange induces the dangerous dimension-six SM operators. Even in the case that they violate B or L only but not both, they are constrained by various phenomena [239, 240]. For example, the primordial baryon number in the Universe is washed out unless the dimensionless coupling constants are less than 10^{-7} [241–243]. Both types of operators can be eliminated by requiring R parity [244], which distinguishes Higgs multiplets from ordinary matter multiplets. R parity or its cousin, matter parity [22–27, 245, 246], act as $F \to -F$, $H \to H$ with $F = \{\mathbf{10}, \overline{\mathbf{5}}\}$, $H = \{\overline{\mathbf{5}}_H, \mathbf{5}_H\}$ in SU(5). This R parity forbids the dimension-four operator $(\mathbf{10}\,\overline{\mathbf{5}}\,\overline{\mathbf{5}})$, but allows the Yukawa couplings for quark and lepton masses of the form $(\mathbf{10}\,\overline{\mathbf{5}}\,\overline{\mathbf{5}}_H)$ and $(\mathbf{10}\,\mathbf{10}\,\mathbf{5}_H)$. It also forbids the dimension-three, L-violating operator $(\overline{\mathbf{5}}\,\mathbf{5}_H) \supset (L\,H_u)$ as well as the dimension-five, B-violating operator $(\mathbf{10}\,\mathbf{10}\,\mathbf{10}\,\overline{\mathbf{5}}_H) \supset (Q\,Q\,Q\,H_d) + \cdots$. In SU(5), the Higgs multiplet $\overline{\mathbf{5}}_H$ and the matter multiplets $\overline{\mathbf{5}}$ have identical gauge quantum numbers. In E_6, Higgs and matter multiplets could be unified within the fundamental **27** representation. Only in SO(10) are Higgs and matter multiplets distinguished by their gauge quantum numbers. The $\mathbb{Z}_4$ center of SO(10) distinguishes **10**s from **16**s and can be associated with R parity [247].

The baryon-number-violating dimension-five operators in SUSY GUTs arise with dimensionful couplings, typically suppressed by $1/M_G$, as they are generated by integrating out the color-triplet Higgs fields with GUT-scale masses. Both triplet higgsinos—due to their fermionic nature—and triplet Higgs scalars—via their mass-enhanced trilinear couplings to matter—contribute to the generation of these operators. Since the resulting operators involve squarks and/or sleptons, nucleon decay requires these scalar superpartners to be converted into light quarks or leptons through the exchange of a gaugino or higgsino in the SUSY SM. The corresponding nucleon lifetime scales as $M_G^2\,\widetilde{m}^2/m_N^5$, where $\widetilde{m}$ denotes the characteristic SUSY scalar mass. Consequently, dimension-five operators can induce nucleon decay rates significantly faster than those from dimension-six operators. In the absence of accidental cancellations, the dominant decay modes from these operators often include a kaon, such as $p \to K^+\bar{\nu}$ and $n \to K^0\bar{\nu}$. This can be understood from symmetry considerations. The relevant superpotential terms take the schematic form $(Q_i\,Q_j\,Q_k\,L_l)$ and $(u_i^c\,u_j^c\,d_k^c\,e_l^c)$, where $i, j, k, l = 1, 2, 3$ label generations, and color and weak indices are implicit. These operators must be invariant under both $SU(3)_C$ and $SU(2)_L$, implying that the color and weak indices must be antisymmetrized. However, as they arise from bosonic superfields, they must be totally symmetric under interchange of all flavor and gauge indices. This leads to the vanishing of the first operator when $i = j = k$, and of the second when $i = j$. As a result, contributions involving second- or third-generation fields dominate unless they are accidentally suppressed [245, 246].

The Super-Kamiokande experiment places stringent constraints on dimension-five proton decay operators. With an exposure of 306 kton · years, the current lower bound on the partial lifetime is $\tau_p/\mathrm{Br}(p \to K^+\bar{\nu}) > 6.61 \times 10^{33}$ years at 90% confidence level [248]. In the minimal SUSY SU(5) model, the predicted partial lifetime is less than about 10^{31} years if the color-triplet Higgs mass is 10^{16} GeV and the SUSY scale is $\widetilde{m} = 1$ TeV [249]. To evade this experimental limit, the color-triplet Higgs would need to be significantly heavier than the GUT scale, which, as discussed in Sec. 92.5, conflicts with the requirement for successful gauge coupling unification. As a result, the minimal SUSY SU(5) model is placed under significant tension by current proton decay constraints [184].

Since nucleon decay induced by the color-triplet Higgs is a serious issue in SUSY GUTs, a variety of mechanisms have been proposed to suppress it. One possibility is that an accidental symmetry or structural feature in non-minimal Higgs sectors suppresses the dimension-five operators [52,53,63–72,250,251]. A central idea behind such constructions is that nucleon decay can be suppressed if the Higgs triplets in the $\mathbf{5}_H$ and $\overline{\mathbf{5}}_H$ do not acquire a common mass term, but instead obtain their masses through couplings to additional SU(5) multiplets. Second, the SUSY-breaking scale may lie in the range $\mathcal{O}$(10–100) TeV, as discussed in Sec. 92.5. In such scenarios, nucleon decay is automatically suppressed due to the heavy sfermion masses, while the observed Higgs boson mass can be explained [252–258]. Third, accidental cancellations among contributing diagrams, arising from a finely tuned structure of squark and slepton flavor mixings, may also lead to suppressed decay rates [259]. The predicted upper bounds on the nucleon lifetime in some of these theories lie roughly an order of magnitude above current experimental limits, which may be within the reach of future experiments, such as JUNO [260, 261], Hyper-Kamiokande [235], and DUNE [262].

Orbifold GUTs and string theories contain grand unified symmetries realized in higher dimensions. In the process of compactification and GUT symmetry breaking, the triplet Higgs states may be removed (projected out of the massless sector of the theory). In such models, the nucleon decay due to dimension-five operators can be severely suppressed or eliminated completely. However, nucleon decay due to dimension-six operators may be enhanced, since the gauge-bosons mediating proton decay obtain mass at the compactification scale, M_c, which is typically less than the 4d GUT scale (cf. Sec. 92.5). Alternatively, the same projections which eliminate the triplet Higgs may rearrange the quark and lepton states such that the massless states of one family come from different higher-dimensional GUT multiplets. This can suppress or completely eliminate even dimension-six proton decay. Thus, enhancement or suppression of dimension-six proton decay is model-dependent. In some complete 5d orbifold GUT models [171, 263, 264] the lifetime for the decay $\tau_p/\mathrm{Br}(p \to \pi^0 e^+)$ can be near the bound of 1×10^{34} years with, however, large model-dependence and/or theoretical uncertainties. In other cases, the modes $p \to K^+\bar{\nu}$ and $p \to K^0\mu^+$ may be dominant [171].

In orbifold GUTs or string theory, new discrete symmetries consistent with SUSY GUTs can forbid all dimension-three and four baryon- and lepton-number-violating operators. Even the μ term and dimension-five baryon- and lepton-number-violating operators can be forbidden to all orders in perturbation theory [93–95]. The μ term and dimension-five baryon- and lepton-number-violating operators may then be generated, albeit sufficiently suppressed, via non-perturbative effects. The simplest example of this is a $\mathbb{Z}_4^R$ symmetry which is the unique discrete R symmetry consistent with SO(10) [93–95]. Even though it forbids the dimension-five proton decay operator to the desired level, it allows the required dimension-five neutrino mass term. In this case, proton decay is dominated by dimension-six operators, leading to decays such as $p \to \pi^0 e^+$.

92.7 Yukawa coupling unification

In the SM, the masses and mixings of quarks and leptons arise from their Yukawa couplings to the Higgs doublet; however, the origin and structure of these couplings remain unexplained. GUTs offer at least a partial explanation by embedding each generation into unified multiplets. In this framework, quarks and leptons are treated as components of the same representation, and the GUT

symmetry imposes relations among their Yukawa couplings.

In SU(5), there are two types of independent renormalizable Yukawa interactions given by $\lambda_{ij}(\mathbf{10}_i\,\mathbf{10}_j\,\mathbf{5}_H) + \lambda'_{ij}(\mathbf{10}_i\,\overline{\mathbf{5}}_j\,\overline{\mathbf{5}}_H)$. These contain the SM interactions $\lambda_{ij}(Q_i\,u^c_j\,H_u)+\lambda'_{ij}(Q_i\,d^c_j\,H_d+ e^c_i\,L_j\,H_d)$, where $i,j = 1,2,3$ are family indices. At the GUT scale, this leads to tree-level relations among Yukawa couplings of the charged leptons and down-type quarks. For instance, one obtains $\lambda_b = \lambda_\tau$, where $\lambda_{b,\tau}$ denote the bottom quark and tau lepton Yukawa couplings, respectively [265–268]. In SO(10), there exists only one type of independent renormalizable Yukawa interaction, $\lambda_{ij}(\mathbf{16}_i\,\mathbf{16}_j\,\mathbf{10}_H)$, which implies unified relations among all Yukawa couplings within a single generation [269–282], such as $\lambda_t = \lambda_b = \lambda_\tau$, where λ_t denotes the top quark Yukawa coupling.

In addition to gauge coupling unification, the ratio of the b quark mass to the τ lepton mass has long been a key focus in GUT studies, ever since it was observed that this ratio, after accounting for QCD corrections, is remarkably consistent with experimental data [265, 266]. With the current high-precision determinations of quark masses and gauge couplings, this mass ratio has evolved into a target of detailed and quantitative analyses within the GUT framework, as discussed below.

92.7.1 *The third generation, b–τ or t–b–τ unification*

The third-generation Yukawa couplings are significantly larger than those of the first two generations. As a result, the fermion mass relations predicted by the renormalizable GUT interactions introduced above are expected to be more robust and reliable. To confront these predictions with experimental data, one must account for radiative corrections arising from RG evolution between the GUT scale and the fermion mass scale, as well as threshold corrections from integrating out heavy fields at the GUT and SUSY scales and from weak-scale physics.

Since the unification of Yukawa couplings can only be meaningfully tested in models that also achieve successful gauge coupling unification, we focus here on SUSY GUTs. In the MSSM, the masses of the top and bottom quarks and the τ lepton are related to their respective Yukawa couplings evaluated at the scale m_Z as

$$m_t(m_Z) = \lambda_t(m_Z)\,v_u\left(1+\frac{\delta m_t}{m_t}\right)\,,$$
$$m_{b,\tau}(m_Z) = \lambda_{b,\tau}(m_Z)\,v_d\left(1+\frac{\delta m_{b,\tau}}{m_{b,\tau}}\right)\,, \qquad (92.15)$$

where $v_u = \sin\beta\, v/\sqrt{2}$ and $v_d = \cos\beta\, v/\sqrt{2}$, with $v \simeq 246$ GeV, and $\delta m_f/m_f$ $(f = t, b, \tau)$ denotes the threshold correction arising from integrating out SUSY particles. For the b quark mass, it has been shown [283, 284] that the dominant corrections originate from gluino-sbottom and Higgsino-stop loop diagrams,

$$\left(\frac{\delta m_b}{m_b}\right)_{g_3} \simeq \frac{g_3^2}{6\pi^2}\,\frac{m_{\tilde{g}}\,\mu}{\widetilde{m}^2}\tan\beta\,, \qquad \left(\frac{\delta m_b}{m_b}\right)_{\lambda_t} \simeq \frac{\lambda_t^2}{16\pi^2}\,\frac{A_t\mu}{\widetilde{m}^2}\tan\beta\,, \qquad (92.16)$$

where $m_{\tilde{g}}$, μ, A_t, and $\widetilde{m}$ denote the gluino mass, higgsino mass, trilinear stop coupling, and the characteristic stop/sbottom mass scale, respectively. It should be noted that Eq. (92.16) captures only the schematic structure of the corrections; the full functional dependence on the soft SUSY-breaking parameters of order $\widetilde{m}$ has been omitted for clarity. For the complete one-loop expressions for the b quark mass corrections, see for example Ref. [285].

Note also that these corrections do not vanish even when SUSY particles are significantly heavier than the electroweak scale. For $\tan\beta = \mathcal{O}(10)$, they can alter the b quark mass by as much as $\mathcal{O}(10)\%$. The overall effect is sensitive to the relative phase between $m_{\tilde{g}}$ and μ, especially because the infrared fixed-point behavior of the RGE for A_t tends to drive $A_t \simeq -m_{\tilde{g}}$ [286] in scenarios where SUSY-breaking terms originate from Planck-scale physics, such as gravity mediation. Similar corrections affect the τ lepton mass, although typically only at the few-percent level. Corrections to the top quark mass are not enhanced by $\tan\beta$ and reach at most $\sim 10\%$ [287].

By including one-loop threshold corrections at the electroweak scale and performing the necessary RG evolution, one obtains the masses of the top quark, bottom quark, and τ lepton. In SUSY GUTs, b–τ Yukawa unification allows for two viable solutions corresponding to either small $\tan\beta \sim 1$ or large $\tan\beta = \mathcal{O}(10)$. The small $\tan\beta$ scenario can be realized in the MSSM if the superpartner masses lie at $\mathcal{O}(10)$ TeV [202]. On the other hand, large $\tan\beta$ values, such as $\tan\beta \sim 40$–50, are consistent with the SO(10) symmetry relation [287,288]. In this regime, threshold corrections to down-type quark masses become significant, as discussed earlier. Consequently, successful Yukawa unification is only achieved within a restricted region of the SUSY parameter space, leading to important implications for SUSY searches [287,289–293]. More recent studies of Yukawa unification in light of LHC results can be found in Refs. [294–297].

92.7.2 *Beyond leading order: three-family models*

Simple Yukawa unification does not work for the first two generations. In particular, the minimal implementation of SU(5) predicts the relations $\lambda_s = \lambda_\mu$ and $\lambda_d = \lambda_e$, which imply $\lambda_s/\lambda_d = \lambda_\mu/\lambda_e$. This relation is preserved under RG evolution and leads to the prediction $m_s/m_d = m_\mu/m_e$ at the weak scale, which is clearly incompatible with experimental observations, where $m_s/m_d \sim 20$ and $m_\mu/m_e \sim 200$. A compelling solution to this discrepancy was proposed by Georgi and Jarlskog [298]; for a more recent treatment in the context of SUSY, see Ref. [299].

More generally, it is important to recall that all previous discussions of Yukawa couplings were based on the assumption of renormalizable interactions and minimal matter and Higgs content. However, since the GUT scale lies close to the Planck scale, higher-dimensional operators involving GUT-breaking Higgs fields can lead to significant corrections, particularly for the first and second generations. A representative example is the dimension-five operator $\mathbf{10}\,\overline{\mathbf{5}}\,\overline{\mathbf{5}}_H\,\mathbf{24}_H$, where $\mathbf{24}_H$ denotes the SU(5) GUT-breaking Higgs field. Such operators can be used to fit the observed fermion masses, albeit at the cost of introducing some degree of fine-tuning. Moreover, the SM Higgs doublet itself may originate, at least in part, from higher-dimensional representations of the GUT group. For instance, the **45** representation of SU(5) contains an $\mathrm{SU}(2)_L$ doublet with the correct hypercharge to serve as a SM Higgs field [298]. This **45** can arise from larger representations such as the **120** or **126** of SO(10), once the symmetry is broken down to SU(5) [300–302]. These additional Higgs fields can also have renormalizable couplings to SM fermions, modifying the relations among the Yukawa couplings when the SM Higgs is a linear combination of doublets from different SU(5) multiplets. Finally, the embedding of SM fermions into GUT multiplets may not follow the minimal assignment. In minimal SO(10) models, all quarks and leptons reside in **16**-dimensional representations, but renormalizable Yukawa couplings with a single $\mathbf{10}_H$ cannot account for the observed CKM mixing angles. This issue can be alleviated by introducing additional matter multiplets, such as **10**s. After the breaking of $\mathrm{U}(1)_X$—which distinguishes the $\overline{\mathbf{5}}$ components originating from the **16** and **10** representations—the right-handed down-type quarks and left-handed leptons of the SM can be linear combinations of states from **16** and **10**. In this case, the two types of Yukawa couplings in SU(5) need not be identical [303].

To construct realistic three-family models, it is typically necessary to incorporate some or all of the effects discussed above. However, grand unification alone is generally insufficient to yield a predictive framework for fermion masses and mixing angles. Additional ingredients are required—most notably, global family symmetries. In particular, non-Abelian family symmetries can significantly reduce the number of free parameters by restricting the allowed structure of effective higher-dimensional operators that govern fermion masses. Moreover, the sequential breaking of family symmetries can naturally correlate with the observed fermion mass hierarchies [304]. A simple and widely studied approach is to assign each $\mathbf{10}_i$ representation a suppression factor ϵ^{3-i} in its Yukawa couplings, where ϵ is a small expansion parameter. This setup automatically generates a stronger hierarchy in the up-type quark Yukawa couplings compared to those of the down-

type quarks and charged leptons, and no strong hierarchy in the neutrino sector—qualitatively consistent with observations. Fully realistic three-family models incorporating these ingredients have been constructed and are capable of reproducing the full spectrum of fermion masses and mixing parameters, including those in the neutrino sector [66–72, 305–313].

Finally, a particularly ambitious variant of unification is to require that the fermions of all three generations come from a single representation of a large gauge group. A somewhat weaker assumption is that the flavor group (*e.g.*, SU(3)) unifies with the SM gauge group in a simple gauge group at some energy scale $M \geq M_G$. Early work on such 'flavor-unified GUTs', see, *e.g.*, Refs. [303,314–320], has been reviewed in Refs. [321,322]. For a selection of more recent papers see Refs. [323–327]. In such settings, Yukawa couplings are generally determined by gauge couplings together with symmetry breaking VEVs. This is reminiscent of heterotic string GUTs, where all couplings come from the 10d gauge coupling. However, while the $E_8 \to SU(3) \times E_6$ branching rule $\mathbf{248} = (\mathbf{8},\mathbf{1}) + (\mathbf{1},\mathbf{78}) + (\mathbf{3},\mathbf{27}) + (\overline{\mathbf{3}},\overline{\mathbf{27}})$ looks very suggestive in this context, the way in which most modern heterotic models arrive at three generations is actually more complicated.

92.8 Neutrino masses

Neutrino oscillation experiments have firmly established that neutrinos possess nonzero masses. By adding three "sterile" neutrinos ν_i^c with Yukawa couplings $\lambda_{\nu,ij}(\nu_i^c\, L_j\, H_u)$ $(i,j = 1,2,3)$, one obtains three massive Dirac neutrinos with mass $m_\nu^D = \lambda_\nu v_u$, analogously to quark and charged lepton masses. However, in order to obtain a τ neutrino with mass of order 0.1 eV, one requires the exceedingly small coupling ratio $\lambda_{\nu_\tau}/\lambda_\tau \lesssim 10^{-10}$. By contrast, in GUTs the seesaw mechanism *naturally* explains such tiny neutrino masses as follows [2–8]: The sterile neutrinos have no SM gauge quantum numbers so that there is no symmetry other than lepton number which forbids the Majorana mass term $\frac{1}{2}M_{ij}\nu_i^c\nu_j^c$. Note also that sterile neutrinos can be identified with the right-handed neutrinos necessarily contained in complete multiplets of SO(10), the flipped SU(5), or $G_{\rm PS}$. Since the Majorana mass term violates these gauge symmetries, one might expect $M_{ij} \sim M_G$. The heavy sterile neutrinos can be integrated out, yielding an EFT with only light active neutrinos with the effective dimension-five operator

$$\mathcal{L}_{\rm eff} = -\frac{1}{2}c_{ij}(L_i\, H_u)(L_j\, H_u) + \text{h.c.}\,, \qquad (92.17)$$

where $c = \lambda_\nu^T M^{-1}\lambda_\nu$. This leads to a 3×3 Majorana neutrino mass matrix $m_\nu = (m_\nu^D)^T M^{-1} m_\nu^D$ after the electroweak symmetry breaking. For example, if the neutrino Yukawa coupling λ_{ν_τ} is unified with the top quark Yukawa coupling at the GUT scale, $\lambda_{\nu_\tau} = \lambda_t$, as predicted in SO(10), flipped SU(5), or Pati–Salam models, then the observed value $m_{\nu_\tau} \sim 0.1$ eV implies a right-handed neutrino mass scale $M \sim 10^{14}$ GeV, intriguingly close to the GUT scale.

The seesaw mechanism implemented by right-handed neutrinos is sometimes called the type-I seesaw model. There are variant models in which the dimension-five operator for neutrino masses is induced in different ways: In the type-II model, an $SU(2)_L$ triplet Higgs boson Σ is introduced to have couplings ΣL^2 and also ΣH_u^2 [300,328–331]. In the type-III model, an $SU(2)_L$ triplet of fermions $\widetilde{\Sigma}$ with a Yukawa coupling $\widetilde{\Sigma}LH_u$ is introduced [332]. In these models, the dimension-five operator is generated by integrating out either the triplet Higgs bosons or fermions. Such mechanisms can be embedded into GUT frameworks by introducing, for example, Higgs bosons in the **15** or fermions in the **24** representations of SU(5), which can originate from the **126** representation of SO(10). It is important to note that the gauge non-singlet fields involved in type-II and type-III seesaw mechanisms typically acquire masses at an intermediate scale. As a result, gauge coupling unification is not automatically preserved when these mechanisms are implemented in SUSY GUTs.

The neutrino sector presents a challenge for GUTs: while the quark mixing angles in the CKM matrix are small, two of the lepton mixing angles in the PMNS matrix are large. Global fits to neutrino masses and mixing parameters can be found in Sec. 14. For reviews of SUSY GUT models that successfully reproduce quark and lepton masses, see Refs. [333, 334]. A compilation of the range of SUSY GUT predictions for neutrino mixing angles is provided in Ref. [335].

It is also worth noting that, both within and beyond the GUT framework, considerable effort has been devoted to constructing models of neutrino masses—and more broadly, flavor structure—based on discrete symmetries (see, *e.g.*, Refs. [334, 336, 337]). A particularly interesting recent development in this context is the application of the (non-linearly realized) modular group $SL(2,\mathbb{Z})$ as a discrete flavor symmetry [338]. This group plays a central role in string theory as the group of large diffeomorphisms of the two-torus, which appears both as the string worldsheet and—as is especially relevant here—as part of the compactification space in torus orbifold models (cf. Sec. 92.4). For a selection of recent activity in this direction, see, *e.g.*, Refs. [339–342].

92.9 Selected topics

92.9.1 *Global symmetries*

As discussed above, global symmetries are often introduced in GUT models to control higher-dimensional operators. This is particularly crucial in the context of nucleon decay, but such symmetries also play important roles in solutions to the doublet-triplet splitting problem, GUT-based flavor model building, and cosmological applications such as baryogenesis and inflation. However, relying on global symmetries to suppress specific interactions is not always as straightforward. Broadly speaking, two possibilities exist: First, the relevant symmetry may be gauged at a high scale. In this case, the effects of the VEVs responsible for its spontaneous breaking can, in principle, induce dangerous operators, and their impact must be carefully assessed. Second, the symmetry may be truly global, as is necessarily the case for anomalous symmetries whose breaking arises through non-perturbative effects and may therefore be exponentially suppressed. Nonetheless, it is widely believed that exact global symmetries cannot be preserved in the presence of quantum gravity (see, *e.g.*, Refs. [343,344]). One must then determine the degree of suppression—whether polynomial or exponential—arising from Planck-scale physics. For instance, dimension-five baryon-number-violating operators suppressed by only a single power of the Planck or string scale are highly problematic in SUSY models [345].

In light of the above, it is worth recalling that in string-theoretic models, 4d global symmetries typically originate from higher-dimensional gauge symmetries [111–114, 346]. Here, the term 'global' refers to a symmetry whose gauge boson acquires a Stückelberg mass. This mass generation is necessary in the case of anomalous symmetries (via the Green–Schwarz mechanism [347]), but it can also occur for non-anomalous ones. In such scenarios, one generally expects no symmetry violation beyond well-understood non-perturbative effects. Discrete symmetries arise as subgroups of continuous gauge symmetries—for example, $\mathbb{Z}_N \subset U(1)$. Notably, non-anomalous subgroups of Stückelberg-massive U(1)s correspond to unbroken discrete gauge symmetries, which are exact even non-perturbatively (see, *e.g.*, Refs. [348,349]). Such discrete gauge symmetries can also emerge as remnants of spontaneously broken continuous gauge symmetries in 4d.

92.9.2 *Anomaly constraints vs. GUT paradigm*

As emphasized at the very beginning, the fact that the SM fermions of one generation fill out the $\mathbf{10} + \overline{\mathbf{5}}$ of SU(5) appears to provide strong evidence for some form of GUT embedding. However, one should be aware that a counterargument can be made which is related to the issue of 'charge quantization by anomaly cancellation' (see Refs. [350–354] for some early papers and Ref. [355] for a more detailed reference list): Imagine we only knew that the low-energy gauge group were $G_{\rm SM}$ and the matter content included $(\mathbf{3},\mathbf{2})_Y$, *i.e.*, a 'quark doublet' with U(1)-charge Y. One can then ask which possibilities exist of adding further matter to ensure the cancellation of all triangle anomalies. It turns out that this problem has only three different, minimal[14]

[14] Adding extra vector-like sets of fields, *e.g.*, two fermions which only transform under U(1) and have charges Y and $-Y$, is considered to violate minimality.

solutions [354]. One of those is precisely a single SM generation, with the apparent 'SU(5)-ness' emerging accidentally. Thus, if one randomly picks models from the set of consistent gauge theories, preconditioning on $G_{\rm SM}$ and $(\mathbf{3},\mathbf{2})_Y$, one may easily end up with '$\mathbf{10}+\overline{\mathbf{5}}$' of an SU(5) that is in no way dynamically present. This is precisely what happens in the context of non-GUT string model building [356–358].

92.9.3 *Topological defects and phase transitions*

Among the various topological defects that can arise in the broken phase of GUT models, magnetic monopoles are the most well-known. These are localized classical solutions carrying magnetic charge under an unbroken U(1) subgroup [359, 360]. Magnetic monopoles with masses of $\mathcal{O}(M_G/\alpha_G)$ can be produced during a GUT phase transition in the early Universe. Experimentally, the flux of such monopoles is constrained to be $\lesssim 10^{-16}$ cm$^{-2}\cdot$s$^{-1}\cdot$sr^{-1} [361–363]. It was also shown that GUT monopoles can catalyze nucleon decay [364–368], leading to significantly stronger constraints on the monopole flux when considering, for example, X-ray emission from radio pulsars induced by monopole capture and subsequent nucleon decay [369]. Nonetheless, GUTs typically predict a monopole abundance far exceeding these limits—this is the so-called monopole problem.

One of the original motivations for proposing inflation was to resolve the monopole problem by exponentially diluting their density after the GUT phase transition (for a review on inflation, see Sec. 23). Notably, the current upper bound on the inflationary vacuum energy scale is remarkably close to the GUT scale, given by $V_{\rm inf}^{1/4} = (1.88\times10^{16}\ {\rm GeV})\times(r/0.10)^{1/4}$, where the scalar-to-tensor ratio is constrained to be $r<0.036$ [370]. This ensures that reheating does not reach temperatures above the GUT scale M_G, thereby solving the monopole problem—provided M_G is not significantly lower than expected. Alternative mechanisms to address the monopole problem include sweeping monopoles away with domain walls [371], breaking the electromagnetic U(1) symmetry at high temperatures [372], or avoiding GUT symmetry restoration altogether [373].

Topological defects other than monopoles are also common, see, *e.g.*, Refs. [374–376]. They can be cosmologically relevant in GUT models based on a gauge group larger than SU(5), say, SO(10), where an intermediate gauge theory may appear. The breaking of this intermediate gauge symmetry can a priori occur anywhere between the GUT and the electroweak scales. Right-handed neutrino masses favor a value near $\mathcal{O}(10^{14})$ GeV and non-SUSY coupling unification may profit from such a two-step GUT breaking scheme (cf., Sec. 92.5). Crucially for the present context, the last breaking step may occur after inflation, generating topological defects (like cosmic strings) which are not diluted. Their signature can be probed through gravitational waves [377–381], with the metastable string case being of particular phenomenological interest [382–387]. Metastability arises because the nucleation of a monopole-anti-monopole pair, each of which serves as an endpoint for the string, allow the cosmic string to break. The lifetime becomes long and hence the string stable as the ratio between monopole mass and the square root of the string tension grows. This is related to the ratio of the two symmetry-breaking scales. It is of phenomenological interest that metastability allows the string network to evade the recent bound of $G\mu\lesssim10^{-10}$ (or $\sqrt{\mu}\lesssim10^{14}$ GeV) [387], where G is the gravitational constant and μ is the string tension. Moreover the spectrum is blue-tilted compared to the stable string case. Finally, we note that if the intermediate gauge symmetry breaking proceeds with a (strong) first order phase transition, this could also generate gravitational waves [387–391]. However, due to the relatively high energy scales involved, the peak frequency tends to be high, with signals hopefully to be explored in future gravitational wave experiments.

92.9.4 *Flavor violation*

Yukawa interactions involving GUT-scale particles and SM quarks and leptons can imprint flavor-violating structures onto the soft SUSY-breaking terms [392]. To illustrate this, consider the MSSM with flavor-universal soft terms given at the Planck scale. Working in a basis where the up-type quark and charged lepton Yukawa matrices are diagonal, one finds that the large top Yukawa coupling drives a radiative suppression of the third-generation left-handed squark mass squared via RG evolution. After CKM rotation, this leads to sizable off-diagonal entries in the left-handed down-type squark mass matrix. In GUTs, however, additional sources of flavor violation arise. For instance, in SU(5), the color-triplet Higgs radiatively generates flavor-violating right-handed slepton mass terms via the Yukawa interaction $\lambda_{ij}(\mathbf{10}_i\,\mathbf{10}_j\,\mathbf{5}_H)$ [393, 394]. In the SU(5) extension of the type-I seesaw mechanism—where right-handed neutrinos are introduced as SU(5) singlets with the interaction $\lambda''_{ij}(\mathbf{1}_i\,\overline{\mathbf{5}}_j\,\mathbf{5}_H)$—both the doublet and color-triplet Higgs bosons acquire additional Yukawa couplings. These give rise to radiatively induced flavor violation in the left-handed slepton sector [395–398] and in the right-handed down-type squark sector [399, 400]. Note that even if flavor-universal soft terms are assumed at the GUT scale, sizable flavor violation in the left-handed slepton masses can still be generated through the RG running from the GUT scale down to the right-handed neutrino mass scale, driven by the right-handed neutrino Yukawa couplings. These flavor-violating SUSY-breaking terms generate new contributions to flavor-changing neutral current (FCNC) processes in both the quark and lepton sectors, such as $\mu\to e\gamma$, K^0–$\bar{K}^0$ mixing, and B^0–$\bar{B}^0$ mixing. Flavor violation in the sfermion mass matrices can also enhance nucleon decay induced by the dimension-five baryon-number-violating operators, as not only higgsino and wino exchange but also gluino-mediated processes can contribute in this case [401]. Electric dipole moments (EDMs) may also arise when both left- and right-handed squarks or sleptons receive flavor-violating mass terms with relative complex phases. This has been discussed in the context of SO(10) [402] and SU(5) models with right-handed neutrinos [403]. Thus, low-energy flavor and CP-violating observables serve as important probes of GUT-scale interactions.

92.9.5 *From GUT baryogenesis to leptogenesis and B/L-violating transitions*

During inflation, any conserved quantum number is exponentially diluted. Consequently, the observed baryon asymmetry of the Universe must be generated during or after reheating. The situation, however, is somewhat more subtle: both B and L are classical global symmetries of the SM, but the combination $(B+L)$ is anomalous and violated by thermal fluctuations in the early Universe via sphaleron processes [404]. In addition, $(B+L)$ is also violated in GUTs, as evidenced by nucleon decay. By contrast, the combination $(B-L)$ is anomaly-free and remains conserved in both the SM and in gauge interactions of GUTs such as SU(5) and SO(10).

The classic idea of GUT baryogenesis [405–412] involves generating a $(B+L)$ asymmetry—and hence a baryon asymmetry—via the out-of-equilibrium decay of color-triplet Higgs bosons. However, such an asymmetry produced at the GUT scale is erased by sphaleron processes that become efficient at temperatures below $T\sim10^{12}$ GeV.[15] This issue can be circumvented [413] by using lepton-number-violating interactions of neutrinos to convert part of the initial $(B+L)$ asymmetry into a $(B-L)$ asymmetry before sphaleron processes become active. The resulting $(B-L)$ asymmetry is preserved throughout the sphaleron era. However, this mechanism is not viable in the minimal SUSY GUT, where the triplet Higgs lies above the GUT scale. In such cases, achieving the required out-of-equilibrium decay would necessitate a reheating temperature exceeding the GUT scale, which—as discussed earlier—is disfavored by cosmological observations.

However, the most widely accepted resolution to this dilemma is to generate a net $(B-L)$ asymmetry dynamically in the early Universe, using right-handed neutrinos. If the decay of heavy right-handed neutrinos occurs out of equilibrium and violates both L and CP, it can produce a net lepton asymmetry. This lepton asymmetry is then partially converted into a baryon asymmetry through electroweak sphaleron processes. This mechanism is known as leptogenesis [414].

If the three heavy Majorana neutrinos have a hierarchical

[15] Strictly speaking, if lepton flavor asymmetries L_i $(i=1,2,3)$ are present with $(L_i-L_j)\neq0$ for $i\neq j$, nonzero values of B and L may persist even when $(B-L)=0$ [243].

mass spectrum, the net lepton asymmetry is primarily generated by the decay of the lightest one. The resulting asymmetry is proportional to the CP asymmetry in its decay. It is found that in order to account for the observed baryon asymmetry of the Universe, the mass of the lightest heavy neutrino must be $\gtrsim 10^9$ GeV [415, 416].[16] Consequently, the reheating temperature after inflation must also be $\gtrsim 10^9$ GeV to ensure thermal production of the heavy neutrinos. In SUSY models, however, there exists a potential tension between the thermal leptogenesis and Big Bang Nucleosynthesis (BBN), particularly if gravitinos are long-lived and decay during or after the BBN epoch. This so-called gravitino problem imposes an upper bound on the reheating temperature, typically in the range $\lesssim 10^{6\text{–}10}$ GeV, depending on the details of the SUSY breaking scenario [419]. This tension can be alleviated in the non-thermal leptogenesis scenario, in which right-handed neutrinos are produced non-thermally via the decay of inflaton [420–422]. For recent reviews of leptogenesis, see Refs. [423–425].

One of the key experimental probes of leptogenesis is the search for neutrinoless double-beta ($0\nu\beta\beta$) decay. In $0\nu\beta\beta$ decay, a nucleus emits two electrons without accompanying (anti)neutrinos, in contrast to the standard double-beta decay, where two antineutrinos are emitted alongside the electrons. This process violates lepton number by two units ($\Delta L = 2$). At the nucleon level, $0\nu\beta\beta$ decay is described by dimension-nine effective operators mediating the process $nn \to ppee$. These operators can originate from combinations of SM weak interactions and lower-dimensional L-violating operators. The leading contribution typically arises from the dimension-five Weinberg operator in Eq. (92.17). Thus, if lepton-number violation originates at energy scales much higher than the electroweak scale, the $0\nu\beta\beta$ decay rate is proportional to the Majorana neutrino masses. The current experimental status of $0\nu\beta\beta$ searches is reviewed in Ref. [170]. For recent studies incorporating all SM effective operators up to dimension nine, see Ref. [426] and references therein.

In addition to lepton-number violation, one can also consider processes that violate B or $(B - L)$. Such processes are of intrinsic theoretical interest and may also play a role in baryogenesis. The relevant operators typically have mass dimensions higher than the well-known dimension-six $(B + L)$-violating operators (cf., Sec. 92.6). Such higher-dimensional operators may arise in SO(10) GUTs featuring an intermediate scale at which baryogenesis is realized, as discussed in Refs. [427–429]. For instance, one may consider interactions that induce nucleon decay with $\Delta(B - L) = 2$, such as $n \to e^- \pi^+$. These processes are mediated by dimension-seven effective operators in the SM, suppressed by the Higgs VEV or derivative interactions. Another important class involves neutron-antineutron (n–$\bar{n}$) oscillations, which violate baryon number by two units ($\Delta B = 2$) and are described by dimension-nine effective operators. The current experimental lower bound on the n–$\bar{n}$ oscillation time is derived using free neutrons [430], while complementary constraints come from limits on the decay of bound neutrons in ^{16}O, obtained by Super-Kamiokande [431]. These bounds are of similar magnitude. Super-Kamiokande has also searched for dinucleon decay modes with $\Delta B = 2$, such as $pp \to \pi^+\pi^+$ and $nn \to \pi^\pm\pi^\mp$ [432].

92.9.6 *The QCD Axion*

The axion is a pseudo-Nambu–Goldstone boson arising from the spontaneous breaking of the Peccei–Quinn symmetry, which is capable of resolving the strong CP problem [433–436] and may potentially be related to GUT physics.[17] In particular, the strength of the direct coupling of the QCD axion to photons, relative to its coupling to gluons, may be seen as a phenomenological signature of grand unification. It is quantified by the predicted anomaly ratio $E/N = 8/3$ (see Sec. 89 and Refs. [443, 444]). This ratio follows from the GUT normalization of the relevant generators together with the completeness of GUT multiplets contributing to the anomaly.[18] It hence arises in both the DFSZ [445, 446] and KSVZ [447, 448] axion models as long as the Peccei-Quinn symmetry commutes with the GUT group (see, *e.g.*, [449, 450]). We, however, note that, in bottom-up approaches and in the presence of split GUT multiplets, other anomaly ratios can appear (cf., *e.g.*, Refs. [451, 452]). Their embedding in a UV GUT structure, possibly with explicit GUT symmetry breaking, requires case-by-case study. The ratio $E/N = 8/3$ also arises in string-theoretic GUTs [443, 453]. In this case, the axion does not come from the phase of a complex scalar but is a fundamental shift-symmetric real field, coupling through a higher-dimension operator directly to the product of the GUT field-strength and its dual.

92.10 Conclusion

In its most conservative form, grand unification assumes that some or all of the SM gauge interactions—$\mathrm{U}(1)_Y$, $\mathrm{SU}(2)_L$, and $\mathrm{SU}(3)_C$—are embedded within a larger gauge symmetry at high energies. In most models, particularly in the simplest and most compelling realizations based on SU(5) or SO(10), the unification hypothesis goes significantly further: one expects the SM gauge couplings to merge (up to small threshold corrections) at a single unification scale, M_G, the SM matter fields to be (partially) unified into larger multiplets, and the nucleon to become unstable due to exchange of GUT-scale fields. SUSY GUTs provide by far the most predictive and economical framework that achieves perturbative gauge coupling unification. Further details beyond the scope of this article can be found in reviews [321, 454–456] and textbooks [457–460]. See also Refs. [461, 462] for more recent overviews.

Thus, the three classical pillars of GUTs are: gauge coupling unification at $M_G \simeq 2 \times 10^{16}$ GeV, low-energy SUSY (with a large SUSY desert), and nucleon decay. Among these, gauge coupling unification remains robust even if the SUSY particle masses lie somewhat above the weak scale. However, from a conceptual standpoint, the steadily increasing experimental lower bound on the SUSY scale poses a challenge for the SUSY GUT framework. If the original motivation for low-energy SUSY—namely, the stabilization of the electroweak scale—is entirely discarded, then the SUSY scale becomes an arbitrary parameter, and the first two pillars lose their theoretical foundation. This highlights the importance of continuing to improve bounds on nucleon decay, which—though not a universal prediction of all GUT models—is arguably a more generic and robust feature of grand unification than low-energy SUSY.

Whether or not Yukawa couplings unify is highly model dependent. Nevertheless, regardless of the degree to which Yukawa unification is realized, there exists a rich and potentially fruitful interplay between flavor model building and grand unification. This interplay is particularly pronounced in the neutrino sector, where ongoing experimental developments continue to shape theoretical approaches.

It is probably fair to say that, due to limitations of the 4d approach, including especially remaining ambiguities (free parameters or ad hoc assumptions) in models of flavor and GUT breaking, the string theoretic approach has become more important in GUT model building. In this framework, challenges include learning how to deal with the many vacua of the 'landscape' as well as, for each vacuum, developing the tools for reliably calculating phenomenological observables. Finally, due to limitations of space, the present article has barely touched on the interesting cosmological implications of GUTs. They may become more important in the future, especially in the case that a high inflationary energy scale is established observationally.

[16] This requirement can be circumvented in resonant leptogenesis [417, 418], where the heavy right-handed neutrinos are nearly degenerate in mass.

[17] For alternative approaches to addressing the strong CP problem within the context of GUTs, see Refs. [437–442].

[18] See, *e.g.*, Eq. (312) of Ref. [444].

93. Leptoquarks

Revised October 2025 by S. Rolli (DOE) and M. Tanabashi (Nagoya U.; KMI, Nagoya U.).

Leptoquarks (LQs) are hypothetical particles carrying both baryon number (B) and lepton number (L). The possible quantum numbers of LQ states can be constrained by assuming that their direct interactions with the ordinary Standard Model (SM) fermions are dimensionless and invariant under the SM gauge group. Table 93.1 lists all possible quantum numbers under this assumption [1]. The columns labeled $SU(3)_C$, $SU(2)_W$, and $U(1)_Y$ in Table 93.1 indicate the QCD representation, the weak isospin representation, and the weak hypercharge, respectively. The spin of a LQ state is taken to be either 1 (vector LQ) or 0 (scalar LQ). If we do not require LQ states to couple directly with SM fermions, quantum number assignments beyond those listed in Table 93.1 become possible [2,3].

LQ states are predicted in various extensions of the SM. The Pati-Salam model [4] is one such example. LQs also apear in grand unified theories based on $SU(5)$ [5], $SO(10)$ [6] which includes Pati-Salam color $SU(4)$, and larger gauge groups. The presence of LQs at TeV-scale affect the renormalization group of the standard model gauge coupling strengths and may enable gauge coupling unification required by the grand unified theories [7]. Scalar quarks in supersymmetric models with R-parity violation may also exhibit LQ-like Yukawa couplings. Consequently, bounds on LQ states can constrain R-parity-violating supersymmetric models [8,9]. LQs are expected to exist at the TeV-scale in extended technicolor models [10,11] where they appear as bound states of techni-fermions. Models involving quark and lepton compositeness also predict light LQ states [12]. LQ-induced two-quark two-lepton interactions often lead to lepton-flavor non-universalities in heavy quark decays. The so called $R(D)$, $R(D^*)$ anomaly observed in the semi-leptonic B decays [13] may be explained by models with TeV-scale LQs.

Bounds on LQ states are obtained both directly and indirectly. Direct limits arise from production cross sections at colliders, while indirect limits are derived from constraints on LQ-induced two-quark two-lepton interactions. The quantum number assignments in Table 93.1 allow several LQ states to couple to both left- and right-handed quarks simultaneously. Such LQ states are termed non-chiral and give rise to low-energy interactions of the form:

$$(\bar{u}_R q_{Li})(\bar{e}_R \ell_{Lj})\epsilon^{ij} \qquad (\bar{d}_R q_{Li})(\bar{\ell}^i_L e_R)\,. \tag{93.1}$$

Here q_L and ℓ_L denote the left-handed quark and lepton $SU(2)_W$ doublets, while u_R, d_R and e_R are the right-handed up-type quark, down-type quark and charged lepton $SU(2)_W$ singlets. Indices i and j correspond to weak isospin, and ϵ^{ij} is the antisymmetric Levi-Civita tensor of $SU(2)_W$. These interactions affect the ratio $\Gamma(\pi \to e\nu)/\Gamma(\pi \to \mu\nu)$ [14]. Non-chiral scalar LQs also contribute to the anomalous magnetic moments of charged leptons [15,16]. On the other hand, chiral LQ exchanges induce effective two-quark two-lepton interactions below the LQ mass scale:

$$\begin{array}{lll}
(\bar{q}^i_L\gamma^\mu q_{Li})(\bar{\ell}^j_L\gamma_\mu \ell_{Lj})\,, & (\bar{q}^i_L\gamma^\mu q_{Li})(\bar{e}_R\gamma_\mu e_R)\,, & (\bar{q}^i_L\gamma^\mu(\vec{\sigma})_i{}^j q_{Lj})\cdot(\bar{\ell}^k_L\gamma_\mu(\vec{\sigma})_k{}^l \ell_{Ll})\,, \\
(\bar{u}_R\gamma^\mu u_R)(\bar{\ell}^j_L\gamma_\mu \ell_{Lj})\,, & (\bar{u}_R\gamma^\mu u_R)(\bar{e}_R\gamma_\mu e_R)\,, & \\
(\bar{d}_R\gamma^\mu d_R)(\bar{\ell}^j_L\gamma_\mu \ell_{Lj})\,, & (\bar{d}_R\gamma^\mu d_R)(\bar{e}_R\gamma_\mu e_R)\,. &
\end{array} \tag{93.2}$$

Here $(\vec{\sigma})_i{}^j$ denotes the Pauli matrices of $SU(2)_W$. Generation labels for quarks and leptons are suppressed in (93.1) and (93.2). If a LQ couples to quarks and leptons from multiple generations in the mass eigenbasis, it can induce flavor-changing neutral currents and lepton-family-number violations. Indirect limits provide stringent constraints on non-chiral or flavor-violating LQs. Therefore, collider searches often assume that a LQ state couples only to a single generation of quarks and leptons in a chiral interaction, for which indirect limits are weaker. LQs that couple exclusively to the first, second, and third generation are referred to as first-, second-, and third-generation LQs, respectively. It is also possible to consider LQ states which couple dominantly with the i-th generation quarks and the j-th generation leptons ($i \neq j$) without conflicting with indirect constraints. Such couplings have recently gained renewed attention. See Ref. [17,18] and [19], and references therein for collider search strategies and limits on the pair-production cross sections of this class of LQ states.

Limits on the LQ induced two-quark two-lepton interactions can be derived from low-energy experiments and from collider experiments below threshold. Refs. [20–22] give extensive lists of such limits. For the isoscalar scalar and vector LQs, S_0 and V_0, for example, which couple with the first- (second-) generation left-handed quark, and the first-generation left-handed lepton, the bounds $\lambda^2 < 0.07 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for S_0, and $\lambda^2 < 0.4 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for V_0 ($\lambda^2 < 0.7 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for S_0, and $\lambda^2 < 0.5 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for V_0) can be derived from the limits listed in Ref. [22]. Here λ and $M_{\rm LQ}$ denote the LQ coupling strength and the LQ mass, respectively. See also Refs. [23,24] for earlier studies. The e^+e^- collider experiments are sensitive to the indirect effects coming from t- and u-channel exchanges of LQs in the $e^+e^- \to q\bar{q}$ process. The HERA experiments give bounds on the LQ-induced two-quark two-lepton interaction. It should also be stressed that the measurements of the high-mass Drell-Yan (DY) cross sections, $pp \to \ell\nu$ and $pp \to \ell^+\ell^-$, and low energy neutrino-nucleus coherent scattering measurements [25] are also sensitive to these LQ-induced interactions. NLO QCD corrections to the neutral DY process have been computed in the context of LQ models in Refs. [26,27]. For detailed bounds obtained in this way, see *e.g.,* Ref. [21], and the Heavy Boson Particle Listings under "Indirect Limits for Leptoquarks", and the references therein.

The two-quark two-lepton interactions arising from the LQ exchanges in Eq.(93.1) and Eq.(93.2) can also be interpreted as contributions to more general dimension-six operators within the framework of the SM Effective Field Theory (SMEFT). See *e.g.,* Refs. [28, 29] for reviews. A complete catalog of SM gauge-invariant dimension-six operators can be found in Refs. [30, 31]. A computation of the one-loop anomalous dimension matrix for SMEFT operators are found in Refs. [32–34]. LQ-induced two-quark two-lepton interactions may cause the lepton flavor non-universality in the heavy quark decays. In particular, models with TeV-scale LQs may accommodate solutions to the $R(D)$ and $R(D^*)$ anomaly [13] observed in the semi-leptonic $b \to c$ decays.

Collider experiments provide direct limits on the LQ states through limits on the pair- and single-production cross sections. Among these, constraints on single-production often yield limits severer than those on pair-production. This is because, when particles colliding in the collider interact directly and strongly enough with heavy LQ particles, the energy required for the LQ production is lower in the single-production processes. Conversely, if the direct interaction between the colliding particles and LQs is weak, constraints from pair-production processes become more relevant.

LQs are produced singly in ep collisions through

$$e + q \to {\rm LQ}\,, \tag{93.3}$$

and at hadron colliders through [35],

$$g + q \to {\rm LQ} + \ell\,. \tag{93.4}$$

Depending on the LQ coupling with $q\ell$, the LQ single-production process (93.4) allows extending the mass reach higher than the

mass reach of the pair-production process [36]. The NLO computations for the single-production of the scalar LQ states at the LHC energies have been performed in Refs. [37–40]. Since protons contain leptons inside, it is possible to target lepton-induced processes (93.3) at high energy pp colliders. For a scalar LQ, the leading-order single-production cross section of the parton process (93.3) may be written as

$$\hat{\sigma}_{\rm LO}\left[eq \to {\rm LQ}\right] = \frac{\pi\lambda^2}{4}\delta(\hat{s} - M_{\rm LQ}^2)\,. \tag{93.5}$$

The LQ Yukawa coupling is denoted by λ. The single LQ production cross sections induced from the lepton-quark collisions at the LHC have been computed at LO in Refs. [41–43] and at NLO in Ref. [44]. Ref. [45] performed searches for the LQ states produced in lepton-quark collisions at the LHC.

Pair-production of LQs has been studied at LHC, Tevatron and LEP. The LQ pair-production cross sections in e^+e^- collisions depend on the LQ $SU(2)_W \times U(1)_Y$ quantum numbers and Yukawa coupling with electron [46]. For a scalar LQ, the leading-order pair-production cross sections of the parton processes at hadron colliders

$$\begin{aligned} q + \bar{q} &\to {\rm LQ} + \overline{\rm LQ} \\ g + g &\to {\rm LQ} + \overline{\rm LQ} \end{aligned} \tag{93.6}$$

may be written as [47]

$$\begin{aligned} \hat{\sigma}_{\rm LO}\left[q\bar{q} \to {\rm LQ} + \overline{\rm LQ}\right] &= \frac{2\alpha_s^2\pi}{27\hat{s}}\beta^3, \\ \hat{\sigma}_{\rm LO}\left[gg \to {\rm LQ} + \overline{\rm LQ}\right] &= \frac{\alpha_s^2\pi}{96\hat{s}} \times \\ &\left[\beta(41 - 31\beta^2) + (18\beta^2 - \beta^4 - 17)\log\frac{1+\beta}{1-\beta}\right]. \end{aligned} \tag{93.7}$$

Here $\sqrt{\hat{s}}$ is the invariant energy of the parton subprocess, and $\beta \equiv \sqrt{1 - 4M_{\rm LQ}^2/\hat{s}}$. The QCD gauge coupling is given by

$$\alpha_s \equiv \frac{g_s^2}{4\pi}\,. \tag{93.8}$$

The cross sections of the pair-productions of scalar LQs in pp collisions at the LHC energies have been computed in Refs. [48,49] at the next-to-leading order (NLO) in QCD. The gauge couplings of a scalar LQ are determined uniquely according to its quantum numbers in Table 93.1. Since all of the LQ states belong to color-triplet representation, the QCD-induced scalar LQ pair-production cross section at the Tevatron and LHC can be determined solely as a function of the LQ mass without making further assumptions if we are able to neglect contributions from electroweak and Yukawa interactions in the parton cross sections. This is in contrast to the indirect or single-production limits, which give constraints in the LQ mass-coupling plane.

Vector LQ pair-production calculation often violate perturbative unitarity at high energies. Ultraviolet (UV) completion is required, either via extending gauge symmetries (treating vector LQs as gauge bosons) or compositeness (treating them as bound states). Additional heavy particles are typically introduced in both scenarios. Magnetic-dipole and electric-quadrupole interactions of vector LQs are not fixed by gauge quantum numbers [50]. LHC searches often assume gluon-mediated diagrams dominate near threshold, with two benchmark chromomagnetic dipole moments: Yang-Mills case ($\kappa = 1$) and minimal-coupling case ($\kappa = 0$).

Due to the typical decay of the LQ into charged and neutral leptons and quarks, the searches for the LQ states in collider experiments are carried on in signatures including high p_T charged leptons, high E_T jets and large missing transverse energy. Additionally, searches for pair-produced LQs are often organized by the decay mode of the pair of LQs, via the decay parameter β, which represents the branching fraction into a charged lepton vs a neutrino: $\beta = 1$ for LQs decaying into a charged lepton with 100% branching fraction, $\beta = 0.5$ for LQs decaying into a charged lepton with 50% branching fraction. It is worth noting that organizing LQs by flavor quantum number first before organizing them by gauge quantum number is becoming more common and advantageous because it relates more closely to some of the experimental searches being performed at the hadron colliders. See Ref. [21] for a comprehensive review on the LQ phenomenology in precision experiments and particle colliders.

Since the previous versions of this review, both ATLAS and CMS continue to update their results concerning searches for pair-productions of first, second, and third generation LQs and LQ states which couple only with the i-th generation quarks and the j-th generation leptons ($i \neq j$) without causing conflicts with severe indirect constraints. The datasets were almost all collected at center of mass energy of 13 TeV and corresponding to the latest integrated luminosity collected before the shutdown of the LHC occurring in 2019 and 2020. Older results from the Tevatron run can be found here: [51–54].

Current results extend previous mass limits for scalar LQs to > 1435 GeV (first generation, CMS, $\beta = 1$, $\sqrt{s} = 13$ TeV) and > 1270 GeV (first generation, CMS, $\beta = 0.5$, $\sqrt{s} = 13$ TeV) [55]; > 1800 GeV (first generation, ATLAS, $\beta = 1$, $\sqrt{s} = 13$ TeV) [56] and > 1290 GeV (first generation, ATLAS, $\beta = 0.5$, $\sqrt{s} = 13$ TeV) [57]; > 1530 GeV (second generation, CMS, $\beta = 1$, $\sqrt{s} = 13$ TeV) and > 1285 GeV (second generation, CMS, $\beta = 0.5$, $\sqrt{s} = 13$ TeV) [58]; and > 1700 GeV (second generation, ATLAS, $\beta = 1$, $\sqrt{s} = 13$ TeV) [56] and > 1230 GeV (second generation, ATLAS, $\beta = 0.5$, $\sqrt{s} = 13$ TeV) [57]. All limits are presented at 95% confidence level (C.L.).

As for third generation LQs, CMS results are the following: 1) assuming that all LQs decay to a top quark and a τ lepton, the existence of pair-produced, third-generation LQ up to a mass of 1120 GeV ($\beta = 1$, $\sqrt{s} = 13$ TeV) is excluded at 95% C.L. [59]; 2) assuming that all LQs decay to a bottom quark and a τ lepton, the existence of pair-produced, third-generation LQ up to a mass of 1020 GeV ($\beta = 1$, $\sqrt{s} = 13$ TeV) is excluded at 95% C.L. [60]; 3) assuming that all LQs decay to a bottom quark and a τ neutrino, the existence of pair-produced, third-generation LQ up to a mass of 1185 GeV ($\beta = 0$, $\sqrt{s} = 13$ TeV) is excluded at 95% C.L. [61]. In [62] signatures of $t\tau\nu b$ and $t\tau\nu$ were analyzed in the context of searches for scalar LQ of charge $(-1/3)e$ coupling to $t\tau$ or $b\nu$, or a vector particle of charge $(2/3)e$, coupling to $t\nu$ or $b\tau$. These choices are motivated by models that can explain a series

of anomalies observed in the measurement of B meson decays. The data are found to be in agreement with the SM prediction. Lower limits at 95% C.L. are set on the LQ mass in the range 0.98–1.73 TeV, depending on the LQ spin and its coupling λ to a lepton and a quark, and assuming equal couplings for the two LQ decay modes considered.

In [63] ATLAS present the result of searches for pair-production of third-generation scalar LQs decaying into a top quark and a τ-lepton, using 139 fb^{-1} of data collected at 13 TeV. Scalar LQs decaying exclusively into tτ are excluded up to masses of 1.43 TeV while, for a branching fraction of 50% into tτ , the lower mass limit is 1.22 TeV. In [64] and [65] ATLAS searched for pair-produced scalar or vector LQs decaying into a b-quark and a τ-lepton. Scalar LQ masses below 1.46 TeV are excluded assuming a 100% branching ratio, while for vector LQs the corresponding limit is 1.91 TeV (1.65 TeV) in the Yang–Mills $\kappa = 1$ (minimal-coupling $\kappa = 0$) scenario. Additionally, a search for pair-production of LQs with decays into third-generation leptons and quarks in final states with hadronically decaying τ leptons, b-jets, and missing transverse momentum was performed in [66]: depending on the branching fraction into charged leptons, LQs with masses up to around 1.25 TeV can be excluded at the 95% C.L. for the case of scalar LQs and up to 1.8 TeV (1.5 TeV) for vector LQs in a Yang–Mills (minimal-coupling) scenario.

As we explained before, the LQ models which couples only to quarks of the i-th generation and leptons of the j-th generation ($i \neq j$) are attracting attention. In this framework, in [67] and [59] CMS presents a search for pair-production of LQs coupled to a top quark and a leptons. As no deviation from the SM prediction was observed, scalar LQs decaying exclusively into top quark and lepton are excluded below $1.12 - 1.42$ TeV depending on the lepton flavor. In [68] ATLAS conducted a search for pair-production of LQs, each decaying into first and second generation leptons and a third generation quarks. This is part of LQ search using ATLAS data to investigate cross- generational couplings. All possible decays of the pair-produced LQs into quarks of the third generation and charged or neutral leptons of the first or second generation with exactly one electron or muon in the final state are investigated. No significant deviations from the SM expectation are observed. Upper limits on the production cross-section are provided for different models as a function of the LQ mass and the branching ratio of the LQ into the charged or neutral lepton. Some of these models have the goal of providing an explanation for the recent B-anomalies. In such models, a vector LQ decays into charged and neutral leptons of the second generation with a similar branching fraction. Lower limits of 1.98 TeV (1.71 TeV) are set on the vector leptoquark mass for Yang-Mills (minimal-coupling) scenario with $B(b\mu) = B(t\nu) = 0.5$. In [69] CMS search for pair-production of scalar and vector LQs decaying to μb. Assuming $B(\mu b) = 1$, Scalar LQs with $M_{\rm LQ} < 1.81$ TeV are excluded with 95% C.L.; Vector LQs with $M_{\rm LQ} < 2.46$ TeV (2.12 TeV) are excluded in the Yang-Mills (minimal) coupling scenario. CMS also set limits on the t-channel vector LQ exchange $\tau\tau$ production amplitude [70] and $\tau\nu$ production amplitude [71] in pp collisions at $\sqrt{s} = 13$ TeV. Their limits on the dimensionless vector LQ coupling to $q\tau$ and $q\nu$ range from 1 for $M_{\rm LQ} = 1$ TeV to 6 for $M_{\rm LQ} = 5$ TeV, depending on the scenario. ATLAS search result for pair-production of scalar and vector LQs decaying to te or $t\mu$ have been reported in [72]. Under the assumption of exclusive decays into te ($t\mu$), the lower limit on the scalar LQ mass is at 1.58 TeV (1.59 TeV), on the vector LQ mass with Yang-Mills coupling at 1.95 TeV (1.95 TeV), and on the vector LQ mass with minimal-coupling at 1.67 TeV (1.67 TeV). In [73] ATLAS have reported their results on searches for pair-production of scalar LQ decaying into $c\tau$. LQs with masses below 1.3 TeV are excluded at 95% C.L. when $B(c\tau) = 1$. A statistical combination of ATLAS searches for pair-produced LQs decaying into a third generation quark (t or b) and any charged or neutral lepton has been reported in [74]. The lower limits on the masses of scalar LQs range from 1.23 TeV to 1.73 TeV, depending on the branching ratio, LQ charge and flavor. Limits are also placed on benchmark vector LQ models. The mass limit on the charge $(2/3)e$ vector LQ ranges from 1.84 TeV to 1.98 TeV (from 1.58 TeV to 1.71 TeV) for 50% branching fraction, depending on LQ flavor in the Yang-Mills case $\kappa = 1$ (minimal-coupling case $\kappa = 0$).

Previous search results from CMS for squarks and gluinos have been reinterpreted to constrain models of LQ pair-production [75]. For a vector LQ decaying to $t\nu$ with 50% branching fraction, masses below 1.53 TeV are excluded assuming the Yang-Mills case $\kappa = 1$, or 1.115 TeV in the minimal-coupling case $\kappa = 0$. These results and the ones in [76] were updated in [61] where searches for phenomena beyond the standard model (BSM) were performed using events with hadronic jets and significant transverse momentum imbalance to constrain a range of BSM models including the pair-production of LQs each decaying to a neutrino and a top, bottom, or light-flavor quark.

Searches for first generation LQ singly produced were performed by the HERA experiments. Since the leptoquark single-production cross section depends on its Yukawa coupling, the LQ mass limits from HERA are usually displayed in the mass-coupling plane. For leptoquark Yukawa coupling $\lambda = 0.1$, early ZEUS Collaboration bounds on the first-generation LQ range from 248 to 290 GeV, depending on the LQ species [77]. The ZEUS Collaboration has released a paper [78] where data corresponding to a luminosity of around 1 fb^{-1} have been used in the framework of $eeqq$ contact interactions (CI) to set limits on possible high-energy contributions beyond the SM to electron-quark scattering. The analysis of the ep data has been based on simultaneous fits of parton distribution functions including contributions of Contact Interaction (CI) couplings to ep scattering. Several general CI models and scenarios with heavy leptoquarks were considered. As unambiguous deviations from the SM cannot be established, limits for CI compositeness scales and LQ mass scales were set that are in the TeV range. The H1 Collaboration has a comprehensive summary of searches for first generation LQs using the full data sample collected in ep collisions at HERA (446 pb^{-1}). No evidence of production of LQs was observed in final states with a large transverse momentum electron or large missing transverse momentum. For a coupling strength $\lambda = 0.3$, first generation leptoquarks with masses up to 800 GeV are excluded at 95% C.L. [79].

At the LHC, the CMS collaboration performed searches for single-production of first and second generation LQs [80], which is complementary to the HERA searches in the high λ region (for coupling strength $\lambda = 1.0$, first generation leptoquarks are excluded for masses up to 1.73 TeV and second generation leptoquark are excluded up to masses of 530 GeV). CMS also searched for third generation LQ decaying into τ and bottom in [81]. Assuming unit Yukawa coupling (λ), a third generation scalar LQ is excluded for masses below 740 GeV. Limits are also set on λ of the hypothesized LQ as a function of its mass. Above $\lambda = 1.4$, the results provide the best upper limit on the mass of a third-generation scalar LQ decaying to a τ lepton and a bottom quark. In [82] a CMS search is presented for a LQ coupled exclusively to $b\tau$. Events with τ and a varying number of jets originating from b are considered, targeting the single- and pair-production of LQs, as well as non-resonant t-channel LQ exchange. An excess is observed and for a benchmark LQ model with $M_{\rm LQ} = 2$ TeV and its coupling with $b\tau$ of 2.5, the excess reaches a local significance of 2.8σ. LQs are excluded below masses of 1.22–1.88 TeV for different LQ models and varying coupling strengths up to 2.5. In [64] and [65] ATLAS searched for single-production of vector LQ with electric charge of $(2/3)e$ and scalar LQ with an electric charge of $(4/3)e$ via bg fusion. For single vector LQ production Two models are considered: the Yang–Mills and Minimal-coupling models. Vector LQs with a mass below 1.58 TeV (1.35 TeV) are excluded in the Yang–Mills (minimal-coupling) scenario, for a LQ coupling of 1.0 and below 2.05 TeV (1.99 TeV) for a LQ coupling of 2.5. scalar LQ masses below 1.28 TeV (1.53 TeV) are excluded for a LQ Yukawa coupling of 1.0 (2.5). Single-production of a multigenerational scalar LQ has also been searched by ATLAS in [83] via charged-lepton-flavor-violating process. In [45] CMS search results for scalar LQ singly produced via quark-τ fusion have been reported.

Searches for LQ will continue with more LHC data, particularly in light of the renewed interest in this type of particle to explain violation of lepton flavor universality and other anomalies, which

point to explanations laying outside the Standard Model.

94. Magnetic Monopoles

Revised August 2025 by D. Milstead (Stockholm U.) and E.J. Weinberg (Columbia U.).

94.1 Theory of magnetic monopoles

The symmetry between electric and magnetic fields in the source-free Maxwell's equations naturally suggests that electric charges might have magnetic counterparts, known as magnetic monopoles. Although the greatest interest has been in the supermassive monopoles that are a firm prediction of all grand unified theories, one cannot exclude the possibility of lighter monopoles.

In either case, the magnetic charge is constrained by a quantization condition first found by Dirac [1]. Consider a monopole with magnetic charge Q_M and a Coulomb magnetic field

$$\mathbf{B} = \frac{Q_M}{4\pi}\frac{\hat{\mathbf{r}}}{r^2}\,. \tag{94.1}$$

Any vector potential $\mathbf{A}$ whose curl is equal to $\mathbf{B}$ must be singular along some line running from the origin to spatial infinity. This Dirac string singularity could potentially be detected through the extra phase that the wavefunction of a particle with electric charge Q_E would acquire if it moved along a loop encircling the string. For the string to be unobservable, this phase must be a multiple of 2π. Requiring that this be the case for any pair of electric and magnetic charges gives the condition that all charges be integer multiples of minimum charges $Q_E^{\rm min}$ and $Q_M^{\rm min}$ obeying

$$Q_E^{\rm min} Q_M^{\rm min} = 2\pi\,. \tag{94.2}$$

(For monopoles which also carry an electric charge, called dyons [2], the quantization conditions on their electric charges can be modified. However, the constraints on magnetic charges, as well as those on all purely electric particles, will be unchanged [3].)

Another way to understand this result is to note that the conserved orbital angular momentum of a point electric charge moving in the field of a magnetic monopole has an additional component, with

$$\mathbf{L} = m\mathbf{r}\times\mathbf{v} - \frac{1}{4\pi}Q_E Q_M \hat{\mathbf{r}} \tag{94.3}$$

Requiring the radial component of $\mathbf{L}$ to be quantized in half-integer units yields Eq. 94.2.

If there are unbroken gauge symmetries in addition to the U(1) of electromagnetism, the above analysis must be modified [4, 5]. The allowed color-magnetic charges are determined by the global structure of the gauge group, e.g., $SU(3)\times U(1)$ vs. $(SU(3)\times U(1))/\mathbb{Z}_3$. For example, in QCD the global structure of the gauge group could be $SU(3)\times U(1)$ or $(SU(3)\times U(1))/\mathbb{Z}_3$. In the latter case the magnetic monopole may carry a $\mathbb{Z}_3$-valued color-magnetic charge. While the color-magnetic charge does not lead to a long-range color magnetic field, its existence modifies the phase quantization underlying Eq. 94.2: the color and color-magnetic charges of a quark combine with the $U(1)$ magnetic charge to render the Dirac string unobservable; so that the U(1) charge could be the Dirac charge $Q_M^D \equiv 2\pi/e$, the result that would be obtained by substituting the electron charge into Eq. (94.2). On the other hand, for monopoles without color-magnetic charge, one would simply insert the quark electric charges into Eq. 94.2 and conclude that Q_M must be a multiple of $6\pi/e$. This is the minimal magnetic charge when the gauge group is not modded out by $\mathbb{Z}_3$.

The prediction of GUT monopoles arises from the work of 't Hooft [6] and Polyakov [7], who showed that certain spontaneously broken gauge theories have nonsingular classical solutions that lead to magnetic monopoles in the quantum theory. The simplest example occurs in a theory where the vacuum expectation value of a triplet Higgs field ϕ breaks an SU(2) gauge symmetry down to the U(1) of electromagnetism and gives a mass M_V to two of the gauge bosons. In order to have finite energy, ϕ must approach a vacuum value at infinity. However, there is a continuous family of possible vacua, since the scalar field potential determines only the magnitude v of $\langle\phi\rangle$, but not its orientation in the internal SU(2) space. In the monopole solution, the direction of ϕ in internal space is correlated with the position in physical space; *i.e.*, $\phi^a \sim v\hat{r}^a$. The stability of the solution follows from the fact that this twisting Higgs field cannot be smoothly deformed to a spatially uniform vacuum configuration. Reducing the energetic cost of the spatial variation of ϕ requires a nonzero gauge potential, which turns out to yield the magnetic field corresponding to a charge $Q_M = 4\pi/e$. Numerical solution of the classical field equations shows that the mass of this monopole is

$$M_{\rm mon} \sim \frac{4\pi M_V}{e^2}\,. \tag{94.4}$$

The essential ingredient here was the fact that the Higgs fields at spatial infinity could be arranged in a topologically nontrivial configuration. A discussion of the general conditions under which this is possible is beyond the scope of this review, so we restrict ourselves to the two phenomenologically most important cases.

The first is the standard electroweak theory, with $\mathrm{SU}(2)\times\mathrm{U}(1)$ broken to U(1). There are no topologically nontrivial configurations of the Higgs field, and hence no topologically stable monopole solutions. Although electroweak scale monopoles are thus not required, there have been claims that they might not be ruled out. For example, there have been a variety of proposals in this direction involving modifications of the Lagrangian.

The second case is when any simple Lie group is broken to a subgroup with a U(1) factor, a case that includes all grand unified theories. Here the spectrum of states must include a topologically stable monopole whose mass is determined by the mass scale of the symmetry breaking that allows nontrivial topology. For example, an SU(5) model with

$$\mathrm{SU}(5) \xrightarrow{M_X} (\mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1))/\mathbb{Z}_6 \xrightarrow{M_W} (\mathrm{SU}(3)\times\mathrm{U}(1))/\mathbb{Z}_6 \tag{94.5}$$

has a monopole [8] with $Q_M = 2\pi/e$ and mass

$$M_{\rm mon} \sim \frac{4\pi M_{\rm X}}{g^2}\,, \tag{94.6}$$

where g is the SU(5) gauge coupling. For a unification scale of 10^{16} GeV, these monopoles would have a mass $M_{\rm mon} \sim 10^{17}$ – 10^{18} GeV.

In theories with several stages of symmetry breaking, monopoles of different mass scales can arise. In an SO(10) theory with

$$\begin{aligned}\mathrm{SO}(10) &\xrightarrow{M_1} (\mathrm{SU}(4)\times\mathrm{SU}(2)\times\mathrm{SU}(2))/\mathbb{Z}_2 \\ &\xrightarrow{M_2} (\mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1))/\mathbb{Z}_6\end{aligned} \tag{94.7}$$

there is monopole with $Q_M = 2\pi/e$ and mass $\sim 4\pi M_1/g^2$ and a much lighter monopole with $Q_M = 4\pi/e$ and mass $\sim 4\pi M_2/g^2$ [9].

The central core of a GUT monopole contains the fields of the superheavy gauge bosons that mediate baryon number violation, so one might expect that baryon number conservation could be violated in baryon–monopole scattering. The surprising feature, pointed out by Callan [10] and Rubakov [11], is that these processes are not suppressed by powers of the gauge boson mass. Instead, the cross-sections for catalysis processes such as p + monopole $\to e^+ + \pi^0$ + monopole are essentially geometric; *i.e.*, $\sigma_{\Delta B}\beta \sim 10^{-27}$ cm^2, where $\beta = v/c$. Note, however, that this catalysis is model-dependent and is not even a universal property of all GUT monopoles.

94.2 Production and Annihilation

GUT monopoles are far too massive to be produced in any foreseeable accelerator. However, they could have been produced in the early Universe as topological defects arising via the Kibble mechanism [12] in a symmetry-breaking phase transition. Estimates of the initial monopole abundance, and of the degree to which it can be reduced by monopole-antimonopole annihilation, predict a present-day monopole abundance that exceeds by many orders of magnitude the astrophysical and experimental bounds described below [13]. Cosmological inflation and other proposed solutions to this primordial monopole problem generically lead to present-day abundances exponentially smaller than could be plausibly detected, although potentially observable abundances can be obtained in scenarios with carefully tuned parameters.

Several theoretical models predict composite magnetic monopole solutions with masses of order of the electroweak scale (for a partial review see Ref. [14]). If monopoles light enough to be produced at colliders exist, one would expect that these could be produced by analogs of the electromagnetic processes that produce pairs of electrically charged particles. Because of the large size of the magnetic charge, this is a strong coupling problem for which perturbation theory cannot be trusted. The Schwinger production of monopole pairs mitigates the problem of the non-perturbative coupling due to the semi-classical calculation of production cross sections [15, 16]. Dyson-Schwinger resummation techniques have also been proposed as a solution to the non-perturbativity [17].

It should also be mentioned that bound monopole-antimonopole states may be formed (monopolium), the mass of which may be in reach at colliders [18, 19].

94.3 Astrophysical and Cosmological Bounds

If there were no galactic magnetic field, one would expect monopoles in the galaxy to have typical velocities of the order of $10^{-3}c$, comparable to the virial velocity in the galaxy (relevant if the monopoles cluster with the galaxy) and the peculiar velocity of the galaxy with respect to the CMB rest frame (relevant if the monopoles are not bound to the galaxy). This situation is modified by the existence of a galactic magnetic field $B \sim 3\mu$G. A monopole with the Dirac charge and mass M would be accelerated by this field to a velocity

$$v_{\rm mag} \sim \begin{cases} c, & M \lesssim 10^{11}{\rm GeV}\,, \\ 10^{-3}c\left(\frac{10^{17}\,{\rm GeV}}{M}\right)^{1/2}, & M \gtrsim 10^{11}{\rm GeV}\,. \end{cases} \tag{94.8}$$

Accelerating these monopoles drains energy from the magnetic field. Parker [20, 21] obtained an upper bound on the flux of monopoles in the galaxy by requiring that the rate of this energy loss be small compared to the time scale on which the galactic field can be regenerated. With reasonable choices for the astrophysical parameters (see Ref. [22] for details), this Parker bound is

$$F < \begin{cases} 10^{-15}\,{\rm cm}^{-2}\,{\rm sr}^{-1}\,{\rm sec}^{-1}\,, & M \lesssim 10^{17}\,{\rm GeV}\,, \\ 10^{-15}\left(\frac{M}{10^{17}\,{\rm GeV}}\right){\rm cm}^{-2}\,{\rm sr}^{-1}\,{\rm sec}^{-1}\,, & M \gtrsim 10^{17}\,{\rm GeV}\,. \end{cases} \tag{94.9}$$

Applying similar arguments to an earlier seed field that was the progenitor of the current galactic field leads to a tighter bound [23],

$$F < \left[\frac{M}{10^{17}{\rm GeV}} + (3\times 10^{-6})\right] 10^{-16}\,{\rm cm}^{-2}{\rm sr}^{-1}{\rm sec}^{-1}. \tag{94.10}$$

Considering magnetic fields in galactic clusters gives a bound [24] which, although less secure, is about three orders of magnitude lower than the Parker bound.

A flux bound can also be inferred from the total mass of monopoles in the Universe. If the monopole mass density is a fraction $\Omega_{\rm M}$ of the critical density, and the monopoles were uniformly distributed throughout the Universe, there would be a monopole flux

$$F_{\rm uniform} = 1.3{\times}10^{-16}\Omega_{\rm M}\left(\frac{10^{17}\,{\rm GeV}}{M}\right)\left(\frac{v}{10^{-3}c}\right){\rm cm}^{-2}{\rm sr}^{-1}{\rm sec}^{-1}. \tag{94.11}$$

If we assume that $\Omega_{\rm M} \sim 0.1$, this gives a stronger constraint than the Parker bound for $M \sim 10^{15}$ GeV. However, monopoles with masses $\sim 10^{17}$ GeV are not ejected by the galactic field and can be gravitationally bound to the galaxy. In this case their flux within the galaxy is increased by about five orders of magnitude for a given value of $\Omega_{\rm M}$, and the mass density bound only becomes stronger than the Parker bound for $M \sim 10^{18}$ GeV.

A much more stringent flux bound applies to GUT monopoles that catalyze baryon number violation. The essential idea is that compact astrophysical objects would capture monopoles at a rate proportional to the galactic flux. These monopoles would then catalyze proton decay, with the energy released in the decay leading to an observable increase in the luminosity of the object. A variety of bounds, based on neutron stars [25–29] , white dwarfs [30], and Jovian planets [31] have been obtained. These depend in the obvious manner on the catalysis cross section, but also on the details of the astrophysical scenarios; *e.g.*, on how much the accumulated density is reduced by monopole-antimonopole annihilation, and on whether monopoles accumulated in the progenitor star survive its collapse to a white dwarf or neutron star. The bounds obtained in this manner lie in the range

$$F\left(\frac{\sigma_{\Delta B}\beta}{10^{-27}{\rm cm}^2}\right) \sim (10^{-18} - 10^{-29}){\rm cm}^{-2}{\rm sr}^{-1}{\rm sec}^{-1}. \tag{94.12}$$

It is important to remember that not all GUT monopoles catalyze baryon number nonconservation. In particular, the intermediate mass monopoles that arise in some GUTs at later stages of symmetry-breaking are examples of theoretically motivated monopoles that are exempt from the bound of the above equation.

94.4 Searches for Magnetic Monopoles

To date there have been no confirmed observations of exotic particles possessing magnetic charge. Precision measurements of the properties of known particles have led to tight limits on the values of magnetic charge they may possess. Using the induction method (see below), the electron's magnetic charge has been found to be $Q_e^m < 10^{-24}Q_M^D$ [32]. Furthermore, measurements of the anomalous magnetic moment of the muon have been used to place a model dependent lower limit of 120 GeV on the monopole mass [1] [33]. Nevertheless, guided mainly by Dirac's argument and the predicted existence of monopoles from spontaneous symmetry breaking mechanisms, searches have been routinely made for monopoles produced at accelerators, in cosmic rays, and bound in matter [34]. Although the resultant limits from such searches are usually made under the assumption of a particle possessing only magnetic charge, most of the searches are also sensitive to dyons.

94.5 Search Techniques

Search strategies are determined by the expected interactions of monopoles as they pass through matter. These would give rise to a number of striking characteristic signatures. Since a complete description of monopole search techniques falls outside of the scope of this minireview, only the most common methods are described below. More comprehensive descriptions of search techniques can be found in Refs. [14, 35, 36].

The induction method exploits the long-range electromagnetic interaction of the monopole with the quantum state of a superconducting ring which would lead to a monopole which passes through such a ring inducing a permanent current. The induction technique typically uses Superconducting Quantum Interference Devices (SQUID) technology for detection and is employed for searches for monopoles in cosmic rays and matter. Another approach is to exploit the electromagnetic energy loss of monopoles. Monopoles with Dirac charge would typically lose energy at a rate which is several thousand times larger than that expected from particles possessing the elementary electric charge. Consequently, scintillators, gas chambers and nuclear track detectors (NTDs) have been used in cosmic ray and collider experiments. A further approach, which has been used at colliders, is to search for particles describing a non-helical path in a uniform magnetic field.

94.5.1 *Searches for Monopoles Bound in Matter*

Monopoles have been sought in a range of bulk materials which it is assumed would have absorbed incident cosmic ray monopoles over a long exposure time of order million years. Materials which have been studied include moon rock, meteorites, manganese modules, and sea water [37, 38]. A stringent upper limit on the monopoles per nucleon ratio of $\sim 10^{-29}$ has been obtained [38].

[1] Where no ambiguity is likely to arise, a reference to a monopole implies a particle possessing Dirac charge.

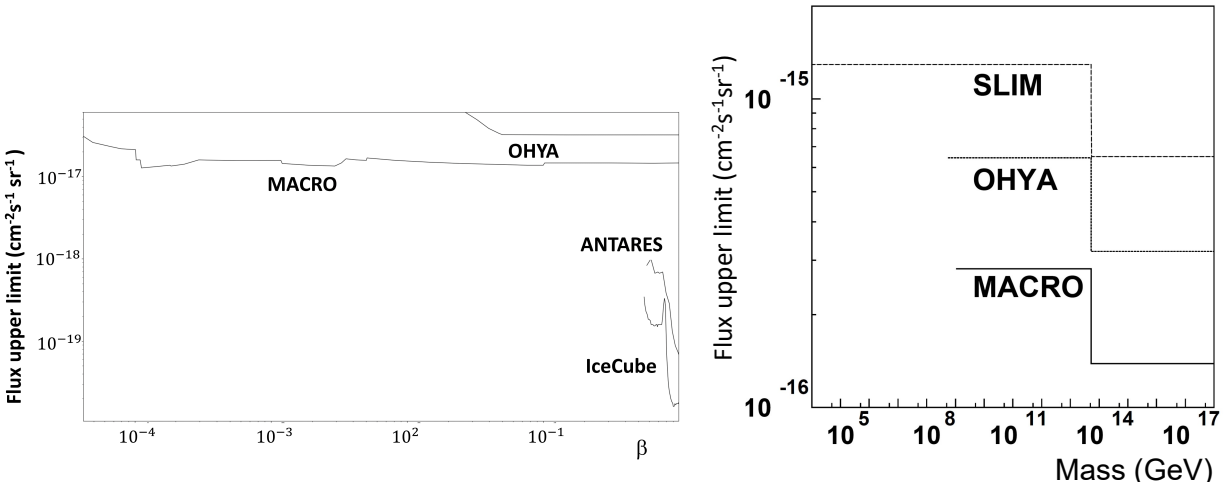

Figure 94.1: Left: upper flux limits for GUT monopoles as a function of β. Right: upper flux limits for monopoles as a function of monopole mass for $\beta > 0.05$.

94.5.2 *Searches in Cosmic Rays*

Direct searches for monopoles in cosmic rays refer to those experiments in which the passage of the monopole is measured by an active detector. Searches made assuming a catalysis processes in which GUT monopoles could induce nucleon decay are discussed in the next section. To interpret the results of the non-catalysis searches, the cross section for the catalysis process is typically either set to zero [39] or assigned a modest value (1mb) [40].

Although early cosmic ray searches using the induction technique [41] and NTDs [42] observed monopole candidates, none of these apparent observations have been confirmed. Recent experiments have typically employed large scale detectors. The MACRO experiment at the Gran Sasso underground laboratory comprised three different types of detector: liquid scintillator, limited stream tubes, and NTDs, which provided a total acceptance of $\sim 10000\text{m}^2$ for an isotropic flux. As shown in Fig. 94.1, this experiment has so far provided the most extensive β-dependent flux limits for GUT monopoles with Dirac charge [40]. Also shown are limits from an experiment at the OHYA mine in Japan [39], which used a 2000m^2 array of NTDs, and from the IceCube [43,44] and Antares [45] experiments which each employ the Cerenkov method.

In Fig. 94.1, upper flux limits are also shown as a function of monopole mass for monopole speed $\beta > 0.05$. In addition to MACRO and OYHA flux limits, results from the SLIM [46] high-altitude experiment are shown. The SLIM experiment provided a good sensitivity to intermediate mass monopoles ($10^5 \lesssim M \lesssim 10^{12}$ GeV).

In addition to the results shown in Fig. 94.1, the NoVA experiment [47] has recently set an upper limit on monopole flux of 2×10^{-14} cm^{-2}s^{-1}sr^{-1} for speeds $6 \times 10^{-4} < \beta < 10^{-3}$ for masses greater thsan 5×10^8 GeV. Stringent constraints on the flux of ultra-relativistic monopoles have been obtained at the Pierre Auger Observatory [48] which was sensitive to monopoles with γ values ranging from 10^9 to 10^{12}, leading to flux limits in the range $10^{-15} - 2.5 \times 10^{-21}$ cm^{-2}s^{-1}sr^{-1}. The RICE [49] and ANITA-II experiments [50] at the South Pole have also sought ultra-relativistic monopoles with γ values of $10^7 \lesssim \gamma \lesssim 10^{12}$ and $10^9 \lesssim \gamma \lesssim 10^{13}$, respectively, and which produced flux limits as low as 2.5×10^{-21} cm^{-2}s^{-1}sr^{-1}.

94.5.3 *Searches via the Catalysis of Nucleon-Decay*

Searches have been performed for evidence of the catalysed decay of a nucleon by a monopole, as predicted by the Callan-Rubakov mechanism. The searches are thus sensitive to the assumed value of the catalysis decay cross section. Searches have been made with the Soudan [51] and Macro [52] experiments, using tracking detectors. Searches at IMB [53], the underwater Lake Baikal experiment [54,55] and the IceCube experiment [56] which exploit the Cerenkov effect have also been made. The resulting β-dependent flux limits from these experiments typically vary between $\sim 10^{-18}$ and $\sim 10^{-14}$cm^{-2}sr^{-1}s^{-1}. A search for low energy neutrinos (assumed to be produced from induced proton decay in the sun) was made at Super-Kamiokande [57]. A model- and β-dependent limit of $6.3 \times 10^{-24}(\frac{\beta}{10^{-3}})^2$cm^{-2}sr^{-1}s^{-1} was obtained.

94.5.4 *Searches at Colliders*

Searches have been performed at hadron-hadron, electron-positron and lepton-hadron experiments. Collider searches can be broadly classed as being direct or indirect. In a direct search, evidence of the passage of a monopole through material, such as a charged particle track, is sought. In indirect searches, virtual monopole processes are assumed to influence the production rates of certain final states.

94.5.4.1 *Direct Searches at Colliders*

Collider experiments typically express their results in terms of upper limits on a production cross section and/or monopole mass. To calculate these limits, ansatzes are used to model the kinematics of monopole-antimonopole pair production processes since perturbative field theory cannot be used to calculate the rate and kinematic properties of produced monopoles. Limits therefore suffer from a degree of model-dependence, implying that a comparison between the results of different experiments can be problematic, in particular when this concerns excluded mass regions. A conservative approach with as little model-dependence as possible is thus to present representative values of the upper cross-section limits as a function of the centre-of-mass energy of the collisions, as shown in Fig. 94.2 for recent results from high energy colliders.

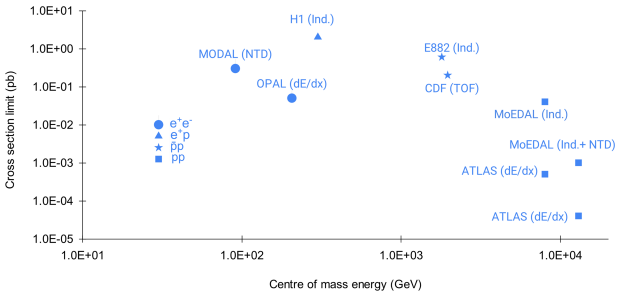

Figure 94.2: Upper limits on the production cross sections of monopoles from various collider-based experiments. Results from positron-proton, electron-positron, proton-antiproton, and proton-proton experiments are shown. The search techniques are also indicated: induction (Ind.), TOF, and $\frac{dE}{dx}$.

Searches for monopoles produced at the highest available energies in hadron-hadron collisions were made in pp collisions at the LHC by the ATLAS [58–60] and MoEDAL [61–67] experiments, with the latter including the first direct dyon search at the LHC [63]. ATLAS exploited the characteristic monopole energy loss behaviour ($\frac{dE}{dx}$) in the tracker and calorimeter. MoEDAL used a NTD to tag highly ionising particles and the induction method to search for stopped monopoles. The charge-dependent mass limits extend up to around 4 TeV. The ATLAS experiment has considered hypotheses of monopoles with charges between $0.5Q_M^D$ and $2Q_M^D$ while MoEDAL has quoted limits for monopoles in the charge range Q_M^D to $10Q_M^D$. Models considered include monopole-pair production via photon fusion along with, as is commonly used in hadron-hadron collisions, Drell-Yan processes [68]. MoEDAL has also looked for monopole produced via the Schwinger mechanism in the intense magnetic field created in PbPb collisions [65, 67]. A search has also been made by ATLAS with PbPb collisions which also considers the Schwinger mechanism [69]. Tevatron searches have also been carried out by the CDF [70] and E882 [71] experiments. The CDF experiment used a dedicated time-of-flight (TOF) system whereas the E882 experiment employed the induction technique to search for stopped monopoles in discarded detector material which had been part of the CDF and D0 detectors using periods of luminosity. Earlier searches at the Tevatron, such as [72], used NTDs and were based on comparatively modest amounts of integrated luminosity. Lower energy hadron-hadron experiments have employed a variety of search techniques including plastic track detectors [73] and searches for trapped monopoles [74].

The only LEP-2 search, based on the $\frac{dE}{dx}$ method, was made by OPAL [75] which quoted cross section limits for the production of monopoles possessing masses up to around 103 GeV. At LEP-1, searches were made with NTDs deployed around an interaction region. This allowed a range of charges to be sought for masses up to ~ 45 GeV. The MODAL detector [76] gave limits for monopoles with charges in the range $0.9Q_M^D$ and $3.6Q_M^D$, whilst an earlier search by the MODAL was sensitive to monopoles with charges as low as $0.1Q_M^D$ [77]. The deployment of NTDs around the beam interaction point was also used at earlier e^+e^- colliders such as KEK [78] and PETRA [79]. Searches at e^+e^- facilities have also been made for particles following non-helical trajectories [80, 81].

There has so far been one search for monopole production in lepton-hadron scattering. Using the induction method, monopoles were sought which could have stopped in the aluminium beampipe which had been used by the H1 experiment at HERA [82]. Cross section limits were set for monopoles with charges in the range $Q_M^D - 6Q_M^D$ for masses up to around 140 GeV.

94.5.4.2 *Indirect Searches at Colliders*

It has been proposed that virtual monopoles can mediate processes which give rise to multi-photon final-states [83,84]. Photon-based searches were made by the D0 [85] and L3 [86] experiments. The D0 work led to spin-dependent lower mass limits of between 610 and 1580 GeV, while L3 reported a lower mass limit of 510 GeV. Another indirect way to constrain monopoles is via the search for a monopolium (a bound state of a monopole and antimonopole) through multi-photon decays [87]. While there exist theoretical difficulties in estimating uncertainties related to these limits, stringent lower bounds of magnetic monopole masses in theoretical models can be derived (modulo the uncertainties arising due to the large coupling) by means of exploiting [88] the observed light-by-light scattering at the ATLAS [89, 90] and CMS [91, 92] experiments.

VOLUME II: TABLE OF CONTENTS

PARTICLE LISTINGS*

Illustrative key and abbreviations 1227

Gauge and Higgs bosons
(γ, gluon, graviton, W, Z, Higgs, Axions) 1241

Leptons
(e, μ, τ, Heavy-charged lepton searches, Neutrino properties, Number of neutrino types Double-β decay, Neutrino mixing, Heavy-neutral lepton searches) 1369

Quarks
(u, d, s, c, b, t, b', t' (4th gen.), Free quarks) 1447

Mesons
Light unflavored (π, ρ, a, b) (η, ω, f, ϕ, h) 1491
Strange (K, K^*) 1623
Charmed (D, D^*) 1677
Charmed, strange (D_s, D_s^*, D_{sJ}) 1749
Bottom (B, V_{cb}/V_{ub}, B^*, B_J^*) 1775
Bottom, strange (B_s, B_s^*, B_{sJ}^*) 1965
Bottom, charmed (B_c) 1996
$c\overline{c}$ (η_c, $J/\psi(1S)$, χ_c, h_c, ψ) 2002
$b\overline{b}$ (η_b, Υ, χ_b, h_b) 2142
Other mesons (T_c, T_b tetraquarks) 2183

Baryons
N 2203
Δ 2263
Λ 2289
Σ 2315
Ξ 2347
Ω 2361
Charmed (Λ_c, Σ_c, Ξ_c, Ω_c) 2364
Doubly charmed (Ξ_{cc}) 2396
Bottom (Λ_b, Σ_b, Ξ_b, Ω_b, b-baryon admixture) 2398
Exotic baryons (P_c pentaquarks) 2423

Illustrative Key to the Particle Listings

Name of particle. "Old" name used before 1986 renaming scheme also given if different. See the section "Naming Scheme for Hadrons" for details.

$a_0(1200)$ $I^G(J^{PC}) = 1^-(0^{++})$ — Particle quantum numbers (where known).

OMITTED FROM SUMMARY TABLE — Indicates particle omitted from Particle Physics Summary Table, implying particle's existence is not confirmed.

Evidence not compelling, may be a kinematic effect.

Quantity tabulated below.

$a_0(1200)$ MASS

General comments on particle.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	CHG	COMMENT
1206± 7 OUR AVERAGE						
1210± 8±9	3000	FENNER	87	MMS	−	3.5 $\pi^- p$
1198±10		PIERCE	83	ASPK	+	2.1 $K^- p$
1216±11±9	1500	[1] MERRILL	81	HBC	0	3.2 $K^- p$
• • • We do not use the following data for averages, fits, limits, etc. • • •						
1192±16	200	LYNCH	81	HBC	±	2.7 $\pi^- p$

Top line gives our best value (and error) of quantity tabulated here, based on weighted average of measurements used. Could also be from fit, best limit, estimate, or other evaluation. See next page for details.

"Document id" for this result; full reference given below.

Footnote number linking measurement to text of footnote.

Measurement technique. (See abbreviations on next page.)

[1] Systematic error was added quadratically by us in our 1986 edition.

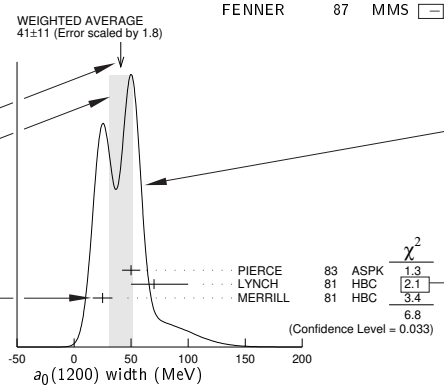
$a_0(1200)$ WIDTH

Number of events *above background*.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	CHG	COMMENT
41±11 OUR AVERAGE Error includes scale factor of 1.8. See the ideogram below.						
50± 8		PIERCE	83	ASPK	+	2.1 $K^- p$
70^{+30}_{-20}	200	LYNCH	81	HBC	±	2.7 $\pi^- p$
25 ± 5±7		MERRILL	81	HBC	0	3.2 $K^- p$
• • • We do not use the following data for averages, fits, limits, etc. • • •						
<60		FENNER	87	MMS	−	3.5 $\pi^- p$

Measured value used in averages, fits, limits, etc.

Scale factor > 1 indicates possibly inconsistent data.



Error in measured value (often statistical only; followed by systematic if separately known; the two are combined in quadrature for averaging and fitting.)

Reaction producing particle, or general comments.

"Change bar" indicates result added or changed since previous edition.

Measured value *not used* in averages, fits, limits, etc. See the Introductory Text for explanations.

Charge(s) of particle(s) detected.

Ideogram to display possibly inconsistent data. Curve is sum of Gaussians, one for each experiment (area of Gaussian = 1/error; width of Gaussian = ±error). See Introductory Text for discussion.

Arrow points to weighted average.

Shaded pattern extends $\pm 1\sigma$ (scaled by "scale factor" S) from weighted average.

Value and error for each experiment.

Contribution of experiment to χ^2 (if no entry present, experiment not used in calculating χ^2 or scale factor because of very large error).

$a_0(1200)$ DECAY MODES

Mode		Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Γ_1	3π	(65.2±1.3) %	S=1.7
Γ_2	$K\overline{K}$	(34.8±1.3) %	S=1.7
Γ_3	$\eta\pi^\pm$	< 5 $\times 10^{-4}$	CL=95%

Partial decay mode (labeled by Γ_i).

Our best value for branching fraction as determined from data averaging, fitting, evaluating, limit selection, etc. This list is basically a compact summary of results in the Branching Ratio section below.

$a_0(1200)$ BRANCHING RATIOS

Branching ratio.

$\Gamma(3\pi)/\Gamma_{total}$ — Γ_1/Γ

VALUE	DOCUMENT ID		TECN	CHG	COMMENT
0.652±0.013 OUR FIT Error includes scale factor of 1.7.					
0.643±0.010 OUR AVERAGE					
0.64 ±0.01	PIERCE	83	ASPK	+	2.1 $K^- p$
0.74 ±0.06	MERRILL	81	HBC	0	3.2 $K^- p$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
0.48 ±0.15	[2] LYNCH	81	HBC	±	2.7 $\pi^- p$

Our best value (and error) of quantity tabulated, as determined from constrained fit (using *all significant* measured branching ratios for this particle).

Weighted average of measurements of this ratio only.

[2] Data has questionable background subtraction.

Footnote (referring to LYNCH 81).

$\Gamma(K\overline{K})/\Gamma_{total}$ — Γ_2/Γ

VALUE	DOCUMENT ID		TECN	CHG	COMMENT
0.348±0.013 OUR FIT Error includes scale factor of 1.7.					
0.35 ±0.05	PIERCE	83	ASPK	+	2.1 $K^- p$

Branching ratio in terms of partial decay mode(s) Γ_i above.

$\Gamma(K\overline{K})/\Gamma(3\pi)$ — Γ_2/Γ_1

VALUE	DOCUMENT ID		TECN	CHG	COMMENT
0.535±0.030 OUR FIT Error includes scale factor of 1.7.					
0.50 ±0.03	MERRILL	81	HBC	0	3.2 $K^- p$

$\Gamma(\eta(\text{neutral decay})\pi^\pm)/\Gamma_{total}$ — $0.71\Gamma_3/\Gamma$

VALUE (units 10^{-4})	CL%	DOCUMENT ID		TECN	CHG	COMMENT
<3.5	95	PIERCE	83	ASPK	+	2.1 $K^- p$

Confidence level for measured upper limit.

$a_0(1200)$ REFERENCES

References, ordered inversely by year, then author.

Partial list of author(s) in addition to first author.

FENNER	87	PRL 55 14	H. Fenner *et al.*	(SLAC)	
PIERCE	83	PL 123B 230	J.H. Pierce	(FNAL)	JP
LYNCH	81	PR D24 610	G.R. Lynch *et al.*	(CLEO Collab.)	
MERRILL	81	PRL 47 143	D.W. Merrill *et al.*	(SACL, CERN)	

"Document id" used on data entries above.

Quantum number determinations in this reference.

Journal, report, preprint, etc. (See abbreviations on next page.)

Institution(s) of author(s). (See abbreviations on next page.)

Indicator of Procedure Used to Obtain Our Result

OUR AVERAGE	From a weighted average of selected data.
OUR FIT	From a constrained or overdetermined multiparameter fit of selected data.
OUR EVALUATION	Not from a direct measurement, but evaluated from measurements of other quantities.
OUR ESTIMATE	Based on the observed range of the data. Not from a formal statistical procedure.
OUR LIMIT	For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

Measurement Techniques (i.e., Detectors and Methods of Analysis)

A1	A1 Collaboration at MAMI
A2MM	A2 spectrometer at the Mainz Microtron, MAMI
ABRA	ABRACADABRA QCD axion dark matter search
ACCM	ACCMOR Collaboration
ADMX	Axion Dark Matter Experiment
AEMS	Argonne effective mass spectrometer
ALCE	ALICE detector at CERN LHC

AMY	AMY detector at KEK-TRISTAN
ANAI	Direct DM detection exp. with NaI at Canfranc Underground Lab, Spain
ANIC	ANTARES and IceCube combined analysis
ANIT	Antarctic Impulsive Transient Antenna balloon mission
ANTR	ANTARES underwater neutrino telescope in the Western Mediterranean Sea
APEX	FNAL APEX Collab.
ARG	ARGUS detector at DORIS
ARGD	Fit to semicircular amplitude path on Argand diagram
ASP	Anomalous single-photon detector
ASPK	Automatic spark chambers
ASTE	ASTERIX detector at LEAR
ASTR	Astronomy
ATLS	ATLAS detector at CERN LHC
AUGE	Pierre Auger Observatory
AURG	Resonant-mass gravitational wave AURIGA detector
B787	BNL experiment 787 detector
B791	BNL experiment 791 detector
B845	BNL experiment 845 detector
B852	BNL E-852
B865	BNL E865 detector
B871	BNL experiment 871 detector
B949	BNL E949 detector at AGS
BABR	BaBar Collab.
BAIK	Lake Baikal neutrino telescope
BAKS	Baksan underground scintillation telescope
BC	Bubble chamber
BDMP	Beam dump
BEAT	CERN BEATRICE Collab.
BEBC	Big European bubble chamber at CERN
BEL2	Belle II Collab.
BELL	Belle Collab.
BES	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BES2	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BES3	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BEST	Baksan Experiment on Sterile Transitions
BIS2	BIS-2 spectrometer at Serpukhov
BKEI	BENKEI spectrometer system at KEK Proton Synchroton
BOLO	Bolometer, a cryogenic thermal detector
BONA	Bonanza nonmagnetic detector at DORIS
BORX	BOREXINO
BPWA	Barrelet-zero partial-wave analysis
BRAS	BRASS: Broadband Radiometric Axion/ALPs Search Setup
BRED	GigaBREAD room-temperature dish antenna
C100	COSINE-100 experiment in South Korea
CALO	Calorimeter
CAPP	CAPP18T haloscope detector
CASK	CULTASK: CAPPs Ultra Low Temperature Axion Search in Korea
CASP	Cosmic Axion Spin Precession Experiments
CAST	CAST experiment at CERN
CBAL	Crystal Ball detector at SLAC-SPEAR or DORIS
CBAR	Crystal Barrel detector at CERN-LEAR
CBOX	Crystal Box at LAMPF
CBTP	CBELSA/TAPS Collaboration
CC	Cloud chamber
CCFR	Columbia-Chicago-Fermilab-Rochester detector
CCM	Coherent CAPTAIN-Mills 10-ton liquid Ar detector at Los Alamos
CDEX	China Dark Matter Experiment
CDF	Collider detector at Fermilab
CDF2	CDF-II Collab.
CDHS	CDHS neutrino detector at CERN
CDM2	CDMS II, Cryogenic Dark Matter Search at Soudan Underground Lab.
CDMS	CDMS Collaboration
CELL	CELLO detector at DESY
CGNT	CoGeNT dark matter search experiment
CHER	Cherenkov detector
CHM2	CHARM-II neutrino detector (glass) at CERN
CHOZ	Nuclear Power Station near Chooz, France
CHRM	CHARM neutrino detector (marble) at CERN
CHRS	CHORUS Collaboration – CERNS SPS
CIB	Cosmic Infrared Background
CIBS	CERN-IHEP boson spectrometer
CLAS	Jefferson CLAS Collab.
CLE2	CLEO II detector at CESR
CLE3	CLEO III detector at CESR
CLEC	CLEO-c detector at CESR
CLEO	Cornell magnetic detector at CESR
CMB	Cosmic Microwave Background
CMD	Cryogenic magnetic detector at VEPP-2M, Novosibirsk
CMD2	Cryogenic magnetic detector 2 at VEPP-2M, Novosibirsk
CMD3	Cryogenic magnetic detector 3 at VEPP-2000, Novosibirsk
CMS	CMS detector at CERN LHC
CNTR	Counters
COHR	COHERENT experiment at the SNS, Oak Ridge
COMB	Combined analysis of data from independent experiments.
COMP	COMPASS experiment at the CERN SPS
CONN	CONNIE: Coherent Neutrino-Nucleus Interaction Experiment
COSM	Cosmology and astrophysics
COSN	COSINUS Collab. undergroud searches
COSY	COSY-TOF Collaboration
COUP	COUPP (the Chicagoland Observatory for Underground Particle Physics) Collab.
CPLR	CPLEAR Collaboration
CRBT	Crystal Ball and TAPS detector at MAMI
CRES	CRESST cryogenic detector
CRYB	Crystal Ball at BNL
CRYM	Crystal Ball detector at Mainz Microtron MAMI
CSB2	Columbia U. - Stony Brook BGO calorimeter inserted in NaI array
CSME	COSME Collaboration
CUOR	CUORICINO experiment at Gran Sasso Laboratory.
CUSB	Columbia U. - Stony Brook segmented NaI detector at CESR
D0	D0 detector at Fermilab Tevatron Collider
DAMA	DAMA, dark matter detector at Gran Sasso National Lab.
DAMP	The DArk Matter Particle Explorer, DAMPE, detector
DANC	DANCE axion search experiment
DASP	DESY double-arm spectrometer
DAYA	Daya Bay Collaboration
DBC	Deuterium bubble chamber
DCHZ	Double Chooz Collaboration
DEAP	DEAP-3600 DM search with argon at SNOLAB
DISP	Graviton mass measurement based on dispersion measure
DLCO	DELCO detector at SLAC-SPEAR or SLAC-PEP
DLPH	DELPHI detector at LEP
DM1	Magnetic detector no. 1 at Orsay DCI collider
DM2	Magnetic detector no. 2 at Orsay DCI collider
DMIC	DAMIC Dark Matter in CCD experiment at Fermilab
DMTP	Dark Matter Time Projection Chamber (DMTPC) directional detection experiment
DONU	DONUT Collab.
DORR	DOSUE-RR Collab., dark photon dark matter search
DPWA	Energy-dependent partial-wave analysis
DRFT	Directional dark matter detector at Boulby Underground Science Facility
DS50	DarkSide-50 Liquid Argon TPC at Gran Sasso National Laboratory
E137	SLAC E137 beam-dump experiment
E621	Fermilab E621 detector
E653	Fermilab E653 detector

Abbreviations Used in the Particle Listings

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

E665	Fermilab E665 detector
E687	Fermilab E687 detector
E691	Fermilab E691 detector
E705	Fermilab E705 Spectrometer-Calorimeter
E731	Fermilab E731 Spectrometer-Calorimeter
E756	Fermilab E756 detector
E760	Fermilab E760 detector
E761	Fermilab E761 detector
E771	Fermilab E771 detector
E773	Fermilab E773 Spectrometer-Calorimeter
E789	Fermilab E789 detector
E791	Fermilab E791 detector
E799	Fermilab E799 Spectrometer-Calorimeter
E835	Fermilab E835 detector
EDE2	EDELWEISS II dark matter search Collaboration
EDE3	EDELWEISS III dark matter search Collaboration
EDEL	EDELWEISS dark matter search Collaboration
EDGS	EDGES: Global EoR (Epoch of Reionization) Signature experiment
EHS	Four-pi detector at CERN
ELEC	Electronic combination
EMC	European muon collaboration detector at CERN
EMUL	Emulsions
EPTA	The European Pulsar Timing Array
ESR	Electron spin resonance spectroscopy
EXO2	Enriched Xenon Observatory 200-kg liquid Xe TPC
FASR	FASER light dark matter search at LHC
FAST	Fiber Active Scintillator Target detector at PSI
FBC	Freon bubble chamber
FENI	FENICE (at the ADONE collider of Frascati)
FIT	Fit to previously existing data
FLAT	Large Area Telescope onboard the Fermi Gamma-Ray Space Telescope (Fermi-LAT)
FMPS	Fermilab Multiparticle Spectrometer
FOCS	FNAL E831_FOCUS Collab.
FRAB	ADONE $B\overline{B}$ group detector
FRAG	ADONE $\gamma\gamma$ group detector
FRAM	ADONE MEA group detector
FREJ	FREJUS Collaboration – modular flash chamber detector (calorimeter)
FUNK	Finding U(1)'s of a Novel Kind experiment
GA24	Hodoscope Cherenkov γ calorimeter (IHEP GAMS-2000) (CERN GAMS-4000)
GALX	GALLEX solar neutrino detector in the Gran Sasso Underground Lab.
GAM2	IHEP hodoscope Cherenkov γ calorimeter GAMS-2000
GAM4	CERN hodoscope Cherenkov γ calorimeter GAMS-4000
GAMS	IHEP hodoscope Cherenkov γ calorimeter GAMS-4π
GLUX	GlueX exotic hybrid mesons search at JLAB
GNME	Global Network of Optical Magnetometers for Exotic searches (GNOME)
GNO	Gallium Neutrino Observatory in the Gran Sasso Underground Lab.
GOLI	CERN Goliath spectrometer
GRAL	GRAAL Collaboration
H1	H1 detector at DESY/HERA
HAWC	High Altitude Water Cherenkov Observatory experiment at Sierra Negra, Mexico
HBC	Hydrogen bubble chamber
HDBC	Hydrogen and deuterium bubble chambers
HDES	HADES Collaboration at GSI in Darmstadt
HDMO	Heidelberg-Moscow Experiment
HDMS	Heidelberg Dark Matter Search Experiment
HEBC	Helium bubble chamber
HEPT	Helium proportional tubes
HERA	H1 and ZEUS Collaborations at DESY/HERA
HERB	HERA-B detector at DESY/HERA
HERM	HERMES detector at DESY/HERA
HESS	High Energy Stereoscopic System gamma-ray instrument
HFR	HighFlow Reactor at the Institut Laue-Langevin
HFS	Hyperfine structure
HLBC	Heavy-liquid bubble chamber
HOME	Homestake underground scintillation detector
HPGE	High-purity Germanium detector
HPS	Heavy Photon Search experiment at JLAB
HPW	Harvard-Pennsylvania-Wisconsin detector
HRS	SLAC high-resolution spectrometer
HYBR	Hybrid: bubble chamber + electronics
HYCP	HyperCP Collab. (FNAL E-871)
HYST	HAYSTAC axion search experiment
IACT	Imaging Air Cherenkov Telescope
ICAR	ICARUS experiment at Gran Sasso Laboratory.
ICCB	IceCube neutrino detector at South Pole
IGEX	IGEX Collab.
IMB	Irvine-Michigan-Brookhaven underground Cherenkov detector
IMB3	Irvine-Michigan-Brookhaven underground Cherenkov detector
INDU	Magnetic induction
INDX	InDEx: Indian Dark matter search Experiment at Jaduguda
IPWA	Energy-independent partial-wave analysis
ISTR	IHEP ISTRA+ spectrometer-calorimeter
JADE	JADE detector at DESY
JPAC	Joint Physics Analysis Center (JPAC) Collaboration
JWST	James Webb Space Telescope
K246	KEK E246 detector with polarimeter
K2K	KEK to Super-Kamiokande
K391	KEK E391a detector
K470	KEK-E470 Stopping K detector
KAM2	KAMIOKANDE-II underground Cherenkov detector
KAMI	KAMIOKANDE underground Cherenkov detector
KAR2	KARMEN2 calorimeter at the ISIS neutron spallation source at Rutherford
KARM	KARMEN calorimeter at the ISIS neutron spallation source at Rutherford
KEDR	detector operating at VEPP-4M collider (Novosibirsk)
KIMS	Korea Invisible Mass Search experiment at YangYang, Korea
KLND	KamLand Collab. (Japan)
KLNZ	KamLAND-Zen Collaboration
KLOE	KLOE detector at DAFNE (the Frascati e+e- collider Italy)
KM3N	KM3NeT water Cherenkov ν detector in Mediterranean Sea
KOLR	Kolar Gold Field underground detector
KOTO	KOTO experiment with K_L^0 beam at J-PARC
KTEV	KTeV Collaboration
L3	L3 detector at LEP
LASR	Laser
LASS	Large-angle superconducting solenoid spectrometer at SLAC
LATT	Lattice calculations
LEBC	Little European bubble chamber at CERN
LEGS	BNL LEGS Collab.
LENA	Nonmagnetic lead-glass NaI detector at DORIS
LEP	From combination of all 4 LEP experiments: ALEPH, DELPHI, L3, OPAL
LEPS	Low-Energy Pion Spectrometer at the Paul Scherrer Institute
LGW	Lead Glass Wall collaboration at SPEAR/SLAC
LHAS	Large High Altitude Air Shower Observatory (LHAASO)
LHC	Combined analysis of LHC experiments
LHCB	LHCb detector at CERN LHC
LIDA	Laser-Interferometric Detector for Axions
L+P	Multichannel L + P model fit
LSD	Mont Blanc liquid scintillator detector
LSND	Liquid Scintillator Neutrino Detector
LSW	Light Shining through a Wall
LUX	Large Underground Xenon experiment at SURF
LZ	LUX-ZEPLIN dark matter Xe CPT detector at SURF
MAC	MAC detector at PEP/SLAC
MAJD	Majorana Demonstrator experiment at SURF
MBNE	Fermilab MiniBooNE neutrino experiment
MBR	Molecular beam resonance technique
MCBN	Fermilab MicroBooNE neutrino experiment
MCRO	MACRO detector in Gran Sasso
MD1	Magnetic detector at VEPP-4, Novosibirsk
MDHI	Multilayer Dielectric Haloscope Investigation
MDMX	Magnetized Disc and Mirror Axion eXperiment
MDRP	Millikan drop measurement
MEER	MeerKAT Galaxy Cluster Legacy Survey
MEG	Muon to electron conversion detector at PSI
MGFL	MAGIC and Fermi-LAT Collaborations
MGIC	MAGIC Telescopes gamma-ray observatory
MICA	Underground mica deposits
MICR	MICROSCOPE satellite test of weak equivalence principle
MINS	Fermilab MINOS experiment
MIRA	MIRABELLE Liquid-hydrogen bubble chamber
MLEV	Magnetic levitation
MLS	Modified Laurent Series
MMS	Missing mass spectrometer
MOED	MoEDAL magnetic monopoles search experiment at LHC

Abbreviations Used in the Particle Listings

MPS Multiparticle spectrometer at BNL
MPS2 Multiparticle spectrometer upgrade at BNL
MPSF Multiparticle spectrometer at Fermilab
MPWA Model-dependent partial-wave analysis
MRK1 SLAC Mark-I detector
MRK2 SLAC Mark-II detector
MRK3 SLAC Mark-III detector
MRKJ Mark-J detector at DESY
MRS Magnetic resonance spectrometer
MUG2 Muon (g-2)
MWPC Multi-Wire Proportional Chamber
NA14 CERN NA14
NA31 CERN NA31 Spectrometer-Calorimeter
NA32 CERN NA32 Spectrometer
NA48 CERN NA48 Collaboration
NA49 CERN NA49 Collaboration
NA60 CERN NA60 Collaboration
NA62 CERN NA62 Experiment
NA64 CERN SPS NA64 Experiment
NAGE NEWAGE, New generation WIMP-search experiment with advanced gaseous tracking
NAIA NAIAD (NaI Advanced Detector) dark matter search experiment
ND NaI detector at VEPP-2M, Novosibirsk
NEOS NEOS Collaboration
NEWS NEWS-G direct dark matter search at LSM
NICE Serpukhov nonmagnetic precision spectrometer
NIT Nano-imaging technology
NMR Nuclear magnetic resonance
NOMD NOMAD Collaboration, CERN SPS
NOVA NOvA experiment with Fermilab's NuMI neutrino beam
NTEV NuTeV Collab. at Fermilab
nTRV neutron Time-Reversal Violation
NUST NuSTAR, Nuclear Spectroscopic Telescope Array X-ray observatory
NUSX Mont Blanc NUSEX underground detector
OBLX OBELIX detector at LEAR
OKA OKA collaboration at U70 accelerator in Protvino, Russia
OLYA Detector at VEPP-2M and VEPP-4, Novosibirsk
OMEG CERN OMEGA spectrometer
OPAL OPAL detector at LEP
OPER OPERA experiment with emulsion tracking at Gran Sasso
ORGN ORGAN (Oscillating Resonant Group AxioN) experiment
ORPH ADMX-Orpheus Dark Matter Experiment
OSPK Optical spark chamber
PIBE The PIBETA detector at the Paul Scherrer Institute (PSI), Switzerland.
PICA PICASSO dark matter search experiment
PICO PICO bubble chamber experiment in SNOLAB underground laboratory
PIE3 πE3 beam-line of Paul Scherrer Institute
PLAS Plastic detector
PLUT DESY PLUTO detector
PMLA PAMELA space spectrometer on Resurs-DK1 satellite
PNDX PandaX dual-phase liquid xenon dark matter experiment at Jin-Ping
PPTA Parkes Pulsar Timing Array
PRMX The PRIMEX detector in Hall B at TJNAF
PTA Pulsar timing array
PWA Partial-wave analysis
QRDL QROCODILE, Quantum Resolution-Optimized Cryogenic Observatory for DM
QUAX QUAX axion search experiment
QULP QUALIPHIDE, quantum limited photons in the dark exp.
RADE CAST-RADES haloscope search for axions.
RDK2 NIST rare radioactive decay experiment
REDE Resonance depolarization
RENO RENO Collaboration
RICE Radio Ice Cherenkov Experiment
RVUE Review of previous data
SAGE US - Russian Gallium Experiment
SAPH SAPPHIRES collaboration search for sub-eV Axion LPs
SCDM SuperCDMS experiment at Soudan Underground Lab.
SELX FNAL SELEX Collab.
SENS Sub-Electron-Noise Skipper CCD Experimental Instrument (SENSEI)
SFM CERN split-field magnet
SHF SLAC Hybrid Facility Photon Collaboration
SHFT Search for Halo Axions with Ferromagnetic Toroids
SHNE Superconducting cavity new hidden particles explorer
SHUK SHUKET: search for U(1) dark matter with an electromagnetic telescope
SIGM Serpukhov CERN-IHEP magnetic spectrometer (SIGMA)
SILI Silicon detector
SIMP SIMPLE, dark matter detector at Laboratori Nazionali del Sud
SKAM Super-Kamiokande Collab.
SKT2 Super-Kamiokande and T2K Collaborations
SLAX Solar Axion Experiment in Canfranc Underground Laboratory
SLD SLC Large Detector for $e^+ e^-$ colliding beams at SLAC
SLIC ADMX SLIC (Superconducting LC Circuit Investigating Cold Axions)
SMPL SIMPLE, Superheated Instrument for Massive ParticLe Experiments
SND Novosibirisk Spherical neutral detector at VEPP-2M
SNDR SINDRUM spectrometer at PSI
SNO SNO Collaboration (Sudbury Neutrino Observatory)
SNO+ SNO+ Collaboration (Sudbury Neutrino Observatory)
SNSP SNSPD, Superconducting Nanowire Single-Photon Detectors
SOU2 Soudan 2 underground detector
SOUD Soudan underground detector
SPEC Spectrometer
SPED From maximum of speed plot or resonant amplitude
SPHR Bonn SAPHIR Collab.
SPNX SPHINX spectrometer at IHEP accelerator
SPRK Spark chamber
SQID SQUID device
SRPH SERAPH (SupERconducting Axion and Paraphoton Haloscope) experiment
STRC Streamer chamber
SVD2 SVD-2 experiment at IHEP, Protvino
T2K T2K Collaboration
TASE Taiwan Axion Search Experiment with a Haloscope, TASEH, experiment
TASS DESY TASSO detector
TESS TESSERACT, DM search below the proton mass
TEVA Combined analysis of CDF and DØ experiments
TEXO TEXONO Collab., ultra low energy Ge detector at Kuo-Sheng Laboratory
THEO Theoretical or heavily model-dependent result
TNF TNF-IHEP facility at 70 GeV IHEP accelerator
TOF Time-of-flight
TOPZ TOPAZ detector at KEK-TRISTAN
TPC TPC detector at PEP/SLAC
TPS Tagged photon spectrometer at Fermilab
TRAP Penning trap
TWST TWIST spectrometer at TRIUMF
UA1 UA1 detector at CERN
UA2 UA2 detector at CERN
UA5 UA5 detector at CERN
UCNA UCNA collaboration using polarizeed ultracold neutrons at LANSCE
UKDM UK Dark Matter Collab.
UPLD UPLOAD, upconversion low-noise oscillator axion detection experiment
VES Vertex Spectrometer Facility at 70 GeV IHEP accelerator
VLBI Very Long Baseline Interferometer
VNS VENUS detector at KEK-TRISTAN
VRTS Very Energetic Radiation Imaging Telescope Array System (VERITAS)
WA75 CERN WA75 experiment
WA82 CERN WA82 experiment
WA89 CERN WA89 experiment
WARP Liquid argon detector for CDM searches at Gran Sasso
WASA WASA detector at CELSIUS, Uppsala and at COSY, Juelich
WDMX WISP Dark Matter eXperiment (WISPDMX) for direct hidden photon search
WIRE Wire chamber
X100 XENON100 dark matter search experiment at Gran Sasso National Laboratory
XE10 XENON10 experiment at Gran Sasso National Laboratory
XE1T XENON1T dark matter search experiment at Gran Sasso National Laboratory
XEBC Xenon bubble chamber
XENT XENONnT dark matter search experiment at Gran Sasso National Laboratory
XMAS XMASS, liquid xenon scintillation detector at Kamioka Observatory

GAUGE AND HIGGS BOSONS

γ (photon) $I(J^{PC}) = 0,1(1^{--})$

γ MASS

Results prior to 2008 are critiqued in GOLDHABER 10. All experimental results published prior to 2005 are summarized in detail by TU 05.

The following conversions are useful: 1 eV = 1.783×10^{-36} kg = 1.957×10^{-6} m_e; $\lambda\!\!\!^{-}_C = (1.973\times10^{-7}\ \text{m})\times(1\ \text{eV}/m_\gamma)$.

[1] RYUTOV 07 extends the method of RYUTOV 97 to the radius of Pluto's orbit.

[2] CHANG 25 sets upper limit on the photon mass using time delay between gravitationally lensed images of FRB 20190308C.

[3] LEMOS 25 gives constraints on the photon mass using, under several assumptions, data from Fast Radio Bursts and Supernovae. Do not present an upper limit.

[4] MALTA 24 gives an upper limit on the photon mass by analysing the gravitational time delay in a weak-field approximation using Doppler-tracking data from the Cassini mission.

[5] YAN 24A put constraints on the photon mass modelling non-zero-mass effects on the Jupiter magnetic field and using data of the JUNO Mission.

[6] WANG 23B use fast radio burst photon mass dependent dispersion relation to determine an upper limit of the photon mass.

[7] MALTA 22 consider the effect of a finite photon mass on Schumann resonances in the Earth-ionosphere cavity, improve limit by KROLL 71A by considering realistic conductivity profiles for the atmosphere.

[8] BONETTI 17 uses frequency-dependent time delays of repeating FRB with well-determined redshift, assuming the DM is caused by expected dispersion in IGM. There are several uncertainties, leading to mass limit 2.2×10^{-14} eV.

[9] BONETTI 16 uses frequency-dependent time delays of FRB, assuming the DM is caused by expected dispersion in IGM. There are several uncertainties, leading to mass limit 1.8×10^{-14} eV, if indeed the FRB is at the initially reported redshift.

[10] RETINO 16 looks for deviations from Ampere's law in the solar wind, using Cluster four spacecraft data. Authors quote a range of limits from 1.9×10^{-15} eV to 7.9×10^{-14} eV depending on the assumptions of the vector potential from the interplanetary magnetic field.

[11] EGOROV 14 studies chromatic dispersion of lensed quasar positions ("gravitational rainbows") that could be produced by any of several mechanisms, among them via photon mass. Limit not competitive but obtained on cosmological distance scales.

[12] ACCIOLY 10 limits come from possible alterations of anomalous magnetic moment of electron and gravitational deflection of electromagnetic radiation. Reported limits are not "claimed" by the authors and in any case are not competitive.

[13] When trying to measure m one must distinguish between measurements performed on large and small scales. If the photon acquires mass by the Higgs mechanism, the large-scale behavior of the photon might be effectively Maxwellian. If, on the other hand, one postulates the Proca regime for all scales, the very existence of the galactic field implies $m < 10^{-26}$ eV, as correctly calculated by YAMAGUCHI 59 and CHIBISOV 76.

[14] TU 06 continues the work of LUO 03, with extended LAKES 98 method, reporting the improved limit $\mu^2A = (0.7\pm1.7)\times10^{-13}$ T/m if $A = 0.2\ \mu$G out to 4×10^{22} m. Reported result $\mu = (0.9\pm1.5)\times10^{-52}$ g reduces to the frequentist mass limit 1.2×10^{-19} eV (FELDMAN 98). While the results of the torsion balance method give a value for the local limit on μ^2A, the deduced limit on the photon mass μ is open to question. See the discussions in TU 05 and GOLDHABER 03.

[15] FULLEKRUG 04 adopted KROLL 71A method with newer and better Schumann resonance data. Result questionable because assumed frequency shift with photon mass is assumed to be linear. It is quadratic according to theorem by GOLDHABER 71B, KROLL 71, and PARK 71.

[16] LUO 03 extends LAKES 98 technique to set a limit on μ^2A, where μ^{-1} is the Compton wavelength $\lambda\!\!\!^{-}_C$ of the massive photon and A is the ambient vector potential. The important departure is that the apparatus rotates, removing sensitivity to the direction of A. They take $A = 10^{12}$ Tm, due to "cluster level fields." But see comment of GOLDHABER 03 and reply by LUO 03B.

[17] LAKES 98 reports limits on torque on a toroid Cavendish balance, obtaining a limit on $\mu^2A < 2\times10^{-9}$ Tm/m^2 via the Maxwell-Proca equations, where μ^{-1} is the characteristic length associated with the photon mass and A is the ambient vector potential in the Lorentz gauge. Assuming $A \approx 1\times10^{12}$ Tm due to cluster fields he obtains $\mu^{-1} > 2\times10^{10}$ m, corresponding to $\mu < 1\times10^{-17}$ eV. A more conservative limit, using $A \approx (1\ \mu\text{G})\times(600\ \text{pc})$ based on the galactic field, is $\mu^{-1} > 1\times10^{9}$ m or $\mu < 2\times10^{-16}$ eV.

[18] RYUTOV 97 uses a magnetohydrodynamics argument concerning survival of the Sun's field to the radius of the Earth's orbit. "To reconcile observations to theory, one has to reduce [the photon mass] by approximately an order of magnitude compared with" per DAVIS 75. "Secure limit, best by this method" (per GOLDHABER 10).

[19] FISCHBACH 94 analysis is based on terrestrial magnetic fields; approach analogous to DAVIS 75. Similar result based on a much smaller planet probably follows from more precise B field mapping. "Secure limit, best by this method" (per GOLDHABER 10).

[20] CHERNIKOV 92, motivated by possibility that photon exhibits mass only below some unknown critical temperature, searches for departure from Ampere's Law at 1.24 K. See also RYAN 85.

[21] RYAN 85, motivated by possibility that photon exhibits mass only below some unknown critical temperature, sets mass limit at $< (1.5\pm1.4)\times10^{-42}$ g based on Coulomb's Law departure limit at 1.36 K. We report the result as frequentist 90% CL (FELDMAN 98).

[22] CHIBISOV 76 depends in critical way on assumptions such as applicability of virial theorem. Some of the arguments given only in unpublished references.

[23] DAVIS 75 analysis of Pioneer-10 data on Jupiter's magnetic field. "Secure limit, best by this method" (per GOLDHABER 10).

[24] FRANKEN 71 method is of dubious validity (KROLL 71A, JACKSON 99, GOLDHABER 10, and references therein).

[25] KROLL 71A used low frequency Schumann resonances in cavity between the conducting earth and resistive ionosphere, overcoming objections to resonant-cavity methods (JACKSON 99, GOLDHABER 10, and references therein). "Secure limit, best by this method" (per GOLDHABER 10).

[26] WILLIAMS 71 is landmark test of Coulomb's law. "Secure limit, best by this method" (per GOLDHABER 10).

γ CHARGE

OKUN 06 has argued that schemes in which all photons are charged are inconsistent. He says that if a neutral photon is also admitted to avoid this problem, then other problems emerge, such as those connected with the emission and absorption of charged photons by charged particles. He concludes that in the absence of a self-consistent phenomenological basis, interpretation of experimental data is at best difficult.

[1] ALTSCHUL 07B looks for Aharonov-Bohm phase shift in addition to geometric phase shift in radio interference fringes (VSOP mission).

[2] CAPRINI 05 uses isotropy of the cosmic microwave background to place stringent limits on possible charge asymmetry of the Universe. Charge limits are set on the photon, neutrino, and dark matter particles. Valid if charge asymmetries produced by different particles are not anticorrelated.

[3] KOBYCHEV 05 considers a variety of observable effects of photon charge for extragalactic compact radio sources. Best limits if source observed through a foreground cluster of galaxies.

[4] SEMERTZIDIS 03 reports the first laboratory limit on the photon charge in the last 30 years. Straightforward improvements in the apparatus could attain a sensitivity of 10^{-20} e.

[5] SIVARAM 95 requires that CMB photon charge density not overwhelm gravity. Result scales as $\Omega_M\ h^2$.

[6] RAFFELT 94 notes that COCCONI 88 neglects the fact that the time delay due to dispersion by free electrons in the interstellar medium has the same photon energy dependence as that due to bending of a charged photon in the magnetic field. His limit is based on the assumption that the entire observed dispersion is due to photon charge. It is a factor of 200 less stringent than the COCCONI 88 limit.

[7] See COCCONI 92 for less stringent limits in other frequency ranges. Also see RAFFELT 94 note.

graviton

$J = 2$

graviton MASS

It is likely that the graviton is massless. More than fifty years ago Van Dam and Veltman (VANDAM 70), Iwasaki (IWASAKI 70), and Zakharov (ZAKHAROV 70) almost simultaneously showed that in the linear approximation a theory with a finite graviton mass does not approach GR as the mass approaches zero. Attempts have been made to evade this "vDVZ discontinuity" by invoking modified gravity or nonlinear theory by De Rahm (DE-RHAM 17) and others. More recently, the analysis of gravitational wave dispersion has led to bounds that are largely independent of the underlying model, even if not the strongest. We quote the best of these as our best limit.

Experimental limits have been set based on a Yukawa potential (YUKA), dispersion relation (DISP), or other modified gravity theories (MGRV).

The following conversions are useful: $1\ \text{eV} = 1.783\times10^{-36}$ kg $= 1.957\times10^{-6}\ m_e$; $\lambda\!\!\!^{-}_C = (1.973\times10^{-7}\ \text{m})\times(1\ \text{eV}/m_g)$.

[1] ABBOTT 21 assumed modified gravitational-wave dispersion to establish a limit on graviton mass, using LIGO-Virgo O1-O3a binary black hole (BBH) events.

[2] DEFELICE 24 limits graviton mass in context of the "extended Minimal Theory of Massive Gravity" recently proposed by two of the authors, using constraints from Planck-CMB, BAO and SNe1a.

[3] WANG 24 investigates sensitivity to the graviton mass of overlap reduction functions due to stochastic gravitational wave background in the nano-Hertz band as observed in pulsar timing arrays.

[4] DEFELICE 21 studies the normal branch of the Minimal Theory of Massive Gravity (MTMG) to find that after five parameters are adjusted to obtain agreement with all presently available data, today's squared mass $m_g^2 = (2.5^{+4.5}_{-4.8})\times10^{-67}\ \text{eV}^2$ or $m_g < 8.4\times10^{-33}$ eV, both at the 95% CL.

[5] BERNUS 20 use the latest solution of the ephemeris INPOP (19a) in order to improve the constraint in BERNUS 19 on the existence of a Yukawa suppression to the Newtonian potential, generically associated to a gravitons mass.

[6] SHAO 20 sets limit, 95% CL, based on non-observation of excess gravitational radiation in 14 well-timed binary pulsars in the context of the cubic Galileon model.

[7] ABBOTT 19, ABBOTT 17, and ABBOTT 16 assumed modified gravitational waves dispersion to establish limits on graviton mass.

[8] BERNUS 19 use the planetary ephemeris INPOP 17b to constraint the existence of a Yukawa suppression to the Newtonian potential, generically associated to a gravitons mass.

[9] MIAO 19 90% CL limit is based on orbital period decay rates of 9 binary pulsars using a Bayesian prior uniform in graviton mass. Limit becomes $< 5.2\times10^{-21}$ eV for a prior uniform in $\ln(m_g)$.

[10] DESAI 18 limit based on dynamical mass models of galaxy cluster Abell 1689.

[11] GUPTA 18 obtains graviton mass limits using stacked clusters from 3 disparate surveys.

[12] RANA 18 limit, 68% CL, obtained using weak lensing mass profiles out to the radius at which the cluster density falls to 200 times the critical density of the Universe. Limit is based on the fractional change between Newtonian and Yukawa accelerations for the 50 most massive galaxy clusters in the Local Cluster Substructure Survey. Limits for other CL's and other density cuts are also given.

[13] RANA 18 limit, 68% CL, obtained using mass measurements via the SZ effect out to the radius at which the cluster density falls to 500 times the critical density of the Universe for 182 optically confirmed galaxy clusters in an Altacama Cosmology Telescope survey. Limits for other CL's and other density cuts are also given.

[14] WILL 18 limit from perihelion advances of the planets, notably Earth, Mars, and Saturn. Alternate analysis yields $< 6\times10^{-24}$.

[15] ZAKHAROV 16 constrains range of Yukawa gravity interaction from S2 star orbit about black hole at Galactic center. The limit is $< 2.9\times10^{-21}$ eV for $\delta = 100$.

[16] BRITO 13 explore massive graviton (spin-2) fluctuations around rotating black holes.

[17] GRUZINOV 05 uses the DGP model (DVALI 00) showing that non-perturbative effects restore continuity with Einstein's equations as the gravition mass approaches zero, then bases his limit on Solar System observations.

[18] CHOUDHURY 04 concludes from a study of weak-lensing data that masses heavier than about the inverse of 100 Mpc seem to be ruled out if the gravitation field has the Yukawa form.

[19] GERSHTEIN 04 use non-Einstein field relativistic theory of gravity (RTG), with a massive graviton, to obtain the 95% CL mass limit implied by the value of $\Omega_{tot} = 1.02 \pm 0.02$ current at the time of publication.

[20] FINN 02 analyze the orbital decay rates of PSR B1913+16 and PSR B1534+12 with a possible graviton mass as a parameter. The combined frequentist mass limit is at 90%CL.

[21] As of 2020, limits on dP/dt are now about 0.1% (see T. Damour, "Experimental tests of gravitational theory," in this *Review*).

[22] GOLDHABER 74 establish this limit considering the binding of galactic clusters, corrected to Planck $h_0 = 0.67$.

See the related review(s):
Mass and Width of the W Boson

W MASS

The W-mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass-dependent width. To obtain the world average of various measurements, common systematic uncertainties between experiments are evaluated and accounted for in combinations [SCHAEL 13A, AMOROSO 24]. Until 2022, the measurements of the W-boson mass at lepton and hadron colliders, LEP-2 (ALEPH, DELPHI, L3, and OPAL), Tevatron (CDF and D0), and LHC (ATLAS and LHCb), were in good agreement with each other [PDG 22]. However, with the 2022 CDF result [AALTONEN 22] based on their complete Run-II data set, this is no longer the case. The LHC-TeV MW Working Group, including W-mass experts from CDF, D0, ATLAS, CMS and LHCb, has examined this issue in depth [AMOROSO 24]. In May 2026 the LHC-TeV MW Working Group updated their combination [LHC-TeVatron M_W Working Group, Compatibility and combination of world W-boson mass measurements, 7 May 2026], including the improved ATLAS result [AAD 24CJ] and the new CMS result [CHEKHOVSKY 26]. They report that a combination of all W-mass measurements corrected to a common theory description and PDF set, has a probability of compatibility of 0.06% only. A 96.9% probability of compatibility is obtained when the CDF measurement [AALTONEN 22] is removed. The corresponding value of the W boson mass is 80362.5 ± 7.7 MeV, which we quote as the World Average. More information is given in [M. Grunewald, A. Gurtu, J.Kretzschmar, "Mass and Width of the W Boson" review, PDG 26] and references therein.

[1] CHEKHOVSKY 26 analyse W-boson production and decay in the muon channel. The mass of the W boson is determined from analysing the differential distribution in muon transverse momentum (in the range from 26 GeV to 56 GeV) and muon pseudo rapidity (in the range from −2.4 to +2.4) separately for positively and negatively charged muons.

[2] AAD 24CJ provides an improved determination of the W boson mass using the same data as analysed for AABOUD 18J, thus superseding that W boson mass measurement. The distributions of the transverse lepton momentum and of the transverse mass are analysed to determine the W boson mass.

[3] AAIJ 22C analyse W production in the muon decay channel, with the transverse momentum of the muon required to be between 28 and 52 GeV. Analysing the distribution of the muon charge divided by the muon transverse momentum of approximately 2.4 million selected W candidates, a value of M_W = 80354 ± 23(stat.) ± 10(exp.) ± 17(theo.) ± 9(PDF) MeV is obtained; we combine the three systematic uncertainties in quadrature.

[4] Combination of results from ABAZOV 12F and ABAZOV 09AB as quoted in ABAZOV 12F.

[5] ABDALLAH 08A use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu$ and $W^+W^- \to q\overline{q}q\overline{q}$ events for energies 172 GeV and above. The W mass was also extracted from the dependence of the WW cross section close to the production threshold and combined appropriately to obtain the final result. The systematic error includes ±0.025 GeV due to final state interactions and ±0.009 GeV due to LEP energy uncertainty.

[6] ABBIENDI 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The result quoted here is obtained combining this mass value with the results using $W^+W^- \to \ell\nu_\ell\ell'\nu_{\ell'}$ events in the energy range 183–207 GeV (ABBIENDI 03C) and the dependence of the WW production cross-section on m_W at threshold. The systematic error includes ±0.009 GeV due to the uncertainty on the LEP beam energy.

[7] ACHARD 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events in the C.M. energy range 189–209 GeV. The result quoted here is obtained combining this mass value with the results obtained from a direct W mass reconstruction at 172 and 183 GeV and with those from the dependence of the WW production cross-section on m_W at 161 and 172 GeV (ACCIARRI 99).

[8] SCHAEL 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events in the C.M. energy range 183–209 GeV. The result quoted here is obtained combining this mass value with those obtained from the dependence of the W pair production cross-section on m_W at 161 and 172 GeV (BARATE 97 and BARATE 97S respectively). The systematic error includes ±0.009 GeV due to possible effects of final state interactions in the $q\overline{q}q\overline{q}$ channel and ±0.009 GeV due to the uncertainty on the LEP beam energy.

[9] ABAZOV 02D improve the measurement of the W-boson mass including $W \to e\nu_e$ events in which the electron is close to a boundary of a central electromagnetic calorimeter module. Properly combining the results obtained by fitting $m_T(W)$, $p_T(e)$, and $p_T(\nu)$, this sample provides a mass value of 80.574 ± 0.405 GeV. The value reported here is a combination of this measurement with all previous DØ W-boson mass measurements.

[10] AALTONEN 22 select a data sample of about 4 million W boson candidates in 8.8 fb^{-1} of Run-II data. The mass is determined using the transverse mass, transverse lepton momentum and transverse missing momentum distributions of W decays into electrons or muons, accounting for correlations. This measurement supersedes AALTONEN 12E, but is not used in OUR EVALUATION.

[11] AABOUD 18J select 4.61M $W^+ \to \mu^+\nu_\mu$, 3.40M $W^+ \to e^+\nu_e$, 3.23M $W^- \to \mu^-\overline{\nu}_\mu$ and 2.49M $W^- \to e^-\overline{\nu}_e$ events in 4.6 fb^{-1} pp data at 7 TeV. The W mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations. The systematic error includes 0.011 GeV experimental and 0.014 GeV modelling uncertainties.

[12] ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic e^+p and e^-p neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.

[13] AALTONEN 12E select 470k $W \to e\nu$ decays and 625k $W \to \mu\nu$ decays in 2.2 fb^{-1} of Run-II data. The mass is determined using the transverse mass, transverse lepton momentum and transverse missing energy distributions, accounting for correlations. This result supersedes AALTONEN 07F. AALTONEN 14D gives more details on the procedures followed by the authors. This measurement is superseded by AALTONEN 22.

[14] ABAZOV 12F select 1677k $W \to e\nu$ decays in 4.3 fb^{-1} of Run-II data. The mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations.

[15] ABAZOV 09AB study the transverse mass, transverse electron momentum, and transverse missing energy in a sample of 0.5 million $W \to e\nu$ decays selected in Run-II data. The quoted result combines all three methods, accounting for correlations.

[16] AALTONEN 07F obtain high purity $W \to e\nu_e$ and $W \to \mu\nu_\mu$ candidate samples totaling 63,964 and 51,128 events respectively. The W mass value quoted above is derived by simultaneously fitting the transverse mass and the lepton, and neutrino p_T distributions.

[17] AKTAS 06 fit the Q^2 dependence ($300 < Q^2 < 30{,}000$ GeV^2) of the charged-current differential cross section with a propagator mass. The first error is experimental and the second corresponds to uncertainties due to input parameters and model assumptions.

[18] CHEKANOV 02C fit the Q^2 dependence ($200 < Q^2 < 60000$ GeV^2) of the charged-current differential cross sections with a propagator mass fit. The last error is due to the uncertainty on the probability density functions.

Gauge & Higgs Boson Particle Listings

W

[19] AFFOLDER 01E fit the transverse mass spectrum of 30115 $W \to e\nu_e$ events (M_W= 80.473 ± 0.065 ± 0.092 GeV) and of 14740 $W \to \mu\nu_\mu$ events (M_W= 80.465 ± 0.100 ± 0.103 GeV) obtained in the run IB (1994-95). Combining the electron and muon results, accounting for correlated uncertainties, yields M_W= 80.470 ± 0.089 GeV. They combine this value with their measurement of ABE 95P reported in run IA (1992-93) to obtain the quoted value.

[20] BREITWEG 00D fit the Q^2 dependence ($200 < Q^2 < 22500$ GeV^2) of the charged-current differential cross sections with a propagator mass fit. The last error is due to the uncertainty on the probability density functions.

[21] ALITTI 92B result has two contributions to the systematic error (±0.83); one (±0.81) cancels in m_W/m_Z and one (±0.17) is noncancelling. These were added in quadrature. We choose the ALITTI 92B value without using the LEP m_Z value, because we perform our own combined fit.

[22] There are two contributions to the systematic error (±0.84): one (±0.81) which cancels in m_W/m_Z and one (±0.21) which is non-cancelling. These were added in quadrature.

[23] ABE 89I systematic error dominated by the uncertainty in the absolute energy scale.

[24] ALBAJAR 89 result is from a total sample of 299 $W \to e\nu$ events.

[25] ALBAJAR 89 result is from a total sample of 67 $W \to \mu\nu$ events.

[26] ALBAJAR 89 result is from $W \to \tau\nu$ events.

−0.19 ±0.58	1722	ABE	90G	CDF	$E_{cm}^{p\overline{p}}$= 1.8 TeV

[1] AABOUD 18J select 4.61M $W^+ \to \mu^+\nu_\mu$, 3.40M $W^+ \to e^+\nu_e$, 3.23M $W^- \to \mu^-\overline{\nu}_\mu$ and 2.49M $W^- \to e^-\overline{\nu}_e$ events in 4.6 fb^{-1} pp data at 7 TeV. The W mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations. The systematic error includes 0.007 GeV experimental and 0.024 GeV modelling uncertainties.

W WIDTH

The W width listed here corresponds to the width parameter in a Breit-Wigner distribution with mass-dependent width. To obtain the world average, common systematic uncertainties between experiments are properly taken into account. The LEP-2 average W width based on published results is 2.195 ± 0.083 GeV [SCHAEL 13A]. The combined Tevatron data yields an average W width of 2.046 ± 0.049 GeV [TEVEWWG 10]. OUR AVERAGE uses these average LEP and Tevatron width values and combines them together with the ATLAS result, assuming no correlations.

[1] AAD 24CJ provides an improved determination of the W boson mass using the same data as analysed for AABOUD 18J. In addition, the distributions of the transverse lepton momentum and of the transverse mass are analysed to determine the W boson width.

[2] SCHAEL 13A result combines the measurements from the LEP experiments ALEPH (SCHAEL 06), DELPHI(ABDALLAH 08A), L3 (ACHARD 06) and OPAL(ABBIENDI 06). The average of these four results takes correlations into account and has a χ^2 probability of 27%.

[3] TEVEWWG 10 result combines the measurements from the Tevtatron experiments CDF (ABE 95C, AFFOLDER 00M, AALTONEN 08B) and D0 (ABAZOV 02E, ABAZOV 09AK). The average of these five results takes correlations into account and has a χ^2 probability of 84%.

[4] ABAZOV 09AK obtain this result fitting the high-end tail (100-200 GeV) of the transverse mass spectrum in $W \to e\nu$ decays.

[5] AALTONEN 08B obtain this result fitting the high-end tail (90–200 GeV) of the transverse mass spectrum in semileptonic $W \to e\nu_e$ and $W \to \mu\nu_\mu$ decays.

[6] ABDALLAH 08A use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The systematic error includes ±0.065 GeV due to final state interactions.

[7] ABBIENDI 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The systematic error includes ±0.003 GeV due to the uncertainty on the LEP beam energy.

[8] ACHARD 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events in the C.M. energy range 189–209 GeV. The result quoted here is obtained combining this value of the width with the result obtained from a direct W mass reconstruction at 172 and 183 GeV (ACCIARRI 99).

[9] SCHAEL 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The systematic error includes ±0.05 GeV due to possible effects of final state interactions in the $q\overline{q}q\overline{q}$ channel and ±0.01 GeV due to the uncertainty on the LEP beam energy.

[10] ABAZOV 02E obtain this result fitting the high-end tail (90–200 GeV) of the transverse-mass spectrum in semileptonic $W \to e\nu_e$ decays.

[11] ABBOTT 00B measure R = 10.43 ± 0.27 for the $W \to e\nu_e$ decay channel. They use the SM theoretical predictions for $\sigma(W)/\sigma(Z)$ and $\Gamma(W \to e\nu_e)$ and the world average for $B(Z \to ee)$. The value quoted here is obtained combining this result (2.169 ± 0.070 GeV) with that of ABBOTT 99H.

[12] AFFOLDER 00M fit the high transverse mass (100–200 GeV) $W \to e\nu_e$ and $W \to \mu\nu_\mu$ events to obtain $\Gamma(W)$= 2.04 ± 0.11(stat)±0.09(syst) GeV. This is combined with the earlier CDF measurement (ABE 95C) to obtain the quoted result.

[13] ABE 95W measured R = 10.90 ± 0.32 ± 0.29. They use m_W=80.23 ± 0.18 GeV, $\sigma(W)/\sigma(Z)$ = 3.35 ± 0.03, $\Gamma(W \to e\nu)$ = 225.9 ± 0.9 MeV, $\Gamma(Z \to e^+e^-)$ = 83.98 ± 0.18 MeV, and $\Gamma(Z)$ = 2.4969 ± 0.0038 GeV.

[14] ALITTI 92 measured $R = 10.4^{+0.7}_{-0.6} \pm 0.3$. The values of $\sigma(Z)$ and $\sigma(W)$ come from $O(\alpha_s^2)$ calculations using m_W = 80.14 ± 0.27 GeV, and m_Z = 91.175 ± 0.021 GeV along with the corresponding value of $\sin^2\theta_W$ = 0.2274. They use $\sigma(W)/\sigma(Z)$ = 3.26 ± 0.07 ± 0.05 and $\Gamma(Z)$ = 2.487 ± 0.010 GeV.

[15] ALBAJAR 91 measured $R = 9.5^{+1.1}_{-1.0}$ (stat. + syst.). $\sigma(W)/\sigma(Z)$ is calculated in QCD at the parton level using m_W = 80.18 ± 0.28 GeV and m_Z = 91.172 ± 0.031 GeV along with $\sin^2\theta_W$ = 0.2322 ± 0.0014. They use $\sigma(W)/\sigma(Z)$ = 3.23 ± 0.05 and $\Gamma(Z)$ = 2.498 ± 0.020 GeV. This measurement is obtained combining both the electron and muon channels.

[a] ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

[b] This represents the width for the decay of the W boson into a charged particle with momentum below detectability, p< 200 MeV.

W PARTIAL WIDTHS

Γ(invisible) Γ_{12}

This represents the width for the decay of the W boson into a charged particle with momentum below detectability, p< 200 MeV.

VALUE (MeV)	DOCUMENT ID		TECN	COMMENT
$30^{+52}_{-48}\pm33$	[1] BARATE	99I	ALEP	E^{ee}_{cm}= 161+172+183 GeV
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[2] BARATE	99L	ALEP	E^{ee}_{cm}= 161+172+183 GeV

[1] BARATE 99I measure this quantity using the dependence of the total cross section σ_{WW} upon a change in the total width. The fit is performed to the WW measured cross sections at 161, 172, and 183 GeV. This partial width is < 139 MeV at 95%CL.

[2] BARATE 99L use W-pair production to search for effectively invisible W decays, tagging with the decay of the other W boson to Standard Model particles. The partial width for effectively invisible decay is < 27 MeV at 95%CL.

W BRANCHING RATIOS

Overall fits are performed to determine the branching ratios of the W boson. Averages on $W \to e\nu$, $W \to \mu\nu$, and $W \to \tau\nu$, and their correlations are obtained by combining results from the four LEP experiments properly taking into account the common systematic uncertainties and their correlations [SCHAEL 13A]. A first fit determines the three individual leptonic braching ratios B($W \to e\nu$), B($W \to \mu\nu$), and B($W \to \tau\nu$). This fit has a $\chi^2 = 6.3$ for 9 degrees of freedom. The correlation coefficients between the branching fractions are 0.14 ($e-\mu$), −0.20 ($e-\tau$), −0.12 ($\mu-\tau$). A second fit assumes lepton universality and determines the leptonic branching ratio B($W \to \ell\nu$) and the hadronic branching ratio is derived as B($W \to$ hadrons) = 1 − 3 B($W \to \ell\nu$). This fit has a χ^2 = 15.4 for 11 degrees of freedom.

10.61±0.28		[1] ABAZOV	04D	TEVA	$E^{p\overline{p}}_{cm}$= 1.8 TeV

[1] ABAZOV 04D take into account all correlations to properly combine the CDF (ABE 95W) and DØ (ABBOTT 00B) measurements of the ratio R in the electron channel. The ratio R is defined as $[\sigma_W \cdot \text{B}(W \to e\nu_e)] / [\sigma_Z \cdot \text{B}(Z \to ee)]$. The combination gives $R^{Tevatron} = 10.59 \pm 0.23$. σ_W / σ_Z is calculated at next–to–next–to–leading order (3.360 ± 0.051). The branching fraction B($Z \to ee$) is taken from this *Review* as (3.363 ± 0.004)%.

[1] AAD 24CG analyse $t\overline{t}$ production rates in the ee, $e\mu$ and $\mu\mu$ dilepton final states. Using the ratio of B($Z \to \mu\mu$)/B($Z \to ee$) measured precisely at e^+e^- colliders, the ratio B($W \to \mu\nu$)/B($W \to e\nu$) is determined.

[2] AABOUD 17Q make a precise determination of $W \to e\nu$ and $W \to \mu\nu$ production in the follwoing fiducial phase space: lepton pseudo-rapidity range $|\eta| < 2.5$, lepton and neutrino transverse momenta larger than 25 GeV each, and W transverse mass larger than 25 GeV. They determine the ratio of the W branching fractions B($W \to e\nu$)/B($W \to \mu\nu$) = 0.9967 ± 0.0004 ± 0.0101 = 0.997 ± 0.010.

[3] AAIJ 16AJ make precise measurements of forward $W \to e\nu$ and $W \to \mu\nu$ production in proton-proton collisions at 8 TeV and determine the ratio of the W branching fractions B($W \to e\nu$)/B($W \to \mu\nu$) = 1.020 ± 0.002 ± 0.019.

[4] ABACHI 95D obtain this result from the measured σ_WB($W \to \mu\nu$)= 2.09 ± 0.23 ± 0.11 nb and σ_WB($W \to e\nu$)= 2.36 ± 0.07 ± 0.13 nb in which the first error is the combined statistical and systematic uncertainty, the second reflects the uncertainty in the luminosity.

[5] ABE 92I obtain σ_WB($W \to \mu\nu$)= 2.21 ± 0.07 ± 0.21 and combine with ABE 91C σ_W B(($W \to e\nu$)) to give a ratio of the couplings from which we derive this measurement.

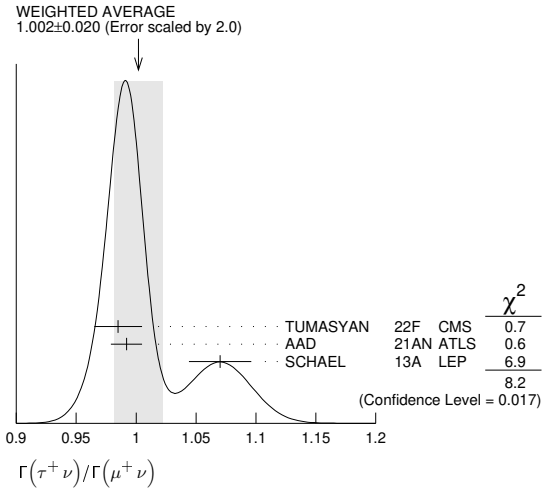
[1] AAD 25Z use a sample of Ws produced from top quark decays, the Ws decaying leptonically as $W \to e\nu_e$ and $W \to \tau\nu_\tau$ with $\tau \to e\nu_e\nu_\tau$. These decay states are distinguished using differences in the impact parameter and transverse momentum spectra of the electrons to determine the ratio of branching fractions B($W \to \tau\nu$)/B($W \to e\nu$).

[2] ABBOTT 00D measure σ_W×B($W \to \tau\nu_\tau$) = 2.22 ± 0.09 ± 0.10 ± 0.10 nb. Using the ABBOTT 00B result σ_W×B($W \to e\nu_e$) = 2.31 ± 0.01 ± 0.05 ± 0.10 nb, they quote the ratio of the couplings from which we derive this measurement.



[3] ABE 92E use two procedures for selecting $W \to \tau\nu_\tau$ events. The missing E_T trigger leads to $132 \pm 14 \pm 8$ events and the τ trigger to $47 \pm 9 \pm 4$ events. Proper statistical and systematic correlations are taken into account to arrive at $\sigma B(W \to \tau\nu) = 2.05 \pm 0.27$ nb. Combined with ABE 91C result on $\sigma B(W \to e\nu)$, ABE 92E quote a ratio of the couplings from which we derive this measurement.
[4] This measurement is derived by us from the ratio of the couplings of ALITTI 92F.

[1] ABBIENDI 06A measure $\langle N_{\rm charged} \rangle$ = 38.74 ± 0.12 ± 0.26 when both W bosons decay hadronically and $\langle N_{\rm charged} \rangle$ = 19.39 ± 0.11 ± 0.09 when one W boson decays semileptonically. The value quoted here is obtained under the assumption that there is no color reconnection between W bosons; the value is a weighted average taking into account correlations in the systematic uncertainties.

[2] ABREU,P 00F measure $\langle N_{\rm charged} \rangle$ = 39.12 ± 0.33 ± 0.36 and 38.11 ± 0.57 ± 0.44 in the fully hadronic final states at 189 and 183 GeV respectively, and $\langle N_{\rm charged} \rangle$ = 19.49 ± 0.31 ± 0.27 and 19.78 ± 0.49 ± 0.43 in the semileptonic final states. The value quoted is a weighted average without assuming any correlations.

[3] ABBIENDI 99N use the final states $W^+W^- \to q\overline{q}\,\ell\overline{\nu}_\ell$ to derive this value.

[4] ABREU 98C combine results from both the fully hadronic as well semileptonic WW final states after demonstrating that the W decay charged multiplicity is independent of the topology within errors.

TRIPLE GAUGE COUPLINGS (TGC'S)

Revised April 2017 by M.W. Grünewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Fourteen independent couplings, seven each for ZWW and γWW, completely describe the VWW vertices within the most general framework of the electroweak Standard Model (SM) consistent with Lorentz invariance and U(1) gauge invariance. Of each of the seven TGCs, three conserve C and P individually, three violate CP, and one violates C and P individually while conserving CP. Assumption of C and P conservation and electromagnetic gauge invariance reduces the number of independent VWW couplings to five: one common set [1,2] is $(\kappa_\gamma, \kappa_Z, \lambda_\gamma, \lambda_Z, g_1^Z)$, where $\kappa_\gamma = \kappa_Z = g_1^Z = 1$ and $\lambda_\gamma = \lambda_Z = 0$ in the Standard Model at tree level. The parameters κ_Z and λ_Z are related to the other three due to constraints of gauge invariance as follows: $\kappa_Z = g_1^Z - (\kappa_\gamma - 1)\tan^2\theta_W$ and $\lambda_Z = \lambda_\gamma$, where θ_W is the weak mixing angle. The W magnetic dipole moment, μ_W, and the W electric quadrupole moment, q_W, are expressed as $\mu_W = e\,(1 + \kappa_\gamma + \lambda_\gamma)/2M_W$ and $q_W = -e\,(\kappa_\gamma - \lambda_\gamma)/M_W^2$.

Precision measurements of suitable observables at LEP1 has already led to an exploration of much of the TGC parameter space. At LEP2, the VWW coupling arises in W-pair production via s-channel exchange, or in single W production via the radiation of a virtual photon off the incident e^+ or e^-. At the Tevatron and the LHC, hard-photon bremsstrahlung off a produced W or Z signals the presence of a triple-gauge vertex. In order to extract the value of one TGC, the others are generally kept fixed to their SM values. While most analyses use the above gauge constraints in the extraction of TGCs, one analysis of W-pair events also determines the real and imaginary parts of all 14 couplings using unconstrained single-parameter fits [3]. The results are consistent. Some experiments have determined limits on the couplings under various non-LEP scenarios and assuming different values of the form factor Λ, where the coupling parameters are scaled by $1/(1+s/\Lambda^2)^2$. For practical reasons it is not possible to quote all such determinations in the listings. For that the individual papers may be consulted. Recently, EFT-inspired sets of couplings [4,5], such as $c_{WWW}/\Lambda^2, c_W/\Lambda^2, c_B/\Lambda^2$ which are linearly related to the couplings discussed above, are also determined by the LHC experiments.

W

[1] ABDALLAH 10 use data on the final states $e^+e^- \to jj\ell\nu$, $jjjj$, jjX, ℓX, at center-of-mass energies between 189–209 GeV at LEP2, where j = jet, ℓ = lepton, and X represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

[2] SCHAEL 05A study single–photon, single–W, and WW–pair production from 183 to 209 GeV. The result quoted here is derived from the WW–pair production sample. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[3] ABBIENDI 04D combine results from W^+W^- in all decay channels. Only CP-conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $0.923 < g_1^Z < 1.054$.

[4] ACHARD 04D study WW–pair production, single–W production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained from the WW–pair production sample including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[5] SIRUNYAN 20BA study electroweak production of a W boson in association with two jets, using W decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of 2.39 ± 0.17 (1.054 ± 0.058) million events. Analyzing the transverse momentum distribution of the charged leptons from W decay, the following 95% C.L. limit is obtained: $0.971 < g_1^Z < 1.044$. Combining this result with that from the closely-related electroweak Z-jet-jet production SIRUNYAN 18BZ, the limit becomes: $0.979 < g_1^Z < 1.034$.

[6] SIRUNYAN 19CL study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $0.9939 < g_1^Z < 1.0074$.

[7] SIRUNYAN 18BZ study $pp \to$ *Z jet jet* events at 13 TeV where $Z \to e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with p_T of the leading/sub-leading lepton $>$ 30/20 GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the Z mass. The two highest p_T jets are selected with p_T of the leading/sub-leading jet $>$ 50/30 GeV respectively and dijet invariant mass > 200 GeV. Templates in the transverse momentum of the Z are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limit is obtained: $0.965 < g_1^Z < 1.042$.

[8] AABOUD 17S analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.87 < g_1^Z < 1.12$.

[9] AABOUD 17U analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.979 < g_1^Z < 1.024$.

[10] KHACHATRYAN 17O analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $0.982 < g_1^Z < 1.035$.

[11] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\overline{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WV events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $0.9913 < g_1^Z < 1.024$.

[12] AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming the LEP formulation and setting the form-factor Λ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.984 < g_1^Z < 1.027$.

[13] AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analyzing the WZ transverse momentum distribution, the resulting 95% C.L. limit is: $0.981 < g_1^Z < 1.029$.

[14] AAD 14Y determine the electroweak Z-dijet cross section in 8 TeV pp collisions. $Z \to ee$ and $Z \to \mu\mu$ decays are selected with the di-lepton $p_T > 20$ GeV and mass in the 81–101 GeV range. Minimum two jets are required with $p_T > 55$ and 45 GeV and no additional jets with $p_T > 25$ GeV in the rapidity interval between them. The normalized p_T balance between the Z and the two jets is required to be < 0.15. This leads to a selection of 900 events with dijet mass > 1 TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit $0.5 < g_1^Z < 1.26$ for a form factor value $\Lambda = \infty$.

[15] AAD 13AL study WW production in pp collisions and select 1325 WW candidates in decay modes with electrons or muons with an expected background of 369 ± 61 events. Assuming the LEP formulation and setting the form-factor Λ = infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.961 < g_1^Z < 1.052$. Supersedes AAD 12AC.

[16] CHATRCHYAN 13BF determine the W^+W^- production cross section using unlike sign di-lepton (e or μ) events with high $\not{p}_T$. The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of 247 ± 34. The p_T distribution of the leading lepton is fitted to obtain 95% C.L. limits of $0.905 \le g_1^Z \le 1.095$.

[17] AAD 12CD study WZ production in pp collisions and select 317 WZ candidates in three $\ell\nu$ decay modes with an expected background of 68.0 ± 10.0 events. The resulting 95% C.L. range is: $0.943 < g_1^Z < 1.093$. Supersedes AAD 12V.

[18] AALTONEN 12AC study WZ production in $p\overline{p}$ collisions and select 63 WZ candidates in three $\ell\nu$ decay modes with an expected background of 7.9 ± 1.0 events. Based on the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported: $0.92 < g_1^Z < 1.20$ for a form factor of $\Lambda = 2$ TeV.

[19] ABAZOV 12AG combine new results with already published results on $W\gamma$, WW and WZ production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $g_1^Z = 1.022^{+0.032}_{-0.030}$.

[20] ABAZOV 11 study the $p\overline{p} \to 3\ell\nu$ process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the p_T spectrum of the Z boson leads to a 95% C.L. limit of $0.944 < g_1^Z < 1.154$, for a form factor $\Lambda = 2$ TeV.

[21] AALTONEN 10K study $p\overline{p} \to W^+W^-$ with $W \to e/\mu\nu$. The p_T of the leading (second) lepton is required to be > 20 (10) GeV. The final number of events selected is 654 of which 320 ± 47 are estimated to be background. The 95% C.L. interval is $0.76 < g_1^Z < 1.34$ for $\Lambda = 1.5$ TeV and $0.78 < g_1^Z < 1.30$ for $\Lambda = 2$ TeV.

[22] ABAZOV 09AD study the $p\overline{p} \to \ell\nu 2$jet process arising in WW and WZ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the p_T spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $0.88 < g_1^Z < 1.20$.

[23] ABAZOV 09AJ study the $p\overline{p} \to 2\ell 2\nu$ process arising in WW production. They select 100 events with an expected WW signal of 65 events. An analysis of the p_T spectrum of the two charged leptons leads to 95% C.L. limits of $0.86 < g_1^Z < 1.3$, for a form factor $\Lambda = 2$ TeV.

[24] ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \to W^+W^- \to (qq)(\ell\nu)$, where $\ell = e$ or μ. Values of all other couplings are fixed to their standard model values.

[25] ABAZOV 07Z set limits on anomalous TGCs using the measured cross section and $p_T(Z)$ distribution in WZ production with both the W and the Z decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $0.86 < g_1^Z < 1.35$.

[26] ABAZOV 05S study $\overline{p}p \to WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\overline{\ell}'$ (ℓ and $\ell' = e$ or μ). Three events (estimated background 0.71 ± 0.08 events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale $\Lambda = 1.5$ TeV is $0.51 < g_1^Z < 1.66$, fixing λ_Z and κ_Z to their Standard Model values.

[27] ABREU 01I combine results from e^+e^- interactions at 189 GeV leading to W^+W^- and $We\nu_e$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $0.84 < g_1^Z < 1.13$.

[28] ABBOTT 99I perform a simultaneous fit to the $W\gamma$, $WW \to$ dilepton, $WW/WZ \to e\nu jj$, $WW/WZ \to \mu\nu jj$, and $WZ \to$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95%CL limits are $0.63 < g_1^Z < 1.57$, fixing λ_Z and κ_Z to their Standard Model values, and assuming Standard Model values for the $WW\gamma$ couplings.

[1] ABDALLAH 10 use data on the final states $e^+e^- \to jj\ell\nu$, $jjjj$, jjX, ℓX, at center-of-mass energies between 189–209 GeV at LEP2, where j = jet, ℓ = lepton, and X represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

[2] SCHAEL 05A study single–photon, single–W, and WW–pair production from 183 to 209 GeV. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[3] ABBIENDI 04D combine results from W^+W^- in all decay channels. Only *CP*-conserving couplings are considered and each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $0.73 < \kappa_\gamma < 1.07$.

[4] ACHARD 04D study WW–pair production, single–W production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[5] AABOUD 17U analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.939 < \kappa_\gamma < 1.064$.

[6] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\overline{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WV events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $0.956 < \kappa_\gamma < 1.063$.

[7] CHATRCHYAN 14AB measure $W\gamma$ production cross section for $p_T^\gamma > 15$ GeV and R($\ell\gamma$) > 0.7, which is the separation between the γ and the final state charged lepton (e or μ) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. After background subtraction the number of $e\nu\gamma$ and $\mu\nu\gamma$ events is determined to be 3200 ± 325 and 4970 ± 543 respectively, compatible with expectations from the SM. This leads to a 95% CL limit of $0.62 < \kappa_\gamma < 1.29$, assuming other parameters have SM values.

[8] AAD 13AN study $W\gamma$ production in pp collisions. In events with no additional jet, 4449 (6578) W decays to electron (muon) are selected, with an expected background of 1662 ± 262 (2538 ± 362) events. Analysing the photon p_T spectrum above 100 GeV yields a 95% C.L. limit of $0.59 < \kappa_\gamma < 1.46$. Supersedes AAD 12BX.

[9] CHATRCHYAN 13BF determine the W^+W^- production cross section using unlike sign di-lepton (e or μ) events with high $\not{p}_T$. The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of 247 ± 34. The p_T distribution of the leading lepton is fitted to obtain 95% C.L. limits of $0.79 \leq k_\gamma \leq 1.22$.

[10] ABAZOV 12AG combine new results with already published results on $W\gamma$, WW and WZ production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $\kappa_\gamma = 1.048^{+0.106}_{-0.105}$.

[11] ABAZOV 11AC study $W\gamma$ production in $p\overline{p}$ collisions at 1.96 TeV, with the W decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon E_T spectrum above 15 GeV yields at 95% C.L. the result: $0.6 < \kappa_\gamma < 1.4$ for a formfactor $\Lambda = 2$ TeV.

[12] CHATRCHYAN 11M study $W\gamma$ production in pp collisions at $\sqrt{s} = 7$ TeV using 36 pb^{-1} pp data with the W decaying to electron and muon. The total cross section is measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$. The number of candidate (background) events is 452 (228 ± 21) for the electron channel and 520 (277 ± 25) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of $-0.11 < \kappa_\gamma < 2.04$.

[13] AALTONEN 10K study $p\overline{p} \to W^+W^-$ with $W \to e/\mu\nu$. The p_T of the leading (second) lepton is required to be > 20 (10) GeV. The final number of events selected is 654 of which 320 ± 47 are estimated to be background. The 95% C.L. interval is $0.37 < \kappa_\gamma < 1.72$ for $\Lambda = 1.5$ TeV and $0.43 < \kappa_\gamma < 1.65$ for $\Lambda = 2$ TeV.

[14] AARON 09B study single-W production in ep collisions at 0.3 TeV C.M. energy. They select 53 $W \to e/\mu\nu$ events with a standard model expectation of 54.1 ± 7.4 events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of $-3.7 < \kappa_\gamma < -1.5$ or $0.3 < \kappa_\gamma < 1.5$, where the ambiguity is due to the quadratic dependence of the cross section to the coupling parameter.

[15] ABAZOV 09AD study the $p\overline{p} \to \ell\nu 2$jet process arising in WW and WZ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the p_T spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $0.56 < \kappa_\gamma < 1.55$.

[16] ABAZOV 09AJ study the $p\overline{p} \to 2\ell 2\nu$ process arising in WW production. They select 100 events with an expected WW signal of 65 events. An analysis of the p_T spectrum of the two charged leptons leads to 95% C.L. limits of $0.46 < \kappa_\gamma < 1.83$, for a form factor $\Lambda = 2$ TeV.

[17] ABAZOV 08R use 0.7 fb^{-1} $p\overline{p}$ data at $\sqrt{s} = 1.96$ TeV to select 263 $W\gamma + X$ events, of which 187 constitute signal, with the W decaying into an electron or a muon, which is required to be well separated from a photon with $E_T > 9$ GeV. A likelihood fit to the photon E_T spectrum yields a 95% CL limit $0.49 < \kappa_\gamma < 1.51$ with other couplings fixed to their Standard Model values.

[18] ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \to W^+W^- \to (q\overline{q})(\ell\nu)$, where $\ell = e$ or μ. Values of all other couplings are fixed to their standard model values.

[19] AALTONEN 07L set limits on anomalous TGCs using the $p_T(W)$ distribution in WW and WZ production with the W decaying to an electron or muon and the Z to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are $0.54 < \kappa_\gamma < 1.39$ for a form factor scale $\Lambda = 1.5$ TeV.

[20] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 1$ TeV is $-0.05 < \kappa_\gamma < 2.29$, fixing $\lambda_\gamma = 0$. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $0.68 < \kappa < 1.45$.

[21] ABAZOV 05J perform a likelihood fit to the photon E_T spectrum of $W\gamma$ + X events, where the W decays to an electron or muon which is required to be well separated from the photon. For $\Lambda = 2.0$ TeV the 95% CL limits are $0.12 < \kappa_\gamma < 1.96$. In the fit λ_γ is kept fixed to its Standard Model value.

[22] ABREU 01I combine results from e^+e^- interactions at 189 GeV leading to W^+W^-, $We\nu_e$, and $\nu\overline{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $0.87 < \kappa_\gamma < 1.68$.

[23] BREITWEG 00 search for W production in events with large hadronic p_T. For $p_T > 20$ GeV, the upper limit on the cross section gives the 95%CL limit $-3.7 < \kappa_\gamma < 2.5$ (for $\lambda_\gamma = 0$).

[24] ABBOTT 99I perform a simultaneous fit to the $W\gamma$, $WW \to$ dilepton, $WW/WZ \to e\nu jj$, $WW/WZ \to \mu\nu jj$, and $WZ \to$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95%CL limits are $0.75 < \kappa_\gamma < 1.39$.

λ_γ

[1] ABDALLAH 10 use data on the final states $e^+e^- \to jj\ell\nu$, $jjjj$, jjX, ℓX, at center-of-mass energies between 189–209 GeV at LEP2, where j = jet, ℓ = lepton, and X represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

[2] SCHAEL 05A study single–photon, single–W, and WW–pair production from 183 to 209 GeV. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[3] ABBIENDI 04D combine results from W^+W^- in all decay channels. Only *CP*-conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $-0.13 < \lambda_\gamma < 0.01$.

[4] ACHARD 04D study WW–pair production, single–W production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[5] CHATRCHYAN 14AB measure $W\gamma$ production cross section for $p_T^\gamma > 15$ GeV and R($\ell\gamma$) > 0.7, which is the separation between the γ and the final state charged lepton (e or μ) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. After background subtraction the number of $e\nu\gamma$ and $\mu\nu\gamma$ events is determined to be 3200 ± 325 and 4970 ± 543 respectively, compatible with expectations from the SM. This leads to a 95% CL limit of $-0.050 < \lambda_\gamma < 0.037$, assuming all other parameters have SM values.

[6] AAD 13AN study $W\gamma$ production in pp collisions. In events with no additional jet, 4449 (6578) W decays to electron (muon) are selected, with an expected background of 1662 ± 262 (2538 ± 362) events. Analysing the photon p_T spectrum above 100 GeV yields a 95% C.L. limit of $-0.065 < \lambda_\gamma < 0.061$. Supersedes AAD 12BX.

[7] ABAZOV 12AG combine new results with already published results on $W\gamma$, WW and WZ production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $\lambda_\gamma = 0.007^{+0.021}_{-0.022}$.

[8] ABAZOV 11AC study $W\gamma$ production in $p\overline{p}$ collisions at 1.96 TeV, with the W decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon E_T spectrum above 15 GeV yields at 95% C.L. the result: $-0.08 < \lambda_\gamma < 0.07$ for a formfactor $\Lambda = 2$ TeV.

[9] CHATRCHYAN 11M study $W\gamma$ production in pp collisions at $\sqrt{s} = 7$ TeV using 36 pb^{-1} pp data with the W decaying to electron and muon. The total cross section is measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$. The number of candidate (background) events is 452 (228 ± 21) for the electron channel and 520

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

(277 ± 25) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of $-0.18 < \lambda_\gamma < 0.17$.

[10] AARON 09B study single-W production in ep collisions at 0.3 TeV C.M. energy. They select 53 $W \to e/\mu$ events with a standard model expectation of 54.1 ± 7.4 events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of $-2.5 < \lambda_\gamma < 2.5$.

[11] ABAZOV 09AD study the $p\overline{p} \to \ell\nu$ 2jet process arising in WW and WZ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the p_T spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $-0.10 < \lambda_\gamma < 0.11$.

[12] ABAZOV 09AJ study the $p\overline{p} \to 2\ell 2\nu$ process arising in WW production. They select 100 events with an expected WW signal of 65 events. An analysis of the p_T spectrum of the two charged leptons leads to 95% C.L. limits of $-0.14 < \lambda_\gamma < 0.18$, for a form factor $\Lambda = 2$ TeV.

[13] ABAZOV 08R use 0.7 fb^{-1} $p\overline{p}$ data at $\sqrt{s} = 1.96$ TeV to select 263 $W\gamma + X$ events, of which 187 constitute signal, with the W decaying into an electron or a muon, which is required to be well separated from a photon with $E_T > 9$ GeV. A likelihood fit to the photon E_T spectrum yields a 95% CL limit $-0.12 < \lambda_\gamma < 0.13$ with other couplings fixed to their Standard Model values.

[14] ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \to W^+W^- \to (qq)(\ell\nu)$, where $\ell = e$ or μ. Values of all other couplings are fixed to their standard model values.

[15] AALTONEN 07L set limits on anomalous TGCs using the $p_T(W)$ distribution in WW and WZ production with the W decaying to an electron or muon and the Z to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are $-0.18 < \lambda_\gamma < 0.17$ for a form factor scale $\Lambda = 1.5$ TeV.

[16] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 1$ TeV is $-0.97 < \lambda_\gamma < 1.04$, fixing κ_γ=1. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit (Λ = 2 TeV) is $-0.29 < \lambda < 0.30$.

[17] ABAZOV 05J perform a likelihood fit to the photon E_T spectrum of $W\gamma$ + X events, where the W decays to an electron or muon which is required to be well separated from the photon. For $\Lambda = 2.0$ TeV the 95% CL limits are $-0.20 < \lambda_\gamma < 0.20$. In the fit κ_γ is kept fixed to its Standard Model value.

[18] ABREU 01I combine results from e^+e^- interactions at 189 GeV leading to W^+W^-, $We\nu_e$, and $\nu\overline{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $-0.11 < \lambda_\gamma < 0.23$.

[19] BREITWEG 00 search for W production in events with large hadronic p_T. For p_T >20 GeV, the upper limit on the cross section gives the 95%CL limit $-3.2 < \lambda_\gamma < 3.2$ for κ_γ fixed to its Standard Model value.

[20] ABBOTT 99I perform a simultaneous fit to the $W\gamma$, $WW \to$ dilepton, $WW/WZ \to e\nu jj$, $WW/WZ \to \mu\nu jj$, and $WZ \to$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95%CL limits are $-0.18 < \lambda_\gamma < 0.19$.

κ_Z

This coupling is CP-conserving (C- and P- separately conserving).

[1] ACHARD 04D study WW–pair production, single–W production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the WW–pair production sample. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[2] SIRUNYAN 20BA study electroweak production of a W boson in association with two jets, using W decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of 2.39 ± 0.17 (1.054 ± 0.058) million events. Analysing the transverse momentum distribution of the charged leptons from W decay, the following 95% C.L. limit is obtained: $0.956 < \kappa_Z < 1.044$. Combining this result with that from the closely-related electroweak Z-jet-jet production SIRUNYAN 18BZ, the limit becomes: $0.957 < \kappa_Z < 1.042$.

[3] SIRUNYAN 19CL study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $0.9921 < \kappa_Z < 1.0082$.

[4] AABOUD 17S analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.85 < \kappa_Z < 1.16$.

[5] KHACHATRYAN 17O analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $0.79 < \kappa_Z < 1.25$.

[6] AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming the LEP formulation and setting the form-factor Λ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.975 < \kappa_Z < 1.020$.

[7] AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analyzing the WZ transverse momentum distribution, the resulting 95% C.L. limit is: $0.81 < \kappa_Z < 1.30$.

[8] AAD 13AL study WW production in pp collisions and select 1325 WW candidates in decay modes with electrons or muons with an expected background of 369 ± 61 events. Assuming the LEP formulation and setting the form-factor Λ = infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.957 < \kappa_Z < 1.043$. Supersedes AAD 12AC.

[9] AAD 12CD study WZ production in pp collisions and select 317 WZ candidates in three $\ell\nu$ decay modes with an expected background of 68.0 ± 10.0 events. The resulting 95% C.L. range is: $0.63 < \kappa_Z < 1.57$. Supersedes AAD 12V.

[10] AALTONEN 12AC study WZ production in $p\overline{p}$ collisions and select 63 WZ candidates in three $\ell\nu$ decay modes with an expected background of 7.9 ± 1.0 events. Based on the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported: $0.61 < \kappa_Z < 1.90$ for a form factor of $\Lambda = 2$ TeV.

[11] ABAZOV 11 study the $p\overline{p} \to 3\ell\nu$ process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the p_T spectrum of the Z boson leads to a 95% C.L. limit of $0.600 < \kappa_Z < 1.675$, for a form factor $\Lambda = 2$ TeV.

[12] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $0.55 < \kappa_Z < 1.55$, fixing λ_Z=0. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit (Λ = 2 TeV) is $0.68 < \kappa < 1.45$.

[13] ABAZOV 05S study $\overline{p}p \to WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\overline{\ell}'$ (ℓ and $\ell' = e$ or μ). Three events (estimated background 0.71 ± 0.08 events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale $\Lambda = 1$ TeV is $-1.0 < \kappa_Z < 3.4$, fixing λ_Z and g_1^Z to their Standard Model values.

λ_Z

This coupling is CP-conserving (C- and P- separately conserving).

[1] ACHARD 04D study WW–pair production, single–W production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the WW–pair production sample. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[2] SIRUNYAN 20BA study electroweak production of a W boson in association with two jets, using W decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of 2.39 ± 0.17 (1.054 ± 0.058) million events. Analysing the transverse momentum distribution of the charged leptons from W decay, the following 95% C.L. limit is obtained: -0.0088 < λ_Z < 0.0095. Combining this result with that from the closely-related electroweak Z-jet-jet production SIRUNYAN 18BZ, the limit becomes: $-0.0071 < \lambda_Z < 0.0076$.

[3] SIRUNYAN 19CL study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $-0.0065 < \lambda_Z < 0.0066$.

[4] SIRUNYAN 18BZ study $pp \to Z$ *jet jet* events at 13 TeV where $Z \to e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with p_T of the leading/sub-leading lepton $>$ 30/20 GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the Z mass. The two highest p_T jets are selected with p_T of the leading/sub-leading jet $>$ 50/30 GeV respectively and dijet invariant mass $>$ 200 GeV. Templates in the transverse momentum of the Z are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limit is obtained $-0.010 < \lambda_Z < 0.010$.

[5] AABOUD 17S analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-0.053 < \lambda_Z < 0.042$.

[6] AABOUD 17U analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-0.013 < \lambda_Z < 0.013$.

[7] KHACHATRYAN 17O analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $-0.018 < \lambda_Z < 0.016$.

[8] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\overline{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WV events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $-0.011 < \lambda_Z < 0.011$.

[9] AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming the LEP formulation and setting the form-factor Λ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $-0.019 < \lambda_Z < 0.019$.

[10] AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analyzing the WZ transverse momentum distribution, the resulting 95% C.L. limit is: $-0.016 < \lambda_Z < 0.016$.

[11] AAD 14Y determine the electroweak Z-dijet cross section in 8 TeV pp collisions. $Z \to ee$ and $Z \to \mu\mu$ decays are selected with the di-lepton $p_T > 20$ GeV and mass in the 81–101 GeV range. Minimum two jets are required with $p_T > 55$ and 45 GeV and no additional jets with $p_T > 25$ GeV in the rapidity interval between them. The normalized p_T balance between the Z and the two jets is required to be < 0.15. This leads to a selection of 900 events with dijet mass > 1 TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit $-0.15 < \lambda_Z < 0.13$ for a form factor value $\Lambda = \infty$.

[12] AAD 13AL study WW production in pp collisions and select 1325 WW candidates in decay modes with electrons or muons with an expected background of 369 ± 61 events. Assuming the LEP formulation and setting the form-factor Λ = infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $-0.062 < \lambda_Z < 0.059$. Supersedes AAD 12AC.

[13] CHATRCHYAN 13BF determine the W^+W^- production cross section using unlike sign di-lepton (e or μ) events with high $\not{p}_T$. The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of 247 ± 34. The p_T distribution of the leading lepton is fitted to obtain 95% C.L. limits of $-0.048 \leq \lambda_Z \leq 0.048$.

[14] AAD 12CD study WZ production in pp collisions and select 317 WZ candidates in three $\ell\nu$ decay modes with an expected background of 68.0 ± 10.0 events. The resulting 95% C.L. range is: $-0.046 < \lambda_Z < 0.047$. Supersedes AAD 12V.

[15] AALTONEN 12AC study WZ production in $p\overline{p}$ collisions and select 63 WZ candidates in three $\ell\nu$ decay modes with an expected background of 7.9 ± 1.0 events. Based on the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported: $-0.08 < \lambda_Z < 0.10$ for a form factor of $\Lambda = 2$ TeV.

[16] ABAZOV 11 study the $p\overline{p} \to 3\ell\nu$ process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the p_T spectrum of the Z boson leads to a 95% C.L. limit of $-0.077 < \lambda_Z < 0.093$, for a form factor $\Lambda = 2$ TeV.

[17] AALTONEN 10K study $p\overline{p} \to W^+W^-$ with $W \to e/\mu\nu$. The p_T of the leading (second) lepton is required to be > 20 (10) GeV. The final number of events selected is 654 of which 320 ± 47 are estimated to be background. The 95% C.L. interval is $-0.16 < \lambda_Z < 0.16$ for $\Lambda = 1.5$ TeV and $-0.14 < \lambda_Z < 0.15$ for $\Lambda = 2$ TeV.

[18] ABAZOV 07Z set limits on anomalous TGCs using the measured cross section and $p_T(Z)$ distribution in WZ production with both the W and the Z decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $-0.17 < \lambda_Z < 0.21$.

[19] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $-0.39 < \lambda_Z < 0.39$, fixing κ_Z=1. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $-0.29 < \lambda < 0.30$.

[20] ABAZOV 05S study $\overline{p}p \to WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\overline{\ell}'$ (ℓ and $\ell' = e$ or μ). Three events (estimated background 0.71 ± 0.08 events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale $\Lambda = 1.5$ TeV is $-0.48 < \lambda_Z < 0.48$, fixing g_1^Z and κ_Z to their Standard Model values.

g_5^Z

This coupling is *CP*-conserving but *C*- and *P*-violating.

W ANOMALOUS MAGNETIC MOMENT

The full magnetic moment is given by $\mu_W = e(1+\kappa+\lambda)/2m_W$. In the Standard Model, at tree level, $\kappa = 1$ and $\lambda = 0$. Some papers have defined $\Delta\kappa = 1-\kappa$ and assume that $\lambda = 0$. Note that the electric quadrupole moment is given by $-e(\kappa-\lambda)/m_W^2$. A description of the parameterization of these moments and additional references can be found in HAGIWARA 87 and BAUR 88. The parameter Λ appearing in the theoretical limits below is a regularization cutoff which roughly corresponds to the energy scale where the structure of the *W* boson becomes manifest.

		[6] GRIFOLS	88	THEO	
		[7] GROTCH	87	THEO	
		[8] VANDERBIJ	87	THEO	
		[9] GRAU	85	THEO	
		[10] SUZUKI	85	THEO	
		[11] HERZOG	84	THEO	

[1] ABREU 01I combine results from e^+e^- interactions at 189 GeV leading to W^+W^-, $We\nu_e$, and $\nu\overline{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV to determine Δg_1^Z, $\Delta\kappa_\gamma$, and λ_γ. $\Delta\kappa_\gamma$ and λ_γ are simultaneously floated in the fit to determine μ_W.

[2] ABE 95G report $-1.3 < \kappa < 3.2$ for λ=0 and $-0.7 < \lambda < 0.7$ for κ=1 in $p\overline{p} \to e\nu_e\gamma$X and $\mu\nu_\mu\gamma$X at $\sqrt{s} = 1.8$ TeV.

[3] ALITTI 92C measure $\kappa = 1^{+2.6}_{-2.2}$ and $\lambda = 0^{+1.7}_{-1.8}$ in $p\overline{p} \to e\nu\gamma+$ X at $\sqrt{s} = 630$ GeV. At 95%CL they report $-3.5 < \kappa < 5.9$ and $-3.6 < \lambda < 3.5$.

[4] SAMUEL 92 use preliminary CDF and UA2 data and find $-2.4 < \kappa < 3.7$ at 96%CL and $-3.1 < \kappa < 4.2$ at 95%CL respectively. They use data for $W\gamma$ production and radiative *W* decay.

[5] SAMUEL 91 use preliminary CDF data for $p\overline{p} \to W\gamma$X to obtain $-11.3 \leq \Delta\kappa \leq 10.9$. Note that their $\kappa = 1-\Delta\kappa$.

[6] GRIFOLS 88 uses deviation from ρ parameter to set limit $\Delta\kappa \lesssim 65$ (M_W^2/Λ^2).

[7] GROTCH 87 finds the limit $-37 < \Delta\kappa < 73.5$ (90% CL) from the experimental limits on $e^+e^- \to \nu\overline{\nu}\gamma$ assuming three neutrino generations and $-19.5 < \Delta\kappa < 56$ for four generations. Note their $\Delta\kappa$ has the opposite sign as our definition.

[8] VANDERBIJ 87 uses existing limits to the photon structure to obtain $|\Delta\kappa| < 33$ (m_W/Λ). In addition VANDERBIJ 87 discusses problems with using the ρ parameter of the Standard Model to determine $\Delta\kappa$.

[9] GRAU 85 uses the muon anomaly to derive a coupled limit on the anomalous magnetic dipole and electric quadrupole (λ) moments $1.05 > \Delta\kappa \ln(\Lambda/m_W) + \lambda/2 > -2.77$. In the Standard Model $\lambda = 0$.

[10] SUZUKI 85 uses partial-wave unitarity at high energies to obtain $|\Delta\kappa| \lesssim 190$ $(m_W/\Lambda)^2$. From the anomalous magnetic moment of the muon, SUZUKI 85 obtains $|\Delta\kappa| \lesssim 2.2/\ln(\Lambda/m_W)$. Finally SUZUKI 85 uses deviations from the ρ parameter and obtains a very qualitative, order-of-magnitude limit $|\Delta\kappa| \lesssim 150\ (m_W/\Lambda)^4$ if $|\Delta\kappa| \ll 1$.

[11] HERZOG 84 consider the contribution of *W*-boson to muon magnetic moment including anomalous coupling of $WW\gamma$. Obtain a limit $-1 < \Delta\kappa < 3$ for $\Lambda \gtrsim 1$ TeV.

c_{WWW}/Λ^2, c_W/Λ^2, c_B/Λ^2

These couplings are used in EFT-based approaches to anomalous couplings. They are linearly related to the couplings discussed above.

[1] AAD 25AD measures charged-current Drell-Yan production of *W* bosons decaying to electrons or muons. Analysing the transverse mass and lepton pseudo rapidity single and double differential distributions, the following 95% C.L. limits on EFT couplings are obtained: -0.0047 $< c^{(3)}_{\ell q}/\Lambda^2 <$ 0.0021, -0.60 $< c^{(1)}_{\ell\ell}/\Lambda^2 <$ 1.15, -1.14 $< c^{(3)}_{H\ell}/\Lambda^2 <$ 0.60, -0.61 $< c^{(3)}_{Hq}/\Lambda^2 <$ 1.15, in units of TeV^{-2}.

[2] AAD 25BE study *WZ* production, measuring cross sections and various distributions. Analysing the *WZ* transverse mass distribution without cutoff and considering linear and quadratic contributions, the following 95% C.L. limits on *CP*-conserving operators are derived in units of TeV^{-2}: $-0.093 < c_W/\Lambda^2 < 0.079$, $-0.458 < c_{HWB}/\Lambda^2 < 1.520$, $-5.840 < c_{HD}/\Lambda^2 < 1.680$, $-0.503 < c^{(1)}_{Hq}/\Lambda^2 < 2.550$, $-0.165 < c^{(3)}_{Hq}/\Lambda^2 < 0.015$. Limits on *CP*-violating operators are derived using the *WZ* transverse mass distribution and dedicated *CP*-sensitive observables at 95% C.L. in units of TeV^{-2}: $-1.505 < c_{H\widetilde{W}B}/\Lambda^2 < 1.263$, $-0.109 < c_{\widetilde{W}}/\Lambda^2 < 0.093$.

[3] HAYRAPETYAN 25AM study same-sign *WW* production, with one *W* boson decaying into electrons or muons and the other *W* boson decaying into a tau lepton, in association with at least two jets with large invariant mass and rapidity difference. Multivariate classifiers are used to extract the following 95% C.L. limits in units of TeV^{-2}: $-13.5 < c^{(1)}_{\ell\ell}/\Lambda^2 < 2.11$, $-0.605 < c^{(1)}_{qq}/\Lambda^2 < 0.681$, $-0.842 < c_W/\Lambda^2 < 0.818$, $-8.68 < c_{HW}/\Lambda^2 < 7.60$, $-49.7 < c_{HWB}/\Lambda^2 < 110$, $-20.9 < c_{Hbox}/\Lambda^2 < 22.7$, $-31.4 < c_{HD}/\Lambda^2 < 45.5$, $-69.3 < c^{(1)}_{H\ell}/\Lambda^2 < 68.3$, $-1.59 < c^{(3)}_{H\ell}/\Lambda^2 < 9.94$, $-5.55 < c^{(1)}_{Hq}/\Lambda^2 < 5.60$.

[4] TUMASYAN 22AB study *WZ* production, measuring cross sections and various distributions. Analysing the *WZ* invariant mass distribution, the following 95% C.L. limits are derived in units of TeV^{-2}: $-2.5 < c_W/\Lambda^2 < 0.3$, $-1.0 < c_{WWW}/\Lambda^2 < 1.2$, $-43 < c_b/\Lambda^2 < 113$, $-0.62 < \tilde{c}_{WWW}/\Lambda^2 < 0.53$, $-32 < \tilde{c}_W/\Lambda^2 < 32$.

[5] TUMASYAN 22E measure $W\gamma$ production where the *W* boson decays to electrons or muons. Analysing the photon transverse momentum distribution in bins of lepton azimuth, the following 95% C.L. limit is derived in units of TeV^{-2}: $-0.062 < c_{3W}/\Lambda^2 < 0.052$. This limit is derived including the non-SM, SM and their interference effects.

[6] AAD 21AC study the differential cross-section for the electroweak production of dijets in association with a *Z* boson, where the *Z* boson decays to electrons or muons. The number of events selected in the data is 10,870 (12,125) in the electron (muon) channel. Analyzing the distribution of the azimuthal separation of the two jets, the following 95% C.L. limits are derived in units of TeV^{-2}: $-2.7 < c_{WWW}/\Lambda^2 < 5.8$, $-1.6 < \tilde{c}_{WWW}/\Lambda^2 < 2.0$, $-0.19 < c_W/\Lambda^2 < 0.41$, $-0.11 < \tilde{c}_W/\Lambda^2 < 0.14$, $-6.31 < c_{HWB}/\Lambda^2 < 1.01$, $0.23 < \tilde{c}_{HWB}/\Lambda^2 < 2.35$.

[7] AAD 21W analyze W^+W^- production in association with at least one jet. Events with exactly one oppositely-charged electron-muon pair and at least one hadronic jet of transverse momentum larger than 30 GeV (120 GeV) are selected. In the data, 89,239 (5,825) events are found, with a total Standard-Model expectation of 91600 $\pm$ 2500 (5980 $\pm$ 150). Analyzing the electron-muon invariant mass distribution, the following limit at 95% C.L. is obtained: $-0.33 < c_W/\Lambda^2 < 0.33$ ($-0.60 < c_W/\Lambda^2 < 0.58$), for a fixed choice of $\Lambda = 1$ TeV.

[8] SIRUNYAN 21G measure $W\gamma$ production where the *W* decays into electrons or muons. In the data, 385,224 (395,818) events are selected in the electron (muon) channel, with a total Standard-Model expectation of 396913$\pm$54686 (396257$\pm$22837) events. Analysing the photon transverse momentum distribution, the following 95% C.L. limits are derived in units of TeV^{-2}: $-0.90 < c_{WWW}/\Lambda^2 < 0.91$, $-40 < c_B/\Lambda^2 < 41$, $-0.45 < c_{\overline{W}WW}/\Lambda^2 < 0.45$, $-20 < c_{\overline{W}}/\Lambda^2 < 20$.

[9] SIRUNYAN 20BA study electroweak production of a *W* boson in association with two jets, using *W* decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of 2.39$\pm$0.17 (1.054$\pm$0.058) million events. Analysing the transverse momentum distribution of the charged leptons from *W* decay, the following 95% C.L. limits are obtained in units of TeV^{-2}: $-2.3 < c_{WWW}/\Lambda^2 < 2.5$, $-8.8 < c_W/\Lambda^2 < 16$, $-45 < c_B/\Lambda^2 < 46$. Combining these results with those from the closely-related electroweak *Z*-jet-jet production SIRUNYAN 18BZ, the limits become: $-1.8 < c_{WWW}/\Lambda^2 < 2.0$, $-5.8 < c_W/\Lambda^2 < 10$, $-43 < c_B/\Lambda^2 < 45$.

[10] SIRUNYAN 20BF study W^+W^- production with the *W* bosons decaying to electrons or muons. The leading (subleading) lepton is required to have a transverse momentum larger than 25 (20) GeV. Events with a same-flavor di-lepton invariant mass within 15 GeV of the *Z* mass are rejected, as are event with a third lepton of transverse momentum larger than 10 GeV. In the same- (different-) flavor category a total of 9,604 (20,270) events are selected while the number of expected events is 9640 $\pm$ 490 (20280 $\pm$ 430). Analyzing the different-flavor di-lepton invariant mass distribution, the following 95% C.L. limits are obtained in units of TeV^{-2}: $-1.8 < c_{WWW}/\Lambda^2 < 1.8$, $-3.6 < c_W/\Lambda^2 < 2.8$, $-9.4 < c_B/\Lambda^2 < 8.5$.

[11] AABOUD 19BA study *WW* production in decay modes with an electron and a muon. The charged leptons are each required to have a transverse momentum larger than 27 GeV and rapidity less than 2.5. The electron-muon system is required to have a mass larger than 55 GeV and a transverse momentum larger than 30 GeV. The missing transverse energy must be larger than 20 GeV. Events containing a jet with transverse momentum exceeding 35 GeV and rapidity smaller than 4.5 are rejected. A total of 12,659 events are selected in the data, with an expected background of 4240 $\pm$ 477 events. Analysing the transverse momentum spectrum of the leading charged lepton, the following 95% C.L. limits are derived in units of TeV^{-2}: $-3.4 < c_{WWW}/\Lambda^2 < 3.3$, $-7.4 < c_W/\Lambda^2 < 4.1$, $-21 < c_B/\Lambda^2 < 18$, $-1.6 < c_{\overline{W}WW}/\Lambda^2 < 1.6$, $-76 < c_{\overline{W}}/\Lambda^2 < 76$.

[12] SIRUNYAN 19AD study inclusive *WZ* production, with *W* and *Z* decaying to electrons or muons. The leading (subleading) charged lepton candidate from the *Z* boson decay is required to have a transverse momentum larger than 25 GeV (10 GeV). The charged lepton candidate from the *W* boson decay is required to have a transverse momentum larger than 25 GeV. The invariant mass of the two leptons from *Z* decay is required to be within 15 GeV of the *Z* mass, while the invariant mass of the tri-lepton system is required to exceed 100 GeV. A total of 3,831 tri-lepton events are observed, with a fitted SM *WZ* signal of 3166 $\pm$ 62 events and a fitted background of 666 $\pm$ 45 events.

The approximated WZ invariant mass distribution is analyzed to set 95% C.L. limits as follows: $-4.1 < c_W/\Lambda^2 < 1.1$, $-2.0 < c_{WWW}/\Lambda^2 < 2.1$, $-100 < c_B/\Lambda^2 < 160$, in units of TeV^{-2}.

[13] SIRUNYAN 19CL study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the WW(WZ) category, while in the muon channel 3,996 (3572) events are selected in the WW(WZ) category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limits are obtained in units of TeV^{-2}: $-1.58 < c_{WWW}/\Lambda^2 < 1.59$, $-2.00 < c_W/\Lambda^2 < 2.65$, $-8.78 < c_B/\Lambda^2 < 8.54$.

[14] AABOUD 18Q study $pp \to ZZ$ events at $\sqrt{s} = 13$ TeV with $Z \to e^+e^-$ or $Z \to \mu^+\mu^-$. The number of events observed in the $4e$, $2e\,2\mu$, and 4μ channels is 249, 465, and 303 respectively. Analysing the p_T spectrum of the leading Z boson, the following the following 95% C.L. limits are derived in units of TeV^{-4}: $-5.9 < c_{\widetilde{B}W}/\Lambda^4 < 5.9$, $-3.0 < c_{WW}/\Lambda^4 < 3.0$, $-3.3 < c_{BW}/\Lambda^4 < 3.3$, $-2.7 < c_{BB}/\Lambda^4 < 2.8$.

[15] SIRUNYAN 18BZ study $pp \to Z$ *jet jet* events at 13 TeV where $Z \to e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with p_T of the leading/sub-leading lepton > 30/20 GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the Z mass. The two highest p_T jets are selected with p_T of the leading/sub-leading jet > 50/30 GeV respectively and dijet invariant mass > 200 GeV. Templates in the transverse momentum of the Z are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limits are obtained in units of TeV^{-2}: $-2.6 < c_{WWW}/\Lambda^2 < 2.6$ and $-8.4 < c_W/\Lambda^2 < 10.1$.

[16] AABOUD 17S analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limits at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-33 < c_W/\Lambda^2 < 30$, $-170 < c_B/\Lambda^2 < 160$, $-13 < c_{WWW}/\Lambda^2 < 9$, $-580 < c_{\widetilde{W}}/\Lambda^2 < 580$, $-11 < c_{\widetilde{W}WW}/\Lambda^2 < 11$, in units of TeV^{-2}.

[17] AABOUD 17U analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limits at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-3.1 < c_{WWW}/\Lambda^2 < 3.1$, $-19 < c_B/\Lambda^2 < 20$, $-5.1 < c_W/\Lambda^2 < 5.8$, in units of TeV^{-2}.

[18] KHACHATRYAN 17O analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set 95% C.L. limits of: $-260 < c_B/\Lambda^2 < 210$, $-4.2 < c_W/\Lambda^2 < 8.0$, $-4.6 < c_{WWW}/\Lambda^2 < 4.2$, in units of TeV^{-2}.

[19] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\bar{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WV events observed in the electron and muon channels. The following 95% C.L. limits in units of TeV^{-2} are obtained: $-2.7 < c_{WWW}/\Lambda^2 < 2.7$, $-14 < c_B/\Lambda^2 < 17$, $-2.0 < c_W/\Lambda^2 < 5.7$.

[20] AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming an EFT formulation, a fit to the transverse momentum distribution of the leading charged lepton, leads to 95% C.L. ranges of: $-4.61 < c_{WWW}/\Lambda^2 < 4.60$, $-5.87 < c_W/\Lambda^2 < 10.54$ and $-20.9 < c_B/\Lambda^2 < 26.3$,in units of TeV^{-2}.

[21] AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analyzing the WZ transverse momentum distribution, the resulting 95% C.L. limits are: $-3.9 < c_{WWW}/\Lambda^2 < 4.0$, $-4.3 < c_W/\Lambda^2 < 6.8$, and $-320 < c_B/\Lambda^2 < 210$, in units of TeV^{-2}.

[22] KHACHATRYAN 16BI determine the W^+W^- production cross section using unlike sign di-lepton (e or μ) events with high p_T. The leptons have $p_T > 20$ GeV/c and are isolated. Events are required to have no jets above p_T of 30 GeV/c. 4847 (2233) events are selected with different (same) flavor leptons, with an expected total background of 1179 ± 123 (643 ± 73) events. Analysing the di-lepton invariant mass spectrum, the following values are obtained: $c_{WWW}/\Lambda^2 = 0.1 \pm 3.2$, $c_W/\Lambda^2 = -3.6^{+5.0}_{-4.5}$ and $c_B/\Lambda^2 = -3.2^{+15.0}_{-14.5}$, in units of TeV^{-2}. The limits at 95% C.L. are: $-5.7 < c_{WWW}/\Lambda^2 < 5.9$, $-11.4 < c_W/\Lambda^2 < 5.4$ and $-29.2 < c_B/\Lambda^2 < 23.9$, in units of TeV^{-2}.

ANOMALOUS W/Z QUARTIC COUPLINGS

Revised March 2024 by M.W. Grünewald (U. College Dublin) and A. Gurtu (CERN; TIFR Mumbay).

Quartic couplings, $WWZZ$, $WWZ\gamma$, $WW\gamma\gamma$, and $ZZ\gamma\gamma$, were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowest dimensional representation of operators (dimension 6) which presumes the SU(2)×U(1) gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings, a_0, a_c, a_n, are expressed in terms of the following dimension-6 operators [1,2];

$$L_6^0 = -\frac{e^2}{16\Lambda^2}\, a_0\, F^{\mu\nu}\, F_{\mu\nu}\vec{W}^{\alpha}\cdot\vec{W}_{\alpha}$$
$$L_6^c = -\frac{e^2}{16\Lambda^2}\, a_c\, F^{\mu\alpha}\, F_{\mu\beta}\vec{W}^{\beta}\cdot\vec{W}_{\alpha}$$
$$L_6^n = -i\frac{e^2}{16\Lambda^2}\, a_n\epsilon_{ijk}\, W^{(i)}_{\mu\alpha}\, W^{(j)}_{\nu}\, W^{(k)\alpha}F^{\mu\nu}$$
$$\widetilde{L}_6^0 = -\frac{e^2}{16\Lambda^2}\, \widetilde{a}_0\, F^{\mu\nu}\, \widetilde{F}_{\mu\nu}\vec{W}^{\alpha}\cdot\vec{W}_{\alpha}$$
$$\widetilde{L}_6^n = -i\frac{e^2}{16\Lambda^2}\, \widetilde{a}_n\epsilon_{ijk}\, W^{(i)}_{\mu\alpha}\, W^{(j)}_{\nu}\, W^{(k)\alpha}\widetilde{F}^{\mu\nu}$$

where F, W are photon and W fields, L_6^0 and L_6^c conserve C, P separately ($\widetilde{L}_6^0$ conserves only C) and generate anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ couplings, L_6^n violates CP ($\widetilde{L}_6^n$ violates both C and P) and generates an anomalous $W^+W^-Z\gamma$ coupling, and Λ is an energy scale for new physics. For the $ZZ\gamma\gamma$ coupling the CP-violating term represented by L_6^n does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the $WW\gamma\gamma$ and $ZZ\gamma\gamma$ couplings separately, leading to two sets parametrized as a_0^V/Λ^2 and a_c^V/Λ^2, where $V = W$ or Z.

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned}\mathcal{L}_{AQGC} = &-\frac{e^2}{8}\frac{a_0^W}{\Lambda^2}F_{\mu\nu}F^{\mu\nu}W^{+a}W_a^-\\ &-\frac{e^2}{16}\frac{a_c^W}{\Lambda^2}F_{\mu\nu}F^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+)\\ &-e^2g^2\frac{\kappa_0^W}{\Lambda^2}F_{\mu\nu}Z^{\mu\nu}W^{+a}W_a^-\\ &-\frac{e^2g^2}{2}\frac{\kappa_c^W}{\Lambda^2}F_{\mu\nu}Z^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+)\\ &+\frac{f_{T,0}}{\Lambda^4}Tr[\widehat{W}_{\mu\nu}\widehat{W}^{\mu\nu}]\times Tr[\widehat{W}_{\alpha\beta}\widehat{W}^{\alpha\beta}]\end{aligned}$$

The energy scale of possible new physics is Λ, and $g = e/sin(\theta_W)$, e being the unit electric charge and θ_W the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators a_0^W/Λ^2 and a_c^W/Λ^2 are associated with the $WW\gamma\gamma$ vertex. Among dimension 8 operators, κ_0^W/Λ^2 and κ_c^W/Λ^2 are associated with the $WWZ\gamma$ vertex, whereas the parameter $f_{T,0}/\Lambda^4$ contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters $f_{M,i}/\Lambda^4$ as follows [3]:

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,2}}{\Lambda^4}$$

Gauge & Higgs Boson Particle Listings

W

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,3}}{\Lambda^4}$$

where $g' = e/cos(\theta_W)$ and M_W is the invariant mass of the W boson. This relation provides a translation between limits on dimension 6 operators $a_{0,c}^W$ and $f_{M,j}/\Lambda^4$. It is further required [4] that $f_{M,0} = 2f_{M,2}$ and $f_{M,1} = 2f_{M,3}$ which suppresses contributions to the $WWZ\gamma$ vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total – $f_{S,i},\ i = 1, 2$, $f_{M,i},\ i = 0, \ldots, 8$ and $f_{T,i}, i = 0, \ldots, 9$ – each scaled by $1/\Lambda^4$.

Another approach to couplings is the so called K-matrix framework [7], in which the anomalous couplings can be expressed in terms of two parameters α_4 and α_5, which account for all BSM effects.

The LHC collaborations have published couplings results based on various theoretical frameworks. It is hoped that the collaborations will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison, and to allow for a possible LHC combination.

Anomalous W quartic couplings are measured by the experiments at LEP, the Tevatron, and the LHC. Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below). As discussed in the review on the "Anomalous W/Z quartic couplings (QGCS)," the measurements are typically done using different operator expansions which then do not allow the results to be compared and averaged. At least one common framework should be agreed upon for the use in the future publications by the experiments.

Some publications from LHC experiments derive limits for various assumed values of the form-factor cutoff Λ_{FF}. The values quoted below are for $\Lambda_{FF} \to \infty$.

[1] AAD 25G analyse the production of three massive vector bosons VVZ ($V = W,\ Z$) using their decay modes into electrons or muons. Analysing the rates in terms of EFT couplings, the following 95% C.L. limits are set: $-19 < f_{M,2}/\Lambda^4 < 19$, $-28 < f_{M,3}/\Lambda^4 < 29$, $-12 < f_{M,4}/\Lambda^4 < 12$, $-9.1 < f_{M,5}/\Lambda^4 < 9.3$, in units of TeV^{-4}.

[2] CHEKHOVSKY 25 measure $WZ\gamma$ tri-boson producion where both W and Z decay to electrons or muons. 108 events are observed in the signal region whereas 109 ± 5 are predicted. The observed cross section is 5.48 ± 1.11 fb, compatible with the SM prediction. Analysing the $\ell\ell\ell\gamma$ invariant mass distribution, the following 95% C.L. limits are set: $-2.60 < f_{T,0}/\Lambda^4 < 2.60$, $-3.28 < f_{T,1}/\Lambda^4 < 3.24$, $-7.15 < f_{T,2}/\Lambda^4 < 7.05$, $-2.54 < f_{T,5}/\Lambda^4 < 2.56$, $-3.18 < f_{T,6}/\Lambda^4 < 3.22$, $-6.85 < f_{T,7}/\Lambda^4 < 7.05$, in units of TeV^{-4}.

[3] HAYRAPETYAN 25AM study same-sign WW production, with one W boson decaying into electrons or muons and the other W boson decaying into a tau lepton, in association with at least two jets with large invariant mass and rapidity difference. Multivariate classifiers are used to extract the following 95% C.L. limits in units of TeV^{-4}: $-1.32 < f_{T,0}/\Lambda^4 < 1.38$, $-0.552 < f_{T,1}/\Lambda^4 < 0.613$, $-1.51 < f_{T,2}/\Lambda^4 < 1.76$, $-13.1 < f_{M,0}/\Lambda^4 < 12.8$, $-16.4 < f_{M,1}/\Lambda^4 < 17.7$, $-27.6 < f_{M,7}/\Lambda^4 < 25.8$, $-15.9 < f_{S,0}/\Lambda^4 < 16.1$, $-60.9 < f_{S,1}/\Lambda^4 < 61.8$, $-60.9 < f_{S,2}/\Lambda^4 < 61.8$.

[4] AAD 24AD tag same-sign WW production, with the W bosons decaying into electrons or muons, in association with at least two jets with large invariant mass and rapidity difference. The di-lepton invariant mass distribution is used to extract the following 95% C.L. limits: $-4.1 < f_{M,0}/\Lambda^4 < 4.1$, $-6.8 < f_{M,1}/\Lambda^4 < 7.0$, $-9.8 < f_{M,7}/\Lambda^4 < 9.5$, $-5.9 < f_{S02}/\Lambda^4 < 5.9$, $-23.5 < f_{S,1}/\Lambda^4 < 23.6$, $-0.36 < f_{T,0}/\Lambda^4 < 0.36$, $-0.174 < f_{T,1}/\Lambda^4 < 0.186$, $-0.63 < f_{T,2}/\Lambda^4 < 0.74$, in units of TeV^{-4}.

[5] AAD 24AM tag WZ production, with the bosons decaying into electrons or muons, in association with two jets. The transverse mass of the WZ system is used to extract the following 95% C.L. limits: $-0.57 < f_{T,0}/\Lambda^4 < 0.56$, $-0.39 < f_{T,1}/\Lambda^4 < 0.35$, $-1.2 < f_{T,2}/\Lambda^4 < 1.0$, $-5.8 < f_{M,0}/\Lambda^4 < 5.6$, $-8.6 < f_{M,1}/\Lambda^4 < 8.5$, $-11.3 < f_{M,7}/\Lambda^4 < 11.3$, $-10.4 < f_{S02}/\Lambda^4 < 10.4$, $-30 < f_{S,1}/\Lambda^4 < 30$, in units of TeV^{-4}.

[6] AAD 24C study the production of four charged leptons (electrons or muons) in association with two jets. Analysing the 4-lepton invariant mass distribution and the di-jet invarinat mass distribution leads to the following 95% C.L. limits: $-0.98 < f_{T,0}/\Lambda^4 < 0.93$, $-1.2 < f_{T,1}/\Lambda^4 < 1.2$, $-2.5 < f_{T,2}/\Lambda^4 < 2.4$, $-2.5 < f_{T,5}/\Lambda^4 < 2.4$, $-3.9 < f_{T,6}/\Lambda^4 < 3.9$, $-8.5 < f_{T,7}/\Lambda^4 < 8.1$, $-2.1 < f_{T,8}/\Lambda^4 < 2.1$, $-4.5 < f_{T,9}/\Lambda^4 < 4.5$, in units of TeV^{-4}. The article also reports limits on these couplings by cutting the EFT expansion at various values of the cut-off scale.

[7] AAD 24CH study electroweak $W\gamma$ production in association with two jets. The distribution of the transverse momentum of the two-jet system or of the lepton is analysed to set the following 95% C.L. limits: $-1.8 < f_{T,0}/\Lambda^4 < 1.8$, $-1.1 < f_{T,1}/\Lambda^4 < 1.2$, $-3.1 < f_{T,2}/\Lambda^4 < 3.5$, $-2.4 < f_{T,3}/\Lambda^4 < 2.6$, $-2.2 < f_{T,4}/\Lambda^4 < 2.2$, $-1.2 < f_{T,5}/\Lambda^4 < 1.3$, $-1.0 < f_{T,6}/\Lambda^4 < 1.1$, $-2.7 < f_{T,7}/\Lambda^4 < 2.8$, $-24 < f_{M,0}/\Lambda^4 < 24$, $-37 < f_{M,1}/\Lambda^4 < 38$, $-8.6 < f_{M,2}/\Lambda^4 < 8.5$, $-13 < f_{M,3}/\Lambda^4 < 14$, $-15 < f_{M,4}/\Lambda^4 < 15$, $-14 < f_{M,5}/\Lambda^4 < 12$, $-66 < f_{M,7}/\Lambda^4 < 65$, in units of TeV^{-4}.

[8] AAD 23BH study $pp \to Z\gamma\gamma$ events with the Z boson decaying to electron or muon pairs. The number of observed data events is 148 for the electron mode and 171 for the muon mode. The respective number of (data-background) events is $105.5 \pm 12.2(\text{stat}) \pm 8.1(\text{syst})$ and $120.4 \pm 13.1(\text{stat}) \pm 9.4(\text{syst})$. The corresponding number of predicted signal events is 91.5 ± 0.9 and 119.5 ± 1.0 using SHERPA (NLO), and 91.0 ± 1.0 and 118.1 ± 1.2 using MADGRAPH 5 AMC (NLO), where the error is statistical only. Analysing the transverse momentum distribution of the dilepton system, the following 95% C.L. limits are derived: $-9.87 < f_{T,0}/\Lambda^4 < 9.33$, $-9.88 < f_{T,1}/\Lambda^4 < 9.34$, $-20.31 < f_{T,2}/\Lambda^4 < 18.68$, $-4.64 < f_{T,5}/\Lambda^4 < 4.54$, $-7.04 < f_{T,6}/\Lambda^4 < 6.94$, $-15.55 < f_{T,7}/\Lambda^4 < 15.04$, $-1.64 < f_{T,8}/\Lambda^4 < 1.61$, $-3.26 < f_{T,9}/\Lambda^4 < 3.26$, in units of TeV^{-4}.

[9] AAD 23K measure Z production in association with a photon and two jets in proton-proton collisions at 13 TeV CM energy, where the Z boson decays into neutrinos. Within a sensitive fiducial phase-space region, 356 signal events are selected, with an expectation of 357 ± 30. Analysing the photon transverse energy distribution, the following 95% C.L. limits are derived in units of TeV^{-4}: $-0.094 < f_{T,0}/\Lambda^4 < 0.084$, $-0.088 < f_{T,5}/\Lambda^4 < 0.099$, $-0.059 < f_{T,8}/\Lambda^4 < 0.059$, $-0.13 < f_{T,9}/\Lambda^4 < 0.13$, $-4.6 < f_{M,0}/\Lambda^4 < 4.6$, $-7.7 < f_{M,1}/\Lambda^4 < 7.7$, $-1.9 < f_{M,2}/\Lambda^4 < 1.9$.

[10] TUMASYAN 23AK study electroweak $W\gamma$ production in association with 2 jets. The events selected for the couplings analysis are required to have a dijet invariant mass in excess of 800 GeV, jet-jet separation of at least 2.5 in rapidity, invariant mass of the $W\gamma$ system larger than 150 GeV and transverse photon momentum larger than 100 GeV. Analysing the $W\gamma$ invariant mass distribution, varying one coupling at a time while fixing the others to their Standard Model value, leads to the following 95% C.L. limits: $-5.6 < f_{M,0}/\Lambda^4 < 5.5$, $-7.8 < f_{M,1}/\Lambda^4 < 8.1$, $-1.9 < f_{M,2}/\Lambda^4 < 1.9$, $-2.7 < f_{M,3}/\Lambda^4 < 2.7$, $-3.7 < f_{M,4}/\Lambda^4 < 3.6$, $-3.9 < f_{M,5}/\Lambda^4 < 3.9$, $-14 < f_{M,7}/\Lambda^4 < 14$, $-0.47 < f_{T,0}/\Lambda^4 < 0.51$, $-0.31 < f_{T,1}/\Lambda^4 < 0.34$, $-0.85 < f_{T,2}/\Lambda^4 < 1.0$, $-0.31 < f_{T,5}/\Lambda^4 < 0.33$, $-0.25 < f_{T,6}/\Lambda^4 < 0.27$, $-0.67 < f_{T,7}/\Lambda^4 < 0.73$, in units of TeV^{-4}.

[11] TUMASYAN 23AM use the combined CMS-TOTEM detector system to study exclusive $\gamma\gamma \to WW$ and $\gamma\gamma \to ZZ$ production in pp collisions at 13 TeV. The W and Z are identified through their hadronic decays with the added requirements of the invariant mass of the di-boson pair to be larger than 1 TeV, and the relative beam proton momentum loss between 0.04 and 0.20. The following limits are obtained at 95% C.L.: (i) on the dimension-6 (LEP like) couplings, in units of GeV^{-2}: $|a_0^W/\Lambda^2| < 4.3 \times 10^{-6}$, $|a_C^W/\Lambda^2| < 1.6 \times 10^{-5}$, $|a_0^Z/\Lambda^2| < 0.9 \times 10^{-5}$, $|a_C^Z/\Lambda^2| < 4.0 \times 10^{-5}$. (ii) on the dimension-8 operators, in units of TeV^{-4}: $|f_{M,0}/\Lambda^4| < 66.0$, $|f_{M,1}/\Lambda^4| < 245.5$, $|f_{M,2}/\Lambda^4| < 9.8$, $|f_{M,3}/\Lambda^4| < 73.0$, $|f_{M,4}/\Lambda^4| < 36.0$, $|f_{M,5}/\Lambda^4| < 67.0$, $|f_{M,7}/\Lambda^4| < 490.9$.

[12] SIRUNYAN 21 study electroweak Z-pair production in association with two jets, with the Z bosons decaying to oppositely-charged electron or muon pairs. Leptons with high transverse momentum are selected, with the di-lepton invariant mass of the two Z boson candidates between 60 GeV and 120 GeV, and the four-lepton invariant mass larger than 180 GeV. A total of 365 events are selected in the data, while the number of expected events is 370 ± 48. Analyzing the four-lepton invariant mass distribution, the following 95% C.L. limits are derived: $-0.24 < f_{T,0}/\Lambda^4 < 0.22$, $-0.31 < f_{T,1}/\Lambda^4 < 0.31$, $-0.63 < f_{T,2}/\Lambda^4 < 0.59$, $-0.43 < f_{T,8}/\Lambda^4 < 0.43$, $-0.92 < f_{T,9}/\Lambda^4 < 0.92$, in units of TeV^{-4}.

[13] TUMASYAN 21A study electroweak $Z\gamma$ production in association with two jets, where the Z boson decays to electron or muon pairs and the pair of two jets has high invariant mass, superseeding SIRUNYAN 20AL. The number of observed (expected) electron events in the barrel and endcap regions are 375 (349 ± 9) and 174 (166 ± 6) events, respectively, while for muon events the respective numbers are 584 (612 ± 13) and 320 (303 ± 8). Analysing the $Z\gamma$ invariant mass distribution, the following 95% C.L. limits are derived: $-15.8 < f_{M,0}/\Lambda^4 < 16.0$, $-35.0 < f_{M,1}/\Lambda^4 < 34.7$, $-6.55 < f_{M,2}/\Lambda^4 < 6.49$, $-13.0 < f_{M,3}/\Lambda^4 < 13.0$, $-13.0 < f_{M,4}/\Lambda^4 < 12.7$, $-22.2 < f_{M,5}/\Lambda^4 < 21.3$, $-56.6 < f_{M,7}/\Lambda^4 < 55.9$, $-0.64 < f_{T,0}/\Lambda^4 < 0.57$, $-0.81 < f_{T,1}/\Lambda^4 < 0.90$, $-1.68 < f_{T,2}/\Lambda^4 < 1.54$, $-0.58 < f_{T,5}/\Lambda^4 < 0.64$, $-1.30 < f_{T,6}/\Lambda^4 < 1.33$, $-2.15 < f_{T,7}/\Lambda^4 < 2.43$, $-0.47 < f_{T,8}/\Lambda^4 < 0.47$, $-0.91 < f_{T,9}/\Lambda^4 < 0.91$, in units of TeV^{-4}.

[14] TUMASYAN 21B measure W or Z boson production in association with two photons, using the leptonic decays modes of W and Z with electrons or muons. The number of selected $W \to e(\mu)\nu$ events is 1987 (2384) and the number of selected $Z \to ee(\mu\mu)$ events is 110 (272) respectively. Analyzing the transverse momentum of the di-photon system, the following 95 % C.L. limits are derived in units of TeV^{-4}: In the W production channel, the observed limits are: $-39.9 < f_{M,2}/\Lambda^4 < 39.5$, $-63.8 < f_{M,3}/\Lambda^4 < 65.0$, $-1.30 < f_{T,0}/\Lambda^4 < 1.30$, $-1.70 < f_{T,1}/\Lambda^4 < 1.66$, $-3.64 < f_{T,2}/\Lambda^4 < 3.64$, $-0.52 < f_{T,5}/\Lambda^4 < 0.60$, $-0.60 < f_{T,6}/\Lambda^4 < 0.68$, $-1.16 < f_{T,7}/\Lambda^4 < 1.16$. In the Z production channel, the observed limits are: $-5.70 < f_{T,0}/\Lambda^4 < 5.46$, $-5.70 < f_{T,1}/\Lambda^4 < 5.46$, $-11.4 < f_{T,2}/\Lambda^4 < 10.9$, $-2.92 < f_{T,5}/\Lambda^4 < 2.92$, $-3.80 < f_{T,6}/\Lambda^4 < 3.88$, $-7.88 < f_{T,7}/\Lambda^4 < 7.72$, $-1.06 < f_{T,8}/\Lambda^4 < 1.10$, $-1.82 < f_{T,9}/\Lambda^4 < 1.82$, in units of TeV^{-4}.

[15] SIRUNAYN 20 study WZ and same-sign WW production in association with two jets, using the leptonic decays modes of the W and Z bosons with electrons or muons. Overall, 524 WW events and 229 WZ events are selected, with a Standard Model expectation of 535 ± 52 and 216 ± 21 events, respectively. Analyzing the transverse mass spectrum of the di-boson system and the di-jet invariant mass, the following 95% C.L. limits are derived, not using any unitarization procedure: $-0.25 < f_{T,0}/\Lambda^4 < 0.28$, $-0.12 < f_{T,1}/\Lambda^4 < 0.14$, $-0.35 < f_{T,2}/\Lambda^4 < 0.48$, $-2.7 < f_{M,0}/\Lambda^4 < 2.9$, $-4.1 < f_{M,1}/\Lambda^4 < 4.2$, $-5.4 < f_{M,6}/\Lambda^4 < 5.8$, $-5.7 < f_{M,7}/\Lambda^4 < 6.0$, $-5.7 < f_{S,0}/\Lambda^4 < 6.1$, $-16 < f_{S,1}/\Lambda^4 < 17$, in units of TeV^{-4}. The article also reports limits on these couplings by cutting the EFT expansion at the unitarity limit.

[16] SIRUNYAN 20AL study electroweak production of a Z boson and a photon in association with two jets in the electron and muon decay modes of the Z. A signal with a significance of 3.9 standard deviations is observed, compared to a Standard Model expectation of 5.2 standard deviations. Combining with KHACHATRYAN 17AA data at 8 TeV the final observed and expected signal significance is 4.7 and 5.5 standard deviations. Analyzing the Z-photon invariant mass distribution, the following 95% C.L. limits are derived: $-19.5 < f_{M,0}/\Lambda^4 < 20.3$, $-40.5 < f_{M,1}/\Lambda^4 < 39.5$, $-8.22 < f_{M,2}/\Lambda^4 < 8.10$, $-17.7 < f_{M,3}/\Lambda^4 < 17.9$, $-15.3 < f_{M,4}/\Lambda^4 < 15.8$, $-25.1 < f_{M,5}/\Lambda^4 < 24.5$, $-38.9 < f_{M,6}/\Lambda^4 < 40.6$, $-60.3 < f_{M,7}/\Lambda^4 < 62.5$, $-0.74 < f_{T,0}/\Lambda^4 < 0.69$, $-0.98 < f_{T,1}/\Lambda^4 < 0.96$, $-1.97 < f_{T,2}/\Lambda^4 < 1.86$, $-0.70 < f_{T,5}/\Lambda^4 < 0.75$, $-1.64 < f_{T,6}/\Lambda^4 < 1.68$, $-2.59 < f_{T,7}/\Lambda^4 < 2.82$, $-0.47 < f_{T,8}/\Lambda^4 < 0.47$, $-1.27 < f_{T,9}/\Lambda^4 < 1.27$, in units of TeV^{-4}.

[17] SIRUNYAN 20BD study electroweak $W\gamma$ production in association with two jets, where the W boson decays to electron or muon and the two jets have high invariant mass. The number of observed (expected) electron events with the photon in the barrel and endcap regions are 393 (397.1 ± 18.5) and 159 (145.2 ± 10.0) respectively, while for muon events the respective numbers are 565 (537.9 ± 21.4) and 201 (188.2 ± 10.5). Analyzing the $W\gamma$ invariant mass distribution, the following 95% C.L. limits are derived: $-8.1 < f_{M,0}/\Lambda^4 < 8.0$, $-12 < f_{M,1}/\Lambda^4 < 12$, $-2.8 < f_{M,2}/\Lambda^4 < 2.8$, $-4.4 < f_{M,3}/\Lambda^4 < 4.4$, $-5.0 < f_{M,4}/\Lambda^4 < 5.0$, $-8.3 < f_{M,5}/\Lambda^4 < 8.3$, $-16 < f_{M,6}/\Lambda^4 < 16$, $-21 < f_{M,7}/\Lambda^4 < 20$, $-0.6 < f_{T,0}/\Lambda^4 < 0.6$, $-0.4 < f_{T,1}/\Lambda^4 < 0.4$, $-1.0 < f_{T,2}/\Lambda^4 < 1.2$, $-0.5 < f_{T,5}/\Lambda^4 < 0.5$, $-0.4 < f_{T,6}/\Lambda^4 < 0.4$, $-0.9 < f_{T,7}/\Lambda^4 < 0.9$, in units of TeV^{-4}.

[18] SIRUNYAN 19BM search for the final state $W^+W^-W^\pm$ using W decays to electrons or muons. Two event samples are considered, events with three leptons, or events with two oppositely charged leptons accompanied by two jets. In a kinematic region selected to enhance the effect of anomalous couplings, no events are selected in the data, and 95% C.L. upper limits are obtained as follows: $-1.2 < f_{T,0}/\Lambda^4 < 1.2$, $-3.3 < f_{T,1}/\Lambda^4 < 3.3$, $-2.7 < f_{T,2}/\Lambda^4 < 2.6$, in units of TeV^{-4} and without application of a form factor.

[19] SIRUNYAN 19BP study WZ plus 2 jets production, using W and Z decay channels with electrons or muons. In the data, 75 events are selected, with a fitted SM signal of 15.1 ± 1.6 events and a fitted background of 62.4 ± 2.8 events. The transverse mass distribution of the WZ system is analyzed to set the following limits at 95% C.L., in units of TeV^{-4}: $-9.15 < f_{M,0}/\Lambda^4 < 9.15$, $-9.15 < f_{M,1}/\Lambda^4 < 9.45$, $-26.5 < f_{S,0}/\Lambda^4 < 27.5$, $-41.2 < f_{S,1}/\Lambda^4 < 42.8$, $-0.75 < f_{T,0}/\Lambda^4 < 0.81$, $-0.49 < f_{T,1}/\Lambda^4 < 0.55$, $-1.49 < f_{T,2}/\Lambda^4 < 1.85$.

[20] SIRUNYAN 19CQ search for anomalous electroweak production of vector boson pairs in association with two jets. Events are selected by requiring two jets with a large invariant mass and rapidity separation, one or two leptons (electrons or muons), and a W or Z boson decaying hadronically. In the WV (ZV) channel, 347 (47) events are selected in the data, with a total expected background of 352 ± 19 (50.3 ± 5.8) events. Analysing the mass distribution of the WV or ZV system, the following 95% C.L. limits are obtained: $-2.7 < f_{S,0}/\Lambda^4 < 2.7$, $-3.4 < f_{S,1}/\Lambda^4 < 3.4$, $-0.69 < f_{M,0}/\Lambda^4 < 0.70$, $-2.0 < f_{M,1}/\Lambda^4 < 2.1$, $-1.3 < f_{M,6}/\Lambda^4 < 1.3$, $-3.4 < f_{M,7}/\Lambda^4 < 3.4$, $-0.12 < f_{T,0}/\Lambda^4 < 0.11$, $-0.12 < f_{T,1}/\Lambda^4 < 0.13$, $-0.28 < f_{T,2}/\Lambda^4 < 0.28$, in units of TeV^{-4}.

[21] SIRUNYAN 18CC study pp collisions at $\sqrt{s} = 13$ TeV leading to a pair of same-sign W pairs decaying leptonically (e or μ) associated with a pair of jets. Isolated leptons with $p_T > 25$ (20) GeV for the leading (trailing) lepton, with $|\eta| < 2.5$ (2.4) for e (μ) and jets with $p_T > 30$ GeV, $|\eta| < 5.0$, $|\Delta\eta_{jj}| > 2.5$ and $m_{jj} > 500$ GeV is required. Further cuts are applied to minimize $Z \to ee$ events, non-prompt leptons and hadronically decaying taus. The number of selected events is 201, with an expected SM signal of 66.9 ± 2.4 and background of 138 ± 13 events. Analysing the dilepton invariant mass spectrum the following 95% C.L. limits are derived: $-7.7 < f_{S,0}/\Lambda^4 < 7.7$, $-21.6 < f_{S,1}/\Lambda^4 < 21.8$, $-6.0 < f_{M,0}/\Lambda^4 < 5.9$, $-8.7 < f_{M,1}/\Lambda^4 < 9.1$, $-11.9 < f_{M,6}/\Lambda^4 < 11.8$, $-13.3 < f_{M,7}/\Lambda^4 < 12.9$, $-0.62 < f_{T,0}/\Lambda^4 < 0.65$, $-0.28 < f_{T,1}/\Lambda^4 < 0.31$, $-0.89 < f_{T,2}/\Lambda^4 < 1.02$.

[22] AABOUD 17AA analyze $W^\pm W^\pm$ production in association with two jets and W decay modes with electrons or muons. In the kinematic region of VBS the effect of anomalous QGCs is enhanced by requiring the transverse mass of the WW system to be larger than 400 GeV. In the data, 8 events are selected with a total background expected from SM processes of 3.8 ± 0.6 events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% CL limits on the QGCs: $-0.14 < \alpha_4 < 0.15$ and $-0.22 < \alpha_5 < 0.22$. Supersedes AAD 14AM.

[23] AABOUD 17AG determine the $WW\gamma$ and $WZ\gamma$ cross sections in 8 TeV pp interactions by studying the final states $e\nu\mu\nu\gamma$ and $e\nu jj\gamma$ or $\mu\nu jj\gamma$. Upper limits on the production cross sections are derived in a fiducial region optimized for BSM physics. These are used to derive the following 95% C.L. upper limits for quartic couplings assuming the form scale factor, $\Lambda_{FF} = \infty$ (all in units of 10^3 TeV^{-4}): $-0.3 < f_{M,0}/\Lambda^4 < 0.3$, $-0.5 < f_{M,1}/\Lambda^4 < 0.5$, $-1.8 < f_{M,2}/\Lambda^4 < 1.8$, $-1.1 < f_{M,4}/\Lambda^4 < 1.1$, $-1.7 < f_{M,5}/\Lambda^4 < 1.7$, $-0.6 < f_{M,6}/\Lambda^4 < 0.6$, $-1.1 < f_{M,7}/\Lambda^4 < 1.1$, $-0.1 < f_{T,0}/\Lambda^4 < 0.1$, $-0.2 < f_{T,1}/\Lambda^4 < 0.2$, $-0.4 < f_{T,4}/\Lambda^4 < 0.4$, $-1.5 < f_{T,5}/\Lambda^4 < 1.6$, $-1.9 < f_{T,6}/\Lambda^4 < 1.9$, $-4.3 < f_{T,7}/\Lambda^4 < 4.3$.

[24] AABOUD 17D analyze electroweak diboson (WV, $V = W, Z$) production in association with a high-mass dijet system. In the data, 32 events are selected with an expected total background of 32 ± 12 events. Analysing the transverse mass distribution of the WV system, the following limits are set at 95% C.L.: $-0.024 < \alpha_4 < 0.030$ and $-0.028 < \alpha_5 < 0.033$.

[25] AABOUD 17J analyze the $Z\gamma$ production in association with a high-mass dijet system, with the Z boson decaying into a pair of electrons, muons, or neutrinos. In the charged lepton (neutrino) channel, events are selected with a dijet mass larger than 500 (600) GeV and a transverse photon energy larger than 250 (150) GeV, with 2 (4) events selected in the data and 0.30 ± 0.08 (1.6 ± 0.5) expected background events. The observed event yield is used to determine 95% CL limits as follows: $-4.1\times10^3 < f_{T,9}/\Lambda^4 < 4.2\times10^3$, $-1.9\times10^3 < f_{T,8}/\Lambda^4 < 2.1\times10^3$, $-1.9\times10^1 < f_{T,0}/\Lambda^4 < 1.6\times10^1$, $-1.6\times10^2 < f_{M,0}/\Lambda^4 < 1.8\times10^2$, $-3.5\times10^2 < f_{M,1}/\Lambda^4 < 3.4\times10^2$, $-8.9\times10^2 < f_{M,2}/\Lambda^4 < 8.9\times10^2$, $-1.7\times10^3 < f_{M,3}/\Lambda^4 < 1.7\times10^3$, in units of TeV^{-4} and without application of a form factor.

[26] AABOUD 17M analyze tri-boson $W^\pm W^\pm W^\mp$ production in decay channels with three charged leptons or two like-sign charged leptons with two jets, where the lepton can be an electron or muon. In the data, 24 tri-lepton events and 21 di-lepton plus jets events are selected, compared to a total event yield expected in the SM of 30.8 ± 3.0 and 21.9 ± 2.0, respectively. Analysing the tri-lepton transverse mass or the transverse momentum sum of the two leptons, two jets and the missing transverse energy, the following limits at 95% CL are derived for the form factor cut-off scale $\Lambda_{FF}\to\infty$: $-0.13 < f_{S,0}/\Lambda^4 < 0.18$, $-0.21 < f_{S,1}/\Lambda^4 < 0.27$, in units of 10^4 TeV^{-4}, which are converted into the following limits: $-0.49 < \alpha_4 < 0.75$ and $-0.48 < \alpha_5 < 0.62$.

[27] KHACHATRYAN 17AA analyse electroweak production of $Z\gamma$ in association with two hadronic jets, with the Z boson decaying to electron or muon pairs. Events with photon transverse momentum larger than 60 GeV and di-jet invariant mass larger than 400 GeV are selected. The $Z\gamma$ inavariant mass spectrum is analysed to set 95% C.L. limits as follows: $-71 < f_{M,0}/\Lambda^4 < 75$, $-190 < f_{M,1}/\Lambda^4 < 182$, $-32 < f_{M,2}/\Lambda^4 < 31$, $-58 < f_{M,3}/\Lambda^4 < 59$, $-3.8 < f_{T,0}/\Lambda^4 < 3.4$, $-4.4 < f_{T,1}/\Lambda^4 < 4.4$, $-9.9 < f_{T,2}/\Lambda^4 < 9.0$, $-1.8 < f_{T,8}/\Lambda^4 < 1.8$, $-4.0 < f_{T,9}/\Lambda^4 < 4.0$, in units of TeV^{-4} and without application of a form factor.

[28] KHACHATRYAN 17M analyse electroweak production of $W\gamma$ in association with two hadronic jets, with the W boson decaying to electrons or muons. Events with photon transverse momentum larger than 200 GeV and di-jet invariant mass larger than 200 GeV are selected. The W transverse momentum spectrum is analysed to set 95% C.L. limits as follows: $-77 < f_{M,0}/\Lambda^4 < 74$, $-125 < f_{M,1}/\Lambda^4 < 129$, $-26 < f_{M,2}/\Lambda^4 < 26$, $-43 < f_{M,3}/\Lambda^4 < 44$, $-40 < f_{M,4}/\Lambda^4 < 40$, $-65 < f_{M,5}/\Lambda^4 < 65$, $-129 < f_{M,6}/\Lambda^4 < 129$, $-164 < f_{M,7}/\Lambda^4 < 162$, $-5.4 < f_{T,0}/\Lambda^4 < 5.6$, $-3.7 < f_{T,1}/\Lambda^4 < 4.0$, $-11 < f_{T,2}/\Lambda^4 < 12$, $-3.8 < f_{T,5}/\Lambda^4 < 3.8$, $-2.8 < f_{T,6}/\Lambda^4 < 3.0$, $-7.3 < f_{T,7}/\Lambda^4 < 7.7$, in units of TeV^{-4} and without application of a form factor.

[29] SIRUNYAN 17AD study pp collisions at $\sqrt{s} = 13$ TeV to determine the cross section of $ZZjj$ with the Z decaying to ee or $\mu\mu$. The ZZ mass distribution is used to set upper limits on the anomalous quartic couplings. The 95% upper limits for the relevant quartic couplings in units of TeV^{-4} are: $-0.46 < f_{T,0}/\Lambda^4 < 0.44$, $-0.61 < f_{T,1}/\Lambda^4 < 0.61$, $-1.2 < f_{T,2}/\Lambda^4 < 1.2$, $-0.84 < f_{T,8}/\Lambda^4 < 0.84$, $-1.8 < f_{T,9}/\Lambda^4 < 1.8$.

[30] SIRUNYAN 17AR study pp collisions at $\sqrt{s} = 8$ TeV to determine the cross section of $pp \to W\gamma\gamma$ and $pp \to Z\gamma\gamma$ where $W \to \ell\nu$ and $Z \to \ell^+\ell^-$, ℓ being an electron or a muon. The number of W events in the e and μ channels is 63 and 108 respectively, and the number of Z events in the e and μ channels is 117 and 141. To increase sensitivity, the transverse momentum of the leading photon is required to be larger than 70 GeV. The 95% C.L. upper limits in units of TeV^{-4} are $-701 < f_{M,2}/\Lambda^4 < 683$, $-1170 < f_{M,3}/\Lambda^4 < 1220$, $-33.5 < f_{T,0}/\Lambda^4 < 34.0$, $-44.3 < f_{T,1}/\Lambda^4 < 44.8$, $-93.8 < f_{T,2}/\Lambda^4 < 93.2$.

[31] AABOUD 16E study WW production in two-photon mediated pp collisions at 8 TeV where the W boson decays into an electron or muon, probing the $\gamma\gamma WW$ vertex for anomalous quartic gauge couplings. The lepton p_T is required to be larger than 30 GeV. Limits on anomalous couplings are determined from events with p_T larger than 120 GeV where the aQGC effect is enhanced and the SM background reduced; in the data corresponding to an integrated luminosity of 20.2fb^{-1}, 1 event is selected with an expected SM background of 0.37 ± 0.13 events. The 95% C.L. limits without a form-factor cutoff ($\Lambda_{\text{cutoff}}\to\infty$) are as follows: $-1.7 < a_0^W/\Lambda^2 < 1.7$ and $-6.4 < a_C^W/\Lambda^2 < 6.3$ in units of 10^{-6} GeV^{-2}. In terms of another set of variables: $-6.6 < f_{M,0}/\Lambda^4 < 6.6$ and $-24 < f_{M,1}/\Lambda^4 < 25$ in units of 10^{-11} GeV^{-4}.

[32] AAD 16Q study $Z\gamma\gamma$ production in pp collisions. In events with no additional jets, 29 (22) Z decays to electron (muon) pairs are selected, with an expected background of 3.3 ± 1.1 (6.5 ± 2.0) events, as well as 19 Z decays to netrino pairs with an expected background of 8.3 ± 4.4 events. Analysing the photon transverse momentum distribution for $m_{\gamma\gamma}$ above 200 GeV (300 GeV) for lepton (neutrino) events, yields the 95% C.L. limits: $-1.6\times10^4 < f_{M,2}/\Lambda^4 < 1.6\times10^4$, $-2.9\times10^4 < f_{M,3}/\Lambda^4 < 2.7\times10^4$, $-0.86\times10^2 < f_{T,0}/\Lambda^4 < 1.03\times10^2$, $-0.69\times10^3 < f_{T,5}/\Lambda^4 < 0.68\times10^3$, $-0.74\times10^4 < f_{T,9}/\Lambda^4 < 0.74\times10^4$ in units of TeV^{-4} and without application of a form factor Λ_{FF}.

[33] KHACHATRYAN 16AX searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \to ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 13 events containing an $e^\pm\mu^\mp$ pair with $p_T(e,\mu) > 30$ GeV are selected in a total luminosity of 19.7 fb^{-1}, with an expected $\gamma\gamma \to WW$ signal of 5.3 ± 0.1 events and an expected background of 3.9 ± 0.5 events. When combining with the data collected at 7 TeV (CHATRCHYAN 13AA), and not assuming a form factor, the following 1-parameter limits at 95% C.L. are obtained from the $p_T(e,\mu)$ spectrum: $|a_0^W/\Lambda^2| < 1.1\times10^{-6}$ GeV^{-2} ($a_C^W = 0$), and $|a_C^W/\Lambda^2| < 4.1\times10^{-6}$ GeV^{-2} ($a_0^W = 0$). In terms of another set of variables: $|f_{M,0}/\Lambda^4| < 4.2\times10^{-12}$ GeV^{-4}, $|f_{M,1}/\Lambda^4| < 16\times10^{-12}$ GeV^{-4}, $|f_{M,2}/\Lambda^4| < 2.1\times10^{-12}$ GeV^{-4}, $|f_{M,3}/\Lambda^4| < 7.8\times10^{-12}$ GeV^{-4}.

[34] AAD 15N study $W\gamma\gamma$ events in 8 TeV pp interactions, where the W decays into an electron or a muon. The events are characterized by an isolated lepton, a missing transverse energy due to the decay neutrino, and two isolated photons, with the p_T of the lepton and the photons being > 20 GeV. The number of candidate events observed in the electron channel for N(jet) ≥ 0 and N(jet) = 0 is 47 and 15, the corresponding numbers for the muon channel being 110 and 53. The backgrounds expected are 30.2 ± 7.4, 8.7 ± 3.0, 52.1 ± 12.2, and 24.4 ± 8.3 respectively. The 95% C.L. limits on the values of the parameters $f_{T,0}/\Lambda^4$, $f_{M,2}/\Lambda^4$ and $f_{M,3}/\Lambda^4$ are -0.9–0.9×10^2, -0.8–0.8×10^4, and -1.5–1.4×10^4 respectively, without application of a form factor Λ_{FF}.

[35] KHACHATRYAN 15D study vector-boson-scattering tagged by two jets, requiring two same-sign charged leptons arising from $W^\pm W^\pm$ production and decay. The two jets must have a transverse momentum larger than 30 GeV, while the leptons, electrons or muons, must have a transverse momentum > 20 GeV. The dijet mass is required to be > 500 GeV, the dilepton mass > 50 GeV, with additional requirement of differing from the Z mass by > 15 GeV. In the two categories W^+W^+ and W^-W^-, 10 and 2 data events are observed in a data sample corresponding to an integrated luminosity of 19.4 fb^{-1}, with an expected background of 3.1 ± 0.6 and 2.6 ± 0.5 events. Analysing the distribution of the dilepton invariant mass, the following limits at 95% C.L. are obtained, in units of TeV^{-4}: $-38 < f_{S,0}/\Lambda^4 < 40$, $-118 < f_{S,1}/\Lambda^4 < 120$, $-33 < f_{M,0}/\Lambda^4 < 32$, $-44 < f_{M,1}/\Lambda^4 < 47$, $-65 < f_{M,6}/\Lambda^4 < 63$, $-70 < f_{M,7}/\Lambda^4 < 66$, $-4.2 < f_{T,0}/\Lambda^4 < 4.6$, $-1.9 < f_{T,1}/\Lambda^4 < 2.2$, $-5.2 < f_{T,2}/\Lambda^4 < 6.4$.

[36] AAD 14AM analyze electroweak production of WW jet same-charge diboson plus two jets production, with the W bosons decaying to electron or muon, to study the quartic $WWWW$ coupling. In a kinematic region enhancing the electroweak production over the strong production, 34 events are observed in the data while 29.8 ± 2.4 events are expected with a backgound of 15.9 ± 1.9 events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% CL limits on the quartic gauge couplings: $-0.14 < \alpha_4 < 0.16$ and $-0.23 < \alpha_5 < 0.24$.

[37] CHATRCHYAN 14Q study $WV\gamma$ production in 8 TeV pp collisions, in the single lepton final state, with $W \to \ell\nu$, $Z \to$ dijet or $W \to \ell\nu$, $W \to$ dijet, the dijet mass resolution precluding differentiation between the W and Z. p_T and pseudo-rapidity cuts are put on the lepton, the photon and the two jets to minimize backgrounds. The dijet mass is required to be between 70–100 GeV and $|\Delta\eta_{jj}| < 1.4$. The selected number of muon (electron) events are 183 (139), with SM expectation being 194.2 ± 11.5 (147.9 ± 10.7) including signal and background. The photon E_T distribution is used to set limits on the anomalous quartic couplings. The following 95% CL limits are deduced (all in units of TeV^{-2} or TeV^{-4}): $-21 < a_0^W/\Lambda^2 < 20$, $-34 < a_c^W/\Lambda^2 < 32$, $-12 < \kappa_0^W/\Lambda^2 < 10$ and $-18 < \kappa_c^W/\Lambda^2 < 17$; and $-25 < f_{T,0}/\Lambda^4 < 24$ TeV^{-4}.

[38] ABAZOV 13D searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \to ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 946 events containing an e^+e^- pair with missing energy are selected in a total luminosity of 9.7 fb^{-1}, with an expectation of 983 ± 108 events from Standard-Model processes. The following 1-parameter limits at 95% CL are otained: $|a_0^W/\Lambda^2| < 4.3\times10^{-4}$ GeV^{-2} ($a_C^W = 0$), $|a_C^W/\Lambda^2| < 1.5\times10^{-3}$ GeV^{-2} ($a_0^W = 0$).

[39] CHATRCHYAN 13AA searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \to ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 2 events containing an $e^\pm\mu^\mp$ pair with $p_T(e,\mu) > 30$ GeV are selected in a total luminosity of 5.05 fb^{-1}, with an expected $ppWW$ signal of 2.2 ± 0.4 events and an expected background of 0.84 ± 0.15 events. The following 1-parameter limits at 95% CL are otained from the $p_T(e,\mu)$ spectrum: $|a_0^W/\Lambda^2| < 4.0\times10^{-6}$ GeV^{-2} ($a_C^W = 0$), $|a_C^W/\Lambda^2| < 1.5\times10^{-5}$ GeV^{-2} ($a_0^W = 0$).

[40] ABBIENDI 04B select 187 $e^+e^- \to W^+W^-\gamma$ events in the C.M. energy range 180–209 GeV, where E_γ >2.5 GeV, the photon has a polar angle $|\cos\theta_\gamma| < 0.975$ and is well isolated from the nearest jet and charged lepton, and the effective masses of both fermion-antifermion systems agree with the W mass within 3 Γ_W. The measured differential cross section as a function of the photon energy and photon polar angle is used to extract the 95% CL limits: -0.020 GeV$^{-2} < a_0/\Lambda^2 < 0.020$ GeV^{-2}, -0.053 GeV$^{-2} < a_c/\Lambda^2 < 0.037$ GeV^{-2} and -0.16 GeV$^{-2} < a_n/\Lambda^2 < 0.15$ GeV^{-2}.

[41] ABBIENDI 04L select 20 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ acoplanar events in the energy range 180–209 GeV and 176 $e^+e^- \to q\overline{q}\gamma\gamma$ events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ quartic couplings. Further combining with the $W^+W^-\gamma$ sample of ABBIENDI 04B the following one–parameter 95% CL limits are obtained: $-0.007 < a_0^Z/\Lambda^2 < 0.023$ GeV^{-2}, $-0.029 < a_C^Z/\Lambda^2 < 0.029$ GeV^{-2}, $-0.020 < a_0^W/\Lambda^2 < 0.020$ GeV^{-2}, $-0.052 < a_c^W/\Lambda^2 < 0.037$ GeV^{-2}.

[42] In the CM energy range 183 to 209 GeV HEISTER 04A select 30 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ events with two acoplanar, high energy and high transverse momentum photons. The photon–photon acoplanarity is required to be > 5°, $E_\gamma/\sqrt{s} > 0.025$ (the more energetic photon having energy > 0.2 $\sqrt{s}$), $p_{T_\gamma}/E_{\text{beam}} > 0.05$ and $|\cos\theta_\gamma| < 0.94$. A likelihood fit to the photon energy and recoil missing mass yields the following one–parameter 95% CL limits: $-0.012 < a_0^Z/\Lambda^2 < 0.019$ GeV^{-2}, $-0.041 < a_C^Z/\Lambda^2 < 0.044$ GeV^{-2}, $-0.060 < a_0^W/\Lambda^2 < 0.055$ GeV^{-2}, $-0.099 < a_C^W/\Lambda^2 < 0.093$ GeV^{-2}.

[43] ABDALLAH 03I select 122 $e^+e^- \to W^+W^-\gamma$ events in the C.M. energy range 189–209 GeV, where E_γ >5 GeV, the photon has a polar angle $|\cos\theta_\gamma| < 0.95$ and is well isolated from the nearest charged fermion. A fit to the photon energy spectra yields $a_c/\Lambda^2 = 0.000^{+0.019}_{-0.040}$ GeV^{-2}, $a_0/\Lambda^2 = -0.004^{+0.018}_{-0.010}$ GeV^{-2}, $\bar{a}_0/\Lambda^2 = -0.007^{+0.019}_{-0.008}$ GeV^{-2}, $a_n/\Lambda^2 = -0.09^{+0.16}_{-0.05}$ GeV^{-2}, and $\bar{a}_n/\Lambda^2 = +0.05^{+0.07}_{-0.15}$ GeV^{-2}, keeping the other parameters fixed to their Standard Model values (0). The 95% CL limits are: -0.063 GeV$^{-2} < a_c/\Lambda^2 < +0.032$ GeV^{-2}, -0.020 GeV$^{-2} < a_0/\Lambda^2 < +0.020$ GeV^{-2}, -0.020 GeV$^{-2} < \bar{a}_0/\Lambda^2 < +0.020$ GeV^{-2}, -0.18 GeV$^{-2} < a_n/\Lambda^2 < +0.14$ GeV^{-2}, -0.16 GeV$^{-2} < \bar{a}_n/\Lambda^2 < +0.17$ GeV^{-2}.

[44] ACHARD 02F select 86 $e^+e^- \to W^+W^-\gamma$ events at 192–207 GeV, where E_γ >5 GeV and the photon is well isolated. They also select 43 acoplanar $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ events in this energy range, where the photon energies are >5 GeV and >1 GeV and the

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

photon polar angles are between 14° and 166°. All these 43 events are in the recoil mass region corresponding to the Z (75–110 GeV). Using the shape and normalization of the photon spectra in the $W^+W^-\gamma$ events, and combining with the 42 event sample from 189 GeV data (ACCIARRI 00T), they obtain: $a_0/\Lambda^2 = 0.000 \pm 0.010$ GeV^{-2}, $a_c/\Lambda^2 = -0.013 \pm 0.023$ GeV^{-2}, and $a_n/\Lambda^2 = -0.002 \pm 0.076$ GeV^{-2}. Further combining the analyses of $W^+W^-\gamma$ events with the low recoil mass region of $\nu\overline{\nu}\gamma\gamma$ events (including samples collected at $183 + 189$ GeV), they obtain the following one-parameter 95% CL limits: -0.015 GeV$^{-2} < a_0/\Lambda^2 < 0.015$ GeV^{-2}, -0.048 GeV$^{-2} < a_c/\Lambda^2 < 0.026$ GeV^{-2}, and -0.14 GeV$^{-2} < a_n/\Lambda^2 < 0.13$ GeV^{-2}.

Z Boson

Z MASS

OUR AVERAGE is given by the weighted average of the combined CDF result and the combined LEP result, assuming no correlations between CDF and LEP. The combined LEP result, 91.1876 ± 0.0021 GeV, is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). The LEP fit is performed using the Z mass and width, the Z hadronic pole cross section, the ratios of hadronic to leptonic partial widths, and the Z pole forward-backward lepton asymmetries. This set is believed to be most free of correlations.

The Z-boson mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass dependent width. The value is 34 MeV greater than the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator. Also the LEP experiments have generally assumed a fixed value of the γ–Z interferences term based on the standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted Z mass. See ACCIARRI 00Q and ABBIENDI 04G for a detailed investigation of both these issues.

90.9 ±0.3 ±0.2	188	[14] ABE	89C	CDF	$E_{cm}^{p\overline{p}}$ = 1.8 TeV
91.14 ±0.12	480	[15] ABRAMS	89B	MRK2	E_{cm}^{ee} = 89–93 GeV
93.1 ±1.0 ±3.0	24	[16] ALBAJAR	89	UA1	$E_{cm}^{p\overline{p}}$ = 546,630 GeV

[1] AAIJ 25AH analyse Z production in the muon decay channel in their 2016 data, with the transverse momentum of the muon required to be above 20 GeV and the pseudorapidity of muons $2.2 < \eta < 4.4$. They obtain a Z mass measurement based on a template fit. The systematic error is dominated by 0.0036 GeV from momentum calibration.

[2] AALTONEN 22 analyse Z decays in the di-muon and di-electron channels using their full Run-II data set. They obtain Z mass values of 91192.0 ± 6.4(stat.) ± 4.0(syst.) MeV and 91194.3 ± 13.8(stat.) ± 7.6(syst.) MeV, respectively. Combining these results using the systematic uncertainty contributions and their correlations as given in AALTONEN 22, we obtain an average of 91192.3 ± 5.8(stat.) ± 4.1(syst.) MeV.

[3] This result combines ABBIENDI 01A, ABREU 00F, ACCIARRI 00C, BARATE 00C, taking correlated uncertainties into account.

[4] ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic e^+p and e^-p neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.

[5] ABBIENDI 04G obtain this result using the S–matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 34 MeV shift with respect to the Breit–Wigner fits.

[6] ACHARD 04C select $e^+e^- \to Z\gamma$ events with hard initial–state radiation. Z decays to $q\overline{q}$ and muon pairs are considered. The fit results obtained in the two samples are found consistent to each other and combined considering the uncertainty due to ISR modelling as fully correlated.

[7] ABBIENDI 01A error includes approximately 2.3 MeV due to statistics and 1.8 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.

[8] The error includes 1.6 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.

[9] The error includes 1.8 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.

[10] ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the γ/Z interference term. The authors have corrected the measurement for the 34.1 MeV shift with respect to the Breit-Wigner fits. The error contains a contribution of ±2.3 MeV due to the uncertainty on the γZ interference.

[11] BARATE 00C error includes approximately 2.4 MeV due to statistics, 0.2 MeV due to experimental systematics, and 1.7 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.

[12] MIYABAYASHI 95 combine their low energy total hadronic cross-section measurement with the ACTON 93D data and perform a fit using an S-matrix formalism. As expected, this result is below the mass values obtained with the standard Breit-Wigner parametrization.

[13] Enters fit through W/Z mass ratio given in the W Particle Listings. The ALITTI 92B systematic error (±0.93) has two contributions: one (±0.92) cancels in m_W/m_Z and one (±0.12) is noncancelling. These were added in quadrature.

[14] First error of ABE 89 is combination of statistical and systematic contributions; second is mass scale uncertainty.

[15] ABRAMS 89B uncertainty includes 35 MeV due to the absolute energy measurement.

[16] ALBAJAR 89 result is from a total sample of 33 $Z \to e^+e^-$ events.

Z WIDTH

OUR EVALUATION is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). Corrections as discussed in VOUTSINAS 20 and JANOT 20 are also included.

VALUE (GeV)	EVTS	DOCUMENT ID		TECN	COMMENT
2.4955±0.0023 OUR EVALUATION					
2.4955±0.0023		[1] JANOT	20		
• • • We do not use the following data for averages, fits, limits, etc. • • •					
2.4955±0.0023		[2] VOUTSINAS	20		
2.4952±0.0023		[3] LEP-SLC	06		E_{cm}^{ee} = 88–94 GeV
2.4943±0.0041		[4] ABBIENDI	04G	OPAL	E_{cm}^{ee} = LEP1 + 130–209 GeV
2.4948±0.0041	4.57M	[5] ABBIENDI	01A	OPAL	E_{cm}^{ee} = 88–94 GeV
2.4876±0.0041	4.08M	[6] ABREU	00F	DLPH	E_{cm}^{ee} = 88–94 GeV
2.5024±0.0042	3.96M	[7] ACCIARRI	00C	L3	E_{cm}^{ee} = 88–94 GeV
2.5025±0.0041	3.97M	[8] ACCIARRI	00Q	L3	E_{cm}^{ee} = LEP1 + 130–189 GeV
2.4951±0.0043	4.57M	[9] BARATE	00C	ALEP	E_{cm}^{ee} = 88–94 GeV
2.50 ±0.21 ±0.06		[10] ABREU	96R	DLPH	E_{cm}^{ee} = 91.2 GeV
3.8 ±0.8 ±1.0	188	ABE	89C	CDF	$E_{cm}^{p\overline{p}}$ = 1.8 TeV
2.42 $^{+0.45}_{-0.35}$	480	[11] ABRAMS	89B	MRK2	E_{cm}^{ee} = 89–93 GeV
2.7 $^{+1.2}_{-1.0}$ ±1.3	24	[12] ALBAJAR	89	UA1	$E_{cm}^{p\overline{p}}$ = 546,630 GeV
2.7 ±2.0 ±1.0	25	[13] ANSARI	87	UA2	$E_{cm}^{p\overline{p}}$ = 546,630 GeV

[1] JANOT 20 applies a correction to LEP-SLC 06 using an updated Bhabha cross section calculation. This result also includes a correction to account for correlated luminosity bias as presented in VOUTSINAS 20.

[2] VOUTSINAS 20 applies a correction to LEP-SLC 06 to account for correlated luminosity bias.

[3] This result combines ABBIENDI 01A, ABREU 00F, ACCIARRI 00C, BARATE 00C, taking correlated uncertainties into account.

[4] ABBIENDI 04G obtain this result using the S–matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 1 MeV shift with respect to the Breit–Wigner fits.

[5] ABBIENDI 01A error includes approximately 3.6 MeV due to statistics, 1 MeV due to event selection systematics, and 1.3 MeV due to LEP energy uncertainty.

[6] The error includes 1.2 MeV due to LEP energy uncertainty.

[7] The error includes 1.3 MeV due to LEP energy uncertainty.

[8] ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the γ/Z interference term. The authors have corrected the measurement for the 0.9 MeV shift with respect to the Breit-Wigner fits.

[9] BARATE 00C error includes approximately 3.8 MeV due to statistics, 0.9 MeV due to experimental systematics, and 1.3 MeV due to LEP energy uncertainty.

[10] ABREU 96R obtain this value from a study of the interference between initial and final state radiation in the process $e^+e^- \to Z \to \mu^+\mu^-$.

[11] ABRAMS 89B uncertainty includes 50 MeV due to the miniSAM background subtraction error.

[12] ALBAJAR 89 result is from a total sample of 33 $Z \to e^+e^-$ events.

[13] Quoted values of ANSARI 87 are from direct fit. Ratio of Z and W production gives either $\Gamma(Z) < (1.09 \pm 0.07) \times \Gamma(W)$, CL = 90% or $\Gamma(Z) = (0.82^{+0.19}_{-0.14} \pm 0.06) \times \Gamma(W)$. Assuming Standard-Model value $\Gamma(W) = 2.65$ GeV then gives $\Gamma(Z) < 2.89 \pm 0.19$ or $= 2.17^{+0.50}_{-0.37} \pm 0.16$.

[a] ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

[b] Here ℓ indicates e or μ.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] This value is updated using the product of (i) the $Z \to b\overline{b}$ fraction from this listing and (ii) the b-hadron fraction in an unbiased sample of weakly decaying b-hadrons produced in Z-decays provided by the Heavy Flavor Averaging Group (HFLAV, http://www.slac.stanford.edu/xorg/hflav/osc/PDG_2009/#FRACZ).

[e] See the Particle Listings below for the γ energy range used in this measurement.

[f] For $m_{\gamma\gamma} = (60 \pm 5)$ GeV.

Z PARTIAL WIDTHS

$\Gamma(e^+e^-)$ Γ_1

For the LEP experiments, this parameter is not directly used in the overall fit but is derived using the fit results; see the note "The *Z* boson" and ref. LEP-SLC 06.

$\Gamma(\ell^+\ell^-)$ Γ_4

ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

In our fit $\Gamma(\ell^+\ell^-)$ is defined as the partial *Z* width for the decay into a pair of massless charged leptons. This parameter is not directly used in the 5-parameter fit assuming lepton universality but is derived using the fit results. See the note "The *Z* boson" and ref. LEP-SLC 06.

Γ(invisible) Γ_7

The *Z* boson also decays to final states invisible in any detector, for example, the decay to a neutrino pair as predicted in the Standard Model. Measurements of Γ(invisible) fall into two categories: direct or indirect. Direct measurements look for final states with missing energy, missing momentum, or missing mass, corresponding to the invisible decay of a produced *Z* boson, including single-photon final states which arise from initial-state radiation. The indirect determination is based on *Z* lineshape analyses performed at the LEP collider, where the invisible decay width is calculated by subtracting all visible partial decay widths from the total decay width of the *Z* boson. Within the framework of the Standard Model these two determinations should be identical, but not in non-SM scenarios.

[1] AAD 24L use the measured ratio of invisible *Z* decays and leptonic *Z* decays to derive the width of the *Z* decaying to invisible particles. Events with transverse momentum of the *Z* larger than 130 GeV and at least one central jet with transverse momentum larger than 110 GeV are selected.

[2] TUMASYAN 23E analyses leptonic *Z* decay modes, with the invisible *Z* decay identified by missing momentum.

[3] The LEP Collaborations perform a combined fit to their line-shape results and determine this quantity as a difference between the total width and the sum of all the visible widths, assuming lepton universality. This result combines ABBIENDI 01A, ABREU 00F, ACCIARRI 00C, BARATE 00C, taking correlated uncertainties into account.
[4] This analysis selects single-photon events arising from inital state radiation.
[5] This is an indirect determination of Γ(invisible) from a fit to the visible Z decay modes. It is included in the determination of the LEP average LEP-SLC 06 reported above.

Γ(hadrons) — Γ_8

This parameter is not directly used in the 5-parameter fit assuming lepton universality, but is derived using the fit results. See the note "The Z boson" and ref. LEP-SLC 06.

$4.83^{+0.23+0.35}_{-0.22-0.32}$	509	[3] SIRUNYAN	18BT	CMS	E_{cm}^{pp} = 13 TeV
$4.9\ ^{+0.8}_{-0.7}\ ^{+0.4}_{-0.2}$	39	[4] KHACHATRY...	16CC	CMS	E_{cm}^{pp} = 13 TeV
4.31±0.34±0.17	172	AAD	14N	ATLS	E_{cm}^{pp} = 7, 8 TeV
$4.6\ ^{+1.0}_{-0.9}$ ±0.2	28	[5] CHATRCHYAN	12BN	CMS	E_{cm}^{pp} = 7 TeV

[1] AAD 21AQ analyze differential cross-sections in four-lepton events. Based on the measured cross section in the $Z \to 4\ell$ channel, a branching fraction of $B(Z \to 4\ell) = (4.41 \pm 0.13 \pm 0.23 \pm 0.09 \pm 0.12) \times 10^{-6}$ is obtained, where the uncertainties are statistical, systematic, theory and luminosity, respectively.
[2] AABOUD 19N reports $(4.70 \pm 0.32 \pm 0.21 \pm 0.14) \times 10^{-6}$, where the uncertainties are statistical, systematic, and luminosity. We have combined the latter two in quadrature.
[3] SIRUNYAN 18BT report the $Z \to 4\ell$ branching fraction $= (4.83^{+0.23+0.32}_{-0.22-0.29} \pm 0.08 \pm 0.12) \times 10^{-6}$, where the uncertainties are statistical, systematic, due to theory, and luminosity. The last three have been added in quadrature to obtain the total systematic error.
[4] KHACHATRYAN 16CC reports $(4.9^{+0.8+0.3+0.2+0.1}_{-0.7-0.2-0.1-0.1}) \times 10^{-6}$ value, where the uncertainties are statistical, systematic, theory, and due to luminosity. We have combined uncertainties in quadrature.
[5] CHATRCHYAN 12BN reports $(4.2^{+0.9}_{-0.8} \pm 0.2) \times 10^{-6}$ value. Their result (both central value and uncertainties) is scaled up by 10% to account for the different phase-space definition used here (see RAINBOLT 19).

[1] ABBIENDI 01A error includes approximately 0.034 due to statistics and 0.027 due to event selection systematics.
[2] BARATE 00C error includes approximately 0.033 due to statistics, 0.020 due to experimental systematics, and 0.005 due to the theoretical uncertainty in t-channel prediction.

Γ((u$\bar{u}$+c$\bar{c}$)/2)/Γ(hadrons) — Γ_9/Γ_8

This quantity is the branching ratio of $Z \to$ "up-type" quarks to $Z \to$ hadrons. Except ACKERSTAFF 97T the values of $Z \to$ "up-type" and $Z \to$ "down-type" branchings are extracted from measurements of Γ(hadrons), and Γ($Z \to \gamma +$ jets) where γ is a high-energy (>5 or 7 GeV) isolated photon. As the experiments use different procedures and slightly different values of M_Z, Γ(hadrons) and α_s in their extraction procedures, our average has to be taken with caution.

0.1623±0.0085±0.0209	[6] ABREU	95D	DLPH	E^{ee}_{cm}= 88–94 GeV

[1] ABE 05F use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $c\overline{c}$ events using a double tag method. The single c-tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere). A multitag approach is used, defining 4 regions of the output value of the neural network and R_c is extracted from a simultaneous fit to the count rates of the 4 different tags. The quoted systematic error includes an uncertainty of ±0.0006 due to the uncertainty on R_b.

[2] ABREU 00 obtain this result properly combining the measurement from the D^{*+} production rate (R_c= 0.1610 ± 0.0104 ± 0.0077 ± 0.0043 (BR)) with that from the overall charm counting (R_c= 0.1692 ± 0.0047 ± 0.0063 ± 0.0074 (BR)) in $c\overline{c}$ events. The systematic error includes an uncertainty of ±0.0054 due to the uncertainty on the charmed hadron branching fractions.

[3] BARATE 00B use exclusive decay modes to independently determine the quantities $R_c \times$f($c \to$ X), X=D^0, D^+, D_s^+, and Λ_c. Estimating $R_c \times$f($c \to \Xi_c/\Omega_c$)= 0.0034, they simply sum over all the charm decays to obtain R_c= 0.1738 ± 0.0047 ± 0.0088 ± 0.0075(BR). This is combined with all previous ALEPH measurements (BARATE 98T and BUSKULIC 94G, R_c= 0.1681 ± 0.0054 ± 0.0062) to obtain the quoted value.

[4] ACKERSTAFF 98E use an inclusive/exclusive double tag. In one jet $D^{*\pm}$ mesons are exclusively reconstructed in several decay channels and in the opposite jet a slow pion (opposite charge inclusive $D^{*\pm}$) tag is used. The b content of this sample is measured by the simultaneous detection of a lepton in one jet and an inclusively reconstructed $D^{*\pm}$ meson in the opposite jet. The systematic error includes an uncertainty of ±0.006 due to the external branching ratios.

[5] ALEXANDER 96R obtain this value via direct charm counting, summing the partial contributions from D^0, D^+, D_s^+, and Λ_c^+, and assuming that strange-charmed baryons account for the 15% of the Λ_c^+ production. An uncertainty of ±0.005 due to the uncertainties in the charm hadron branching ratios is included in the overall systematics.

[6] ABREU 95D perform a maximum likelihood fit to the combined p and p_T distributions of single and dilepton samples. The second error includes an uncertainty of ±0.0124 due to models and branching ratios.

$R_b = \Gamma(b\overline{b})/\Gamma$(hadrons) — Γ_{12}/Γ_8

OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06.

The Standard Model predicts R_b=0.21581 for m_t=174.3 GeV and M_H=150 GeV.

[1] ABE 05F use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $b\overline{b}$ events using a double tag method. The single b–tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere; the key tag is obtained requiring the secondary vertex corrected mass to be above the D–meson mass). ABE 05F obtain R_b =0.21604 ± 0.00098 ± 0.00074 where the systematic error includes an uncertainty of ±0.00012 due to the uncertainty on R_c. The value reported here is obtained properly combining with ABE 98D. The quoted systematic error includes an uncertainty of ±0.00012 due to the uncertainty on R_c.

[2] ACCIARRI 00 obtain this result using a double-tagging technique, with a high p_T lepton tag and an impact parameter tag in opposite hemispheres.

[3] ABBIENDI 99B tag $Z \to b\overline{b}$ decays using leptons and/or separated decay vertices. The b-tagging efficiency is measured directly from the data using a double-tagging technique.

[4] ABREU 99B obtain this result combining in a multivariate analysis several tagging methods (impact parameter and secondary vertex reconstruction, complemented by event shape variables). For R_c different from its Standard Model value of 0.172, R_b varies as $-0.024\times(R_c-0.172)$.

[5] BARATE 97F combine the lifetime-mass hemisphere tag (BARATE 97E) with event shape information and lepton tag to identify $Z \to b\overline{b}$ candidates. They further use c- and $u\,d\,s$-selection tags to identify the background. For R_c different from its Standard Model value of 0.172, R_b varies as $-0.019\times(R_c - 0.172)$.

[6] ABREU 95D perform a maximum likelihood fit to the combined p and p_T distributions of single and dilepton samples. The second error includes an uncertainty of ±0.0023 due to models and branching ratios.

[7] BUSKULIC 94G perform a simultaneous fit to the p and p_T spectra of both single and dilepton events.

[8] JACOBSEN 91 tagged $b\overline{b}$ events by requiring coincidence of ≥ 3 tracks with significant impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties (±0.014).

$\Gamma(b\overline{b}b\overline{b})/\Gamma$(hadrons) — Γ_{13}/Γ_8

[1] SIRUNYAN 19AJ study $Z \to J/\psi\gamma$ with $J/\psi \to \mu^+\mu^-$. Candidate events are selected by requiring a pair of oppositely charged muons and a well isolated photon. The leading (subleading) muon is require to have a transverse momentum larger than 20 GeV (4 GeV), while the photon must have a transverse energy larger than 33 GeV. Requiring the invariant mass of the $\mu\mu$ ($\mu\mu\gamma$) system in the range 3.0 to 3.2 (81 to 101) GeV, selects 183 data events which is consistent with the expected background. The 95% C.L. limit on the Z branching fraction is obtained assuming the J/ψ to be unpolarized.

[2] AABOUD 18BL study $Z \to J/\psi\gamma$ in 13 TeV pp interactions. Two triggers were used: isolated photon of $p_T > 35(25)$ GeV and a muon with $p_T > 18(24)$ GeV. The J/ψ is detected via its dimuon decay and it is required that the azimuthal angle between the photon and the J/ψ in the plane transverse to the beam direction is $> \pi/2$. The number of observed/expected background events is $92/89 \pm 6$ in the dimuon mass range 2.9–3.3 GeV leading to the quoted 95% C.L. limit.

[3] AAD 15I use events with the highest p_T muon in the pair required to have $p_T > 20$ GeV, the dimuon mass required to be within 0.2 GeV of the $J/\psi(1S)$ mass and it's transverse momentum required to be > 36 GeV. The photon is also required to have it's $p_T > 36$ GeV.

$0.67 \pm 0.18 \pm 0.05$	[1] SIRUNYAN	18DZ	CMS	pp at 13 TeV

[1] SIRUNYAN 18DZ observe the decay $Z \to \Psi\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV, where Ψ includes J/ψ as well as $\psi(2S) \to J/\psi X$, and $\ell^+\ell^-$ represents an electron or muon pair while the J/ψ is detected via its $\mu^+\mu^-$ decay channel. To reduce systematic errors they determine the ratio of the branching fraction of this decay to that of $Z \to \mu^+\mu^-\mu^+\mu^-$ within phase-space cuts imposed on lepton transverse momentum and pseudo rapidity, dilepton invariant mass, and J/ψ transverse momentum. The number of selected $\Psi\mu^+\mu^-$ (Ψe^+e^-) candidate events is 29 (18). Analyzing the $\mu^+\mu^-$ and $\mu^+\mu^-\ell^+\ell^-$ invariant mass distributions, a yield of 13.0 ± 3.9 (11.2 ± 3.4) events for the $\Psi\mu^+\mu^-$ (Ψe^+e^-) mode is obtained. The ratio of the branching fractions is determined as $0.67 \pm 0.18 \pm 0.05$ within the selected phase-space cuts. Assuming extrapolation to full phase space cancels in the ratio, and using their measured value of $B(Z \to \mu^+\mu^-\mu^+\mu^-) = (1.20 \pm 0.08) \times 10^{-6}$, they estimate $B(Z \to J/\psi\ell^+\ell^-) = 8 \times 10^{-7}$.

[1] ACKERSTAFF 98O searched for the decay modes $B_c\to J/\psi\pi^+$, $J/\psi a_1^+$, and $J/\psi\ell^+\nu_\ell$, with $J/\psi\to\ell^+\ell^-$, $\ell = e,\mu$. The number of candidates (background) for the three decay modes is 2 (0.63 ± 0.2), 0 (1.10 ± 0.22), and 1 (0.82 ± 0.19) respectively. Interpreting the $2\,B_c\to J/\psi\pi^+$ candidates as signal, they report $\Gamma(B_c^+X)\times B(B_c\to J/\psi\pi^+)/\Gamma(\text{hadrons}) = (3.8^{+5.0}_{-2.4}\pm0.5)\times10^{-5}$. Interpreted as background, the 90% CL bounds are $\Gamma(B_c^+X)*B(B_c\to J/\psi\pi^+)/\Gamma(\text{hadrons}) < 1.06\times10^{-4}$, $\Gamma(B_c^+X)*B(B_c\to J/\psi a_1^+)/\Gamma(\text{hadrons}) < 5.29\times10^{-4}$, $\Gamma(B_c^+X)*B(B_c\to J/\psi\ell^+\nu_\ell)/\Gamma(\text{hadrons}) < 6.96\times10^{-5}$.

[2] ABREU 97E searched for the decay modes $B_c\to J/\psi\pi^+$, $J/\psi\ell^+\nu_\ell$, and $J/\psi(3\pi)^+$, with $J/\psi\to\ell^+\ell^-$, $\ell = e,\mu$. The number of candidates (background) for the three decay modes is 1 (1.7), 0 (0.3), and 1 (2.3) respectively. They report the following 90% CL limits: $\Gamma(B_c^+X)*B(B_c\to J/\psi\pi^+)/\Gamma(\text{hadrons}) < (1.05\text{–}0.84)\times10^{-4}$, $\Gamma(B_c^+X)*B(B_c\to J/\psi\ell\nu_\ell)/\Gamma(\text{hadrons}) < (5.8\text{–}5.0)\times10^{-5}$, $\Gamma(B_c^+X)*B(B_c\to J/\psi(3\pi)^+)/\Gamma(\text{hadrons}) < 1.75\times10^{-4}$, where the ranges are due to the predicted B_c lifetime (0.4–1.4) ps.

[3] BARATE 97H searched for the decay modes $B_c\to J/\psi\pi^+$ and $J/\psi\ell^+\nu_\ell$ with $J/\psi\to\ell^+\ell^-$, $\ell = e,\mu$. The number of candidates (background) for the two decay modes is 0 (0.44) and 2 (0.81) respectively. They report the following 90% CL limits: $\Gamma(B_c^+X)*B(B_c\to J/\psi\pi^+)/\Gamma(\text{hadrons}) < 3.6\times10^{-5}$ and $\Gamma(B_c^+X)*B(B_c\to J/\psi\ell^+\nu_\ell)/\Gamma(\text{hadrons}) < 5.2\times10^{-5}$.

0.022±0.005 OUR AVERAGE				
0.024±0.005±0.006	[1] ALEXANDER	96R	OPAL	E_{cm}^{ee} = 88–94 GeV
0.021±0.003±0.005	[2] BUSKULIC	96Y	ALEP	E_{cm}^{ee} = 88–94 GeV

[1] ALEXANDER 96R measure $R_b\times f(b\to\Lambda_c^+X)\times B(\Lambda_c^+\to pK^-\pi^+) = (0.122\pm0.023\pm0.010)$% in hadronic Z decays; the value quoted here is obtained using our best value $B(\Lambda_c^+\to pK^-\pi^+) = (5.0\pm1.3)$%. The first error is the total experiment's error and the second error is the systematic error due to the branching fraction uncertainty.

[2] BUSKULIC 96Y obtain the production fraction of Λ_c^+ baryons in hadronic Z decays $f(b\to\Lambda_c^+X) = 0.110\pm0.014\pm0.006$ using $B(\Lambda_c^+\to pK^-\pi^+) = (4.4\pm0.6)$%; we have rescaled using our best value $B(\Lambda_c^+\to pK^-\pi^+) = (5.0\pm1.3)$% obtaining $f(b\to\Lambda_c^+X) = 0.097\pm0.013\pm0.025$ where the first error is their total experiment's error and the second error is the systematic error due to the branching fraction uncertainty. The value quoted here is obtained multiplying this production fraction by our value of $R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$.

$\Gamma(\Xi_c^0X)/\Gamma(\text{hadrons})$ Γ_{56}/Γ_8

• • • We do not use the following data for averages, fits, limits, etc. • • •				
seen	[1] ABDALLAH	05C	DLPH	E_{cm}^{ee} = 88–94 GeV

[1] ABDALLAH 05C searched for the charmed strange baryon Ξ_c^0 in the decay channel $\Xi_c^0\to\Xi^-\pi^+$ ($\Xi^-\to\Lambda\pi^-$). The production rate is measured to be $f_{\Xi_c^0}\times B(\Xi_c^0\to\Xi^-\pi^+) = (4.7\pm1.4\pm1.1)\times10^{-4}$ per hadronic Z decay.

$\Gamma(\Xi_bX)/\Gamma(\text{hadrons})$ Γ_{57}/Γ_8

Here Ξ_b is used as a notation for the strange b-baryon states Ξ_b^- and Ξ_b^0.

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
seen	[1] ABDALLAH	05C	DLPH	E_{cm}^{ee} = 88–94 GeV
seen	[2] BUSKULIC	96T	ALEP	E_{cm}^{ee} = 88–94 GeV
seen	[3] ABREU	95V	DLPH	E_{cm}^{ee} = 88–94 GeV

[1] ABDALLAH 05C searched for the beauty strange baryon Ξ_b in the inclusive semileptonic decay channel $\Xi_b\to\Xi^-\ell^-\overline{\nu}_\ell X$. Evidence for the Ξ_b production is seen from the observation of $\Xi^\mp$ production accompanied by a lepton of the same sign. From the excess of "right-sign" pairs $\Xi^\mp\ell^\mp$ compared to "wrong-sign" pairs $\Xi^\mp\ell^\pm$ the production rate is measured to be $B(b\to\Xi_b)\times B(\Xi_b\to\Xi^-\ell^-X) = (3.0\pm1.0\pm0.3)\times10^{-4}$ per lepton species, averaged over electrons and muons.

[2] BUSKULIC 96T investigate Ξ-lepton correlations and find a significant excess of "right–sign" pairs $\Xi^\mp\ell^\mp$ compared to "wrong–sign" pairs $\Xi^\mp\ell^\pm$. This excess is interpreted as evidence for Ξ_b semileptonic decay. The measured product branching ratio is $B(b\to\Xi_b)\times B(\Xi_b\to X_cX\ell^-\overline{\nu}_\ell)\times B(X_c\to\Xi^-X') = (5.4\pm1.1\pm0.8)\times10^{-4}$ per lepton species, averaged over electrons and muons, with X_c a charmed baryon.

[3] ABREU 95V observe an excess of "right-sign" pairs $\Xi^\mp\ell^\mp$ compared to "wrong-sign" pairs $\Xi^\mp\ell^\pm$ in jets: this excess is interpreted as evidence for the beauty strange baryon Ξ_b production, with $\Xi_b\to\Xi^-\ell^-\overline{\nu}_\ell X$. They find that the probability for this signal to come from non b-baryon decays is less than 5×10^{-4} and that Λ_b decays can account for less than 10% of these events. The Ξ_b production rate is then measured to be $B(b\to\Xi_b)\times B(\Xi_b\to\Xi^-\ell^-X) = (5.9\pm2.1\pm1.0)\times10^{-4}$ per lepton species, averaged over electrons and muons.

$\Gamma(b\text{-baryon}\,X)/\Gamma(\text{hadrons})$ Γ_{58}/Γ_8

"OUR EVALUATION" is obtained using our current values for $f(b\to b\text{-baryon})$ and $R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$. We calculate $\Gamma(b\text{-baryon}\,X)/\Gamma(\text{hadrons}) = R_b\times f(b\to b\text{-baryon})$.

VALUE	DOCUMENT ID		TECN	COMMENT
0.0197±0.0032 OUR EVALUATION	(Produced by HFLAV)			
0.0221±0.0015±0.0058	[1] BARATE	98V	ALEP	E_{cm}^{ee}= 88–94 GeV

[1] BARATE 98V use the overall number of identified protons in b-hadron decays to measure $f(b\to b\text{-baryon}) = 0.102\pm0.007\pm0.027$. They assume $BR(b\text{-baryon}\to pX) = (58\pm6)$% and $BR(B_s^0\to pX) = (8.0\pm4.0)$%. The value quoted here is obtained multiplying this production fraction by our value of $R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$.

Z HADRONIC POLE CROSS SECTION

OUR EVALUATION is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). Corrections as discussed in VOUTSINAS 20 and JANOT 20 are also included. This quantity is defined as

$$\sigma_h^0 = \frac{12\pi}{M_Z^2} \frac{\Gamma(e^+e^-)\Gamma(\text{hadrons})}{\Gamma_Z^2}$$

It is one of the parameters used in the Z lineshape fit.

VALUE (nb)	EVTS	DOCUMENT ID		TECN	COMMENT
41.4802±0.0325 OUR EVALUATION					
41.4802±0.0325		[1] JANOT	20		
• • • We do not use the following data for averages, fits, limits, etc. • • •					
41.500 ±0.037		[2] VOUTSINAS	20		
41.541 ±0.037		[3] LEP-SLC	06		E_{cm}^{ee} = 88–94 GeV
41.501 ±0.055	4.10M	[4] ABBIENDI	01A	OPAL	E_{cm}^{ee}= 88–94 GeV
41.578 ±0.069	3.70M	ABREU	00F	DLPH	E_{cm}^{ee}= 88–94 GeV
41.535 ±0.055	3.54M	ACCIARRI	00C	L3	E_{cm}^{ee}= 88–94 GeV

42 ±4	450	ABRAMS	89B	MRK2	E_{cm}^{ee}= 89.2–93.0 GeV

[1] JANOT 20 applies a correction to LEP-SLC 06 using an updated Bhabha cross section calculation. This result also includes a correction to account for correlated luminosity bias as presented in VOUTSINAS 20.
[2] VOUTSINAS 20 applies a correction to LEP-SLC 06 to account for correlated luminosity bias.
[3] This result combines ABBIENDI 01A, ABREU 00F, ACCIARRI 00C, BARATE 00C, taking correlated uncertainties into account.
[4] ABBIENDI 01A error includes approximately 0.031 due to statistics, 0.033 due to event selection systematics, 0.029 due to uncertainty in luminosity measurement, and 0.011 due to LEP energy uncertainty.
[5] BARATE 00C error includes approximately 0.030 due to statistics, 0.026 due to experimental systematics, and 0.025 due to uncertainty in luminosity measurement.

Z VECTOR COUPLINGS

These quantities are the effective vector couplings of the Z to charged leptons and quarks. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e, A_μ, and A_τ. By convention the sign of g_A^e is fixed to be negative (and opposite to that of g^{ν_e} obtained using ν_e scattering measurements). For the light quarks, the sign of the couplings is assigned consistently with this assumption. The LEP/SLD-based fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e, A_μ, and A_τ measurements. See the note "The Z boson" and ref. LEP-SLC 06 for details. Where $p\overline{p}$ and ep data is quoted, OUR FIT value corresponds to a weighted average of this with the LEP/SLD fit result.

$0.399^{+0.152}_{-0.188}\pm0.066$	5026	[4] ACOSTA	05M	CDF	$E_{cm}^{p\overline{p}}$= 1.96 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$0.14\ ^{+0.09}_{-0.09}$		[5] ABRAMOWICZ	16A	ZEUS	
$0.144^{+0.066}_{-0.058}$		[6] ABT	16		
0.27 ±0.13	1500	[7] AKTAS	06	H1	$e^\pm p \to \overline{\nu}_e(\nu_e)X$, $\sqrt{s}\approx 300$ GeV

[1] ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic e^+p and e^-p neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.

[2] ABAZOV 11D study $p\overline{p} \to Z/\gamma^* e^+e^-$ events using 5 fb^{-1} data at $\sqrt{s}$ = 1.96 TeV. The candidate events are selected by requiring two isolated electromagnetic showers with $E_T > 25$ GeV, at least one electron in the central region and the di-electron mass in the range 50–1000 GeV. From the forward-backward asymmetry, determined as a function of the di-electron mass, they derive the axial and vector couplings of the u- and d- quarks and the value of $\sin^2\theta^\ell_{eff} = 0.2309 \pm 0.0008(\text{stat}) \pm 0.0006(\text{syst})$.

[3] LEP-SLC 06 is a combination of the results from LEP and SLC experiments using light quark tagging. s- and d-quark couplings are assumed to be identical.

[4] ACOSTA 05M determine the forward-backward asymmetry of e^+e^- pairs produced via $q\overline{q} \to Z/\gamma^* \to e^+e^-$ in 15 M(e^+e^-) effective mass bins ranging from 40 GeV to 600 GeV. These results are used to obtain the vector and axial-vector couplings of the Z to the light quarks, assuming the electron couplings are as predicted by the Standard Model. Higher order radiative corrections have not been taken into account.

[5] ABRAMOWICZ 16A determine the Z^0 couplings to u- and d-quarks using the ZEUS polarised data from Run II together with the unpolarised data from both ZEUS and H1 Collaborations for Run I and unpolarised H1 data from Run II.

[6] ABT 16 determine the Z^0 couplings to u- and d-quarks using the same techniques and data as ABRAMOWICZ 16A but additionally use the published H1 polarised data.

[7] AKTAS 06 fit the neutral current ($1.5 \le Q^2 \le 30{,}000$ GeV^2) and charged current ($1.5 \le Q^2 \le 15{,}000$ GeV^2) differential cross sections. In the determination of the u-quark couplings the electron and d-quark couplings are fixed to their standard model values.

−0.33 ±0.33	1500	[7] AKTAS	06	H1	$e^\pm p \to \overline{\nu}_e(\nu_e)X$, $\sqrt{s}\approx 300$ GeV

[1] ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic e^+p and e^-p neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.

[2] ABAZOV 11D study $p\overline{p} \to Z/\gamma^* e^+e^-$ events using 5 fb^{-1} data at $\sqrt{s}$ = 1.96 TeV. The candidate events are selected by requiring two isolated electromagnetic showers with $E_T > 25$ GeV, at least one electron in the central region and the di-electron mass in the range 50–1000 GeV. From the forward-backward asymmetry, determined as a function of the di-electron mass, they derive the axial and vector couplings of the u- and d- quarks and the value of $\sin^2\theta^\ell_{eff} = 0.2309 \pm 0.0008(\text{stat}) \pm 0.0006(\text{syst})$.

[3] LEP-SLC 06 is a combination of the results from LEP and SLC experiments using light quark tagging. s- and d-quark couplings are assumed to be identical.

[4] ACOSTA 05M determine the forward-backward asymmetry of e^+e^- pairs produced via $q\overline{q} \to Z/\gamma^* \to e^+e^-$ in 15 M(e^+e^-) effective mass bins ranging from 40 GeV to 600 GeV. These results are used to obtain the vector and axial-vector couplings of the Z to the light quarks, assuming the electron couplings are as predicted by the Standard Model. Higher order radiative corrections have not been taken into account.

[5] ABRAMOWICZ 16A determine the Z^0 couplings to u- and d-quarks using the ZEUS polarised data from Run II together with the unpolarised data from both ZEUS and H1 Collaborations for Run I and unpolarised H1 data from Run II.

[6] ABT 16 determine the Z^0 couplings to u- and d-quarks using the same techniques and data as ABRAMOWICZ 16A but additionally use the published H1 polarised data.

[7] AKTAS 06 fit the neutral current ($1.5 \le Q^2 \le 30{,}000$ GeV^2) and charged current ($1.5 \le Q^2 \le 15{,}000$ GeV^2) differential cross sections. In the determination of the d-quark couplings the electron and u-quark couplings are fixed to their standard model values.

Z AXIAL-VECTOR COUPLINGS

These quantities are the effective axial-vector couplings of the Z to charged leptons and quarks. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e, A_μ, and A_τ. By convention the sign of g_A^e is fixed to be negative (and opposite to that of g^{ν_e} obtained using ν_e scattering measurements). For the light quarks, the sign of the couplings is assigned consistently with this assumption. The LEP/SLD-based fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e, A_μ, and A_τ measurements. See the note "The Z boson" and ref. LEP-SLC 06 for details. Where $p\overline{p}$ and ep data is quoted, OUR FIT value corresponds to a weighted average of this with the LEP/SLD fit result.

VALUE	DOCUMENT ID		TECN	COMMENT
0.502±0.017	[1] VILAIN	94	CHM2	From $\nu_\mu e$ scattering

[1] VILAIN 94 derive this value from their measurement of the couplings $g_A^{e\nu_\mu} = -0.503 \pm 0.017$ and $g_V^{e\nu_\mu} = -0.035 \pm 0.017$ obtained from $\nu_\mu e$ scattering. We have re-evaluated this value using the current PDG values for g^e_A and g^e_V.

Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the Z these quantities are defined as

$$A_f = \frac{2g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$

where g_V^f and g_A^f are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the note "The Z boson" and ref. LEP-SLC 06.

A_e

Using polarized beams, this quantity can also be measured as $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$, where σ_L and σ_R are the e^+e^- production cross sections for Z bosons produced with left-handed and right-handed electrons respectively.

0.153 ± 0.012	1.7M	[2] AAD	15BT	ATLS	$E^{pp}_{\text{cm}} = 7$ TeV

[1] ABE 01B obtain this direct measurement using the left-right production and left-right forward-backward polar angle asymmetries in $\mu^+\mu^-$ decays of the Z boson obtained with a polarized electron beam.

[2] AAD 15BT study $pp \to Z \to \ell^+\ell^-$ events where ℓ is an electron or a muon in the dilepton mass region 70–1000 GeV. The background in the Z peak region is estimated to be $< 1\%$ for the muon channel. The muon asymmetry parameter is derived from the measured forward-backward asymmetry assuming the value of the quark asymmetry parameter from the SM. For this reason it is not used in the average.

A_τ

The LEP and LHC Collaborations collaboration derive this quantity from the measurement of the τ polarization in $Z \to \tau^+\tau^-$. The SLD Collaboration directly extracts this quantity from its measured left-right forward-backward asymmetry in $Z \to \tau^+\tau^-$ produced using a polarized e^- beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e.

0.688 ± 0.041	[3] ABE	01C	SLD	E_{cm}^{ee} = 91.25 GeV

[1] ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $c\overline{c}$ events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying c–quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (9970 events) $A_c = 0.6747 \pm 0.0290 \pm 0.0233$. Taking into account all correlations with earlier results reported in ABE 02G and ABE 01C, they obtain the quoted overall SLD result.
[2] ABE 02G tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously A_b and A_c.
[3] ABE 01C tag $Z \to c\overline{c}$ events using two techniques: exclusive reconstruction of D^{*+}, D^+ and D^0 mesons and the soft pion tag for $D^{*+} \to D^0\pi^+$. The large background from D mesons produced in $b\overline{b}$ events is separated efficiently from the signal using precision vertex information. When combining the A_c values from these two samples, care is taken to avoid double counting of events common to the two samples, and common systematic errors are properly taken into account.

A_b

This quantity is directly extracted from a measurement of the left-right forward-backward asymmetry in $b\overline{b}$ production at SLC using polarized electron beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e. OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06.

0.923 ±0.020 OUR FIT					
$0.9170 \pm 0.0147 \pm 0.0145$		[1] ABE	05	SLD	E_{cm}^{ee} = 91.24 GeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$0.907 \pm 0.020 \pm 0.024$	48028	[2] ABE	03F	SLD	E_{cm}^{ee} = 91.24 GeV
$0.919 \pm 0.030 \pm 0.024$		[3] ABE	02G	SLD	E_{cm}^{ee} = 91.24 GeV
$0.855 \pm 0.088 \pm 0.102$	7473	[4] ABE	99L	SLD	E_{cm}^{ee} = 91.27 GeV

[1] ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $b\overline{b}$ events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying b–quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (25917 events) $A_b = 0.9173 \pm 0.0184 \pm 0.0173$. Taking into account all correlations with earlier results reported in ABE 03F, ABE 02G and ABE 99L, they obtain the quoted overall SLD result.
[2] ABE 03F obtain an enriched sample of $b\overline{b}$ events tagging on the invariant mass of a 3-dimensional topologically reconstructed secondary decay. The charge of the underlying b quark is obtained using a self-calibrating track-charge method. For the 1996–1998 data sample they measure $A_b = 0.906 \pm 0.022 \pm 0.023$. The value quoted here is obtained combining the above with the result of ABE 98I (1993–1995 data sample).
[3] ABE 02G tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously A_b and A_c.
[4] ABE 99L obtain an enriched sample of $b\overline{b}$ events tagging with an inclusive vertex mass cut. For distinguishing b and $\overline{b}$ quarks they use the charge of identified $K^\pm$.

TRANSVERSE SPIN CORRELATIONS IN $Z \to \tau^+\tau^-$

The correlations between the transverse spin components of $\tau^+\tau^-$ produced in Z decays may be expressed in terms of the vector and axial-vector couplings:

$$C_{TT} = \frac{|g_A^\tau|^2 - |g_V^\tau|^2}{|g_A^\tau|^2 + |g_V^\tau|^2}$$

$$C_{TN} = -2\frac{|g_A^\tau||g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2}\sin(\Phi_{g_V^\tau} - \Phi_{g_A^\tau})$$

C_{TT} refers to the transverse-transverse (within the collision plane) spin correlation and C_{TN} refers to the transverse-normal (to the collision plane) spin correlation.

The longitudinal τ polarization P_τ ($= -A_\tau$) is given by:

$$P_\tau = -2\frac{|g_A^\tau||g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2}\cos(\Phi_{g_V^\tau} - \Phi_{g_A^\tau})$$

Here Φ is the phase and the phase difference $\Phi_{g_V^\tau} - \Phi_{g_A^\tau}$ can be obtained using both the measurements of C_{TN} and P_τ.

C_{TT}

[1] BARATE 97D combine their value of C_{TN} with the world average $P_\tau = -0.140 \pm 0.007$ to obtain $\tan(\Phi_{g_V^\tau} - \Phi_{g_A^\tau}) = -0.57 \pm 0.97$.

FORWARD-BACKWARD $e^+e^- \to f\overline{f}$ CHARGE ASYMMETRIES

These asymmetries are experimentally determined by tagging the respective lepton or quark flavor in e^+e^- interactions. Details of heavy flavor (c- or b-quark) tagging at LEP are described in the note on "The Z boson" and ref. LEP-SLC 06. The Standard Model predictions for LEP data have been (re)computed using the ZFITTER package (version 6.36) with input parameters M_Z=91.187 GeV, M_{top}=174.3 GeV, M_{Higgs}=150 GeV, α_s=0.119, $\alpha^{(5)}(M_Z) = 1/128.877$ and the Fermi constant $G_F = 1.16637 \times 10^{-5}$ GeV^{-2} (see the note on "The Z boson" for references). For non-LEP data the Standard Model predictions are as given by the authors of the respective publications.

$A_{FB}^{(0,e)}$ CHARGE ASYMMETRY IN $e^+e^- \to e^+e^-$

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). For the Z peak, we report the pole asymmetry defined by $(3/4)A_e^2$ as determined by the nine-parameter fit to cross-section and lepton forward-backward asymmetry data.

[1] ABDALLAH 05 obtain an enriched samples of $b\overline{b}$ events using lifetime information. The quark (or antiquark) charge is determined with a neural network using the secondary vertex charge, the jet charge and particle identification.

[2] ABDALLAH 04F tag b– and c–quarks using semileptonic decays combined with charge flow information from the hemisphere opposite to the lepton. Enriched samples of $c\overline{c}$ and $b\overline{b}$ events are obtained using lifetime information.

[3] ABBIENDI 03P tag heavy flavors using events with one or two identified leptons. This allows the simultaneous fitting of the b and c quark forward-backward asymmetries as well as the average B^0-$\overline{B}^0$ mixing.

[4] ABBIENDI 02I tag $Z^0 \to b\overline{b}$ decays using a combination of secondary vertex and lepton tags. The sign of the b-quark charge is determined using an inclusive tag based on jet, vertex, and kaon charges.

[5] HEISTER 02H measure simultaneously b and c quark forward-backward asymmetries using their semileptonic decays to tag the quark charge. The flavor separation is obtained with a discriminating multivariate analysis.

[6] HEISTER 01D tag $Z \to b\overline{b}$ events using the impact parameters of charged tracks complemented with information from displaced vertices, event shape variables, and lepton identification. The b-quark direction and charge is determined using the hemisphere charge method along with information from fast kaon tagging and charge estimators of primary and secondary vertices. The change in the quoted value due to variation of A_{FB}^c and R_b is given as $+0.103\ (A_{FB}^c - 0.0651) - 0.440\ (R_b - 0.21585)$.

[7] ABREU 99Y tag $Z \to b\overline{b}$ and $Z \to c\overline{c}$ events by an exclusive reconstruction of several D meson decay modes (D^{*+}, D^0, and D^+ with their charge-conjugate states).

[8] ACCIARRI 99D tag $Z \to b\overline{b}$ events using high p and p_T leptons. The analysis determines simultaneously a mixing parameter $\chi_b = 0.1192 \pm 0.0068 \pm 0.0051$ which is used to correct the observed asymmetry.

[9] ACCIARRI 98U tag $Z \to b\overline{b}$ events using lifetime and measure the jet charge using the hemisphere charge.

[10] ALEXANDER 97C identify the b and c events using a D/D^* tag.

CHARGE ASYMMETRY IN $e^+e^- \to q\overline{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on B^0-$\overline{B}^0$ mixing and on other electroweak parameters.

$\sin^2(\theta_{\text{eff}})$

The leptonic effective electroweak mixing angle, $\sin^2\theta_{\text{eff}}^{\text{lept}}$, is given in terms of the ratio of leptonic vector and axial-vector coupling constants, $r = g_\ell^V/g_\ell^A$ for $\ell = e,\ \mu,\ \tau$, with $\sin^2\theta_{\text{eff}}^{\text{lept}} = (1-r)/4$. It can be extracted directly from the leptonic asymmetry parameter, $A_\ell = 2r/(1+r^2)$. See note "The Z boson" and ref. LEP-SLC 06.

[6] AAD 15BT analyse the forward-backward asymmetry in Drell-Yan production of Z bosons decaying to muon or electron pairs.
[7] AAIJ 15BF analyse the forward-backward asymmetry in Drell-Yan production of Z bosons decaying to muon pairs.
[8] This result combines the six individual results from LEP and SLC. The average, described in LEP-SLC 06, has a χ^2 probability of 3.7%.
[9] ABAZOV 18 analyse the forward-backward asymmetry in Drell-Yan production of Z bosons decaying to muon pairs. Combining this result with the one from ABAZOV 15C, a value of 0.23095 ± 0.00040 is obtained.
[10] AALTONEN 16D analyse the forward-backward asymmetry in Drell-Yan production of Z bosons decaying to electron pairs. Combining this result with the one from AALTONEN 14C, a value of 0.23221 ± 0.00046 is obtained.
[11] ABAZOV 15C analyse the forward-backward asymmetry in Drell-Yan production of Z bosons decaying to electron pairs.
[12] AALTONEN 14C analyse the forward-backward asymmetry in Drell-Yan production of Z bosons decaying to muon pairs.
[13] The result is based on the forward-backward asymmetry measured in leptonic Z decays (electrons, muons, taus). It combines the results of the LEP experiments, ALEPH, DELPHI, L3 and OPAL, taking correlations into account, see LEP-SLC 06.
[14] The result is based on the polarisation of tau leptons measured in Z decays to tau-lepton pairs. It combines the results of the LEP experiments, ALEPH, DELPHI, L3 and OPAL, taking correlations into account, see LEP-SLC 06.
[15] The result is based on the left-right and forward-backward left-right asymmetry measured in leptonic Z decays (electrons, muons, taus). It combines the results of the SLC experiment, SLD, taking correlations into account, see LEP-SLC 06.
[16] The result is based on the forward-backward asymmetry measured at LEP and the forward-backward left-right asymmetry measured at SLC, in both cases using Z decays to b-quarks. It combines the results of the LEP and SLC experiments, ALEPH, DELPHI, L3, OPAL and SLD, taking correlations into account, see LEP-SLC 06.
[17] The result is based on the forward-backward asymmetry measured at LEP and the forward-backward left-right asymmetry measured at SLC, in both cases using Z decays to c-quarks. It combines the results of the LEP and SLC experiments ALEPH, DELPHI, L3, OPAL and SLD, taking correlations into account, see LEP-SLC 06.
[18] The result is based on the inclusive hadronic charge asymmetry measured in hadronic Z decays. It combines the results of the LEP experiments, ALEPH, DELPHI, L3 and OPAL, taking correlations into account, see LEP-SLC 06.

ANOMALOUS $ZZ\gamma$, $Z\gamma\gamma$, AND ZZV COUPLINGS

Revised September 2013 by M.W. Grünewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

In on-shell $Z\gamma$ production, deviations from the Standard Model for the $Z\gamma\gamma^*$ and $Z\gamma Z^*$ couplings may be described in terms of eight parameters, h_i^V $(i = 1, 4;\ V = \gamma, Z)$ [1]. The parameters h_i^γ describe the $Z\gamma\gamma^*$ couplings and the parameters h_i^Z the $Z\gamma Z^*$ couplings. In this formalism h_1^V and h_2^V lead to CP-violating and h_3^V and h_4^V to CP-conserving effects. All these anomalous contributions to the cross section increase rapidly with center-of-mass energy. In order to ensure unitarity, these parameters are usually described by a form-factor representation, $h_i^V(s) = h_{i0}^V/(1 + s/\Lambda^2)^n$, where Λ is the energy scale for the manifestation of a new phenomenon and n is a sufficiently large power. By convention one uses $n = 3$ for $h_{1,3}^V$ and $n = 4$ for $h_{2,4}^V$. Usually limits on h_i^V's are put assuming some value of Λ, sometimes ∞.

In on-shell ZZ production, deviations from the Standard Model for the $ZZ\gamma^*$ and ZZZ^* couplings may be described by means of four anomalous couplings f_i^V $(i = 4, 5; V = \gamma, Z)$ [2]. As above, the parameters f_i^γ describe the $ZZ\gamma^*$ couplings and the parameters f_i^Z the ZZZ^* couplings. The anomalous couplings f_5^V lead to violation of C and P symmetries while f_4^V introduces CP violation. Also here, formfactors depending on a scale Λ are used.

All these couplings h_i^V and f_i^V are zero at tree level in the Standard Model; they are measured in e^+e^-, $p\bar{p}$ and pp collisions at LEP, Tevatron and LHC.

h_i^V

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:

$$-0.12 < h_1^Z < +0.11, \quad -0.07 < h_2^Z < +0.07,$$
$$-0.19 < h_3^Z < +0.06, \quad -0.04 < h_4^Z < +0.13,$$
$$-0.05 < h_1^\gamma < +0.05, \quad -0.04 < h_2^\gamma < +0.02,$$
$$-0.05 < h_3^\gamma < +0.00, \quad +0.01 < h_4^\gamma < +0.05.$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

[1] AAD 16Q study $Z\gamma$ production in pp collisions. In events with no additional jets, 10268 (12738) Z decays to electron (muon) pairs are selected, with an expected background of 1291 ± 340 (1537 ± 408) events, as well as 1039 Z decays to neutrino pairs with an expected background of 450 ± 96 events. Analyzing the photon transverse momentum distribution above 250 GeV (400 GeV) for lepton (neutrino) events, yields the 95% C.L. limits: $-7.8 \times 10^{-4} < h_3^Z < 8.6 \times 10^{-4}$, $-3.0 \times 10^{-6} < h_4^Z < 2.9 \times 10^{-6}$, $-9.5 \times 10^{-4} < h_3^\gamma < 9.9 \times 10^{-4}$, $-3.2 \times 10^{-6} < h_4^\gamma < 3.2 \times 10^{-6}$.

[2] KHACHATRYAN 16AE determine the $Z\gamma \to \nu\bar{\nu}\gamma$ cross section by selecting events with a photon of $E_T > 145$ GeV and $\not{E}_T > 140$ GeV. 630 candidate events are observed with an expected SM background of 269 ± 26. The E_T spectrum of the photon is used to set 95% C.L. limits as follows: $-1.5 \times 10^{-3} < h_3^Z < 1.6 \times 10^{-3}$, $-3.9 \times 10^{-6} < h_4^Z < 4.5 \times 10^{-6}$, $-1.1 \times 10^{-3} < h_3^\gamma < 0.9 \times 10^{-3}$, $-3.8 \times 10^{-6} < h_4^\gamma < 4.3 \times 10^{-6}$.

[3] KHACHATRYAN 15AC study $Z\gamma$ events in 8 TeV pp interactions, where the Z decays into 2 same-flavor, opposite sign leptons (e or μ) and a photon with $p_T > 15$ GeV. The p_T of a lepton is required to be > 20 GeV/c, their effective mass > 50 GeV, and the photon should have a separation $\Delta R > 0.7$ with each lepton. The observed p_T distribution of the photons is used to extract the 95% C.L. limits: $-3.8 \times 10^{-3} < h_3^Z < 3.7 \times 10^{-3}$, $-3.1 \times 10^{-5} < h_4^Z < 3.0 \times 10^{-5}$, $-4.6 \times 10^{-3} < h_3^\gamma < 4.6 \times 10^{-3}$, $-3.6 \times 10^{-5} < h_4^\gamma < 3.5 \times 10^{-5}$.

[4] CHATRCHYAN 14AB measure $Z\gamma$ production cross section for $p_T^\gamma > 15$ GeV and $R(\ell\gamma) > 0.7$, which is the separation between the γ and the final state charged lepton (e or μ) in the azimuthal angle-pseudorapidity $(\phi - \eta)$ plane. The di-lepton mass is required to be > 50 GeV. After background subtraction the number of $ee\gamma$ and $\mu\mu\gamma$ events is determined to be 3160 ± 120 and 5030 ± 233 respectively, compatible with expectations from the SM. This leads to a 95% CL limits of $-1 \times 10^{-2} < h_3^\gamma < 1 \times 10^{-2}$, $-9 \times 10^{-5} < h_4^\gamma < 9 \times 10^{-5}$, $-9 \times 10^{-3} < h_3^Z < 9 \times 10^{-3}$, $-8 \times 10^{-5} < h_4^Z < 8 \times 10^{-5}$, assuming h_1^V and h_2^V have SM values, $V = \gamma$ or Z.

[5] AAD 13AN study $Z\gamma$ production in pp collisions. In events with no additional jet, 1417 (2031) Z decays to electron (muon) pairs are selected, with an expected background of 156 ± 54 (244 ± 64) events, as well as 662 Z decays to neutrino pairs with an expected background of 302 ± 42 events. Analysing the photon p_T spectrum above 100 GeV yields the 95% C.L. limits: $-0.013 < h_3^Z < 0.014$, $-8.7 \times 10^{-5} < h_4^Z < 8.7 \times 10^{-5}$, $-0.015 < h_3^\gamma < 0.016$, $-9.4 \times 10^{-5} < h_4^\gamma < 9.2 \times 10^{-5}$. Supersedes AAD 12BX.

[6] CHATRCHYAN 13BI determine the $Z\gamma \to \nu\bar{\nu}\gamma$ cross section by selecting events with a photon of $E_T > 145$ GeV and a $\not{E}_T > 130$ GeV. 73 candidate events are observed with an expected SM background of 30.2 ± 6.5. The E_T spectrum of the photon is used to set 95% C.L. limits as follows: $|h_3^Z| < 2.7 \times 10^{-3}$, $|h_4^Z| < 1.3 \times 10^{-5}$, $|h_3^\gamma| < 2.9 \times 10^{-3}$, $|h_4^\gamma| < 1.5 \times 10^{-5}$.

[7] ABAZOV 12S study $Z\gamma$ production in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV using 6.2 fb^{-1} of data where the Z decays to electron (muon) pairs and the photon has at least 10 GeV of transverse momentum. In data, 304 (308) di-electron (di-muon) events are observed with an expected background of 255 ± 16 (285 ± 24) events. Based on the photon p_T spectrum, and including also earlier data and the $Z \to \nu\bar{\nu}$ decay mode (from ABAZOV 09L), the following 95% C.L. limits are reported: $|h_{03}^Z| < 0.026$, $|h_{04}^Z| < 0.0013$, $|h_{03}^\gamma| < 0.027$, $|h_{04}^\gamma| < 0.0014$ for a form factor scale of $\Lambda = 1.5$ TeV.

[8] AALTONEN 11S study $Z\gamma$ events in $p\bar{p}$ interactions at $\sqrt{s} = 1.96$ TeV with integrated luminosity 5.1 fb^{-1} for $Z \to e^+e^-/\mu^+\mu^-$ and 4.9 fb^{-1} for $Z \to \nu\bar{\nu}$. For the charged lepton case, the two leptons must be of the same flavor with the transverse

momentum/energy of one $>$ 20 GeV and the other $>$ 10 GeV. The isolated photon must have $E_T > 50$ GeV. They observe 91 events with 87.2 ± 7.8 events expected from standard model processes. For the $\nu\overline{\nu}$ case they require solitary photons with $E_T > 25$ GeV and missing $E_T > 25$ GeV and observe 85 events with standard model expectation of 85.9 ± 5.6 events. Taking the form factor $\Lambda = 1.5$ TeV they derive 95% C.L. limits as $|h_3^{\gamma,Z}| < 0.022$ and $|h_4^{\gamma,Z}| < 0.0009$.

[9] CHATRCHYAN 11M study $Z\gamma$ production in pp collisions at $\sqrt{s} = 7$ TeV using 36 pb^{-1} pp data, where the Z decays to e^+e^- or $\mu^+\mu^-$. The total cross sections are measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$ with the dilepton invariant mass requirement of $M_{\ell\ell} > 50$ GeV. The number of $e^+e^-\gamma$ and $\mu^+\mu^-\gamma$ candidates is 81 and 90 with estimated backgrounds of 20.5 ± 2.5 and 27.3 ± 3.2 events respectively. The 95% CL limits for $ZZ\gamma$ couplings are $-0.05 < h_3^Z < 0.06$ and $-0.0005 < h_4^Z < 0.0005$, and for $Z\gamma\gamma$ couplings are $-0.07 < h_3^\gamma < 0.07$ and $-0.0005 < h_4^\gamma < 0.0006$.

[10] ABAZOV 09L study $Z\gamma$, $Z \to \nu\overline{\nu}$ production in $p\overline{p}$ collisions at 1.96 TeV C.M. energy. They select 51 events with a photon of transverse energy E_T larger than 90 GeV, with an expected background of 17 events. Based on the photon E_T spectrum and including also Z decays to charged leptons (from ABAZOV 07M), the following 95% CL limits are reported: $|h_{30}^\gamma| < 0.033$, $|h_{40}^\gamma| < 0.0017$, $|h_{30}^Z| < 0.033$, $|h_{40}^Z| < 0.0017$.

[11] ABAZOV 07M use 968 $p\overline{p} \to e^+e^-/\mu^+\mu^-\gamma X$ candidates, at 1.96 TeV center of mass energy, to tag $p\overline{p} \to Z\gamma$ events by requiring $E_T(\gamma) > 7$ GeV, lepton-gamma separation $\Delta R_{\ell\gamma} > 0.7$, and di-lepton invariant mass > 30 GeV. The cross section is in agreement with the SM prediction. Using these $Z\gamma$ events they obtain 95% C.L. limits on each h_i^V, keeping all others fixed at their SM values. They report: $-0.083 < h_{30}^Z < 0.082$, $-0.0053 < h_{40}^Z < 0.0054$, $-0.085 < h_{30}^\gamma < 0.084$, $-0.0053 < h_{40}^\gamma < 0.0054$, for the form factor scale $\Lambda = 1.2$ TeV.

[12] Using data collected at $\sqrt{s} = 183$–208, ABDALLAH 07C select 1,877 $e^+e^- \to Z\gamma$ events with $Z \to q\overline{q}$ or $\nu\overline{\nu}$, 171 $e^+e^- \to ZZ$ events with $Z \to q\overline{q}$ or lepton pair (except an explicit τ pair), and 74 $e^+e^- \to Z\gamma^*$ events with a $q\overline{q}\mu^+\mu^-$ or $q\overline{q}e^+e^-$ signature, to derive 95% CL limits on h_i^V. Each limit is derived with other parameters set to zero. They report: $-0.23 < h_1^Z < 0.23$, $-0.30 < h_3^Z < 0.16$, $-0.14 < h_1^\gamma < 0.14$, $-0.049 < h_3^\gamma < 0.044$.

[13] ACHARD 04H select 3515 $e^+e^- \to Z\gamma$ events with $Z \to q\overline{q}$ or $\nu\overline{\nu}$ at $\sqrt{s} = 189$–209 GeV to derive 95% CL limits on h_i^V. For deriving each limit the other parameters are fixed at zero. They report: $-0.153 < h_1^Z < 0.141$, $-0.087 < h_2^Z < 0.079$, $-0.220 < h_3^Z < 0.112$, $-0.068 < h_4^Z < 0.148$, $-0.057 < h_1^\gamma < 0.057$, $-0.050 < h_2^\gamma < 0.023$, $-0.059 < h_3^\gamma < 0.004$, $-0.004 < h_4^\gamma < 0.042$.

[14] ABBIENDI,G 00C study $e^+e^- \to Z\gamma$ events (with $Z \to q\overline{q}$ and $Z \to \nu\overline{\nu}$) at 189 GeV to obtain the central values (and 95% CL limits) of these couplings: $h_1^Z = 0.000 \pm 0.100$ $(-0.190, 0.190)$, $h_2^Z = 0.000 \pm 0.068$ $(-0.128, 0.128)$, $h_3^Z = -0.074^{+0.102}_{-0.103}$ $(-0.269, 0.119)$, $h_4^Z = 0.046 \pm 0.068$ $(-0.084, 0.175)$, $h_1^\gamma = 0.000 \pm 0.061$ $(-0.115, 0.115)$, $h_2^\gamma = 0.000 \pm 0.041$ $(-0.077, 0.077)$, $h_3^\gamma = -0.080^{+0.039}_{-0.041}$ $(-0.164, -0.006)$, $h_4^\gamma = 0.064^{+0.033}_{-0.030}$ $(+0.007, +0.134)$. The results are derived assuming that only one coupling at a time is different from zero.

[15] ABBOTT 98M study $p\overline{p} \to Z\gamma + X$, with $Z \to e^+e^-$, $\mu^+\mu^-$, $\overline{\nu}\nu$ at 1.8 TeV, to obtain 95% CL limits at $\Lambda = 750$ GeV: $|h_{30}^Z| < 0.36$, $|h_{40}^Z| < 0.05$ (keeping $h_i^\gamma = 0$), and $|h_{30}^\gamma| < 0.37$, $|h_{40}^\gamma| < 0.05$ (keeping $h_i^Z = 0$). Limits on the *CP*-violating couplings are $|h_{10}^Z| < 0.36$, $|h_{20}^Z| < 0.05$ (keeping $h_i^\gamma = 0$), and $|h_{10}^\gamma| < 0.37$, $|h_{20}^\gamma| < 0.05$ (keeping $h_i^Z = 0$).

[16] ABREU 98K determine a 95% CL upper limit on $\sigma(e^+e^- \to \gamma +$ invisible particles$) <$ 2.5 pb using 161 and 172 GeV data. This is used to set 95% CL limits on $|h_{30}^\gamma| < 0.8$ and $|h_{30}^Z| < 1.3$, derived at a scale Λ=1 TeV and with n=3 in the form factor representation.

f_i^V

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:

$$-0.28 < f_4^Z < +0.32, \qquad -0.34 < f_5^Z < +0.35,$$
$$-0.17 < f_4^\gamma < +0.19, \qquad -0.35 < f_5^\gamma < +0.32.$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

[1] AAD 23CH measure ZZ production with the Z bosons decaying to electrons or muons. Analysing the angular information of the final-state four-lepton system, the following limits are derived at 95% C.L.: $-0.012 < f_4^Z < 0.012$, $-0.015 < f_4^\gamma < 0.015$.

[2] SIRUNYAN 21Q measure ZZ production where both Z bosons decay in the electron or muon channel. Analyzing the four-lepton invariant mass distribution, the following limits are derived at 95% C.L. in units of 10^{-4}: $-6.6 < f_4^Z < 6.0$, $-5.5 < f_5^Z < 7.5$, $-7.8 < f_4^\gamma < 7.1$, $-6.8 < f_5^\gamma < 7.5$. This set of parameters is linearly related to a set of EFT parameters, resulting in the following limits at 95% C.L. in units of TeV^{-4}: $-2.3 < c_{\widetilde{B}W}/\Lambda^4 < 2.5$, $-1.4 < c_{WW}/\Lambda^4 < 1.2$, $-1.4 < c_{BW}/\Lambda^4 < 1.3$, $-1.2 < c_{B\widetilde{B}}/\Lambda^4 < 1.2$.

[3] AABOUD 19AY study ZZ production in the $\ell\ell\nu\nu$ decay channel. Events with a pair of isolated high-transverse momentum charged leptons (electron pairs or muon pairs), and with large missing energy, are selected. In the data, 371 (416) di-electron (di-muon) events are found, with a total expected background of 128 ± 8 (143 ± 8) events. Analysing the transverse momentum distribution of the charged dilepton system above 150 GeV, the following 95% C.L. limits are derived in units of 10^{-3}: $-1.2 < f_4^\gamma < 1.2$, $-1.0 < f_4^Z < 1.0$, $-1.2 < f_5^\gamma < 1.2$, $-1.0 < f_5^Z < 1.0$.

[4] AABOUD 18Q study $pp \to ZZ$ events at $\sqrt{s} = 13$ TeV with $Z \to e^+e^-$ or $Z \to \mu^+\mu^-$. The number of events observed in the $4e$, $2e\,2\mu$, and 4μ channels is 249, 465, and 303 respectively. Analysing the p_T spectrum of the leading Z boson, the following the following 95% C.L. limits are derived in units of 10^{-4}: $-1.8 < f_4^\gamma < 1.8$, $-1.5 < f_4^Z < 1.5$, $-1.8 < f_5^\gamma < 1.8$, $-1.5 < f_5^Z < 1.5$.

[5] SIRUNYAN 18BT study $ppZZ$ events at $\sqrt{s} = 13$ TeV with $Z \to e^+e^-$ or $Z \to \mu^+\mu^-$. The number of events observed in the $4e$, $2e2\mu$, and 4μ channels is 220, 543 and 335 respectively. Analysing the 4-lepton invariant mass spectrum, the following 95% C.L. limits are derived in units of 10^{-3}: $-1.2 < f_4^\gamma < 1.3$, $-1.2 < f_4^Z < 1.0$, $-1.2 < f_5^\gamma < 1.3$, $-1.0 < f_5^Z < 1.3$.

[6] KHACHATRYAN 15B study ZZ production in 8 TeV pp collisions. In the decay modes $ZZ \to 4e$, 4μ, $2e2\mu$, 54, 75, 148 events are observed, with an expected background of 2.2 ± 0.9, 1.2 ± 0.6, and 2.4 ± 1.0 events, respectively. Analysing the 4-lepton invariant mass spectrum in the range from 110 GeV to 1200 GeV, the following 95% C.L. limits are obtained: $|f_4^Z| < 0.004$, $|f_5^Z| < 0.004$, $|f_4^\gamma| < 0.005$, $|f_5^\gamma| < 0.005$.

[7] KHACHATRYAN 15BC use the cross section measurement of the final state $pp \to ZZ \to 2\ell2\nu$, (ℓ being an electron or a muon) at 7 and 8 TeV to put limits on these triple gauge couplings. Effective mass of the charged lepton pair is required to be in the range 83.5–98.5 GeV and the dilepton $p_T > 45$ GeV. The reduced missing E_T is required to be > 65 GeV, which takes into account the fake missing E_T due to detector effects. The numbers of e^+e^- and $\mu^+\mu^-$ events selected are 35 and 40 at 7 TeV and 176 and 271 at 8 TeV respectively. The production cross sections so obtained are in agreement with SM predictions. The following 95% C.L. limits are set: $-0.0028 < f_4^Z < 0.0032$, $-0.0037 < f_4^\gamma < 0.0033$, $-0.0029 < f_5^Z < 0.0031$, $-0.0033 < f_5^\gamma < 0.0037$. Combining with previous results (KHACHATRYAN 15B and CHATRCHYAN 13B) which include 7 TeV and 8 TeV data on the final states $pp \to ZZ \to 2\ell2\ell'$ where ℓ and ℓ' are an electron or a muon, the best limits are $-0.0022 < f_4^Z < 0.0026$, $-0.0029 < f_4^\gamma < 0.0026$, $-0.0023 < f_5^Z < 0.0023$, $-0.0026 < f_5^\gamma < 0.0027$.

[8] AAD 13Z study ZZ production in pp collisions at $\sqrt{s} = 7$ TeV. In the $ZZ \to \ell^+\ell^-\ell'^+\ell'^-$ final state they observe a total of 66 events with an expected background of 0.9 ± 1.3. In the $ZZ \to \ell^+\ell^-\nu\nu$ final state they observe a total of 87 events with an expected background of 46.9 ± 5.2. The limits on anomalous TGCs are determined using the observed and expected numbers of these ZZ events binned in p_T^Z. The 95% C.L. are as follows: for form factor scale $\Lambda = \infty$, $-0.015 < f_4^\gamma < 0.015$, $-0.013 < f_4^Z < 0.013$, $-0.016 < f_5^\gamma < 0.015$, $-0.013 < f_5^Z < 0.013$; for form factor scale $\Lambda =$ 3 TeV, $-0.022 < f_4^\gamma < 0.023$, $-0.019 < f_4^Z < 0.019$, $-0.023 < f_5^\gamma < 0.023$, $-0.020 < f_5^Z < 0.019$.

[9] CHATRCHYAN 13B study ZZ production in pp collisions and select 54 ZZ candidates in the Z decay channel with electrons or muons with an expected background of 1.4 ± 0.5 events. The resulting 95% C.L. ranges are: $-0.013 < f_4^\gamma < 0.015$, $-0.011 < f_4^Z < 0.012$, $-0.014 < f_5^\gamma < 0.014$, $-0.012 < f_5^Z < 0.012$.

[10] Using data collected in the center of mass energy range 192–209 GeV, SCHAEL 09 select 318 $e^+e^- \to ZZ$ events with 319.4 expected from the standard model. Using this data they derive the following 95% CL limits: $-0.321 < f_4^\gamma < 0.318$, $-0.534 < f_4^Z < 0.534$, $-0.724 < f_5^\gamma < 0.733$, $-1.194 < f_5^Z < 1.190$.

[11] ABAZOV 08K search for ZZ and $Z\gamma^*$ events with 1 fb^{-1} $p\overline{p}$ data at $\sqrt{s} = 1.96$ TeV in $(ee)(ee)$, $(\mu\mu)(\mu\mu)$, $(ee)(\mu\mu)$ final states requiring the lepton pair masses to be > 30 GeV. They observe 1 event, which is consistent with an expected signal of 1.71 ± 0.15 events and a background of 0.13 ± 0.03 events. From this they derive the following limits, for a form factor (Λ) value of 1.2 TeV: $-0.28 < f_{40}^Z < 0.28$, $-0.31 < f_{50}^Z < 0.29$, $-0.26 < f_{40}^\gamma < 0.26$, $-0.30 < f_{50}^\gamma < 0.28$.

[12] Using data collected at $\sqrt{s} = 183$–208 GeV, ABDALLAH 07C select 171 $e^+e^- \to ZZ$ events with $Z \to q\overline{q}$ or lepton pair (except an explicit τ pair), and 74 $e^+e^- \to Z\gamma^*$ events with a $q\overline{q}\mu^+\mu^-$ or $q\overline{q}e^+e^-$ signature, to derive 95% CL limits on f_i^V. Each

limit is derived with other parameters set to zero. They report: $-0.40 < f_4^Z < 0.42$, $-0.38 < f_5^Z < 0.62$, $-0.23 < f_4^\gamma < 0.25$, $-0.52 < f_5^\gamma < 0.48$.

[13] ABBIENDI 04C study ZZ production in e^+e^- collisions in the C.M. energy range 190–209 GeV. They select 340 events with an expected background of 180 events. Including the ABBIENDI 00N data at 183 and 189 GeV (118 events with an expected background of 65 events) they report the following 95% CL limits: $-0.45 < f_4^Z < 0.58$, $-0.94 < f_5^Z < 0.25$, $-0.32 < f_4^\gamma < 0.33$, and $-0.71 < f_5^\gamma < 0.59$.

[14] ACHARD 03D study Z-boson pair production in e^+e^- collisions in the C.M. energy range 200–209 GeV. They select 549 events with an expected background of 432 events. Including the ACCIARRI 99G and ACCIARRI 99O data (183 and 189 GeV respectively, 286 events with an expected background of 241 events) and the 192–202 GeV ACCIARRI 01I results (656 events, expected background of 512 events), they report the following 95% CL limits: $-0.48 \le f_4^Z \le 0.46$, $-0.36 \le f_5^Z \le 1.03$, $-0.28 \le f_4^\gamma \le 0.28$, and $-0.40 \le f_5^\gamma \le 0.47$.

ANOMALOUS W/Z QUARTIC COUPLINGS

Revised March 2024 by M.W. Grünewald (U. College Dublin) and A. Gurtu (CERN; TIFR Mumbay).

Quartic couplings, $WWZZ$, $WWZ\gamma$, $WW\gamma\gamma$, and $ZZ\gamma\gamma$, were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowest dimensional representation of operators (dimension 6) which presumes the SU(2)×U(1) gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings, a_0, a_c, a_n, are expressed in terms of the following dimension-6 operators [1,2];

$$L_6^0 = -\tfrac{e^2}{16\Lambda^2}\, a_0\, F^{\mu\nu}\, F_{\mu\nu}\vec{W}^\alpha \cdot \vec{W}_\alpha$$
$$L_6^c = -\tfrac{e^2}{16\Lambda^2}\, a_c\, F^{\mu\alpha}\, F_{\mu\beta}\vec{W}^\beta \cdot \vec{W}_\alpha$$
$$L_6^n = -i\tfrac{e^2}{16\Lambda^2}\, a_n \epsilon_{ijk}\, W_{\mu\alpha}^{(i)}\, W_\nu^{(j)}\, W^{(k)\alpha} F^{\mu\nu}$$
$$\widetilde{L}_6^0 = -\tfrac{e^2}{16\Lambda^2}\, \widetilde{a}_0\, F^{\mu\nu}\, \widetilde{F}_{\mu\nu}\vec{W}^\alpha \cdot \vec{W}_\alpha$$
$$\widetilde{L}_6^n = -i\tfrac{e^2}{16\Lambda^2}\, \widetilde{a}_n \epsilon_{ijk}\, W_{\mu\alpha}^{(i)}\, W_\nu^{(j)}\, W^{(k)\alpha} \widetilde{F}^{\mu\nu}$$

where F, W are photon and W fields, L_6^0 and L_6^c conserve C, P separately ($\widetilde{L}_6^0$ conserves only C) and generate anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ couplings, L_6^n violates CP ($\widetilde{L}_6^n$ violates both C and P) and generates an anomalous $W^+W^-Z\gamma$ coupling, and Λ is an energy scale for new physics. For the $ZZ\gamma\gamma$ coupling the CP-violating term represented by L_6^n does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the $WW\gamma\gamma$ and $ZZ\gamma\gamma$ couplings separately, leading to two sets parametrized as a_0^V/Λ^2 and a_c^V/Λ^2, where $V = W$ or Z.

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned}\mathcal{L}_{AQGC} = &-\frac{e^2}{8}\frac{a_0^W}{\Lambda^2}F_{\mu\nu}F^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2}{16}\frac{a_c^W}{\Lambda^2}F_{\mu\nu}F^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &-e^2g^2\frac{\kappa_0^W}{\Lambda^2}F_{\mu\nu}Z^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2g^2}{2}\frac{\kappa_c^W}{\Lambda^2}F_{\mu\nu}Z^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &+\frac{f_{T,0}}{\Lambda^4}Tr[\widehat{W}_{\mu\nu}\widehat{W}^{\mu\nu}] \times Tr[\widehat{W}_{\alpha\beta}\widehat{W}^{\alpha\beta}]\end{aligned}$$

The energy scale of possible new physics is Λ, and $g = e/sin(\theta_W)$, e being the unit electric charge and θ_W the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators a_0^W/Λ^2 and a_c^W/Λ^2 are associated with the $WW\gamma\gamma$ vertex. Among dimension 8 operators, κ_0^W/Λ^2 and κ_c^W/Λ^2 are associated with the $WWZ\gamma$ vertex, whereas the parameter $f_{T,0}/\Lambda^4$ contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters $f_{M,i}/\Lambda^4$ as follows [3]:

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,2}}{\Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,3}}{\Lambda^4}$$

where $g' = e/cos(\theta_W)$ and M_W is the invariant mass of the W boson. This relation provides a translation between limits on dimension 6 operators $a_{0,c}^W$ and $f_{M,j}/\Lambda^4$. It is further required [4] that $f_{M,0} = 2f_{M,2}$ and $f_{M,1} = 2f_{M,3}$ which suppresses contributions to the $WWZ\gamma$ vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total – $f_{S,i}$, $i = 1, 2$, $f_{M,i}$, $i = 0, \ldots, 8$ and $f_{T,i}, i = 0, \ldots, 9$ – each scaled by $1/\Lambda^4$.

Another approach to couplings is the so called K-matrix framework [7], in which the anomalous couplings can be expressed in terms of two parameters α_4 and α_5, which account for all BSM effects.

The LHC collaborations have published couplings results based on various theoretical frameworks. It is hoped that the collaborations will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison, and to allow for a possible LHC combination.

a_0/Λ^2, a_c/Λ^2

Combining published and unpublished preliminary LEP results the following 95% CL intervals for the QGCs associated with the $ZZ\gamma\gamma$ vertex are derived (CERN-PH-EP/2005-051 or hep-ex/0511027):

$$-0.008 < a_0^Z/\Lambda^2 < +0.021$$
$$-0.029 < a_c^Z/\Lambda^2 < +0.039$$

Anomalous Z quartic couplings have also been measured by the Tevatron and LHC experiments. As discussed in the review on "Anomalous W/Z quartic couplings," the coupling parameters in the Anomalous QGC Lagrangian may relate to processes involving only the W or only to the Z or to both. Thus, results on all other AQGCs are reported together in the W listings.

VALUE	*DOCUMENT ID*	*TECN*

• • • We do not use the following data for averages, fits, limits, etc. • • •

[1] ABBIENDI	04L	OPAL
[2] HEISTER	04A	ALEP
[3] ACHARD	02G	L3

[1] ABBIENDI 04L select 20 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ acoplanar events in the energy range 180–209 GeV and 176 $e^+e^- \to q\overline{q}\gamma\gamma$ events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ quartic couplings. Further combining with the $W^+W^-\gamma$ sample of ABBIENDI 04B the following one–parameter 95% CL limits are obtained: $-0.007 < a_0^Z/\Lambda^2 < 0.023$ GeV^{-2}, $-0.029 < a_c^Z/\Lambda^2 < 0.029$ GeV^{-2}, $-0.020 < a_0^W/\Lambda^2 < 0.020$ GeV^{-2}, $-0.052 < a_c^W/\Lambda^2 < 0.037$ GeV^{-2}.

[2] In the CM energy range 183 to 209 GeV HEISTER 04A select 30 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ events with two acoplanar, high energy and high transverse momentum photons. The photon–photon acoplanarity is required to be $> 5^\circ$, $E_\gamma/\sqrt{s} > 0.025$ (the more energetic photon having energy $> 0.2\sqrt{s}$), $p_{T_\gamma}/E_{beam} > 0.05$ and $|\cos\theta_\gamma| < 0.94$. A likelihood fit to the photon energy and recoil missing mass yields the following one–parameter 95% CL limits: $-0.012 < a_0^Z/\Lambda^2 < 0.019$ GeV^{-2}, $-0.041 < a_c^Z/\Lambda^2 < 0.044$ GeV^{-2}, $-0.060 < a_0^W/\Lambda^2 < 0.055$ GeV^{-2}, $-0.099 < a_c^W/\Lambda^2 < 0.093$ GeV^{-2}.

[3] ACHARD 02G study $e^+e^- \to Z\gamma\gamma \to q\overline{q}\gamma\gamma$ events using data at center-of-mass energies from 200 to 209 GeV. The photons are required to be isolated, each with energy >5 GeV and $|\cos\theta| < 0.97$, and the di-jet invariant mass to be compatible with that of the Z boson (74–111 GeV). Cuts on Z velocity ($\beta < 0.73$) and on the energy of the most energetic photon reduce the backgrounds due to non-resonant production of the $q\overline{q}\gamma\gamma$ state and due to ISR respectively, yielding a total of 40 candidate events of which 8.6 are expected to be due to background. The energy spectra of the least energetic photon are fitted for all ten center-of-mass energy values from 130 GeV to 209 GeV (as obtained adding to the present analysis 130–202 GeV data of ACCIARRI 01E, for a total of 137 events with an expected background of 34.1 events) to obtain the fitted values $a_0/\Lambda^2 = 0.00^{+0.02}_{-0.01}$ GeV^{-2} and $a_c/\Lambda^2 = 0.03^{+0.01}_{-0.02}$ GeV^{-2}, where the other parameter is kept fixed to its Standard Model value (0). A simultaneous fit to both parameters yields the 95% CL limits -0.02 GeV$^{-2} < a_0/\Lambda^2 < 0.03$ GeV^{-2} and -0.07 GeV$^{-2} < a_c/\Lambda^2 < 0.05$ GeV^{-2}.

H

$J = 0$

was H^0

In the following H refers to the signal that has been discovered in the Higgs searches. Whereas the observed signal is labeled as a spin 0 particle and is called a Higgs Boson, the detailed properties of H and its role in the context of electroweak symmetry breaking need to be further clarified. These issues are addressed by the measurements listed below.

Concerning mass limits and cross section limits that have been obtained in the searches for neutral and charged Higgs bosons, see the sections "Searches for Neutral Higgs Bosons" and "Searches for Charged Higgs Bosons ($H^{\pm}$ and $H^{\pm\pm}$)", respectively.

[1] HAYRAPETYAN 25L use 138 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[2] AAD 23BP combine 13 TeV results of $H \to \gamma\gamma$ (AAD 23BU) and $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$ (AAD 23AU) using 140 fb^{-1} of pp collision data. The result is 125.10 ± 0.09(stat)±0.07(syst) GeV.

[3] SIRUNYAN 20L use 35.9 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV with $H \to \gamma\gamma$.

[4] Combined value from $\gamma\gamma$ and $ZZ^* \to 4\ell$ final states.

[5] ATLAS and CMS data are fitted simultaneously.

[6] AAD 23AU use 139 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[7] AAD 23AU combine 13 TeV results with 7 and 8 TeV results (AAD 14W).

[8] AAD 23BP combine 13 TeV results with 7 and 8 TeV results. The result is 125.11 ± 0.09(stat)±0.06(syst) GeV.

[9] AAD 23BU use 140 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV with $H \to \gamma\gamma$.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[10] AAD 23BU combine 13 TeV results with 7 and 8 TeV results (AAD 15B).

[11] SIRUNYAN 20L result of $H \to \gamma\gamma$ is combined with that of $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$ (SIRUNYAN 17AV).

[12] SIRUNYAN 20L combine 13 TeV results with 7 and 8 TeV results (KHACHATRYAN 15AM).

[13] AABOUD 18BM use 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[14] AABOUD 18BM use 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV with $H \to \gamma\gamma$.

[15] AABOUD 18BM combine 13 TeV results with 7 and 8 TeV results. Other combined results are summarized in their Fig. 4.

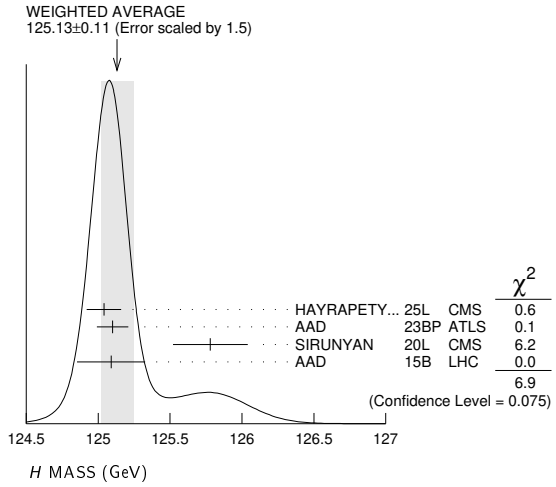
[16] SIRUNYAN 17AV use 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[17] KHACHATRYAN 15AM use up to 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 19.7 fb^{-1} at $E_{cm} = 8$ TeV.

[18] AAD 14W use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at 8 TeV.

[19] CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV.

[20] CHATRCHYAN 14K use 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV.



[21] KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV.

[22] AAD 13AK use 4.7 fb^{-1} of pp collisions at E_{cm}=7 TeV and 20.7 fb^{-1} at E_{cm}=8 TeV. Superseded by AAD 14W.

[23] CHATRCHYAN 13J use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 12.2 fb^{-1} at $E_{cm} = 8$ TeV.

[24] AAD 12AI obtain results based on 4.6–4.8 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.8–5.9 fb^{-1} at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.9 σ is observed at $m_H = 126$ GeV. See also AAD 12DA.

[25] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.1–5.3 fb^{-1} at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.0 σ is observed at about $m_H = 125$ GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

H SPIN AND *CP* PROPERTIES

The observation of the signal in the $\gamma\gamma$ final state rules out the possibility that the discovered particle has spin 1, as a consequence of the Landau-Yang theorem. This argument relies on the assumptions that the decaying particle is an on-shell resonance and that the decay products are indeed two photons rather than two pairs of boosted photons, which each could in principle be misidentified as a single photon.

Concerning distinguishing the spin 0 hypothesis from a spin 2 hypothesis, some care has to be taken in modelling the latter in order to ensure that the discriminating power is actually based on the spin properties rather than on unphysical behavior that may affect the model of the spin 2 state.

Under the assumption that the observed signal consists of a single state rather than an overlap of more than one resonance, it is sufficient to discriminate between distinct hypotheses in the spin analyses. On the other hand, the determination of the *CP* properties is in general much more difficult since in principle the observed state could consist of any admixture of *CP*-even and *CP*-odd components. As a first step, the compatibility of the data with distinct hypotheses of pure *CP*-even and pure *CP*-odd states with different spin assignments has been investigated. In order to treat the case of a possible mixing of different *CP* states, certain cross section ratios are considered. Those cross section ratios need to be distinguished from the amount of mixing between a *CP*-even and a *CP*-odd state, as the cross section ratios depend in addition also on the coupling strengths of the *CP*-even and *CP*-odd components to the involved particles. A small relative coupling implies a small sensitivity of the corresponding cross section ratio to effects of *CP* mixing.

[1] AAD 25BC study *CP* properties in *H* production via VBF using $H \to \tau\tau$ decay channel with 140 fb^{-1} at $E_{cm} = 13$ TeV. By using the Optimal Observable method, the data constrain a parameter $\tilde{d}$, which is for the strength of *CP* violation in an effective field theory using the HISZ basis, and Wilson coefficient $c_{H\widetilde{W}}$ (Warsaw basis with $\Lambda = 1$ TeV) to be [−0.012, 0.044] and [−0.24, 0.83] at 95% CL, respectively, in both cases considering the linear and quadratic terms in the reweighting procedure. See their Fig. 6 and Table 9.

[2] AAD 25BK measure the *CP* properties using $H \to WW^* \to \ell\nu\ell\nu$ ($\ell = e,\ \mu$) with data of 140 fb^{-1} pp collisions at $E_{cm} = 13$ TeV. By adding the azimuthal angular difference between the forward and backward jets to the reduced stage-1.2 simplified template cross section framework (see their Fig. 4), the signal strengths are measured as shown in their Fig. 12, which is compatible with a *CP*-conserving scenario (*p*-value of 75%). EFT interpretations in *CP*-conserving and *CP*-violating scenarios are given as the five rotated-basis Wilson coefficients obtained from the 16 Warsaw-basis Wilson coefficients (see their Fig. 14) for the *CP*-conserving one and the 4 Warsaw-basis Wilson coefficients for the *CP*-violating one. The results are shown in their Figs. 15 and 16, respectively.

[3] HAYRAPETYAN 25R measure the $t\overline{t}H$ and tH productions with $H \to b\overline{b}$ decay channel using 138 fb^{-1} of data at $E_{cm} = 13$ TeV. Two-dimensional likelihood scan of (κ_t, $\tilde{\kappa}_t$) to measure the *CP* structure of the top Yukawa coupling is shown in their Fig. 16, where $\kappa_V = 1$. With other channels (SIRUNYAN 20AS, SIRUNYAN 21AE, TUMASYAN 23P), the *CP*-odd fraction f_{CP} and the *CP* mixing angle α are constrain to be $|f_{CP}| < 0.85$ and $\cos\alpha > 0.39$ at 95% CL.

[4] AAD 24AG search for *CP* violation in the decay kinematics and VBF production of the Higgs boson using $H \to ZZ^* \to 4\ell$ decay channel ($\ell = e,\ \mu$) with 139 fb^{-1} at $E_{cm} = 13$ TeV. By using the optimal observables, the data constrain six *CP*-odd Wilson coefficients in two effective field theory bases: the Warsaw basis and the Higgs basis. The result is given in their Table 5 and Figs. 7–11. The differential fiducial cross sections for the four optimal observables are measured as shown in their Fig. 13. The VBF fiducial cross sections are given in their Table 6.

[5] AAD 24J measure the *CP* structure of the top Yukawa coupling using 139 fb^{-1} of data at $E_{cm} = 13$ TeV. The *CP*-mixing angle α for top Yukawa coupling is measured to be $(11^{+52}_{-73})^\circ$ with the top Yukawa coupling strength modifier κ_t. See their Fig. 3. The data disfavour the pure *CP*-odd ($\alpha = 90^\circ$) at 1.2 σ.

[6] AAD 23AK measure the *CP* structure of the τ Yukawa coupling using 139 fb^{-1} of data at $E_{cm} = 13$ TeV. The *CP*-mixing angle α for τ Yukawa coupling is measured to be $9 \pm 16^\circ$. The data disfavour the pure *CP*-odd ($\alpha = 90^\circ$) at 3.4 σ.

[7] AAD 23AN test *CP* invariance in *H* production via VBF using $H \to \gamma\gamma$ decay channel with 139 fb^{-1} at $E_{cm} = 13$ TeV. By using the Optimal Observable method, the data constrain parameters describing the strength of the *CP*-odd component in the coupling between Higgs and W/Z in effective field theory bases: $\tilde{d}$ in the HISZ basis and $c_{H\widetilde{W}}$ in the Warsaw basis. The result is $-0.010 \leq \tilde{d} \leq 0.040$ and $-0.15 \leq c_{H\widetilde{W}} \leq 0.67$ at 68% CL. See their Table I, which shows the result combined with $H \to \tau\tau$ (AAD 20N): $-0.012 \leq \tilde{d} \leq 0.030$ at 68% CL.

[8] TUMASYAN 23AJ constraint anomalous couplings of the Higgs to vector bosons and fermions using $pp \to H \to \tau\tau$ at $E_{cm} = 13$ TeV with 138 fb^{-1} data. The *CP*-violating parameter in gluon-fusion production f_{a3}^{ggH} and the effective mixing angle α^{Hff} are given in their Table VII with $H \to \tau\tau$ and f_{a3}^{ggH} in their Table X with $H \to \tau\tau$ and $H \to 4\ell$. Using the VBF production analysis, the *CP*-violating parameter f_{a3} and the *CP*-conserving parameters f_{a2}, $f_{\Lambda 1}$ and $f_{\Lambda 1}^{Z\gamma}$ are given in their Table VIII with $H \to$

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use strictly not permitted, except for Open Access articles.

$\tau\tau$ and Table IX with $H \to \tau\tau$ and $H \to 4\ell$. The *CP*-violating parameter f_{CP}^{Htt} is constrained to be $0.03^{+0.17}_{-0.03}$ using $H \to \tau\tau$, $H \to 4\ell$ and $H \to \gamma\gamma$.

[9] TUMASYAN 23P constrain $\tilde{\kappa}_t$ from $t\bar{t}H$ and tH decaying $H \to WW^*$ and $H \to \tau\tau$ (multilepton decay mode) with 138 fb^{-1} pp collision data at E_{cm} = 13 TeV. The $\tilde{\kappa}_t$ is constrained to be $|\tilde{\kappa}_t| \leq 1.4$ at 95% CL by fixing $\kappa_t = 1$ and other couplings (κ_V etc.) to the SM values, see their Table 6 (see their Fig. 9 for 2-dim contours). The fractional contribution of the *CP*-odd component $|f_{CP}^{Htt}|$ is constrained to (0.24, 0.81) at 68% CL with a best fit value of 0.59. The combination with other $t\bar{t}H$ decaying $H \to \gamma\gamma$ (SIRUNYAN 20AS) and $H \to 4\ell$ (SIRUNYAN 21AE) constraints to be $|\tilde{\kappa}_t| \leq 1.07$ at 95% CL and $|f_{CP}^{Htt}| < 0.55$ at 68% CL with a best fit value of 0.28.

[10] AAD 22V measure the *CP* properties of the effective Higgs-gluon interaction using gluon fusion $H \to WW^* \to e\nu\mu\nu$ plus two jets with 36.1 fb^{-1} of data at E_{cm} = 13 TeV. The measured tangent of the *CP*-mixing angle tanα is 0.0 ± 0.4 ± 0.3 assuming the standard model HVV couplings. See their Fig. 6.

[11] TUMASYAN 22Y measure the *CP* structure of the τ Yukawa coupling using 137 fb^{-1} of data at E_{cm} = 13 TeV. The *CP*-mixing angle α for τ Yukawa coupling is measured to be $-1 \pm 19°$. The data disfavour the pure *CP*-odd ($\alpha = 90°$) at 3.0 σ.

[12] AAD 20N test *CP* invariance in *H* production via VBF using $H \to \tau\tau$ decay channel with 36.1 fb^{-1} at E_{cm} = 13 TeV. By using the Optimal Observable method, the data constrain a parameter d, which is for the strength of *CP* violation in an effective field theory, to be $-0.090 \leq \tilde{d} \leq 0.035$ at 68% CL (see their Fig. 6).

[13] AAD 20Z exclude a *CP*-mixing angle α, $|\alpha| > 43°$ at 95% CL, where $\alpha = 0$ represents the Standard Model, in 139 fb^{-1} of data at E_{cm} = 13 TeV. The pure *CP*-odd structure of the top Yukawa coupling ($\alpha = 90°$) is excluded at 3.9 σ.

[14] SIRUNYAN 20AS exclude the pure *CP*-odd structure of the top Yukawa coupling at 3.2 σ using $t\bar{t}H$, $H \to \gamma\gamma$ in 137 fb^{-1} of data at E_{cm} = 13 TeV. The fractional contribution of the *CP*-odd component $f_{CP}^{t\bar{t}H}$ is measured to be 0.00 ± 0.33.

[15] SIRUNYAN 19BL measure the anomalous HVV couplings from on-shell and off-shell production in the 4ℓ final state. Data of 80.2 fb^{-1} at 13 TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV are used. See their Tables VI and VII for anomalous HVV couplings of *CP*-violating and *CP*-conserving parameters with on- and off-shells.

[16] SIRUNYAN 19BZ constrain anomalous HVV couplings of the Higgs boson with data of 35.9 fb^{-1} at E_{cm} = 13 TeV using Higgs boson candidates with two jets produced in VBF, ggF, and VH that decay to $\tau\tau$. See their Table 2 and Fig. 10, which show 68% CL and 95% CL intervals. Combining those with the $H \to 4\ell$ (SIRUNYAN 19BL, on-shell scenario), results shown in their Tables 3, 4, and Fig. 11 are obtained. A *CP*-violating parameter is set to be $f_{a3}\cos(\phi_{a3}) = (0.00 \pm 0.27) \times 10^{-3}$ and *CP*-conserving parameters are $f_{a2}\cos(\phi_{a2}) = (0.08^{+1.04}_{-0.21}) \times 10^{-3}$, $f_{\Lambda 1}\cos(\phi_{\Lambda 1}) = (0.00^{+0.53}_{-0.09}) \times 10^{-3}$, and $f_{\Lambda 1}^{Z\gamma}\cos(\phi_{\Lambda 1}^{Z\gamma}) = (0.0^{+1.1}_{-1.3}) \times 10^{-3}$.

[17] AABOUD 18AJ study the tensor structure of the Higgs boson couplings using an effective Lagrangian using 36.1 fb^{-1} of pp collision data at E_{cm} = 13 TeV. Constraints are set on the non-Standard-Model *CP*-even and *CP*-odd couplings to Z bosons and on the *CP*-odd coupling to gluons. See their Figs. 9 and 10, and Tables 10 and 11.

[18] SIRUNYAN 17AM constrain anomalous couplings of the Higgs boson with 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV, 19.7 fb^{-1} at E_{cm} = 8 TeV, and 38.6 fb^{-1} at E_{cm} = 13 TeV. See their Table 3 and Fig. 3, which show 68% CL and 95% CL intervals. A *CP* violation parameter f_{a3} is set to be $f_{a3}\cos(\phi_{a3}) = [-0.38, 0.46]$ at 95% CL ($\phi_{a3} = 0$ or π).

[19] AAD 16 study $H \to \gamma\gamma$ with an effective Lagrangian including *CP* even and odd terms in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The data is consistent with the expectations for the Higgs boson of the Standard Model. Limits on anomalous couplings are also given.

[20] AAD 16BL study VBF $H \to \tau\tau$ with an effective Lagrangian including a *CP* odd term in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The measurement is consistent with the expectation of the Standard Model. The *CP*-mixing parameter $\tilde{d}$ (a dimensionless coupling $\tilde{d} = -(m_W^2/\Lambda^2) f_{\widetilde{WW}}$) is constrained to the interval of $(-0.11, 0.05)$ at 68% CL under the assumption of $\tilde{d} = \tilde{d}_B$.

[21] KHACHATRYAN 16AB search for anomalous pseudoscalar couplings of the Higgs boson to W and Z with 18.9 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Table 5 and Figs 5 and 6 for limits on possible anomalous pseudoscalar coupling parameters.

[22] AAD 15AX compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV, using the process $H \to WW^* \to e\nu\mu\nu$. 2^+ hypotheses are excluded at 84.5–99.4%CL, 0^- at 96.5%CL, 0^+ (field strength coupling) at 70.8%CL. See their Fig. 19 for limits on possible *CP* mixture parameters.

[23] AAD 15CI compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV, using the processes $H \to ZZ^* \to 4\ell$. $H \to \gamma\gamma$ and combine with AAD 15AX data. 0^+ (field strength coupling), 0^- and several 2^+ hypotheses are excluded at more than 99.9% CL. See their Tables 7–9 for limits on possible *CP* mixture parameters.

[24] AALTONEN 15 combine AALTONEN 15B and ABAZOV 14F data. An upper limit of 0.36 of the Standard Model production rate at 95% CL is obtained both for a 0^- and a 2^+ state. Assuming the SM event rate, the $J^{CP} = 0^-$ (2^+) hypothesis is excluded at the 5.0σ (4.9σ) level.

[25] AALTONEN 15B compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 9.45 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV, using the processes $ZH \to \ell\ell b\overline{b}$, $WH \to \ell\nu b\overline{b}$, and $ZH \to \nu\nu b\overline{b}$. Bounds on the production rates of 0^- and 2^+ (graviton-like) states are set, see their tables II and III.

[26] KHACHATRYAN 15Y compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in up to 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 19.7 fb^{-1} at E_{cm} = 8 TeV, using the processes $H \to 4\ell$, $H \to WW^*$, and $H \to \gamma\gamma$. 0^- is excluded at 99.98% CL, and several 2^+ hypotheses are excluded at more than 99% CL. Spin 1 models are excluded at more than 99.999% CL in ZZ^* and WW^* modes. Limits on anomalous couplings and several cross section fractions, treating the case of *CP*-mixed states, are also given.

[27] ABAZOV 14F compare the $J^{CP} = 0^+$ Standard Model assignment with $J^{CP} = 0^-$ and 2^+ (graviton-like coupling) hypotheses in up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. They use kinematic correlations between the decay products of the vector boson and the Higgs boson in the final states $ZH \to \ell\ell b\overline{b}$, $WH \to \ell\nu b\overline{b}$, and $ZH \to \nu\nu b\overline{b}$. The 0^- (2^+) hypothesis is excluded at 97.6% CL (99.0% CL). In order to treat the case of a possible mixture of a 0^+ state with another J^{CP} state, the cross section fractions $f_X = \sigma_X/(\sigma_{0^+} + \sigma_X)$ are considered, where $X = 0^-$, 2^+. Values for f_{0^-} (f_{2^+}) above 0.80 (0.67) are excluded at 95% CL under the assumption that the total cross section is that of the SM Higgs boson.

[28] CHATRCHYAN 14AA compare the $J^{CP} = 0^+$ Standard Model assignment with various J^{CP} hypotheses in 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. $J^{CP} = 0^-$ and $1^\pm$ hypotheses are excluded at 99% CL, and several $J = 2$ hypotheses are excluded at 95% CL. In order to treat the case of a possible mixture of a 0^+ state with another J^{CP} state, the cross section fraction $f_{a3} = |a_3|^2 \sigma_3 / (|a_1|^2 \sigma_1 + |a_2|^2 \sigma_2 + |a_3|^2 \sigma_3)$ is considered, where the case $a_3 = 1$, $a_1 = a_2 = 0$ corresponds to a pure *CP*-odd state. Assuming $a_2 = 0$, a value for f_{a3} above 0.51 is excluded at 95% CL.

[29] CHATRCHYAN 14G compare the $J^{CP} = 0^+$ Standard Model assignment with $J^{CP} = 0^-$ and 2^+ (graviton-like coupling) hypotheses in 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.4 fb^{-1} at E_{cm} = 8 TeV. Varying the fraction of the production of the 2^+ state via gg and $q\overline{q}$, 2^+ hypotheses are disfavored at CL between 83.7 and 99.8%. The 0^- hypothesis is disfavored against 0^+ at the 65.3% CL.

[30] KHACHATRYAN 14P compare the $J^{CP} = 0^+$ Standard Model assignment with a 2^+ (graviton-like coupling) hypothesis in 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. Varying the fraction of the production of the 2^+ state via gg and $q\overline{q}$, 2^+ hypotheses are disfavored at CL between 71 and 94%.

[31] AAD 13AJ compare the spin 0, *CP*-even hypothesis with specific alternative hypotheses of spin 0, *CP*-odd, spin 1, *CP*-even and *CP*-odd, and spin 2, *CP*-even models using the Higgs boson decays $H \to \gamma\gamma$, $H \to ZZ^* \to 4\ell$ and $H \to WW^* \to \ell\nu\ell\nu$ and combinations thereof. The data are compatible with the spin 0, *CP*-even hypothesis, while all other tested hypotheses are excluded at confidence levels above 97.8%.

[32] CHATRCHYAN 13J study angular distributions of the lepton pairs in the ZZ^* channel where both Z bosons decay to e or μ pairs. Under the assumption that the observed particle has spin 0, the data are found to be consistent with the pure *CP*-even hypothesis, while the pure *CP*-odd hypothesis is disfavored.

H DECAY WIDTH

The total decay width for a light Higgs boson with a mass in the observed range is not expected to be directly observable at the LHC. For the case of the Standard Model the prediction for the total width is about 4 MeV, which is three orders of magnitude smaller than the experimental mass resolution. There is no indication from the results observed so far that the natural width is broadened by new physics effects to such an extent that it could be directly observable. Furthermore, as all LHC Higgs channels rely on the identification of Higgs decay products, the total Higgs width cannot be measured indirectly without additional assumptions. The different dependence of on-peak and off-peak contributions on the total width in Higgs decays to ZZ^* and interference effects between signal and background in Higgs decays to $\gamma\gamma$ can provide additional information in this context. Constraints on the total width from the combination of on-peak and off-peak contributions in Higgs decays to ZZ^* rely on the assumption of equal on- and off-shell effective couplings. Without an experimental determination of the total width or further theoretical assumptions, only ratios of couplings can be determined at the LHC rather than absolute values of couplings.

[1] AAD 25AQ use 140 fb^{-1} at E_{cm} = 13 TeV. The off-shell Higgs boson production in the $ZZ \to 4\ell$ ($\ell = e,\ \mu$) decay channel is combined with the on-shell production in the $ZZ^* \to 4\ell$ (AAD 20AQ) decay channel and the off-shell production in the $ZZ \to 2\ell 2\nu$ decay channel (AAD 23BR, AAD 25AP) to measure the total width assuming the same on-shell and off-shell coupling modifiers for gluon-fusion and for gauge-boson ($\kappa^2_{g,\text{on-shell}}\,\kappa^2_{V,\text{on-shell}} = \kappa^4_{V,\text{on-shell}} = \kappa^2_{g,\text{off-shell}}\,\kappa^2_{V,\text{off-shell}} = \kappa^4_{V,\text{off-shell}}$). $R_{gg} = \kappa^2_{g,\text{on-shell}}/\kappa^2_{g,\text{off-shell}}$ and $R_{VV} = \kappa^2_{V,\text{on-shell}}/\kappa^2_{V,\text{off-shell}}$ are measured to be $1.19^{+0.89}_{-0.66}$ and $0.95^{+0.44}_{-0.35}$, respectively. Using AAD 25AQ and AAD 23BR, $\kappa_{g,\text{off-shell}}$ and $\kappa_{V,\text{off-shell}}$ are measured to be $1.09^{+0.39}_{-0.35}$ and $0.99^{+0.16}_{-0.19}$, respectively. The quoted errors are values at 68%CL.

[2] AAD 25AV measure the total width Γ_H from off-shell $H^* \to WW \to 2\ell 2\nu$ and on-shell $H \to WW^* \to 2\ell 2\nu$ with data of 140 fb^{-1} pp collisions at E_{cm} = 13 TeV, assuming the off- and on-shell coupling modifiers are the same for both ggF and EW production modes. The quoted value corresponds to $\Gamma_H < 13.1$ MeV at 95% CL. The off-shell Higgs signal strength $\mu_{\text{off-shell}}$ is measured to be $0.3^{+0.9}_{-0.3}$ corresponding $\mu_{\text{off-shell}} < 3.4$ at 95% CL. The two off-shell signal strengths for ggF and EW production modes ($\mu^{ggF}_{\text{off-shell}}$, $\mu^{EW}_{\text{off-shell}}$) are measured to be $\mu^{ggF}_{\text{off-shell}} = 0.2^{+1.3}_{-0.2}$ and $\mu^{EW}_{\text{off-shell}} = 0.4^{+3.4}_{-0.4}$.

[3] HAYRAPETYAN 25L use 138 fb^{-1} at E_{cm} = 13 TeV. The on- and off-shell Higgs boson production in the $ZZ \to 4\ell$ ($\ell = e,\ \mu$) decay channel is combined with the off-shell Higgs boson production in the $ZZ \to 2\ell 2\nu$ (TUMASYAN 22AM) decay channel to measure the total width. The off-shell Higgs signal strength is measured to be $0.67^{+0.42}_{-0.32}$. The scenario of no off-shell contribution is excluded at 3.8 σ.

[4] AAD 25E constrain the total width using on-shell Higgs measurements and the four top quarks production with 13 TeV data. The tree-level Higgs-top Yukawa coupling is assumed to be the same for on-shell and off-shell Higgs boson production processes. Another assumption is that no BSM contributions affect the $t\bar{t}t\bar{t}$ production. The quoted value is obtained by assuming the loop-induced ggF, $H \to \gamma\gamma$, and $H \to Z\gamma$ rates can be modeled as a function of κ_t and other SM couplings. Otherwise, $\Gamma_H < 450$ MeV is obtained at 95% CL. Two-dimensional likelihood scan of (Γ_H/Γ^{SM}_H, κ_t) is shown in their Fig. 3.

[5] HAYRAPETYAN 25L obtain an upper limit on the width from the on-shell $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) decays. Data of 138 fb^{-1} pp collisions at E_{cm} = 13 TeV is used.

[6] HAYRAPETYAN 25L use 138 fb^{-1} at E_{cm} = 13 TeV. The on- and off-shell Higgs boson production in the $ZZ \to 4\ell$ ($\ell = e,\ \mu$) decay channel is used assuming that no new particles affect the gluon fusion production. The scenario of no off-shell contribution is excluded at 3.0 σ.

[7] AAD 23BR use 139 fb^{-1} at E_{cm} = 13 TeV. The off-shell Higgs boson production in the $ZZ \to 4\ell$ and $ZZ \to 2\ell 2\nu$ decay channels and the on-shell production in the $ZZ^* \to 4\ell$ ($\ell = e,\ \mu$, AAD 20AQ) decay channels are used to measure the total width. The off-shell Higgs signal strength is measured to be $1.1^{+0.7}_{-0.6}$ assuming the same on-shell and off-shell coupling modifiers are used individually for gluon-fusion and for gauge-boson modes. The scenario of no off-shell contribution is excluded at 3.3 σ. Combining with the on-shell signal strength measurement, the total width normalized to its SM expectation Γ_H/Γ^{SM}_H is measured to be $1.1^{+0.7}_{-0.5}$ assuming the same on-shell and off-shell coupling modifiers are used individually for gluon-fusion and for gauge-boson modes. The observed upper limit on the total width is 10.1 MeV at 95% CL. See their Fig. 7. See corrected width values in their erratum AAD 25AP.

[8] TUMASYAN 22AM use up to 140 fb^{-1} at E_{cm} = 13 TeV. The off-shell Higgs boson production in the $ZZ \to 4\ell$ and $ZZ \to 2\ell 2\nu$ decay channels and the on-shell production in the $ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) decay channels are used to measure the total width. The off-shell Higgs signal strength is measured to be $0.62^{+0.68}_{-0.45}$ without the constraint on the ratio of the off-shell signal strengths for gluon-fusion and gauge-boson modes. The scenario of no off-shell contribution is excluded at 3.6 σ. The results are shown in their Table 1 with other constraint scenarios and the decay widths assuming the same coupling modifiers for on- and off-shell couplings (g_p and g_d in their notation). The measurement of anomalous HVV couplings is shown in their Extended Data Table 1 and Fig. 8.

[9] SIRUNYAN 19BL measure the width and anomalous HVV couplings from on-shell and off-shell production in the 4ℓ final state. Data of 80.2 fb^{-1} at 13 TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV are used. The total width for the SM-like couplings is measured to be also [0.08, 9.16] MeV with 95% CL, assuming SM-like couplings for on- and off-shells (see their Table VIII). Constraints on the total width for anomalous HVV interaction cases are found in their Table IX. See their Table X for the Higgs boson signal strength in the off-shell region.

[10] AABOUD 18BP use 36.1 fb^{-1} at E_{cm} = 13 TeV. An observed upper limit on the off-shell Higgs signal strength of 3.8 is obtained at 95% CL using off-shell Higgs boson production in the $ZZ \to 4\ell$ and $ZZ \to 2\ell 2\nu$ decay channels ($\ell = e,\ \mu$). Combining with the on-shell signal strength measurements, the quoted upper limit on the Higgs boson total width is obtained, assuming the ratios of the relevant Higgs-boson couplings to the SM predictions are constant with energy from on-shell production to the high-mass range.

[11] SIRUNYAN 17AV obtain an upper limit on the width from the $m_{4\ell}$ distribution in $ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) decays. Data of 35.9 fb^{-1} pp collisions at E_{cm} = 13 TeV is used. The expected limit is 1.60 GeV.

[12] KHACHATRYAN 16BA derive constraints on the total width from comparing $WW^{(*)}$ production via on-shell and off-shell H using 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.4 fb^{-1} at 8 TeV.

[13] KHACHATRYAN 16BA combine the $WW^{(*)}$ result with $ZZ^{(*)}$ results of KHACHATRYAN 15BA and KHACHATRYAN 14D.

[14] AAD 15BE derive constraints on the total width from comparing $ZZ^{(*)}$ and $WW^{(*)}$ production via on-shell and off-shell H using 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The K factor for the background processes is assumed to be equal to that for the signal.

[15] KHACHATRYAN 15AM combine $\gamma\gamma$ and $ZZ^* \to 4\ell$ results. The expected limit is 2.3 GeV.

[16] KHACHATRYAN 15BA derive a lower limit on the total width from an upper limit on the decay flight distance $\tau < 1.9 \times 10^{-13}$ s. 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at 8 TeV are used.

[17] KHACHATRYAN 15BA derive constraints on the total width from comparing $ZZ^{(*)}$ production via on-shell and off-shell H with an unconstrained anomalous coupling. 4ℓ final states in 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV are used.

[18] AAD 14W use 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at 8 TeV. The expected limit is 6.2 GeV.

[19] CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. The expected limit is 2.8 GeV.

[20] KHACHATRYAN 14D derive constraints on the total width from comparing $ZZ^{(*)}$ production via on-shell and off-shell H. 4ℓ and $\ell\ell\nu\nu$ final states in 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV are used.

[21] KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. The expected limit is 3.1 GeV.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
$<1.4\times10^{-3}$	95	[2] SIRUNYAN	19BR	CMS	pp, 13 TeV

[1] TUMASYAN 23C search for $H\to\ \Upsilon(\text{nS})\,\Upsilon(\text{mS})$ with $\Upsilon(\text{nS})$, $\Upsilon(\text{mS})\to\ \mu^+\mu^-$ (n, m = 1, 2, 3) with 138 fb^{-1} of pp collision data at $E_{\text{cm}}=13$ TeV. The quoted value is for the Higgs decays for longitudinally polarized mesons. See their Table 1 for other cases.

[2] SIRUNYAN 19BR search for $H\to\ \Upsilon(\text{nS})\,\Upsilon(\text{mS})$ with $\Upsilon(\text{nS})$, $\Upsilon(\text{mS})\to\ \mu^+\mu^-$ (n, m = 1, 2, 3) for 37.5 fb^{-1} of pp collision data at $E_{\text{cm}}=13$ TeV. Υs from the Higgs decay are assumed to be unpolarized. For fully longitudinal (transverse) polarized Υs, limits change by -22% ($+10\%$). The three Υ states selected in a mass range of 8.5–11 GeV are not distinguished.

[1] AAD 23A report the combined results of 7, 8 (AAD 15CX) and 13 TeV assuming the Standard Model cross section ($m_H = 125$ GeV). See their Table 1 and Fig. 3.

[2] AAD 23A report the combined results using 139 fb^{-1} of data at $E_{\text{cm}} = 13$ TeV, where H decaying to invisible final states in VBF (AAD 22P), ZH, $Z \to ee$, $\mu\mu$ (AAD 22D), $pp \to t\bar{t}H$ (AAD 23AF), VBF+γ (AAD 22S) and gluon-fusion production with an energetic jet (AAD 21F) assuming the Standard Model cross section ($m_H = 125$ GeV). See their Table 1 and Fig. 3.

[3] AAD 23AF search for $pp \to t\bar{t}H$ with H decaying to invisible final states using 139 fb^{-1} of data. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model cross section. See their Table 3 for different decay topologies.

[4] TUMASYAN 23BA search for H decaying to invisible final states produced in association with a $t\bar{t}$ or a V, which decay to a fully hadronic final state. 138 fb^{-1} of data is used. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model cross section. See their Fig. 6 for the results of individual topologies.

[5] TUMASYAN 23BA report the combined results of 7, 8, and 13 TeV assuming the Standard Model cross section ($m_H = 125$ GeV). They combine results from TUMASYAN 22G, SIRUNYAN 21A, SIRUNYAN 21B, TUMASYAN 21D, SIRUNYAN 20AH, KHACHATRYAN 17F, CHATRCHYAN 14B as shown in their Table 8. See their Fig. 7 and Table 9 for the results of individual topologies.

[6] AAD 22D search for H decaying to invisible final states associated with a Z decaying $ee/\mu\mu$ using 139 fb^{-1} at 13 TeV. The limit is obtained for $m_H = 125$ GeV and assuming the SM ZH production cross section. The branching ratio is obtained to be $(0.3 \pm 9.0)\%$.

[7] AAD 22P search for $pp \to qqHX$ (VBF) with H decaying to invisible final states using 139 fb^{-1} of data. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model cross section.

[8] AAD 22S observe electroweak $Z(\to \nu\nu)\gamma$+2jets production process with 139 fb^{-1} of data. This result is applicable to search for $pp \to qqH\gamma X$ (VBF+γ) with H decaying to invisible final states. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model cross section.

[9] ATLAS 22 report the combined results using 139 fb^{-1} of data at $E_{\text{cm}} = 13$ TeV, where H decaying to invisible final states in VBF (AAD 22P), and ZH, $Z \to ee$, $\mu\mu$ (AAD 22D), assuming $\kappa_V \leq 1$ and $B_{undetected} \geq 0$.

[10] CMS 22 report the combined results using (a part of) 138 fb^{-1} of data at $E_{\text{cm}} = 13$ TeV, where H decaying to invisible final states in VBF (SIRUNYAN 19BO), associated with an energetic jet or a $V(\to q\bar{q})$ (TUMASYAN 21D), and ZH, $Z \to ee$, $\mu\mu$ (SIRUNYAN 21A) and assuming $\kappa_V \leq 1$ and $B_{undetected} \geq 0$.

[11] TUMASYAN 22G combine 13 TeV 101 fb^{-1} results with 8 TeV (KHACHATRYAN 17F) and other 13 TeV (KHACHATRYAN 17F for 2015 and SIRUNYAN 19BO for 2016) for H decaying to invisible final states with VBF topology. The quoted limit on the branching ratio is given for $m_H = 125.38$ GeV and assumes the Standard Model production rates. The branching ratio is obtained to be $0.086^{+0.054}_{-0.052}$. See their Figs. 11 and 12.

[12] TUMASYAN 22G search for $pp \to qqHX$ (VBF) with H decaying to invisible final states using 101 fb^{-1} of data (2017 and 2018). The quoted limit on the branching ratio is given for $m_H = 125.38$ GeV and assumes the Standard Model cross section. See their Figs. 11 and 12.

[13] AAD 21F search for an invisibly decaying Higgs boson with an energetic jet ($p_T > 150$ GeV) and missing transverse momentum (> 200 GeV) in 139 fb^{-1} at $E_{\text{cm}} = 13$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV.

[14] SIRUNYAN 21A search for H decaying to invisible final states associated with a Z decaying $ee/\mu\mu$ using 137 fb^{-1} at 13 TeV. The limit is obtained for $m_H = 125$ GeV and assuming the SM ZH production cross section.

[15] TUMASYAN 21D search for H decaying to invisible final states associated with an energetic jet or a V, $V \to q\bar{q}$ using 101 fb^{-1} at 13 TeV and the result is combined with SIRUNYAN 18S.

[16] AABOUD 19AI search for $pp \to qqHX$ (VBF) with H decaying to invisible final states using 36.1 fb^{-1} of data. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.

[17] AABOUD 19AL combine results of H decaying to invisible final states with VBF(AABOUD 19AI), ZH, and WH productions (AABOUD 18, AABOUD 18CA), which use 36.1 fb^{-1} of data at 13 TeV. The quoted limit is given for $m_H = 125$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH, and WH productions.

[18] AABOUD 19AL combine results of 7, 8 (AAD 15CX), and 13 TeV for H decaying to invisible final states.

[19] SIRUNYAN 19AT perform a combined fit with visible decay using 35.9 fb^{-1} of data at 13 TeV.

[20] SIRUNYAN 19BO search for $pp \to qqHX$ (VBF) with H decaying to invisible final states using 35.9 fb^{-1} of data. The quoted limit on the branching ratio is given for $m_H = 125.09$ GeV and assumes the Standard Model production rates.

[21] SIRUNYAN 19BO combine the VBF channel with results of other 13 TeV analyses: SIRUNYAN 18BV and SIRUNYAN 18S. The quoted limit on the branching ratio is given for $m_H = 125.09$ GeV and assumes the Standard Model production rates.

[22] SIRUNYAN 19BO combine 13 TeV 35.9 fb^{-1} results with 7, 8, 13 TeV (KHACHATRYAN 17F) for H decaying to invisible final states. The quoted limit on the branching ratio is given for $m_H = 125.09$ GeV and assumes the Standard Model production rates. The branching ratio is obtained to be 0.05 ± 0.03 (stat) ± 0.07(syst).

[23] AABOUD 18 search for $pp \to HZX$, $Z \to ee$, $\mu\mu$ with H decaying to invisible final states in 36.1 fb^{-1} at $E_{\text{cm}} = 13$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rate for HZ production.

[24] AABOUD 18CA search for H decaying to invisible final states using WH, and ZH productions, where W and Z hadronically decay. The data of 36.1 fb^{-1} at $E_{\text{cm}} = 13$ TeV is used. The quoted limit assumes SM production cross sections with combining the contributions from WH, ZH, ggF and VBF production modes.

[25] SIRUNYAN 18BV search for H decaying to invisible final states associated with a Z, $Z \to \ell\ell$ using 35.9 fb^{-1} at 13 TeV.The limit is obtained for $m_H = 125$ GeV and assuming the SM ZH production cross section.

[26] SIRUNYAN 18S search for H decaying to invisible final states associated with an energetic jet or a V, $V \to q\bar{q}$ using 35.9 fb^{-1} at 13 TeV.

[27] AABOUD 17BD search for H decaying to invisible final states with ≥ 1 jet and VBF events using 3.2 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. A cross-section ratio R^{miss} is used in the measurement. The quoted limit is given for $m_H = 125$ GeV.

[28] KHACHATRYAN 17F search for H decaying to invisible final states with gluon fusion, VBF, ZH, and WH productions using 2.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV. The quoted limit is given for $m_H = 125$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH, and WH productions.

[29] AAD 16AF search for $pp \to qqHX$ (VBF) with H decaying to invisible final states in 20.3 fb^{-1} at $E_{\text{cm}} = 8$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.

[30] AAD 16AN perform fits to the ATLAS and CMS data at $E_{\text{cm}} = 7$ and 8 TeV. The branching fraction of decays into BSM particles that are invisible or into undetected decay modes is measured for $m_0 = 125.09$ GeV.

[31] AAD 15BD search for $pp \to HWX$ and $pp \to HZX$ with W or Z decaying hadronically and H decaying to invisible final states using data at $E_{\text{cm}} = 8$ TeV. The quoted limit is given for $m_H = 125$ GeV, assumes the Standard Model rates for the production processes and is based on a combination of the contributions from HW, HZ and the gluon-fusion process.

[32] AAD 15CX search for H decaying to invisible final states with VBF, ZH, and WH productions using 20.3 fb^{-1} at 8 TeV, and 4.7 fb^{-1} at 7 TeV. The quoted limit is given for $m_H = 125.36$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH, and WH productions. The upper limit is improved to 0.23 by adding the measured visible decay rates.

[33] AAD 14O search for $pp \to HZX$, $Z \to \ell\ell$, with H decaying to invisible final states in 4.5 fb^{-1} at $E_{\text{cm}} = 7$ TeV and 20.3 fb^{-1} at $E_{\text{cm}} = 8$ TeV. The quoted limit on the branching ratio is given for $m_H = 125.5$ GeV and assumes the Standard Model rate for HZ production.

[34] CHATRCHYAN 14B search for $pp \to HZX$, $Z \to \ell\ell$ and $Z \to b\bar{b}$, and also $pp \to qqHX$ with H decaying to invisible final states using data at $E_{\text{cm}} = 7$ and 8 TeV. The quoted limit on the branching ratio is obtained from a combination of the limits from HZ and qqH. It is given for $m_H = 125$ GeV and assumes the Standard Model rates for the two production processes.

[35] CHATRCHYAN 14B search for $pp \to HZX$ with H decaying to invisible final states and $Z \to \ell\ell$ in 4.9 fb^{-1} at $E_{\text{cm}} = 7$ TeV and 19.7 fb^{-1} at $E_{\text{cm}} = 8$ TeV, and also with $Z \to b\bar{b}$ in 18.9 fb^{-1} at $E_{\text{cm}} = 8$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rate for HZ production.

[36] CHATRCHYAN 14B search for $pp \to qqHX$ (vector boson fusion) with H decaying to invisible final states in 19.5 fb^{-1} at $E_{\text{cm}} = 8$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rate for qqH production.

[1] AAD 24BH search for H decaying to invisible final states in VBF and ZH production with $Z \to \ell\ell$ using 139 fb^{-1} of data at 13 TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.

[2] SIRUNYAN 21L search for H decaying to invisible final states using 137 fb^{-1} of data at 13 TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.

[3] SIRUNYAN 21L combine results of H decaying to invisible final states with VBF(SIRUNYAN 21A), ZH, and WH productions (SIRUNYAN 18CA), which use 137 fb^{-1} of data at 13 TeV. The quoted limit is given for $m_H = 125$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH, and WH productions.

[4] SIRUNYAN 19CG search for $pp \to HZ$, $H \to \gamma$+ invisible, $Z \to \ell\ell$, 13 TeV

[1] AAD 24BH search for H decaying to an invisible final state plus a γ in the VBF and HZ production using 139 fb^{-1} data at $E_{cm} = 13$ TeV. The invisible state is called a dark photon. The quoted limit on the branching ratio is given for $m_H = 125$ GeV assuming the Standard Model rates. The 95% CL upper limits on the branching ratio for the VBF and HZ production are 1.8% and 2.3%, respectively. See their Fig. 3(a).

[2] SIRUNYAN 21L search for H decaying to an invisible final state plus a γ in the VBF production using 130 fb^{-1} data at $E_{cm} = 13$ TeV. The invisible state is called a dark photon. The quoted limit on the branching ratio is given for $m_H = 125$ GeV assuming the Standard Model rates.

[3] The result of the VBF production is combined with the $pp \to HZ$ result (SIRUNYAN 19CG).

[4] SIRUNYAN 19CG search for $pp \to HZ$, $Z \to ee$, $\mu\mu$ with H decaying to invisible final states plus a γ in 137 fb^{-1} at $E_{cm} = 13$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV assuming the Standard Model rate for HZ production and is obtained in the context of a theoretical model, where the undetected (invisible) particle is massless.

H SIGNAL STRENGTHS IN DIFFERENT CHANNELS

The H signal strength in a particular final state xx is given by the cross section times branching ratio in this channel normalized to the Standard Model (SM) value, $\sigma \cdot B(H \to xx) / (\sigma \cdot B(H \to xx))_{SM}$, for the specified mass value of H. For the SM predictions, see DITTMAIER 11, DITTMAIER 12, and HEINEMEYER 13A. Results for fiducial and differential cross sections are also listed below.

[1] ATLAS 22 report combined results (see their Extended Data Table 1) using up to 139 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.09$ GeV. The Higgs production cross-sections, branching fractions and several ratios are found in their Figs. 2 and 3.

[2] CMS 22 report combined results (see their Extended Data Table 2) using 138 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV. Signal strengths for production modes and decay channels are found in their Fig. 2.

[3] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are $1.03^{+0.16}_{-0.14}$ for gluon fusion, $1.18^{+0.25}_{-0.23}$ for vector boson fusion, $0.89^{+0.40}_{-0.38}$ for WH production, $0.79^{+0.38}_{-0.36}$ for ZH production, and $2.3^{+0.7}_{-0.6}$ for $t\overline{t}H$ production.

[4] AAD 16AN: The uncertainties represent statistics, experimental systematics, and added in quadrature theory systematics on the background and on the signal. The quoted signal strengths are given for $m_H = 125.09$ GeV. In the fit, relative branching ratios and relative production cross sections are fixed to those in the Standard Model.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[6] AAD 20 combine results of up to 79.8 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.09$ GeV: $\gamma\gamma$, ZZ^*, WW^*, $\tau\tau$, $b\overline{b}$, $\mu\mu$, invisible, and off-shell analyses (see their Table I). The signal strengths for individual production processes are 1.04 ± 0.09 for gluon fusion, $1.21^{+0.24}_{-0.22}$ for vector boson fusion, $1.30^{+0.40}_{-0.38}$ for WH production, $1.05^{+0.31}_{-0.29}$ for ZH production, and $1.21^{+0.26}_{-0.24}$ for $t\overline{t}H+tH$ production (see their Fig. 2 and Table IV). Several results with the simplified template cross section and κ-frameworks are presented: see their Figs. 9–11, Figs 20, 21 and Table VIII for stage-1 simplified template cross sections, their Figs. 12–17 and Tables X–XII for the κ-framework.

[7] SIRUNYAN 19AT combine results of 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.09$ GeV. The signal strengths for individual production processes are $1.22^{+0.14}_{-0.12}$ for gluon fusion, $0.73^{+0.30}_{-0.27}$ for vector boson fusion, $2.18^{+0.58}_{-0.55}$ for WH production, $0.87^{+0.44}_{-0.42}$ for ZH production, and $1.18^{+0.30}_{-0.27}$ for $t\overline{t}H$ production. Several results with the simplified template cross section and κ-frameworks are presented: see their Fig. 8 and Table 5 for stage-0 simplified template cross sections, their Figs. 9–18 and Tables 7–11 for the κ-framework.

[8] SIRUNYAN 19BA measure differential cross sections for the Higgs boson transverse momentum, the number of jets, the rapidity of the Higgs boson and the transverse momentum of the leading jet using 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV with $H \to \gamma\gamma$, $H \to ZZ^*$, and $H \to b\overline{b}$. The total cross section for Higgs boson production is measured to be $61.1 \pm 6.0 \pm 3.7$ pb using $H \to \gamma\gamma$ and $H \to ZZ^*$ channels. Several coupling measurements in the κ-framework are performed.

[9] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The third uncertainty in the measurement is theory systematics. The signal strengths for individual production modes are $1.23 \pm 0.14^{+0.09+0.16}_{-0.08-0.12}$ for gluon fusion, $1.23^{+0.28+0.13+0.11}_{-0.27-0.12-0.09}$ for vector boson fusion, $0.80^{+0.31}_{-0.30} \pm 0.17^{+0.10}_{-0.05}$ for W/ZH production, and $1.81^{+0.52+0.58+0.31}_{-0.50-0.55-0.12}$ for $t\overline{t}H$ production. The quoted signal strengths are given for $m_H = 125.36$ GeV.

[10] AAD 15P measure total and differential cross sections of the process $pp \to HX$ at $E_{cm} = 8$ TeV with 20.3 fb^{-1}. $\gamma\gamma$ and 4ℓ final states are used. $\sigma(pp \to HX) = 33.0 \pm 5.3 \pm 1.6$ pb is given. See their Figs. 2 and 3 for data on differential cross sections.

[11] KHACHATRYAN 15AM use up to 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The third uncertainty in the measurement is theory systematics. Fits to each production mode give the value of $0.85^{+0.19}_{-0.16}$ for gluon fusion, $1.16^{+0.37}_{-0.34}$ for vector boson fusion, $0.92^{+0.38}_{-0.36}$ for WH, ZH production, and $2.90^{+1.08}_{-0.94}$ for $t\overline{t}H$ production.

[12] AAD 13AK use 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.7 fb^{-1} at $E_{cm} = 8$ TeV. The combined signal strength is based on the $\gamma\gamma$, $ZZ^* \to 4\ell$, and $WW^* \to \ell\nu\ell\nu$ channels. The quoted signal strength is given for $m_H = 125.5$ GeV. Reported statistical error value modified following private communication with the experiment.

[13] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[14] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[15] AAD 12AI obtain results based on 4.6–4.8 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.8–5.9 fb^{-1} at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.9 σ is observed at $m_H = 126$ GeV. The quoted signal strengths are given for $m_H = 126$ GeV. See also AAD 12DA.

[16] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.1–5.3 fb^{-1} at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.0 σ is observed at about $m_H = 125$ GeV. The combined signal strength is based on the $\gamma\gamma$, ZZ^*, WW^*, $\tau^+\tau^-$, and $b\overline{b}$ channels. The quoted signal strength is given for $m_H = 125.5$ GeV. See also CHATRCHYAN 13Y.

[1] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV. See their Fig. 2 right.

[2] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are 0.84 ± 0.17 for gluon fusion, 1.2 ± 0.4 for vector boson fusion, $1.6^{+1.2}_{-1.0}$ for WH production, $5.9^{+2.6}_{-2.2}$ for ZH production, and $5.0^{+1.8}_{-1.7}$ for $t\overline{t}H$ production.

[3] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_H = 125.09$ GeV.

[4] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[5] AAD 25AG measure the signal strengths using $H \to WW^* \to \ell\nu\ell\nu$ and $H \to WW^* \to \ell\nu jj$ ($\ell = e,\ \mu$) with 140 fb^{-1} data at $E_{cm} = 13$ TeV. The last measurement uncertainty is due to the normalizing SM value. The signal strengths are summarized in their Table 9 and Fig. 12. The sum of WH and ZH cross sections times the $H \to WW^*$ branching ratio is measured to be $0.44^{+0.10}_{-0.09}{}^{+0.06}_{-0.05}$ pb and these two-dimensional likelihood scans are shown in their Fig. 14. Cross sections times the $H \to WW^*$ branching ratio and ratios to the SM values are given in their Tables 12, 13, 14 and Figs. 15 and 16, which are based on the simplified template cross section framework (reduced stage-1.2).

[6] AAD 25BK measure cross-sections times the $H \to WW^*$ branching fraction using $WW^* \to \ell\nu\ell\nu$ ($\ell = e,\ \mu$) with data of 140 fb^{-1} pp collisions at $E_{cm} = 13$ TeV: $\sigma_{ggF}\times B(H \to WW^*) = 12.4^{+1.3}_{-1.2}$ pb and $\sigma_{VBF}\times B(H \to WW^*) = 0.79^{+0.18}_{-0.16}$ pb. See their Fig. 11 for 2-dim contours. Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 simplified template cross section framework (see their Fig. 2) are shown in their Fig. 10. The results are given for $m_H = 125.09$ GeV.

[7] HAYRAPETYAN 25AC measure the ZH production cross section to the SM prediction using $H \to WW^*$ decay channel with 138 fb^{-1} and 62 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV and 13.6 TeV, respectively. Events with 4ℓ ($\ell = e,\ \mu$) are used. The cross section times the $H \to WW^*$ branching fraction and the signal strength for each center of mass energy are shown in their Table I. The corresponding significances are given in their Table II.

[8] HAYRAPETYAN 24AG search for the anomalous couplings of the Higgs boson to vector bosons, including CP violation effects using $H \to WW^* \to e\nu\mu\nu$ decay channel ($\ell = e,\ \mu$) with 138 fb^{-1} at $E_{cm} = 13$ TeV. The anomalous HVV and Hgg coupling parameters are given in their Table 7. The data constrain the SMEFT Higgs and Warsaw bases coupling parameters as shown in their Tables 8, 9 and Fig. 12.

[9] AAD 23AP measure cross-sections times the $H \to WW^*$ branching fraction in the $H \to WW^* \to e\nu\mu\nu$ channel using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV: $\sigma_{ggF}\times B(H \to WW^*) = 12.0 \pm 1.4$ pb, $\sigma_{VBF}\times B(H \to WW^*) = 0.75^{+0.19}_{-0.16}$ pb, and $\sigma_{ggF+VBF}\times B(H \to WW^*) = 12.3 \pm 1.3$ pb. The results are given for $m_H = 125.09$ GeV. Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 (see their Fig. 5) simplified template cross section framework are shown in their Table VII and Fig. 15.

[10] AAD 23BV measure fiducial total and differential cross sections of VBF process at $E_{cm} = 13$ TeV with 139 fb^{-1} using $H \to WW^* \to e\nu\mu\nu$. The measured total fiducial cross section is $1.68 \pm 0.33(\text{stat}) \pm 0.23(\text{syst})$ fb in their fiducial region (Table II and Section V). See their Fig. 9 for the comparison with theory predictions. The fiducial differential cross sections are shown in their Figs. 11, 12, and 13. Wilson coefficients in the Warsaw basis at 95% confidence interval are measured; see their Table V and Fig. 16.

[11] TUMASYAN 23W measure Higgs production rates with $H \to WW^*$ at $E_{cm} = 13$ TeV with 138 fb^{-1} data. The quoted results are given for $m_H = 125.38$ GeV.

[12] The quoted global signal strength is obtained assuming the relative ratios of different Higgs production modes fixed to the SM values.

[13] The 4 signal strengths for gluon-fusion (ggF), VBF, WH and ZH modes are fit assuming $t\overline{t}H$ and $b\overline{b}H$ fixed to the SM values.

[14] The quoted result is for ggF production mode.

[15] The quoted result is for VBF production mode.

[16] The quoted result is for WH production mode.

[17] The quoted result is for ZH production mode.

[18] Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 (see their Fig. 17) simplified template cross section framework (6 ggF, 4 VBF, and 4 VH) are shown in their Table 18 and Fig. 26.

[19] AAD 22V measure the signal strength for ggF+2jets with 36.1 fb^{-1} data at 13 TeV.

[20] AAD 22V probe the Higgs couplings to longitudinally and transversely polarized W and Z using VBF ($H \to WW^* \to e\nu\mu\nu$ plus two jets) with 36.1 fb^{-1} of data at $E_{cm} = 13$ TeV. The ratios of the polarization-dependent couplings $g_{HV_LV_L}$ and $g_{HV_TV_T}$ to the Higgs-V coupling predicted by the SM, $a_L = g_{HV_LV_L}/g^{SM}_{HVV}$ and $a_T = g_{HV_TV_T}/g^{SM}_{HVV}$ are measured to be $0.91^{+0.10}_{-0.18}{}^{+0.09}_{-0.17}$ and $1.2 \pm 0.4^{+0.2}_{-0.3}$, respectively, assuming the standard Hgg coupling. These measurements are translated into pseudo-observables of κ_{VV} and ϵ_{VV}: $\kappa_{VV} = 0.91^{+0.10}_{-0.18}{}^{+0.09}_{-0.17}$ and $\epsilon_{VV} = 0.13^{+0.28}_{-0.20}{}^{+0.08}_{-0.10}$, where $\kappa_{VV} = 1$ and $\epsilon_{VV} = 0$ for the SM. See their Tables 9 and 10.

[21] AABOUD 19F measure cross-sections times the $H \to WW^*$ branching fraction in the $H \to WW^* \to e\nu\mu\nu$ channel using 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV: $\sigma_{ggF}\times B(H \to WW^*) = 11.4^{+1.2}_{-1.1}{}^{+1.8}_{-1.7}$ pb and $\sigma_{VBF}\times B(H \to WW^*) = 0.50^{+0.24}_{-0.22} \pm 0.17$ pb.

[22] AAD 19A use 36.1 fb^{-1} data at 13 TeV. The cross section times branching fraction values are measured to be $0.67^{+0.31}_{-0.27}{}^{+0.18}_{-0.14}$ pb for WH, $H \to WW^*$ and $0.54^{+0.31}_{-0.24}{}^{+0.15}_{-0.07}$ pb for ZH, $H \to WW^*$.

[23] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV.

[24] SIRUNYAN 19AX measure the signal strengths, cross sections and so on using gluon fusion, VBF and VH production processes with 35.9 fb^{-1} of data. The quoted signal strength is given for $m_H = 125.09$ GeV. Signal strengths for each production process is found in their Fig. 9. Measured cross sections and ratios to the SM predictions in the stage-0 simplified template cross section framework are shown in their Fig. 10. $\kappa_F = 1.52^{+0.48}_{-0.41}$ and $\kappa_V = 1.10 \pm 0.08$ are obtained (see their Fig. 11 (right)).

[25] AAD 16AO measure fiducial total and differential cross sections of gluon fusion process at $E_{cm} = 8$ TeV with 20.3 fb^{-1} using $H \to WW^* \to e\nu\mu\nu$. The measured fiducial total cross section is 36.0 ± 9.7 fb in their fiducial region (Table 7). See their Fig. 6 for fiducial differential cross sections. The results are given for $m_H = 125$ GeV.

[26] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.36$ GeV.

[27] AAD 15AA use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The signal strength for the gluon fusion and vector boson fusion mode is $1.02 \pm 0.19^{+0.22}_{-0.18}$ and $1.27^{+0.44}_{-0.40}{}^{+0.30}_{-0.21}$, respectively. The quoted signal strengths are given for $m_H = 125.36$ GeV.

[28] AAD 15AQ use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.36$ GeV.

[29] AAD 15AQ combine their result on W/ZH production with the results of AAD 15AA (gluon fusion and vector boson fusion, slightly updated). The quoted signal strength is given for $m_H = 125.36$ GeV.

[30] CHATRCHYAN 14G use 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.4 fb^{-1} at $E_{cm} = 8$ TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_H = 125.6$ GeV.

[31] AAD 13AK use 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.5$ GeV. Superseded by AAD 15AA.

[32] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[33] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[34] AAD 12AI obtain results based on 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.8 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strengths are given for $m_H = 126$ GeV. See also AAD 12DA.

[35] CHATRCHYAN 12N obtain results based on 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.1 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.5$ GeV. See also CHATRCHYAN 13Y.

[1] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV. See their Fig. 2 right.

[2] AAD 20AQ perform analyses using $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 139 fb^{-1} at $E_{cm} = 13$ TeV. Results are given for $m_H = 125$ GeV.

[3] AAD 20AQ measured the inclusive cross section times branching ratio for $H \to ZZ^*$ decay ($|y(H)| < 2.5$) to be 1.34 ± 0.12 pb (with 1.33 ± 0.08 pb expected in the SM).

[4] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are $1.13^{+0.34}_{-0.31}$ for gluon fusion and $0.1^{+1.1}_{-0.6}$ for vector boson fusion.

[5] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_H = 125.09$ GeV.

[6] AAD 25AQ measure the off-shell Higgs signal strength to be $0.87^{+0.75}_{-0.54}$ using $H^* \to ZZ \to 4\ell$ ($\ell = e,\ \mu$) with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. This result is combined with $ZZ \to 2\ell 2\nu$ decay channel (AAD 23BR), which corresponds to a significance of 3.7 σ. The quoted errors are values at 68%CL.

[7] CHEKHOVSKY 25B measure the fiducial cross section using $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 34.7 fb^{-1} at $E_{cm} = 13.6$ TeV. The inclusive fiducial cross section is $2.89^{+0.53}_{-0.49}{}^{+0.29}_{-0.21}$ fb with their defined fiducial region (see their Table 1), where $3.09^{+0.27}_{-0.24}$ fb is expected in the SM. Differential fiducial cross sections are shown in their Fig. 5. The quoted results are given for $m_H = 125.38$ GeV.

[8] AAD 24AQ measure fiducial and total cross sections at $E_{cm} = 13.6$ TeV with 29.0 fb^{-1} data. The quoted results are given for $m_H = 125.09$ GeV. The inclusive fiducial cross section is 2.80 ± 0.74 fb with their defined fiducial region (see their Table 5), where 3.67 ± 0.19 fb is expected in the SM. Assuming SM values for the acceptance and the branching fraction, the total cross section is 46 ± 12 pb, where 59.9 ± 2.6 pb is expected in the SM.

[9] HAYRAPETYAN 23 measure the cross sections for $pp \to H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) using 138 fb^{-1} at $E_{cm} = 13$ TeV. They give $\sigma = 2.73 \pm 0.22(\text{stat}) \pm 0.15(\text{syst})$ fb in their fiducial region (see their Section5 and Table 2), where 2.86 ± 0.15 fb is expected in the Standard Model for $m_H = 125.38$ GeV. 26 differential and 6 double-differential cross sections are given; see their Figs. 6-23 and 24-25.

[10] SIRUNYAN 21AE obtains constraints on anomalous couplings to vector bosons (W, Z, and gluon) and top quark using $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 137 fb^{-1} at $E_{cm} = 13$ TeV. Their Table 5 and Figs 14–17 show (effective) couplings to gluon and top with combining gluon fusion, $t\bar{t}H$ and tH production channels and the result of $t\bar{t}H$, $H \to \gamma\gamma$ (SIRUNYAN 20AS). Their Tables 6–9 and Figs 18–22 show couplings to W and Z for different assumptions and bases (Higgs and Warsaw).

[11] SIRUNYAN 21S measure cross sections with the $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) channel using 137 fb^{-1} data at $E_{cm} = 13$ TeV. Results are given for $m_H = 125.38$ GeV. The signal strengths for individual production processes in their Table 4. Cross sections are given in their Table 6 and Fig. 14, which are based on the simplified template cross section framework (reduced stage-1.2).

[12] AAD 20AQ present several results for the channel $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with the simplified template cross section with κ-frameworks and the effective field theory (EFT) approach; see their Table 8 and Fig. 10 for simplified template cross sections. $\kappa_V = 1.02 \pm 0.06$ and $\kappa_F = 0.88 \pm 0.16$ are obtained, see their Fig. 12 for the κ-framework. See their Tables 9 and 10 and Figs. 16–18 for the EFT-framework.

[13] AAD 20BA measure the cross section for $pp \to H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) using 139 fb^{-1} at $E_{cm} = 13$ TeV. They give $\sigma \cdot B = 3.28 \pm 0.30 \pm 0.11$ fb in their fiducial region, where 3.41 ± 0.18 fb is expected in the Standard Model for $m_H = 125$ GeV. Various differential cross sections are also given; see their Figs. 19-39. Constraints on Yukawa couplings for bottom and charm quarks are given in their Table 9 and Fig. 41.

[14] AABOUD 19N measure the spectrum of the four-lepton invariant mass $m_{4\ell}$ ($\ell = e$ or μ) using 36.1 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted signal strength upper limit is obtained from 180 GeV $< m_{4\ell} <$ 1200 GeV.

[15] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV.

[16] AABOUD 18AJ perform analyses using $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 36.1 fb^{-1} at $E_{cm} = 13$ TeV. Results are given for $m_H = 125.09$ GeV. The inclusive cross section times branching ratio for $H \to ZZ^*$ decay ($|\eta(H)| < 2.5$) is measured to be $1.73^{+0.26}_{-0.24}$ pb (with $1.34^{+0.09}_{-0.09}$ pb expected in the SM).

[17] AABOUD 18BP measure an off-shell Higgs boson production using $ZZ \to 4\ell$ and $ZZ \to 2\ell 2\nu$ ($\ell = e,\ \mu$) decay channels with 36.1 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted signal strength upper limit is obtained from a combination of these two channels, where 220 GeV $< m_{4\ell} <$ 2000 GeV for $ZZ \to 4\ell$ and 250 GeV $< m_T^{ZZ} <$ 2000 GeV for $ZZ \to 2\ell 2\nu$ (m_T^{ZZ} is defined in their Section 5). See their Table 2 for each measurement.

[18] SIRUNYAN 17AV use 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength, obtained from the analysis of $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) decays, is given for $m_H = 125.09$ GeV. The signal strengths for different production modes are given in their Table 3. The fiducial and differential cross sections are shown in their Fig. 10.

[19] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.36$ GeV.

[20] KHACHATRYAN 16AR use data of 5.1 fb^{-1} at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at 8 TeV. The fiducial cross sections for the production of 4 leptons via $H \to 4\ell$ decays are measured to be $0.56^{+0.67}_{-0.44}{}^{+0.21}_{-0.06}$ fb at 7 TeV and $1.11^{+0.41}_{-0.35}{}^{+0.14}_{-0.10}$ fb at 8 TeV in their fiducial region (Table 2). The differential cross sections at $E_{cm} = 8$ TeV are also shown in Figs. 4 and 5. The results are given for $m_H = 125$ GeV.

[21] AAD 15F use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.36$ GeV. The signal strength for the gluon fusion production mode is $1.66^{+0.45}_{-0.41}{}^{+0.25}_{-0.15}$, while the signal strength for the vector boson fusion production mode is $0.26^{+1.60}_{-0.91}{}^{+0.36}_{-0.23}$.

[22] AAD 14AR measure the cross section for $pp \to H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) using 20.3fb^{-1} at $E_{cm} = 8$ TeV. They give $\sigma \cdot B = 2.11^{+0.53}_{-0.47} \pm 0.08$ fbin their fiducial region, where 1.30 ± 0.13 fb is expected in the Standard Model for m_H= 125.4 GeV. Various differential cross sections are also given; see their Fig. 2.

[23] CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.6$ GeV. The signal strength for the gluon fusion and $t\bar{t}H$ production mode is $0.80^{+0.46}_{-0.36}$, while the signal strength for the vector boson fusion and WH, ZH production mode is $1.7^{+2.2}_{-2.1}$.

[24] AAD 13AK use 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.5$ GeV.

[25] CHATRCHYAN 13J obtain results based on $ZZ \to 4\ell$ final states in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 12.2 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.8$ GeV. Superseded by CHATRCHYAN 14AA.

[26] AAD 12AI obtain results based on 4.7–4.8 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.8 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strengths are given for $m_H = 126$ GeV. See also AAD 12DA.

[27] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.1–5.3 fb^{-1} at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.0 σ is observed at about $m_H = 125$ GeV. The quoted signal strengths are given for $m_H = 125.5$ GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

$\gamma\gamma$ final state

[1] AAD 23Y use 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted results are given for $m_H = 125.09$ GeV and $\Gamma_H = 4.07$ MeV. Measured $\sigma \cdot B$ and ratios to the SM predictions for the different production modes are shown in their Table 9 and Fig. 9. Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 (see their Fig. 11) simplified template cross section framework are shown in their Table 10 and Fig. 12. Wilson coefficients in the Warsaw basis (see their Table 11) at 95% CL are measured; see their Table 16 and Fig. 17.

[2] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV. See their Fig. 2 right.

[3] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are $1.10^{+0.23}_{-0.22}$ for gluon fusion, 1.3 ± 0.5 for vector boson fusion, $0.5^{+1.3}_{-1.2}$ for WH production, $0.5^{+3.0}_{-2.5}$ for ZH production, and $2.2^{+1.6}_{-1.3}$ for $t\bar{t}H$ production.

[4] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_H = 125.09$ GeV.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[6] HAYRAPETYAN 25AL measure fiducial and differential cross sections of $pp \to H \to \gamma\gamma$ at $E_{cm} = 13.6$ TeV with 34.7 fb^{-1} data. The quoted results are given for $m_H = 125.38$ GeV. The inclusive fiducial cross section is $74 \pm 11^{+5}_{-4}$ fb with the fiducial region defined in their Section 6. Differential fiducial cross sections as a function of Higgs boson p_T, rapidity, the number of jets, leading jet p_T are shown in their Figs. 7–10.

strictly not permitted, except for Open Access articles.

[7] AAD 24AQ measure fiducial and total cross sections at E_{cm} = 13.6 TeV with 31.4 fb^{-1} data. The quoted results are given for m_H = 125.09 GeV. The inclusive fiducial cross section is 76^{+14}_{-13} fb with their defined fiducial region (see their Table 2), where 67.6 ± 3.7 fb is expected in the SM. Assuming SM values for the acceptance and the branching fraction, the total cross section is 67^{+12}_{-11} pb, where 59.9 ± 2.6 pb is expected in the SM.

[8] TUMASYAN 23Q measure fiducial and differential cross sections at E_{cm} = 13 TeV with 137 fb^{-1} data. The quoted results are given for m_H = 125.38 GeV. The inclusive fiducial $\sigma{\cdot}B$ is $73.4^{+5.4}_{-5.3}$(stat)$^{+2.4}_{-2.2}$(syst) fb with their defined fiducial region (see their Section 7 and Table 2), where 75.4 ± 4.1 fb is expected in the Standard Model. See their Fig. 8 including other fiducial $\sigma{\cdot}B$ defined in their Table 3. Differential $\sigma{\cdot}B$ are shown in their Figs. 10–15. Double-differential $\sigma{\cdot}B$ are in their Figs. 16 and 17.

[9] AAD 22N measure fiducial and differential cross sections of $pp \to H \to \gamma\gamma$ at E_{cm} = 13 TeV with 139 fb^{-1} data. The quoted results are given for m_H = 125.09 GeV. The inclusive fiducial $\sigma \cdot B$ is 67 ± 5 ± 4 fb with their defined fiducial region. Other fiducial $\sigma{\cdot}B$ are in their Table 3. Differential $\sigma{\cdot}B$ are shown in their Figs. 8–13, 15, 25–32, 35, 36. Double-differential $\sigma{\cdot}B$ are in their Figs. 14, 33, 34. Modifications of the b- and c-quark Yukawa couplings to H, κ_b and κ_c at 95% CL are in their Table 6 and Fig. 18. Wilson coefficients at 95% CL are in their Table 7 and Fig. 21.

[10] SIRUNYAN 21O measures cross sections and couplings with the $H \to \gamma\gamma$ channel using 137 fb^{-1} data at E_{cm} = 13 TeV. Results are given for m_H = 125.38 GeV. The signal strengths for individual production processes are given in their Fig. 16. Cross sections are given in their Tables 12 and 13 and Figs. 18 and 20, which are based on the simplified template cross section framework (reduced stage-1.2). Results in the κ-framework are given in their Fig. 22.

[11] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at E_{cm} = 13 TeV.

[12] SIRUNYAN 19L measure fiducial and differential cross sections of the process $pp \to H \to \gamma\gamma$ at E_{cm} = 13 TeV with 35.9 fb^{-1}. See their Figs. 4–11.

[13] AABOUD 18BO use 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The signal strengths for the individual production modes are: $0.81^{+0.19}_{-0.18}$ for gluon fusion, $2.0^{+0.6}_{-0.5}$ for vector boson fusion, $0.7^{+0.9}_{-0.8}$ for VH production ($V = W, Z$), and 0.5 ± 0.6 for $t\bar{t}H$ and tH production. Other measurements of cross sections and couplings are summarized in their Section 10. The quoted values are given for m_H = 125.09 GeV.

[14] SIRUNYAN 18DS use 35.9 fb^{-1} of $pp \to H$ collisions with $H \to \gamma\gamma$ at E_{cm} = 13 TeV. The Higgs mass is floated in the measurement of a signal strength. The result is $1.18^{+0.12}_{-0.11}$(stat.)$^{+0.09}_{-0.07}$(syst.)$^{+0.07}_{-0.06}$(theory), which is largely insensitive to the Higgs mass around 125 GeV.

[15] KHACHATRYAN 16G measure fiducial and differential cross sections of the process $pp \to HX$, $H \to \gamma\gamma$ at E_{cm} = 8 TeV with 19.7 fb^{-1}. See their Figs. 4–6 and Table 1 for data.

[16] AAD 14BC use 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for m_H = 125.4 GeV. The signal strengths for the individual production modes are: 1.32 ± 0.38 for gluon fusion, 0.8 ± 0.7 for vector boson fusion, 1.0 ± 1.6 for WH production, $0.1^{+3.7}_{-0.1}$ for ZH production, and $1.6^{+2.7}_{-1.8}$ for $t\bar{t}H$ production.

[17] AAD 14BJ measure fiducial and differential cross sections of the process $pp \to HX$, $H \to \gamma\gamma$ at E_{cm} = 8 TeV with 20.3 fb^{-1}. See their Table 3 and Figs. 3–12 for data.

[18] KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for m_H = 124.7 GeV. The signal strength for the gluon fusion and $t\bar{t}H$ production mode is $1.13^{+0.37}_{-0.31}$, while the signal strength for the vector boson fusion and WH, ZH production mode is $1.16^{+0.63}_{-0.58}$.

[19] AAD 13AK use 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.7 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125.5 GeV.

[20] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\bar{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[21] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\bar{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[22] AAD 12AI obtain results based on 4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.9 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strengths are given for m_H = 126 GeV. See also AAD 12DA.

[23] CHATRCHYAN 12N obtain results based on 5.1 fb^{-1} of pp collisions at E_{cm}=7 TeV and 5.3 fb^{-1} at E_{cm}=8 TeV. The quoted signal strength is given for m_H=125.5 GeV. See also CHATRCHYAN 13Y.

[1] HAYRAPETYAN 26 search for $t\bar{t}H$, $H \to c\bar{c}$ together with the $t\bar{t}H$, $H \to b\bar{b}$ measurement using 138 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted limit corresponds to $\sigma_{t\bar{t}H} \cdot B(H \to c\bar{c}) <$ 0.11 pb at 95% CL.

[2] AAD 25Y present measurements of VH, $H \to b\bar{b}$ and $H \to c\bar{c}$ ($V = W, Z$) using 140 fb^{-1} of pp collision data at E_{cm} = 13 TeV. Two-dimensional likelihood scan of $(\mu_{VH}^{bb}, \mu_{VH}^{cc})$ is shown in their Fig. 11.

[3] TUMASYAN 23AD search for Higgs produced with transverse momenta greater than 450 GeV and decaying to $c\bar{c}$ using 138 fb^{-1} of pp collision data at E_{cm} = 13 TeV.

[4] TUMASYAN 23AH search for VH, $H \to c\bar{c}$ ($V = W, Z$) using 138 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The upper limit on $\sigma(pp \to VH){\cdot}B(H \to c\bar{c})$ is 0.94 pb at 95% CL. See their Fig. 4. The quoted values are given for m_H = 125.38 GeV.

[5] AAD 22W search for VH, $H \to c\bar{c}$ ($V = W, Z$) using 139 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The results are given for m_H = 125 GeV.

[6] The analysis of VH, $H \to c\bar{c}$ is combined with VH, $H \to b\bar{b}$ (AAD 21AB). The ratio $|\kappa_c/\kappa_b|$ is constrained to be less than 4.5 at 95% CL. See their Fig. 7.

[7] The constraint on the charm Yukawa coupling modifier κ_c is measured to be $|\kappa_c| <$8.5 at 95% CL. See their Fig. 4.

[8] SIRUNYAN 20AE use 35.9 fb^{-1} at of pp collisions at E_{cm} = 13 TeV. The measured best fit value of $\sigma(pp \to VH){\cdot}B(H \to c\bar{c})$ is $2.40^{+1.12}_{-1.11}{}^{+0.65}_{-0.61}$ pb (equivalent to < 4.5 pb at 95% CL upper limit, i.e. 70 times the standard model), where V is $W \to \ell\nu$, $Z \to \ell\ell$, or $Z \to \nu\nu$ ($\ell = e, \mu$). The quoted values are given for m_H = 125 GeV.

[9] AABOUD 18M use 36.1 fb^{-1} at of pp collisions at E_{cm} = 13 TeV. The upper limit on $\sigma(pp \to ZH){\cdot}B(H \to c\bar{c})$ is 2.7 pb at 95% CL. This corresponds to 110 times the standard model. The quoted values are given for m_H = 125 GeV.

$0.48^{+0.81}_{-0.70}$	[49] CHATRCHYAN	12N	CMS	$pp \to HW/ZX$, 7, 8 TeV

[1] AAD 25Y present measurements of VH, $H \to b\bar{b}$ ($V = W,\ Z$) using 140 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The observed significance for WH and ZH are 5.3 and 4.9 σ, respectively. See their Fig. 12. Cross sections are given in their Table 8 and Figs. 15 and 16, which are based on the simplified template cross section framework (extended stage-1.2).

[2] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV. See their Fig. 2 right.

[3] AAD 21AJ present measurements of $H \to b\bar{b}$ in the VBF production mode. The inclusive VBF cross sections with and without the branching ratio of $H \to b\bar{b}$ are $2.07 \pm 0.70^{+0.46}_{-0.37}$ fb and $3.56 \pm 1.21^{+0.80}_{-0.64}$ fb, respectively. The latter is obtained assuming the SM value of B($H \to b\bar{b}$) = 0.5809 and $m_H = 125$ GeV.

[4] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are 1.0 ± 0.5 for WH production, 0.4 ± 0.4 for ZH production, and 1.1 ± 1.0 for $t\bar{t}H$ production.

[5] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_H = 125.09$ GeV.

[6] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[7] HAYRAPETYAN 26 search for $t\bar{t}H$, $H \to c\bar{c}$ together with the $t\bar{t}H$, $H \to b\bar{b}$ measurement using 138 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV.

[8] CHEKHOVSKY 25A constrain six Wilson coefficients in the Warsaw basis using 138 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The results are shown in their Figs. 7 (for linear and quadratic), 9–13 (two-dimensional likelihood scan). The limits on the energy scale for three different assumptions for each Wilson coefficient are shown in their Fig. 8.

[9] AAD 24F present studies of the VH production mode in the boosted $V \to q\bar{q}$ and $H \to b\bar{b}$ ($p_T(H) > 250$ GeV) using 137 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125.09$ GeV and corresponds to a significance of 1.7 standard deviations. The corresponding inclusive cross section is $3.1 \pm 1.3^{+1.8}_{-1.4}$ pb. The signal strengths and cross sections are given in their Table I for three $p_T(H)$ regions: $250 < p_T(H) < 450$ GeV, $450 < p_T(H) < 650$ GeV, 650 GeV $< p_T(H)$ with $|y(H)| < 2$.

[10] HAYRAPETYAN 24AM search for ZH, $H \to b\bar{b}$, $Z \to b\bar{b}$ using 133 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The upper limit at 95% CL on the ZH production is 5.0 times the SM prediction.

[11] HAYRAPETYAN 24AY present measurements of boosted $H \to b\bar{b}$ ($p_T > 450$ GeV) via VBF or gluon fusion productions using 138 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The result is given for the VBF production. See their Table 3. The VH and $t\bar{t}H$ production rates are fixed to the SM values. The VBF signal strengths and the fiducial cross sections for two different m_{jj} regions and STXS stage 1.2 bins are shown in their Figs. 9 and 10, respectively.

[12] HAYRAPETYAN 24AY present measurements of boosted $H \to b\bar{b}$ ($p_T > 450$ GeV) via VBF or gluon fusion productions using 138 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The result is given for the gluon fusion production. See their Table 3. The VH and $t\bar{t}H$ production rates are fixed to the SM values. The gluon fusion signal strengths and the fiducial cross sections for 6 different p_T regions and STXS stage 1.2 bins are shown in their Figs. 9 and 10, respectively.

[13] HAYRAPETYAN 24U present measurements of $H \to b\bar{b}$ in the VBF production mode using 90.8 fb^{-1} of data at $E_{cm} = 13$ TeV constraining the ggF production to be the SM expectation. The quoted signal strength corresponds to a significance of 2.4 standard deviations.

[14] HAYRAPETYAN 24U present measurements of $H \to b\bar{b}$ in the inclusive (ggF+VBF) production mode using 90.8 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 2.6 standard deviations.

[15] HAYRAPETYAN 24U present measurements of $H \to b\bar{b}$ in the ggF and VBF production modes using 90.8 fb^{-1} of data at $E_{cm} = 13$ TeV. The signal strengths for the ggF and VBF production modes are independently obtained. See their Fig. 11.

[16] TUMASYAN 24 report the measurement of VH, $H \to b\bar{b}$ ($V = W,\ Z$) using 138 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 6.3 standard deviations. Signal strengths for WH and ZH are given in their Fig. 7. Signal strengths and $\sigma \cdot B$ for 8 different bins defined based on the the simplified template cross section framework are given in their Figs. 8 and 9 and Table VII.

[17] AAD 22X measure cross sections using a boosted $H \to b\bar{b}$ with large-radius jets. The data is 136 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. All the results are given for $m_H = 125$ GeV. The inclusive signal strength is given using data with a H candidate jet $p_T > 250$ GeV. The fiducial H production cross section ($p_T(H) > 450$ GeV and $|y(H)| < 2$) is < 115 fb (95% CL) and the upper limits for other four different p_T regions are shown in their Fig 12. The measured fiducial H production cross section ($p_T(H) > 1$ TeV) is $2.3 \pm 3.9(\text{stat}) \pm 1.3(\text{syst}) \pm 0.5(\text{theory})$ fb.

[18] AAD 21AB search for VH, $H \to b\bar{b}$ ($V = W,\ Z$) using 139 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The results are given for $m_H = 125$ GeV. Cross sections are given in their Table 13 and Fig. 7, which are based on the simplified template cross section framework (reduced stage-1.2). Wilson coefficients of the Warsaw-basis operators are given in their Fig. 9.

[19] AAD 21H present measurements of $H \to b\bar{b}$ with a boosted vector boson ($p_T > 250$ GeV) using 139 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. Cross sections are given in their Table 6 and Fig. 4, which are based on the simplified template cross section framework (reduced stage-1.2). Wilson coefficients of the Warsaw-basis operators are given in their Fig. 5.

[20] AAD 21M search for VBF+γ, $H \to b\bar{b}$ using 132 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV.

[21] SIRUNYAN 20BL search for boosted $H \to b\bar{b}$ (a H candidate jet $p_T > 450$ GeV) using 137 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 2.5 standard deviations and is given for $m_H = 125$ GeV. A differential fiducial cross section as a function of Higgs boson p_T for ggF is shown in their Fig. 7, assuming the other production modes occur at the expected SM rates. The reported value is $3.7 \pm 1.2^{+0.8}_{-0.7}{}^{+0.8}_{-0.5}$ where the last uncertainty comes from theoretical modeling. We have combined the systematic uncertainties in quadrature.

[22] AABOUD 19U measure cross sections of $pp \to VH$, $H \to b\bar{b}$ production as a function of the gauge boson transverse momentum using data of 79.8 fb^{-1}. The kinematic fiducial volumes used is based on the simplified template cross section framework (reduced stage-1). See their Table 3 and Fig. 3.

[23] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV.

[24] AABOUD 18BN search for VH, $H \to b\bar{b}$ ($V = W,\ Z$) using 79.8 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 4.9 standard deviations and is given for $m_H = 125$ GeV.

[25] AABOUD 18BN combine results of 79.8 fb^{-1} at $E_{cm} = 13$ TeV with results of VH at $E_{cm} = 7$ and 8 TeV.

[26] AABOUD 18BN combine results of VH at $E_{cm} = 7$, 8 and 13 TeV with results of VBF (+gluon fusion) and $t\bar{t}H$ at $E_{cm} = 7$, 8, and 13 TeV to perform a search for the $H \to b\bar{b}$ decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.4 standard deviations.

[27] AABOUD 18BQ search for $H \to b\bar{b}$ produced through vector-boson fusion (VBF) and VBF+γ with 30.6 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[28] The signal strength is measured including all production modes (VBF, ggF, VH, $t\bar{t}H$).

[29] The signal strength is measured for VBF-only and others (ggF, VH, $t\bar{t}H$) are constrained to Standard Model expectations with uncertainties described in their Section VIII B.

[30] AALTONEN 18C use 5.4 fb^{-1} of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The upper limit at 95% CL on $p\bar{p} \to H \to b\bar{b}$ is 33 times the SM prediction, which corresponds to a cross section of 40.6 pb.

[31] SIRUNYAN 18AE use 35.9 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to 3.3 standard deviations and is given for $m_H = 125.09$ GeV.

[32] SIRUNYAN 18AE combine the result of 35.9 fb^{-1} at $E_{cm} = 13$ TeV with the results obtained from data of up to 5.1 fb^{-1} at $E_{cm} = 7$ TeV and up to 18.9 fb^{-1} at $E_{cm} = 8$ TeV (CHATRCHYAN 14AI and KHACHATRYAN 15Z). The quoted signal strength corresponds to 3.8 standard deviations and is given for $m_H = 125.09$ GeV.

[33] SIRUNYAN 18DB search for VH, $H \to b\bar{b}$ ($V = W,\ Z$) using 77.2 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 4.4 standard deviations and is given for $m_H = 125.09$ GeV.

[34] SIRUNYAN 18DB combine the result of 77.2 fb^{-1} at $E_{cm} = 13$ TeV with the results obtained from data of up to 5.1 fb^{-1} at $E_{cm} = 7$ TeV and up to 18.9 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength corresponds to a significance of 4.8 standard deviations and is given for $m_H = 125.09$ GeV.

[35] SIRUNYAN 18DB combine results of 77.2 fb^{-1} at $E_{cm} = 13$ TeV with results of gluon fusion (ggF), VBF and $t\bar{t}H$ at $E_{cm} = 7$ TeV, 8 TeV and 13 TeV to perform a search for the $H \to b\bar{b}$ decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.6 standard deviations and is given for $m_H = 125.09$ GeV.

[36] SIRUNYAN 18E use 35.9 fb^{-1} at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV. They measure $\sigma \cdot B$ for gluon fusion production of $H \to b\bar{b}$ with $p_T > 450$ GeV, $|\eta| < 2.5$ to be $74 \pm 48^{+17}_{-10}$ fb.

[37] AABOUD 17BA use 36.1 fb^{-1} at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV. They give $\sigma(\text{W H}) \cdot B(H \to b\bar{b}) = 1.08^{+0.54}_{-0.47}$ pb and $\sigma(\text{Z H}) \cdot B(H \to b\bar{b}) = 0.57^{+0.26}_{-0.23}$ pb.

[38] AABOUD 17BA combine 7, 8 and 13 TeV analyses. The quoted signal strength is given for $m_H = 125$ GeV.

[39] AABOUD 16X search for vector-boson fusion production of H decaying to $b\bar{b}$ in 20.2 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[40] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.36$ GeV.

[41] AAD 15G use 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.36$ GeV.

Gauge & Higgs Boson Particle Listings

H

[42] KHACHATRYAN 15Z search for vector-boson fusion production of H decaying to $b\overline{b}$ in up to 19.8 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125 GeV.

[43] KHACHATRYAN 15Z combined vector boson fusion, WH, ZH production, and $t\overline{t}H$ production results. The quoted signal strength is given for m_H = 125 GeV.

[44] CHATRCHYAN 14AI use up to 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 18.9 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125 GeV. See also CHATRCHYAN 14AJ.

[45] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[46] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[47] AAD 12AI obtain results based on 4.6–4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The quoted signal strengths are given in their Fig. 10 for m_H = 126 GeV. See also Fig. 13 of AAD 12DA.

[48] AALTONEN 12T combine AALTONEN 12Q, AALTONEN 12R, AALTONEN 12S, ABAZOV 12O, ABAZOV 12P, and ABAZOV 12K. An excess of events over background is observed which is most significant in the region m_H = 120–135 GeV, with a local significance of up to 3.3 σ. The local significance at m_H = 125 GeV is 2.8 σ, which corresponds to $(\sigma(HW) + \sigma(HZ)) \cdot B(H \to b\overline{b}) = (0.23^{+0.09}_{-0.08})$ pb, compared to the Standard Model expectation at m_H = 125 GeV of 0.12 ± 0.01 pb. Superseded by AALTONEN 13M.

[49] CHATRCHYAN 12N obtain results based on 5.0 fb^{-1} of pp collisions at E_{cm}=7 TeV and 5.1 fb^{-1} at E_{cm}=8 TeV. The quoted signal strength is given for m_H=125.5 GeV. See also CHATRCHYAN 13Y.

[1] AAD 25AR search for $H \to \mu^+\mu^-$ using 140 fb^{-1} of pp data at E_{cm} = 13 TeV and 165 fb^{-1} of pp data at E_{cm} = 13.6 TeV. The quoted signal strength corresponds to a significance of 3.4 standard deviations assuming m_H = 125.09 GeV.

[2] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.38 GeV. See their Fig. 2 right.

[3] AAD 25AR search for $H \to \mu^+\mu^-$ using 165 fb^{-1} of pp collision data at E_{cm} = 13.6 TeV. The quoted signal strength corresponds to a significance of 2.8 standard deviations assuming m_H = 125.09 GeV.

[4] AAD 21 search for $H \to \mu^+\mu^-$ using 139 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 2.0 standard deviations and is given for m_H = 125.09 GeV. The upper limit on the cross section times branching fraction is 2.2 times the SM prediction at 95% CL, which corresponds to the branching fraction upper limit of 4.7×10^{-4} (assuming SM production cross sections).

[5] SIRUNYAN 21 search for $H \to \mu^+\mu^-$ using 137 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 3.0 standard deviations and is given for m_H = 125.38 GeV.

[6] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at E_{cm} = 13 TeV.

[7] SIRUNYAN 19E search for $H \to \mu^+\mu^-$ using 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV and combine with results of 7 TeV (5.0 fb^{-1}) and 8 TeV (19.7 fb^{-1}). The upper limit at 95% CL on the signal strength is 2.9, which corresponds to the SM Higgs boson branching fraction to a muon pair of 6.4×10^{-4}.

[8] AABOUD 17Y use 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV, 20.3 fb^{-1} at 8 TeV and 4.5 fb^{-1} at 7 TeV. The quoted signal strength is given for m_H = 125 GeV.

[9] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_H = 125.09 GeV.

[10] KHACHATRYAN 15H use 5.0 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at 8 TeV. The quoted signal strength is given for m_H = 125 GeV.

[11] AAD 14AS search for $H \to \mu^+\mu^-$ in 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125.5 GeV.

[1] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.38 GeV. See their Fig. 2 right.

[2] AABOUD 19AQ use 36.1 fb^{-1} of data. The first, second and third quoted errors are statistical, experimental systematic and theory systematic uncertainties, respectively. The quoted signal strength is given for m_H = 125 GeV and corresponds to 4.4 standard deviations. Combining with 7 TeV and 8 TeV results (AAD 15AH), the observed significance is 6.4 standard deviations. The cross sections in the $H \to \tau\tau$ decay channel (m_H = 125 GeV) are measured to $3.77^{+0.60}_{-0.59}$ (stat) $^{+0.87}_{-0.74}$ (syst) pb for the inclusive, $0.28 \pm 0.09^{+0.11}_{-0.09}$ pb for VBF, and $3.1 \pm 1.0^{+1.6}_{-1.3}$ pb for gluon-fusion production. See their Table XI for the cross sections in the framework of simplified template cross sections.

[3] AAD 16AN perform fits to the ATLAS and CMS data at E_{cm} = 7 and 8 TeV. The signal strengths for individual production processes are 1.0 ± 0.6 for gluon fusion, 1.3 ± 0.4 for vector boson fusion, -1.4 ± 1.4 for WH production, $2.2^{+2.2}_{-1.8}$ for ZH production, and $-1.9^{+3.7}_{-3.3}$ for $t\overline{t}H$ production.

[4] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_H = 125.09 GeV.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[6] AAD 25W measure different types of cross sections with $pp \to H \to \tau\tau$ at E_{cm} = 13 TeV with 140 fb^{-1} data. Their Fig. 5 show $\sigma \cdot B$ relative to the SM expectations for the total and per-production-mode, and their Figs. 6 and 8 show those in the simplified template cross section framework. Their Table 7 show the measurements of $\sigma \cdot B$ for per-production-mode. The differential fiducial cross sections defined in their Table 8 are given in their Fig. 10. Six Wilson coefficients in the Warsaw basis are in their Figs. 12 and 13 at 95% CL. The constraints on the Wilson coefficients c_{HW} and $c_{H\widetilde{W}}$ are obtained to be [−1.90, +0.51] and [−0.31, +0.88] at 95% CL, respectively, for the interference term alone (the linear term) assuming only one of the Wilson coefficients is non-zero.

[7] AAD 24BE measure the VH Higgs production ($V = W,\ Z$) with $H \to \tau\tau$ at E_{cm} = 13 TeV with 140 fb^{-1} data. The quoted signal strength corresponds to 4.2 standard deviations. The signal strengths for individual WH and ZH productions are $1.48^{+0.56}_{-0.50}$ and $1.09^{+0.51}_{-0.44}$, respectively. The results are given for m_H = 125 GeV. See their Fig. 4.

[8] HAYRAPETYAN 24AT present measurements of the boosted $H \to \tau\tau$ ($p_T > 250$ GeV) using 138 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 3.5 standard deviations. The fiducial inclusive production cross section is measured to be $3.88^{+1.69}_{-1.35}$ fb. The differential fiducial cross sections as a function of Higgs boson and leading jet p_T are given in their Fig. 3.

[9] TUMASYAN 23Y measure Higgs production with $pp \to H \to \tau\tau$ at E_{cm} = 13 TeV with 138 fb^{-1} data. The quoted results are given for m_H = 125.38 GeV.

[10] The inclusive $\sigma \cdot B$ is 2800^{+356}_{-335} fb (see their Figs. 10 and 14). See their Fig. 15 for the 68 % and 95 % CL contours in the $\kappa_V - \kappa_F$ plane.

[11] The quoted result is for the stage-0 simplified template cross section (STXS) and the $\sigma_{ggF} \cdot B$ is 2030^{+598}_{-555} fb (see their Figs. 10 and 14). Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 STXS (see their Fig. 1) are shown in their Table 9 and Figs. 12 and 14.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[12] The quoted result is for the stage-0 STXS and the $\sigma_{VBF} \cdot B$ is $267^{+53.9}_{-52.6}$ fb (see their Figs. 10 and 14). Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 STXS (see their Fig. 2) are shown in their Table 9 and Figs. 12, 14.

[13] The quoted result is for the stage-0 STXS and the $\sigma_{VH} \cdot B$ is $79.0^{+20.5}_{-18.6}$ fb (see their Figs. 10 and 14). Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 STXS (see their Fig. 3) are shown in their Table 9 and Figs. 12, 14.

[14] AAD 22Q measure cross sections of $pp \to H \to \tau\tau$ at $E_{cm} = 13$ TeV with 139 fb^{-1} data. The quoted results are given for $m_H = 125.09$ GeV and $|y(H)| < 2.5$ is required. The inclusive fiducial $\sigma \cdot B$ is $2.94 \pm 0.21^{+0.37}_{-0.32}$ pb. The fiducial $\sigma \cdot B$ for the four dominant production modes are $2.65 \pm 0.41^{+0.91}_{-0.67}$ pb for ggF, $0.197 \pm 0.028^{+0.032}_{-0.026}$ pb for VBF, $0.115 \pm 0.058^{+0.042}_{-0.040}$ pb for VH, $0.033 \pm 0.031^{+0.022}_{-0.017}$ pb for $t\bar{t}H$. The cross sections using simplified template cross section framework (STXS) are given in their Fig. 14(a) and Table 15. The STXS bins (a reduced stage 1.2) are defined in their Fig. 1.

[15] TUMASYAN 22AJ measure cross sections with $pp \to H \to \tau\tau$ at $E_{cm} = 13$ TeV with 138 fb^{-1} data. The fiducial inclusive $\sigma \cdot B$ is 426 ± 102 fb while 408 ± 27 fb is expected in the Standard Mode for $m_H = 125.38$ GeV. Three differential cross sections are given; see their Fig. 1.

[16] SIRUNYAN 19AF use 35.9 fb^{-1} of data. The quoted signal strength is given for $m_H = 125$ GeV and corresponds to 2.3 standard deviations.

[17] SIRUNYAN 19AF use 35.9 fb^{-1} of data. HW/Z channels are added with a few updates on gluon fusion and vector boson fusion with respect to SIRUNYAN 18Y. The quoted signal strength is given for $m_H = 125$ GeV and corresponds to 5.5 standard deviations. The signal strengths for the individual production modes are: $1.12^{+0.53}_{-0.50}$ for gluon fusion, $1.13^{+0.45}_{-0.42}$ for vector boson fusion, $3.39^{+1.68}_{-1.54}$ for WH and $1.23^{+1.62}_{-1.35}$ for ZH. See their Fig. 7 for other couplings (κ_V, κ_f).

[18] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV. This combination is based on SIRUNYAN 18Y.

[19] SIRUNYAN 18Y use 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125.09$ GeV and corresponds to 4.9 standard deviations.

[20] SIRUNYAN 18Y combine the result of 35.9 fb^{-1} at $E_{cm} = 13$ TeV with the results obtained from data of 4.9 fb^{-1} at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV (KHACHATRYAN 15AM). The quoted signal strength is given for $m_H = 125.09$ GeV and corresponds to 5.9 standard deviations.

[21] AAD 16AC measure the signal strength with $pp \to HW/ZX$ processes using 20.3 fb^{-1} of $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[22] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.36$ GeV.

[23] AAD 15AH use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The third uncertainty in the measurement is theory systematics. The signal strength for the gluon fusion mode is $2.0 \pm 0.8^{+1.2}_{-0.8} \pm 0.3$ and that for vector boson fusion and W/ZH production modes is $1.24^{+0.49}_{-0.45}{}^{+0.31}_{-0.29} \pm 0.08$. The quoted signal strength is given for $m_H = 125.36$ GeV.

[24] CHATRCHYAN 14K use 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125$ GeV. See also CHATRCHYAN 14AJ.

[25] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[26] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[27] AAD 12AI obtain results based on 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The quoted signal strengths are given in their Fig. 10 for $m_H = 126$ GeV. See also Fig. 13 of AAD 12DA.

[28] CHATRCHYAN 12N obtain results based on 4.9 fb^{-1} of pp collisions at E_{cm}=7 TeV and 5.1 fb^{-1} at E_{cm}=8 TeV. The quoted signal strength is given for m_H=125.5 GeV. See also CHATRCHYAN 13Y .

[1] AAD 24D report combined results of ATLAS (AAD 20AG) and CMS (TUMASYAN 23F). The reported signal strength corresponds to a significance of 3.4 σ.

[2] TUMASYAN 23F search for $H \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV. $\sigma(pp \to H) \cdot B(H \to Z\gamma)$ is measured to be 0.21 ± 0.08 pb. The ratio of branching fractions $B(H \to Z\gamma)/B(H \to \gamma\gamma)$ is measured to be $1.5^{+0.7}_{-0.6}$.

[3] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV. See their Fig. 2 right.

[4] AAD 20AG search for $H \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The signal strength is $2.0 \pm 0.9^{+0.4}_{-0.3}$ at $m_H = 125.09$ GeV, which corresponds to a significance of 2.2 σ. The upper limit of $\sigma(pp \to H) \cdot B(H \to Z\gamma)$ is 305 fb at 95% CL.

[5] SIRUNYAN 18DQ search for $H \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength (see their Figs. 6 and 7) is given for $m_H = 125$ GeV.

[6] AABOUD 17AW search for $H \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125.09$ GeV. The upper limit on the branching ratio of $H \to Z\gamma$ is 1.0% at 95% CL assuming the SM Higgs boson production.

[7] AAD 14J search for $H \to Z\gamma \to \ell\ell\gamma$ in 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.5$ GeV.

[8] CHATRCHYAN 13BK search for $H \to Z\gamma \to \ell\ell\gamma$ in 5.0 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.6 fb^{-1} at $E_{cm} = 8$ TeV. A limit on cross section times branching ratio which corresponds to (4–25) times the expected Standard Model cross section is given in the range $m_H = 120$–160 GeV at 95% CL. The quoted limit is given for $m_H = 125$ GeV, where 10 is expected for no signal.

[1] AAD 21I search for $H \to \ell\ell\gamma$ ($\ell = e$, μ) in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The mass of dilepton $m_{\ell\ell}$ is smaller than 30 GeV. This region is dominated by the decay through γ^*. The quoted signal strength corresponds to a significance of 3.2 standard deviations and is given for $m_H = 125.09$ GeV. The cross section times the branching ratio of $H \to \ell\ell\gamma$ for $m_{\ell\ell} < 30$ GeV is measured to be $8.7 \pm 2.7^{+0.7}_{-0.6}$ fb.

[2] SIRUNYAN 18DQ search for $H \to \gamma^*\gamma$, $\gamma^* \to \mu\mu$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The mass of γ^* is smaller than 50 GeV except in J/ψ and Υ mass regions. The quoted signal strength (see their Figs. 6 and 7) is given for $m_H = 125$ GeV.

[3] KHACHATRYAN 16B search for $H \to \gamma^*\gamma \to e^+e^-\gamma$ and $\mu^+\mu^-\gamma$ (with $m(e^+e^-) < 3.5$ GeV and $m(\mu^+\mu^-) < 20$ GeV) in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 6 for limits on individual channels.

[1] HAYRAPETYAN 25R measure the $t\overline{t}H$ and tH productions with $H \to b\overline{b}$ decay channel using 138 fb^{-1} of data at $E_{cm} = 13$ TeV. Two-dimensional likelihood scan of (κ_t, κ_V) is shown in their Fig. 15. Assuming $\kappa_V = 1$, κ_t is measured to be $[-0.55, -0.24]$ and $[0.20, 0.72]$ at 68% CL.

[2] AAD 24J measure the CP structure of the top Yukawa coupling using 139 fb^{-1} of data at $E_{cm} = 13$ TeV. The top Yukawa coupling strength modifier κ_t is measured with the CP-mixing angle α. See their Fig. 3.

[3] AAD 23BC measure the production of four top quarks with same-sign and multilepton final states with 140 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The results constraint the ratio of the top quark Yukawa coupling y_t to its Standard Model value, yielding $|y_t/y_t^{SM}| < 1.9$ (see their erratum) at 95% CL. See their Fig. 8 as a function of κ_t and CP-mixing angle.

[4] AAD 23Y constrain κ_t from Higgs production rates with $H \to \gamma\gamma$ with 139 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The quoted result is obtained assuming the SM loop structure in $gg \to H$ and $H \to \gamma\gamma$. See their Fig. 14.

[5] AAD 23Y constrain κ_t from Higgs production rates with $H \to \gamma\gamma$ with 139 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The quoted result is obtained assuming effective couplings κ_{gluon} and κ_γ for $gg \to H$ and $H \to \gamma\gamma$, respectively. See their Fig. 14.

[6] TUMASYAN 23P constrain κ_t from $t\overline{t}H$ and tH decaying $H \to WW^*$ and $H \to \tau\tau$ (multilepton decay mode) with 138 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The κ_t is obtained by fixing $\widetilde{\kappa}_t = 0$ and other couplings (κ_V etc.) to the SM values. See their Fig. 9 for 2-dim contours and Table 6.

[7] The quoted result is obtained by combining with other $t\overline{t}H$ decaying $H \to \gamma\gamma$ (SIRUNYAN 20AS) and $H \to 4\ell$ (SIRUNYAN 21AE) and $\widetilde{\kappa}_t = 0$. See their Fig. 12 for 2-dim contours and Table 7.

[8] ATLAS 22 report combined results (see their Extended Data Table 1) using up to 139 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.09$ GeV.

[9] All modifiers(κ) > 0, and $\kappa_c = \kappa_t$ ($B_{inv} = B_{undetected} = 0$) are assumed. Only SM particles assume to contribute to the loop-induced processes.See their Fig. 5, which shows both $\kappa_c = \kappa_t$ andκ_c floating.

[10] $B_{inv} = B_{undetected} = 0$ is assumed. Coupling strength modifiers including effective photon, $Z\gamma$ and gluon are measured. See their Fig. 6.

[11] B_{inv} floating, $B_{undetected} \geq 0$, and $\kappa_V \leq 1$ are assumed. Coupling strength modifiers including effective photon, $Z\gamma$ and gluon are measured. See their Fig. 6.

[12] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV.

[13] Only SM particles assume to contribute to the loop-induced processes. See their Fig. 3 right.

[14] Coupling strength modifiers including effective photon, $Z\gamma$ and gluon are measured. See their Fig. 4 left.

[15] SIRUNYAN 21R constrain the ratio of the top quark Yukawa coupling y_t to its Standard Model value from $t\overline{t}H$ and tH production rates using 137 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. Assuming a SM Higgs couplings to τ's, the joint interval $-0.9 < \kappa_t(=y_t/y_t^{SM}) < -0.7$ and $0.7 < \kappa_t < 1.1$ is obtained at 95% CL (see their Fig. 17).

[16] SIRUNYAN 20C search for the production of four top quarks with same-sign and multilepton final states with 137 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The results constraint the ratio of the top quark Yukawa coupling y_t to its Standard Model value by comparing to the central value of a theoretical prediction (see their Refs. [1-2]), yielding $|y_t/y_t^{SM}| < 1.7$ at 95% CL. See their Fig. 5.

[17] SIRUNYAN 19BY measure the top quark Yukawa coupling from $t\overline{t}$ kinematic distributions, the invariant mass of the top quark pair and the rapidity difference between t and $\overline{t}$, in the ℓ+jets final state with 35.8 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The results constraint the ratio of the top quark Yukawa coupling to its the Standard Model to be $1.07^{+0.34}_{-0.43}$ with an upper limit of 1.67 at 95% CL (see their Table III).

[18] SIRUNYAN 18BU search for the production of four top quarks with same-sign and multilepton final states with 35.9 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The results constraint the ratio of the top quark Yukawa coupling y_t to its the Standard Model by comparing to the central value of a theoretical prediction (see their Ref. [16]), yielding $|y_t/y_t^{SM}| < 2.1$ at 95% CL.

[1] AAD 25Y present measurements of VH, $H \to b\overline{b}$ and $H \to c\overline{c}$ ($V = W$, Z) using 140 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted value is obtained assuming $\kappa_c = 1$, all other couplings to their SM predictions, and only SM decays.

[2] AAD 23C combine results of $H \to \gamma\gamma$ and $H \to ZZ^* \to 4\ell$ ($\ell = e$, μ) using 139 fb^{-1} at $E_{cm} = 13$ TeV. The Higgs boson transverse momentum (p_T^H) distribution constrains κ_b and κ_c, assuming other couplings fixed to the SM values. The κ_b is obtained using the p_T^H shape and normalisation. Other cases are given in their Tables 6 and 7.

[3] AAD 23CD search for $H \to \Upsilon(nS)\gamma$, $\Upsilon(nS) \to \mu^+\mu^-$ (n=1,2,3) with 138 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. They interpret the $H \to \Upsilon(nS)\gamma$ search to constraint the bottom Yukawa coupling by comparing to $H \to \gamma\gamma$. An observed 95% CL interval of (-37, 40) is obtained for κ_b/κ_γ.

[4] HAYRAPETYAN 23 measure the cross sections for $pp \to H \to ZZ^* \to 4\ell$ ($\ell = e$, μ) using 138 fb^{-1} at $E_{cm} = 13$ TeV. The κ_b is obtained from the p_T differential cross section of the ggF production employing the dependence of the branching fraction on κ_b and κ_c.

[1] HAYRAPETYAN 26 search for $t\bar{t}H$, $H \to c\bar{c}$ together with the $t\bar{t}H$, $H \to b\bar{b}$ measurement using 138 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted value is obtained by combining with the VH channel and assuming $\kappa_b = 1$.

[2] AAD 25Y present measurements of VH, $H \to b\bar{b}$ and $H \to c\bar{c}$ ($V = W,\ Z$) using 140 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted value is obtained assuming $\kappa_b = 1$, all other couplings to their SM predictions, and only SM decays. The ratio of κ_b and κ_c is measured to be $\lvert\kappa_c/\kappa_b\rvert < 3.6$ at 95% CL.

[3] CHEKHOVSKY 25G search for the $H\gamma$ production with $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) decay channel with data of 138 fb^{-1} at E_{cm} = 13 TeV. Coupling modifiers κ_u, κ_d, κ_s and κ_c are simultaneously obtained assuming the SM Yukawa couplings for the bottom and top quarks ($\kappa_b = 1$, κ_t =1) and constraining the HVV couplings ($\kappa^2_{ZZ} \leq 1$, $\kappa^2_{WW} = \kappa^2_{ZZ}$). See their Tables III.

[4] CHEKHOVSKY 25L search for the production of a Higgs boson and one or more charm quarks (H+c) with $H \to \gamma\gamma$ using 138 fb^{-1} of data at E_{cm} = 13 TeV. The quoted value is obtained assuming the SM rates for all other Higgs production processes.

[5] HAYRAPETYAN 25H search for $H \to J/\psi\gamma$, $J/\psi \to \mu^+\mu^-$ with 123 fb^{-1} of pp collision data at E_{cm} = 13 TeV. They interpret the $H \to J/\psi\gamma$ search to constrain the charm Yukawa coupling by comparing to $H \to \gamma\gamma$. An observed 95% CL interval of (-157, 199) is obtained for κ_c/κ_γ. The quoted value is obtained assuming $\kappa_\gamma = 1$.

[6] HAYRAPETYAN 24D search for the $H\gamma$ production using $H \to WW^* \to e\nu\mu\nu$ with 138 fb^{-1} of pp collision data at E_{cm} = 13 TeV. They interpret the $H\gamma$ search to constraint the charm Yukawa coupling assuming that the charm quark and the Higgs interaction vertex shown in their Fig. 1 is the only parameter. See their Table II.

[7] AAD 23C combine results of $H \to \gamma\gamma$ and $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) using 139 fb^{-1} at E_{cm} = 13 TeV. The Higgs boson transverse momentum (p_T^H) distribution constrains κ_b and κ_c, assuming other couplings fixed to the SM values. The κ_c is obtained using the p_T^H shape and normalisation. Other cases are given in their Tables 6 and 7. See their Table 8 for results combined with VH, $H \to b\bar{b}$ and $c\bar{c}$.

[8] AAD 23CD search for $H \to J/\psi\gamma$, $J/\psi \to \mu^+\mu^-$ with 138 fb^{-1} of pp collision data at E_{cm} = 13 TeV. They interpret the $H \to J/\psi\gamma$ search to constraint the charm Yukawa coupling by comparing to $H \to \gamma\gamma$. An observed 95% CL interval of (-133, 175) is obtained for κ_c/κ_γ.

[9] HAYRAPETYAN 23 measure the cross sections for $pp \to H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) using 138 fb^{-1} at E_{cm} = 13 TeV. The κ_c is obtained from the p_T differential cross section of the ggF production employing the dependence of the branching fraction of κ_b and κ_c.

[10] TUMASYAN 23AH search for VH, $H \to c\bar{c}$ ($V = W,\ Z$) using 138 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted values are obtained from the measured signal strength in the κ-framework, where only the Higgs decay width for $H \to c\bar{c}$ is changed while assuming all the other decay widths and the production cross section to be SM ones. The quoted values are given for m_H = 125.38 GeV.

[11] ATLAS 22 report combined results (see their Extended Data Table 1) using up to 139 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.09 GeV, and all modifiers (κ) > 0 ($B_{inv} = B_{undetected} = 0$). Only SM particles assume to contribute to the loop-induced processes. See their Fig. 5, which shows both $\kappa_c = \kappa_t$ and κ_c floating.

[1] AAD 25AJ measure the $t\bar{t}H$ production with $H \to b\bar{b}$ decay channel using 140 fb^{-1} of data at $E_{cm} = 13$ TeV. The $t\bar{t}H$ cross section is measured to be 411^{+101}_{-92} fb for a Higgs boson mass of 125.09 GeV. The signal strengths with simplified template cross section bins are given in their Fig. 3.
[2] HAYRAPETYAN 25R measure the $t\bar{t}H$ and tH productions with $H \to b\bar{b}$ decay channel using 138 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted value is obtained assuming the tH contribution predicted in the SM. The signal strengths with simplified template cross section bins are given in their Fig. 12. Two-dimensional likelihood scan of $(\mu_{tH}, \mu_{t\bar{t}H})$ is shown in their Fig. 14.
[3] SIRUNYAN 21R search for $t\bar{t}H$ in final states with electrons, muons and hadronically decaying τ leptons ($H \to WW^*$, ZZ^*, $\tau\tau$) with 137 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 4.7 standard deviations and is given for $m_H = 125$ GeV.
[4] AAD 20Z measure $\sigma_{t\bar{t}H} \cdot B(H \to \gamma\gamma)$ to be $1.64^{+0.38+0.17}_{-0.36-0.14}$ fb in 139 fb^{-1} of data at $E_{cm} = 13$ TeV.
[5] AABOUD 18AC search for $t\bar{t}H$ production with H decaying to $\tau\tau$, $WW^*(\to \ell\nu\ell\nu, \ell\nu q\bar{q})$, $ZZ^*(\to \ell\ell\nu\nu, \ell\ell q\bar{q})$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV. See their Table 13 and Fig. 13.
[6] AAD 16AN: In the fit, relative branching ratios are fixed to those in the Standard Model. The quoted signal strength is given for $m_H = 125.09$ GeV.
[7] HAYRAPETYAN 26 search for $t\bar{t}H$, $H \to c\bar{c}$ together with the $t\bar{t}H$, $H \to b\bar{b}$ measurement using 138 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV.
[8] TUMASYAN 23AI measure boosted $H \to b\bar{b}$ ($p_T > 200$ GeV) in $t\bar{t}H$ production using 138 fb^{-1} of data at $E_{cm} = 13$ TeV. The differential cross section for the Higgs p_T is shown in their Fig. 8 and Table V. Limits on eight Wilson coefficients at 68% and 95% CL are shown in their Fig. 10 and Table VI.
[9] AAD 22M measure $H \to b\bar{b}$ in $t\bar{t}H$ production using 139 fb^{-1} of data at $E_{cm} = 13$ TeV. See their Fig. 14. The signal strengths and 95% CL cross section upper limits with simplified template cross section bins are given in their Figs. 18 and 19, respectively.
[10] SIRUNYAN 20AS measure $\sigma_{t\bar{t}H} \cdot B(H \to \gamma\gamma)$ to be $1.56^{+0.34}_{-0.32}$ fb in 137 fb^{-1} of data at $E_{cm} = 13$ TeV.
[11] SIRUNYAN 19R search for $t\bar{t}H$ production with H decaying to $b\bar{b}$ in 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.
[12] AABOUD 18AC combine results of $t\bar{t}H$, $H \to \tau\tau$, $WW^*(\to \ell\nu\ell\nu, \ell\nu q\bar{q})$, $ZZ^*(\to \ell\ell\nu\nu, \ell\ell q\bar{q})$ with results of $t\bar{t}H$, $H \to b\bar{b}$ (AABOUD 18T), $\gamma\gamma$ (AABOUD 18BO), $ZZ^*(\to 4\ell)$ (AABOUD 18AJ) in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV. See their Table 14.
[13] AABOUD 18BK use 79.8 fb^{-1} data for $t\bar{t}H$ production with $H \to \gamma\gamma$ and $ZZ^* \to 4\ell$ ($\ell = e, \mu$) and 36.1 fb^{-1} for other decay channels at $E_{cm} = 13$ TeV. A significance of 5.8 standard deviations is observed for $m_H = 125.09$ GeV and its signal strength without the uncertainty of the $t\bar{t}H$ cross section is $1.32^{+0.28}_{-0.26}$. Combining with results of 7 and 8 TeV (AAD 16K), the significance is 6.3 standard deviations. Assuming Standard Model branching fractions, the total $t\bar{t}H$ production cross section at 13 TeV is measured to be $670 \pm 90^{+110}_{-100}$ fb.
[14] AABOUD 18T search for $t\bar{t}H$ production with H decaying to $b\bar{b}$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[15] SIRUNYAN 18BD search for $t\bar{t}H$, $H \to b\bar{b}$ in the all-jet final state with 35.9 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[16] SIRUNYAN 18BQ search for $t\bar{t}H$ in final states with electrons, muons and hadronically decaying τ leptons ($H \to WW^*$, ZZ^*, $\tau\tau$) with 35.9 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 3.2 standard deviations and is given for $m_H = 125$ GeV.

[17] SIRUNYAN 18L use up to 5.1, 19.7 and 35.9 fb^{-1} of pp collisions at $E_{cm} = 7$, 8, and 13 TeV, respectively. The quoted signal strength corresponds to a significance of 5.2 standard deviations and is given for $m_H = 125.09$ GeV. H decay channels of WW^*, ZZ^*, $\gamma\gamma$, $\tau\tau$, and $b\bar{b}$ are used. See their Table 1 and Fig. 2 for results on individual channels.

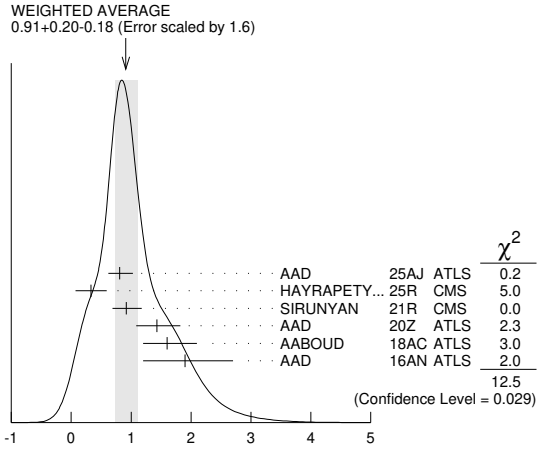
[18] AAD 16AL search for $t\bar{t}H$ production with H decaying to $\gamma\gamma$ in 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and $b\bar{b}$, $\tau\tau$, $\gamma\gamma$, WW^*, and ZZ^* in 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125$ GeV. This paper combines the results of previous papers, and the new result of this paper only is: $\mu = 1.6 \pm 2.6$.

[19] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV.

[20] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The third uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_H = 125.36$ GeV.

[21] AAD 15 search for $t\bar{t}H$ production with H decaying to $\gamma\gamma$ in 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted result on the signal strength is equivalent to an upper limit of 6.7 at 95% CL and is given for $m_H = 125.4$ GeV.

[22] AAD 15BC search for $t\bar{t}H$ production with H decaying to $b\bar{b}$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The corresponding upper limit is 3.4 at 95% CL. The quoted signal strength is given for $m_H = 125$ GeV.



[23] AAD 15T search for $t\bar{t}H$ production with H resulting in multilepton final states (mainly from WW^*, $\tau\tau$, ZZ^*) in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The quoted result on the signal strength is given for $m_H = 125$ GeV and corresponds to an upper limit of 4.7 at 95% CL. The data sample is independent from AAD 15 and AAD 15BC.

[24] KHACHATRYAN 15AN search for $t\bar{t}H$ production with H decaying to $b\bar{b}$ in 19.5 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The quoted result on the signal strength is equivalent to an upper limit of 4.2 at 95% CL and is given for $m_H = 125$ GeV.

[25] KHACHATRYAN 14H search for $t\bar{t}H$ production with H decaying to $b\bar{b}$, $\tau\tau$, $\gamma\gamma$, WW^*, and ZZ^*, in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.6$ GeV.

[26] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[27] CHATRCHYAN 13X search for $t\bar{t}H$ production followed by $H \to b\bar{b}$, one top decaying to $\ell\nu$ and the other to either $\ell\nu$ or $q\bar{q}$ in 5.0 fb^{-1} and 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ and 8 TeV. A limit on cross section times branching ratio which corresponds to (4.0–8.6) times the expected Standard Model cross section is given for $m_H = 110$–140 GeV at 95% CL. The quoted limit is given for $m_H = 125$ GeV, where 5.2 is expected for no signal.

$t\bar{t}H$ production

$b\bar{b}H$ production

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<3.7	95	[1] HAYRAPETY...25	CMS	pp, 13 TeV, $H \to \tau\tau$, WW^*

[1] HAYRAPETYAN 25 search for $b\bar{b}H$ and bH in final states with leptons using 138 fb^{-1} of data at $E_{cm} = 13$ TeV. $H \to \tau\tau$ or $H \to WW^* \to \ell\nu\ell\nu$ are considered. Upper limits at 95% CL on the signal strength for each final state are found in their Fig. 3. Combing with TUMASYAN 23Y, two-dimensional exclusion regions as a function of the κ_b and κ_t parameters are shown in their Fig. 4. The best fit value is $(\kappa_t, \kappa_b) = (-0.73, 1.58)$. All other Higgs couplings are fixed to the SM values.

[1] AAD 25BD search for tH in final states with leptons (electron or muon) ($H \to b\bar{b}$, WW^*, ZZ^*, $\tau\tau$) with 140 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to the cross-section of $\sigma(tH) = 720 \pm 270$ fb and a significance of 2.8 standard deviations.

[2] SIRUNYAN 21R search for tH in final states with electrons, muons and hadronically decaying τ leptons ($H \to WW^*$, ZZ^*, $\tau\tau$) with 137 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 1.4 standard deviations and is given for $m_H = 125$ GeV.

[3] AAD 25BD search for tH in final states with leptons (electron or muon) ($H \to b\bar{b}$, WW^*, ZZ^*, $\tau\tau$) with 140 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV.

[4] HAYRAPETYAN 25R measure the $t\bar{t}H$ and tH productions with $H \to b\bar{b}$ decay channel using 138 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted value is obtained assuming the $t\bar{t}H$ contribution predicted in the SM. Two-dimensional likelihood scan of $(\mu_{tH}, \mu_{t\bar{t}H})$ is shown in their Fig. 14.

[5] AAD 20Z search for the tH associated production using $H \to \gamma\gamma$ in 139 fb^{-1} of data at $E_{cm} = 13$ TeV. An upper limit on its rate is set to be 12 times the Standard Model at 95% CL ($m_H = 125.09$ GeV).

[6] SIRUNYAN 19BK search for the tH associated production using multilepton signatures ($H \to WW^*$, $H \to \tau\tau$, $H \to ZZ^*$) and signatures with a single lepton and a $b\bar{b}$ pair ($H \to b\bar{b}$) using 35.9 fb^{-1} at $E_{cm} = 13$ TeV. Results are combined with $H \to \gamma\gamma$ (SIRUNYAN 18DS). The observed 95% CL upper limit on the tH production cross section times $H \to WW^* + \tau\tau + ZZ^* + b\bar{b} + \gamma\gamma$ branching fraction is 1.94 pb (assuming SM $t\bar{t}H$ production cross section). See their Table X and Fig. 14. The values outside the ranges of $[-0.9, -0.5]$ and $[1.0, 2.1]$ times the standard model top quark Yukawa coupling are excluded at 95% CL.

[7] KHACHATRYAN 16AU search for the tH associated production in 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The 95% CL upper limits on the tH associated production cross section is measured to be 600–1000 fb depending on the assumed $\gamma\gamma$ branching ratios of the Higgs boson. The $\gamma\gamma$ branching ratio is varied to be by a factor of 0.5–3.0 of the Standard Model Higgs boson ($m_H = 125$ GeV). The results of the signal strengths for a negative Higgs-boson trilinear coupling are given. The results are given for $m_H = 125$ GeV.

<14.3	95	[1] HAYRAPETY...25B	CMS	pp, 13 TeV, VBF WH, coupling sign
< 9.0	95	[2] AAD 24BM	ATLS	pp, 13 TeV, VBF WH, coupling sign

[1] HAYRAPETYAN 25B present the determination of the relative sign of κ_W and κ_Z with VBF WH, $H \to b\bar{b}$ using 148 fb^{-1} of data at $E_{cm} = 13$ TeV. The upper limit at 95% CL on the cross section for VBF WH production is obtained. The signal strength is measured to be $2.2^{+6.1}_{-5.8}$.

[2] AAD 24BM present the determination of the relative sign of κ_W and κ_Z with VBF WH, $H \to b\bar{b}$ using 140 fb^{-1} of data at $E_{cm} = 13$ TeV. The upper limit at 95% CL on the cross section for VBF WH production is obtained. The signal strength is measured to be $0.9^{+4.0}_{-4.3}$.

γH production

	[1] CHEKHOVSKY 25G	CMS	pp, 13 TeV, $H \to b\bar{b}$, $H \to ZZ^* \to 4\ell$

[1] CHEKHOVSKY 25G search for the γH production using a boosted Higgs boson recoiling against a high-energy photon with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. The production cross section is constraint to be $\sigma_{\gamma H} < 16.4$ fb at 95% CL. Constraints on four anomalous couplings involving $HZ\gamma$ and $H\gamma\gamma$ are shown in their Table I.

HH production

The HH production cross section relative to the SM prediction.

[1] AAD 23AT combine results from 126–139 fb^{-1} of data at E_{cm} = 13 TeV for $pp \to HH \to b\bar{b}b\bar{b}$ (AAD 23BK), $b\bar{b}\tau\tau$ (AAD 23Z), and $b\bar{b}\gamma\gamma$ (AAD 22Y).

[2] AAD 24AZ search for non-resonant HH production using $HH \to b\bar{b}\tau\tau$ with data of 140 fb^{-1} at E_{cm} = 13 TeV. The result is interpreted: limits on Wilson coefficients of the Higgs effective field theory (HEFT) and the SM effective field theory (SMEFT) are shown in their Table IV and Figs. 11 and 12; the ggF HH production cross sections (7 benchmark points) of HEFT are shown in their Fig. 10. In those interpretations the VBF HH production is neglected.

[3] AAD 24BG search for non-resonant HH production targeting the $b\bar{b}ZZ^*$, VVVV, $VV\tau\tau$, $\tau\tau\tau\tau$, $\gamma\gamma VV$, $\gamma\gamma\tau\tau$ decay channels with data of 140 fb^{-1} at E_{cm} = 13 TeV. Signal strengths for the 11 different signal regions are given in their Fig. 8.

[4] AAD 24BL combine results from 126–140 fb^{-1} of data at E_{cm} = 13 TeV for $pp \to HH \to b\bar{b}b\bar{b}$ (AAD 23BK, AAD 24BV), $b\bar{b}\tau\tau$ (AAD 24AZ), $b\bar{b}\gamma\gamma$ (AAD 24X), multilepton (AAD 24BG), and $b\bar{b}\ell\ell$ (AAD 24Y). See their Fig. 2. The signal strength is measured to be $0.5^{+1.2}_{-1.0}$. Constraints for three interaction parameters (c_{tthh}, c_{gghh}, c_{hhh}) in the Higgs effective field theory are set. See their Fig. 4.

[5] AAD 24X search for non-resonant HH production using $HH \to b\bar{b}\gamma\gamma$ with data of 140 fb^{-1} at E_{cm} = 13 TeV. The result is interpreted: limits on three Wilson coefficients and the ggF HH production cross sections (7 benchmark points shown in their Table 5) of the Higgs effective field theory are shown in their Table 4 and Fig. 8, respectively; limits on two Wilson coefficients of the SM effective field theory are shown in their Table 6 and Fig. 9. In those interpretations only the ggF HH production is considered instead of both ggF and VBF.

[6] AAD 24Y search for non-resonant HH production in $2b + 2\ell + \nu$s final state ($\ell = e, \mu$) targeting $b\bar{b}WW^*$, $b\bar{b}ZZ^*$, and $b\bar{b}\tau\tau$ decay channels with data of 140 fb^{-1} at E_{cm} = 13 TeV. The signal strength is measured to be $-8.5^{+7.7}_{-8.4}$. See their Fig. 6.

[7] HAYRAPETYAN 24AE search for non-resonant HH production using $HH \to b\bar{b}WW^*$ with data of 138 fb^{-1} at E_{cm} = 13 TeV. The result is interpreted: the ggF HH production cross sections (20 benchmark points) of the Higgs effective field theory are shown in their Fig. 16; the coupling between two top quarks and two Higgs bosons is constrained between [-0.8, 1.3] at 95%CL (see their Fig. 17) with all other Higgs couplings fixed to the SM values.

[8] HAYRAPETYAN 24AW search for non-resonant HH production in association with a vector boson using $HH \to b\bar{b}b\bar{b}$ with data of 138 fb^{-1} at E_{cm} = 13 TeV. The vector boson decays both leptonically ($W \to \ell\nu$, $Z \to \ell\ell$, $\nu\nu$, $\ell = e, \mu$) and hadronically. The quoted value is the upper limit of the VHH cross section. See their Figs. 13 and 16 (left) for the best fit and the upper limit of the VHH cross section, respectively. In addition, upper limits at 95% CL on VHH and HH cross sections are shown as a function of κ_λ, κ_{2V}, and κ_V in their Figs. 17, 18, and 19.

[9] AAD 23AD search for non-resonant HH production in association with a vector boson using $HH \to b\bar{b}b\bar{b}$ with data of 139 fb^{-1} at E_{cm} = 13 TeV. The vector boson decays leptonically ($W \to \ell\nu$, $Z \to \ell\ell$, $\nu\nu$, $\ell = e, \mu$).

[10] AAD 23BK search for non-resonant HH production using $HH \to b\bar{b}b\bar{b}$ with data of 126 fb^{-1} at E_{cm} = 13 TeV.

[11] AAD 23Z search for non-resonant HH production using $HH \to b\bar{b}\tau\tau$ with data of 139 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is measured to be 140 fb, which corresponds to 4.7 times the SM prediction (see their Table 6).

[12] TUMASYAN 23AE search for HH production using $HH \to b\bar{b}b\bar{b}$, where both $b\bar{b}$ pairs are highly boosted, with data of 138 fb^{-1} at E_{cm} = 13 TeV.

[13] TUMASYAN 23D search for non-resonant HH production using $HH \to b\bar{b}\tau\tau$ with data of 138 fb^{-1} at E_{cm} = 13 TeV.

[14] The upper limit on the $pp \to HH$ production cross section (gluon fusion and VBF) at 95% CL is measured to be 102 fb, which corresponds to 3.3 times the SM prediction (see their Table 2).

[15] The upper limit on the VBF $pp \to HH$ production cross section at 95% CL is measured to be 212 fb, which corresponds to 124 times the SM prediction (see their Table 3).

[16] TUMASYAN 23I search for non-resonant HH production using $HH \to b\bar{b}ZZ^*$ ($ZZ^* \to 4\ell$, $\ell = e, \mu$) with data of 138 fb^{-1} at E_{cm} = 13 TeV.

[17] TUMASYAN 23O search for non-resonant HH production using $HH \to WW^*WW^*$, $WW^*\tau\tau$, and $\tau\tau\tau\tau$ (multilepton) with data of 138 fb^{-1} at E_{cm} = 13 TeV. See their Fig. 9 for different final states and these combination.

[18] AAD 22Y search for non-resonant HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 139 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is measured to be 130 fb, which corresponds to 4.2 times the SM prediction.

[19] CMS 22 report combined results (see their Extended Data Table 2) using 138 fb^{-1} of data at E_{cm} = 13 TeV. See their Fig. 5 (left) for different final states and these combination.

[20] TUMASYAN 22AN search for non-resonant HH production using $HH \to b\bar{b}b\bar{b}$ with data of 138 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is measured to be 120 fb, which corresponds to 3.9 times the SM prediction.

[21] SIRUNYAN 21K search for non-resonant HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 137 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to \gamma\gamma b\bar{b}$ production cross section at 95% CL is measured to be 0.67 fb, which corresponds to about 7.7 times the SM prediction.

[22] AAD 20C combine results of up to 36.1 fb^{-1} data at E_{cm} = 13 TeV for $pp \to HH \to b\bar{b}\gamma\gamma$, $b\bar{b}\tau\tau$, $b\bar{b}b\bar{b}$, $b\bar{b}WW^*$, $WW^*\gamma\gamma$, WW^*WW^* (AABOUD 18CW, AABOUD 18CQ, AABOUD 19A, AABOUD 19O, AABOUD 18BU, and AABOUD 19T).

[23] AAD 20E search non-resonant for HH production using $HH \to b\bar{b}\ell\nu\ell\nu$, where one of the Higgs bosons decays to $b\bar{b}$ and the other decays to either WW^*, ZZ^*, or $\tau\tau$, with data of 139 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is measured to be 1.2 pb, which corresponds to about 40 times the SM prediction.

[24] AAD 20X search for $HH \to b\bar{b}b\bar{b}$ process via VBF with data of 126 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the SM non-resonant HH production cross section is 1460 fb at 95% CL, which corresponds to 840 times the SM prediction.

[25] AABOUD 19A search for HH production using $HH \to b\bar{b}b\bar{b}$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to b\bar{b}b\bar{b}$ production cross section at 95% is measured to be 147 fb, which corresponds to about 12.9 times the SM prediction.

[26] AABOUD 19O search for HH production using $HH \to b\bar{b}WW^*$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is calculated to be 10 pb from the observed upper limit on the $pp \to HH \to b\bar{b}WW^*$ production cross section of 2.5 pb assuming the SM branching fractions. The former corresponds to about 300 times the SM prediction.

[27] AABOUD 19T search for HH production using $HH \to WW^*WW^*$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% is measured to be 5.3 pb, which corresponds to about 160 times the SM prediction.

[28] SIRUNYAN 19 search for HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to \gamma\gamma b\bar{b}$ production cross section at 95% CL is measured to be 2.0 fb, which corresponds to about 24 times the SM prediction.

[29] SIRUNYAN 19AB search for HH production using $HH \to b\bar{b}b\bar{b}$, where 4 heavy flavor jets from two Higgs bosons are resolved, with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to b\bar{b}b\bar{b}$ production cross section at 95% is measured to be 847 fb, which corresponds to about 75 times the SM prediction.

[30] SIRUNYAN 19BE combine results of 13 TeV 35.9 fb^{-1} data: SIRUNYAN 19, SIRUNYAN 18A, SIRUNYAN 19AB, SIRUNYAN 19H, and SIRUNYAN 18F.

[31] SIRUNYAN 19H search for HH production using $HH \to b\bar{b}b\bar{b}$, where one of $b\bar{b}$ pairs is highly boosted and the other one is resolved, with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to b\bar{b}b\bar{b}$ production cross section at 95% is measured to be 1980 fb, which corresponds to about 179 times the SM prediction.

[32] AABOUD 18BU search for HH production using $\gamma\gamma WW^*$ with the final state of $\gamma\gamma\ell\nu jj$ using data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is measured to be 7.7 pb, which corresponds to about 230 times the SM prediction. The upper limit on the $pp \to HH \to \gamma\gamma WW^*$ at 95% CL is measured to be 7.5 fb (see thier Table 6).

[33] AABOUD 18CQ search for HH production using $HH \to b\bar{b}\tau\tau$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to b\bar{b}\tau\tau$ production cross section at 95% is measured to be 30.9 fb, which corresponds to about 12.7 times the SM prediction.

[34] AABOUD 18CW search for HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% is measured to be 0.73 pb, which corresponds to about 22 times the SM prediction.

[35] SIRUNYAN 18A search for HH production using $HH \to b\bar{b}\tau\tau$ with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $gg \to HH \to b\bar{b}\tau\tau$ production cross section is measured to be 75.4 fb, which corresponds to about 30 times the SM prediction.

[36] SIRUNYAN 18F search non-resonant for HH production using $HH \to b\bar{b}\ell\nu\ell\nu$, where $\ell\nu\ell\nu$ is either $WW \to \ell\nu\ell\nu$ or $ZZ \to \ell\ell\nu\nu$ (ℓ is e, μ or a leptonically decaying τ), with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $HH \to b\bar{b}\ell\nu\ell\nu$ production cross section at 95% CL is measured to be 72 fb, which corresponds to about 79 times the SM prediction.

[37] SIRUNYAN 17CN search for HH production using $HH \to b\bar{b}\tau\tau$ with data of 18.3 fb^{-1} at E_{cm} = 8 TeV. Results are then combined with the published results of the $HH \to \gamma\gamma b\bar{b}$ and $HH \to b\bar{b}b\bar{b}$, which use data of up to 19.7 fb^{-1} at E_{cm} = 8 TeV. The upper limit on the $gg \to HH$ production cross section is measured to be 0.59 pb from $b\bar{b}\tau\tau$, which corresponds to about 59 times the SM prediction (gluon fusion). The combined upper limit is 0.43 pb, which is about 43 times the SM prediction. The quoted values are given for m_H = 125 GeV.

[38] AABOUD 16I search for HH production using $HH \to b\bar{b}b\bar{b}$ with data of 3.2 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to b\bar{b}b\bar{b}$ production cross section is measured to be 1.22 pb. This result corresponds to about 108 times the SM prediction (gluon fusion), which is $11.3^{+0.9}_{-1.0}$ fb (NNLO+NNLL) including top quark mass effects. The quoted values are given for m_H = 125 GeV.

[39] KHACHATRYAN 16BQ search for HH production using $HH \to \gamma\gamma b\overline{b}$ with data of 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The upper limit on the $gg \to HH \to \gamma\gamma b\overline{b}$ production is measured to be 1.85 fb, which corresponds to about 74 times the SM prediction and is translated into 0.71 pb for $gg \to HH$ production cross section.

[40] AAD 15CE search for HH production using $HH \to b\overline{b}\tau\tau$ and $HH \to \gamma\gamma WW$ with data of 20.3 fb^{-1} at $E_{cm} = 8$ TeV. These results are then combined with the published results of the $HH \to \gamma\gamma b\overline{b}$ and $HH \to b\overline{b}b\overline{b}$, which use data of up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The upper limits on the $gg \to HH$ production cross section are measured to be 1.6 pb, 11.4 pb, 2.2 pb and 0.62 pb from $b\overline{b}\tau\tau$, $\gamma\gamma WW$, $\gamma\gamma b\overline{b}$ and $b\overline{b}b\overline{b}$, respectively. The combined upper limit is 0.69 pb, which corresponds to about 70 times the SM prediction. The quoted results are given for $m_H = 125.4$ GeV. See their Table 4.

HHH production

The HHH production cross section relative to the SM prediction.

[1] AAD 24BL combine results from 126–140 fb^{-1} of data at $E_{cm} = 13$ TeV for $pp \to HH \to b\overline{b}b\overline{b}$ (AAD 23BK, AAD 24BV), $b\overline{b}\tau\tau$ (AAD 24AZ), $b\overline{b}\gamma\gamma$ (AAD 24X), multilepton (AAD 24BG), and $b\overline{b}\ell\ell$ (AAD 24Y). See their Fig. 3. All other Higgs couplings are fixed to the SM values.

[2] AAD 25J search for non-resonant HHH production using $HHH \to b\overline{b}b\overline{b}b\overline{b}$ with data of 126 fb^{-1} at $E_{cm} = 13$ TeV. Two-dimensional likelihood scan of (κ_3 (=κ_λ), κ_4) is shown in their Fig. 9. The quoted values are obtained by assuming $\kappa_4 = 1$. Note that the quoted values are calculated using the kappa framework, which outside the unitarity bounds requires additional modification to preserve unitarity for their results.

[3] HAYRAPETYAN 25F constrain the Higgs trilinear self-coupling using single and double Higgs production with data at $E_{cm} = 13$ TeV. The production modes and decay channels used are listed in their Tables 1 and 2 for single- and double-Higgs, respectively. Only single- and double-Higgs channels give $-1.8 < \kappa_\lambda < 12.0$ and $-1.7 < \kappa_\lambda < 7.0$, respectively. All the other Higgs boson couplings are fixed to their SM values. Their Table 3 shows results with some of the couplings are loosened. Two-dimensional likelihood scan of (κ_λ, κ_t) is shown in their Fig. 5.

[4] AAD 24AZ search for non-resonant HH production using $HH \to b\overline{b}\tau\tau$ with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. Two-dimensional exclusion regions as a function of the κ_λ and κ_{2V} couplings are shown in their Fig. 9. All other Higgs couplings are fixed to the SM values.

[5] AAD 24BG search for non-resonant HH production targeting the $b\overline{b}ZZ^*$, VVVV, $VV\tau\tau$, $\tau\tau\tau\tau$, $\gamma\gamma VV$, $\gamma\gamma\tau\tau$ decay channels with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. The limits are obtained with the values of all other couplings fixed to their SM value.

[6] AAD 24X search for non-resonant HH production using $HH \to b\overline{b}\gamma\gamma$ with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. Two-dimensional exclusion regions as a function of the κ_λ and κ_{2V} couplings are shown in their Fig. 6. All other Higgs couplings are fixed to the SM values.

[7] AAD 24Y search for non-resonant HH production in $2b + 2\ell + \nu$s final state ($\ell = e$, μ) targeting $b\overline{b}WW^*$, $b\overline{b}ZZ^*$, and $b\overline{b}\tau\tau$ decay channels with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. All other coupling modifiers are set to their SM values.

[8] HAYRAPETYAN 24AE search for non-resonant HH production using $HH \to b\overline{b}WW^*$ with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. Two-dimensional exclusion regions as a function of the (κ_λ, κ_{2V}) and (κ_λ, κ_t) are shown in their Figs. 13 and 15. All other Higgs couplings are fixed to the SM values.

[9] HAYRAPETYAN 24AW search for non-resonant HH production in association with a vector boson using $HH \to b\overline{b}b\overline{b}$ with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. The vector boson decays both leptonically ($W \to \ell\nu$, $Z \to \ell\ell$, $\nu\nu$, $\ell = e$, μ) and hadronically. All other Higgs couplings are fixed to the SM values. Two-dimensional exclusion regions as a function of the κ_{2V} and κ_λ parameters are shown in their Fig. 14, with other couplings fixed to the SM values. The best fit value is (κ_λ, κ_{2V}) = (-2.6, 10.1).

[10] AAD 23AD search for non-resonant HH production in association with a vector boson using $HH \to b\overline{b}b\overline{b}$ with data of 139 fb^{-1} at $E_{cm} = 13$ TeV. The vector boson decays leptonically ($W \to \ell\nu$, $Z \to \ell\ell$, $\nu\nu$, $\ell = e$, μ). The quoted κ_λ is measured assuming all other Higgs boson couplings are at their SM value.

[11] AAD 23AT combine results from 126–139 fb^{-1} of data at $E_{cm} = 13$ TeV for $pp \to HH \to b\overline{b}b\overline{b}$ (AAD 23BK), $b\overline{b}\tau\tau$ (AAD 23Z), and $b\overline{b}\gamma\gamma$ (AAD 22Y). The quoted values are obtained from the profile likelihood scan as a function of κ_λ as shown in their Fig. 5(a). All other coupling modifiers are assumed to have their SM values.

[12] AAD 23AT combine results from 126–139 fb^{-1} of data at $E_{cm} = 13$ TeV for $pp \to HH \to b\overline{b}b\overline{b}$ (AAD 23BK), $b\overline{b}\tau\tau$ (AAD 23Z), and $b\overline{b}\gamma\gamma$ (AAD 22Y) with single-Higgs boson analyses ($\gamma\gamma$, ZZ^*, WW^*, $\tau\tau$, $b\overline{b}$, see their Table 1). The quoted values are obtained from the profile likelihood scan as a function of κ_λ as shown in their Fig. 5(a), assuming that all other Higgs boson couplings are at their SM values. Results with other assumptions are shown in their Table 2.

[13] AAD 23BK search for non-resonant HH production using $HH \to b\overline{b}b\overline{b}$ with data of 126 fb^{-1} at $E_{cm} = 13$ TeV. The quoted values are obtained from the one-dimensional profile likelihood scan as a function of κ_λ. See their Fig. 12 (a). The $\mu_{ggF+VBF}$ measurement for different values of κ_λ constrains $-3.9 < \kappa_\lambda < 11.1$ at 95% CL as shown in their Fig. 10 (a). $\kappa_{2V} = \kappa_V = 1$ is assumed in both cases.

[14] HAYRAPETYAN 23 measure the cross sections for $pp \to H \to ZZ^* \to 4\ell$ ($\ell = e$, μ) using 138 fb^{-1} at $E_{cm} = 13$ TeV.

[15] TUMASYAN 23AE search for HH production using $HH \to b\overline{b}b\overline{b}$, where both $b\overline{b}$ pairs are highly boosted, with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. The quoted κ_λ is measured assuming all other Higgs boson couplings are at their SM values.

[16] TUMASYAN 23D search for non-resonant HH production using $HH \to b\overline{b}\tau\tau$ with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. The quoted values are obtained from the upper limit on the HH production cross section times the $b\overline{b}\tau\tau$ branching fraction for different values of κ_λ. See their Fig. 8 (left). All other coupling modifiers are assumed to be 1. In addition, two-dimensional exclusion regions as a function of the κ_λ and κ_t couplings, with $\kappa_{2V} = \kappa_V = 1$, are shown in their Fig. 9 (left). The one-dimensional likelihood scan as a function of κ_λ is given in their Fig 10 (left), from which a 95% confidence interval of $-1.77 < \kappa_\lambda < 8.73$ is extracted.

[17] TUMASYAN 23AI search for non-resonant HH production using $HH \to b\overline{b}ZZ^*$ ($ZZ^* \to 4\ell$, ℓ=e,μ) with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. See their Fig. 4.

[18] TUMASYAN 23O search for non-resonant HH production using $HH \to WW^*WW^*$, $WW^*\tau\tau$, and $\tau\tau\tau\tau$ (multilepton) with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. See their Fig. 10 for different final states and these combination. Limits are set on a variety of new-physics models using an effective field theory approach. See their Figs. 11, 12, and 13.

[19] AAD 22Y search for non-resonant HH production using $HH \to \gamma\gamma b\overline{b}$ with data of 139 fb^{-1} at $E_{cm} = 13$ TeV. The quoted κ_λ is obtained from their Fig. 12 where the theory uncertainties are not included while a negative log-likelihood scan vs. $\kappa_\lambda$is shown in their Fig. 13 with the theory uncertainties, which provides $\kappa_\lambda = 2.8^{+2.0}_{-2.2}$ for the 1σ confidence interval.

[20] CMS 22 report combined results (see their Extended Data Table 2) using 138 fb^{-1} of data at $E_{cm} = 13$ TeV. See their Fig. 6 (left).

[21] TUMASYAN 22AN search for non-resonant HH production using $HH \to b\overline{b}b\overline{b}$ with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is shown as a function of κ_λ in their Fig. 2 (top).

[22] SIRUNYAN 21K search for non-resonant HH production using $HH \to \gamma\gamma b\overline{b}$ with data of 137 fb^{-1} at $E_{cm} = 13$ TeV.

[23] AAD 20C combine results of up to 36.1 fb^{-1} data at $E_{cm} = 13$ TeV for $pp \to HH \to b\overline{b}\gamma\gamma$, $b\overline{b}\tau\tau$, $b\overline{b}b\overline{b}$, $b\overline{b}WW^*$, $WW^*\gamma\gamma$, WW^*WW^* (AABOUD 18CW, AABOUD 18CQ, AABOUD 19A, AABOUD 19O, AABOUD 18BU, and AABOUD 19T).

[24] SIRUNYAN 19 search for HH production using $HH \to \gamma\gamma b\overline{b}$ with data of 35.9 fb^{-1} at $E_{cm} = 13$ TeV. The quoted κ_λ is measured assuming all other Higgs boson couplings are at their SM value.

[25] SIRUNYAN 19BE combine results of 13 TeV 35.9 fb^{-1} data: SIRUNYAN 19, SIRUNYAN 18A, SIRUNYAN 19AB, SIRUNYAN 19H, and SIRUNYAN 18F.

[26] AABOUD 18CW search for HH production using $HH \to \gamma\gamma b\overline{b}$ with data of 36.1 fb^{-1} at $E_{cm} = 13$ TeV. The quoted κ_λ is measured assuming all other Higgs boson couplings are at their SM value.

[27] SIRUNYAN 18A search for HH production using $HH \to b\overline{b}\tau\tau$ with data of 35.9 fb^{-1} at $E_{cm} = 13$ TeV. The upper limit on production cross section times branching fraction at 95% CL is shown as a function of κ_λ/κ_t in their Fig. 6 (top) where $\kappa_t = y_t / y_t^{SM}$ (top Yukawa coupling y_t).

[28] KHACHATRYAN 16BQ search for HH production using $HH \to \gamma\gamma b\overline{b}$ with data of 19.7 fb^{-1} at $E_{cm} = 8$ TeV.

Higgs quartic self coupling modifier κ_4

Signal strength relative to the SM prediction, $\kappa_4 = \lambda_{HHHH} / \lambda^{SM}_{HHHH}$.

[1] AAD 24BL combine results from 126–140 fb^{-1} of data at $E_{cm} = 13$ TeV for $pp \to HH \to b\bar{b}b\bar{b}$ (AAD 23BK, AAD 24BV), $b\bar{b}\tau\tau$ (AAD 24AZ), $b\bar{b}\gamma\gamma$ (AAD 24X), multilepton (AAD 24BG), and $b\bar{b}\ell\ell$ (AAD 24Y). See their Fig. 3. All other Higgs couplings are fixed to the SM values.

[2] HAYRAPETYAN 25F constrain the Higgs trilinear self-coupling using single and double Higgs production with data at $E_{cm} = 13$ TeV. The production modes and decay channels used are listed in their Tables 1 and 2 for single- and double-Higgs, respectively. Two-dimensional likelihood scan of (κ_V, κ_{2V}) is shown in their Fig. 6.

[3] AAD 24AZ search for non-resonant HH production using $HH \to b\bar{b}\tau\tau$ with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. Two-dimensional exclusion regions as a function of the κ_λ and κ_{2V} couplings are shown in their Fig. 9. All other Higgs couplings are fixed to the SM values.

[4] AAD 24BG search for non-resonant HH production targeting the $b\bar{b}ZZ^*$, VVVV, $VV\tau\tau$, $\tau\tau\tau\tau$, $\gamma\gamma VV$, $\gamma\gamma\tau\tau$ decay channels with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. The limits are obtained with the values of all other couplings fixed to their SM value.

[5] AAD 24BV search for non-resonant HH production via vector boson fusion in the $b\bar{b}b\bar{b}$ final state using two boosted Higgs ($p_T > 250$ GeV) with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. The result is obtained by combining with the resolved result (AAD 23BK). The value $\kappa_{2V} = 0$ is excluded with a significance of 3.8 σ with other Higgs couplings fixed to their SM values. Two-dimensional exclusion regions as a function of the κ_λ and κ_{2V} parameters are shown in their Fig. 6. All other Higgs couplings are fixed to the SM values.

[6] AAD 24BV search for non-resonant HH production via vector boson fusion in the $b\bar{b}b\bar{b}$ final state using two boosted Higgs ($p_T > 250$ GeV) with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. The value $\kappa_{2V} = 0$ is excluded with a significance of 3.4 σ with other Higgs couplings fixed to their SM values.

[7] AAD 24X search for non-resonant HH production using $HH \to b\bar{b}\gamma\gamma$ with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. Two-dimensional exclusion regions as a function of the κ_λ and κ_{2V} couplings are shown in their Fig. 6. All other Higgs couplings are fixed to the SM values.

[8] AAD 24Y search for non-resonant HH production in $2b + 2\ell + \nu$s final state ($\ell = e, \mu$) targeting $b\bar{b}WW^*$, $b\bar{b}ZZ^*$, and $b\bar{b}\tau\tau$ decay channels with data of 140 fb^{-1} at $E_{cm} = 13$ TeV. All other coupling modifiers are set to their SM values.

[9] HAYRAPETYAN 24AE search for non-resonant HH production using $HH \to b\bar{b}WW^*$ with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. Two-dimensional exclusion regions as a function of the (κ_λ, κ_{2V}) and (κ_V, κ_{2V}) are shown in their Figs. 13 and 14. All other Higgs couplings are fixed to the SM values.

[10] HAYRAPETYAN 24AW search for non-resonant HH production in association with a vector boson using $HH \to b\bar{b}b\bar{b}$ with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. The vector boson decays both leptonically ($W \to \ell\nu$, $Z \to \ell\ell$, $\nu\nu$, $\ell = e, \mu$) and hadronically. All other Higgs couplings are fixed to the SM values. Two-dimensional exclusion regions as a function of the κ_{2V} and κ_λ parameters are shown in their Fig. 14, with other couplings fixed to the SM values. The best fit value is (κ_λ, κ_{2V}) = (-2.6, 10.1). The constraints on κ_{2W} and κ_{2Z} are separately measured to be $-14.0 < \kappa_{2W} < 15.4$ and $-17.4 < \kappa_{2Z} < 18.5$ (95% CL). The quoted κ_{2V} ($V = W, Z$) is measured assuming all other Higgs boson couplings are at their SM value. See their Table 7.

[11] AAD 23AD search for non-resonant HH production in association with a vector boson using $HH \to b\bar{b}b\bar{b}$ with data of 139 fb^{-1} at $E_{cm} = 13$ TeV. The vector boson decays leptonically ($W \to \ell\nu$, $Z \to \ell\ell$, $\nu\nu$, $\ell = e, \mu$). The constraints on κ_{2W} and κ_{2Z} are separately measured to be $-12.3 < \kappa_{2W} < 13.5$ and $-9.9 < \kappa_{2Z} < 11.3$ (95% CL). The quoted κ_{2V} ($V = W, Z$) is measured assuming all other Higgs boson couplings are at their SM value.

[12] AAD 23AT combine results from 126–139 fb^{-1} of data at $E_{cm} = 13$ TeV for $pp \to HH \to b\bar{b}b\bar{b}$ (AAD 23BK), $b\bar{b}\tau\tau$ (AAD 23Z), and $b\bar{b}\gamma\gamma$ (AAD 22Y). The quoted values are obtained from the 95% CL VBF HH cross-section upper limit as a function of κ_{2V} as shown in their Fig. 4(b). All other coupling modifiers are assumed to have their SM values.

[13] AAD 23BK search for non-resonant HH production using $HH \to b\bar{b}b\bar{b}$ with data of 126 fb^{-1} at $E_{cm} = 13$ TeV. The quoted values are obtained from the one-dimensional profile likelihood scan as a function of κ_{2V}. See their Fig. 12 (b). The μ_{VBF} measurement for different values of κ_{2V} constrains $-0.03 < \kappa_{2V} < 2.11$ at 95% CL as shown in their Fig. 10 (b). $\kappa_\lambda = \kappa_V = 1$ is assumed in both cases.

[14] TUMASYAN 23AE search for HH production using $HH \to b\bar{b}b\bar{b}$, where both $b\bar{b}$ pairs are highly boosted, with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. The $\kappa_{2V} = 0$ is excluded at 6.3 σ assuming all other Higgs boson couplings are at their SM values.

[15] TUMASYAN 23D search for non-resonant HH production using $HH \to b\bar{b}\tau\tau$ with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. The quoted values are obtained from the upper limits on the HH production cross section times the $b\bar{b}\tau\tau$ branching fraction for different values of κ_{2V}. See their Fig. 8 (right). All other coupling modifiers are assumed to be 1. In addition, two-dimensional exclusion regions as a function of the κ_{2V} and κ_V couplings, with $\kappa_\lambda = \kappa_t = 1$, are shown in their Fig. 9 (right). The one-dimensional likelihood scan as a function of κ_{2V} is given in their Fig. 10 (right), from which a 95% confidence interval of $-0.34 < \kappa_{2V} < 2.49$ is extracted.

[16] CMS 22 report combined results (see their Extended Data Table 2) using 138 fb^{-1} of data at $E_{cm} = 13$ TeV. See their Fig. 6 (right).

[17] TUMASYAN 22AN search for non-resonant HH production using $HH \to b\bar{b}b\bar{b}$ with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is shown as a function of κ_{2V} in their Fig. 2 (bottom).

[18] SIRUNYAN 21K search for non-resonant HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 137 fb^{-1} at $E_{cm} = 13$ TeV.

[19] AAD 20X search for $HH \to b\bar{b}b\bar{b}$ process via VBF with data of 126 fb^{-1} at $E_{cm} = 13$ TeV.

H production cross section in pp collisions at $\sqrt{s} = 13$ TeV

69^{+10}_{-9} ±5	[6] AABOUD	17CO	ATLS	pp, 13 TeV, $ZZ^* \to 4\ell$

[1] AAD 23C combine AAD 22N and AAD 20BA, where both use 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The Higgs production cross sections at $E_{cm} = 7$ and 8 TeV are obtained to be 34^{+11}_{-10} pb and $33.3^{+5.8}_{-5.4}$ pb, respectively. The quoted value is given for $m_H = 125.09$ GeV. The differential cross sections are given in their Figs. 3 and 4.

[2] SIRUNYAN 19BA use 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted value is given for $m_H = 125.09$ GeV.

[3] AAD 22N use 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted value is given for $m_H = 125.09$ GeV.

[4] AAD 20BA use 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e, \mu$. The quoted value is given for $m_H = 125$ GeV and assumes the Standard Model branching ratio.

[5] AABOUD 18CG use 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. All the quoted values are given for $m_H = 125.09$ GeV.

[6] AABOUD 17CO use 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e, \mu$ for $m_H = 125$ GeV. Differential cross sections for the Higgs boson transverse momentum, Higgs boson rapidity, and other related quantities are measured as shown in their Figs. 8 and 9.

H production cross section in pp collisions at $\sqrt{s} = 13.6$ TeV

VALUE (pb)	DOCUMENT ID		TECN	COMMENT
58.2±8.7	[1] AAD	24AQ	ATLS	pp, 13.6 TeV, $\gamma\gamma$, $ZZ^* \to 4\ell$ ($\ell = e, \mu$)

[1] AAD 24AQ measure the total cross section to be 67^{+12}_{-11} pb and 46 ± 12 pb using $H \to \gamma\gamma$ and $H \to ZZ^* \to 4\ell$, respectively, with data of 31.4 fb^{-1} and 29.0 fb^{-1} of pp collisions at $E_{cm} = 13.6$ TeV. The SM expected value is 59.9 ± 2.6 pb. All the values are given for $m_H = 125.09$ GeV.

Electroweak Constraints on the Standard Model Higgs Boson Mass

MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN SUPERSYMMETRIC MODELS

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars [H_1^0 and H_2^0, where we define $m_{H_1^0} < m_{H_2^0}$], a pseudoscalar (A^0), and a charged Higgs pair ($H^\pm$). H_1^0 and H_2^0 are also called h and H in the literature. There are two free parameters in the Higgs sector which can be chosen to be m_{A^0} and $\tan\beta = v_2/v_1$, the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be $m_{H_1^0} \leq m_Z$, $m_{H_2^0} \geq m_Z$, $m_{A^0} \geq m_{H_1^0}$, and $m_{H^\pm} \geq m_W$. However, as described in the review on "Status of Higgs Boson Physics" in this Volume these relations are violated by radiative corrections.

The observed signal at about 125 GeV, see section "*H*", can be interpreted as one of the neutral Higgs bosons of supersymmetric models. Unless otherwise noted, we identify the lighter scalar H_1^0 with the Higgs discovered at 125 GeV at the LHC (AAD 12AI, CHATRCHYAN 12N).

Unless otherwise noted, the experiments in e^+e^- collisions search for the processes $e^+e^- \to H_1^0 Z^0$ in the channels used for the Standard Model Higgs searches and $e^+e^- \to H_1^0 A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$. Unless otherwise stated, the following results assume no invisible H_1^0 or A^0 decays. Unless otherwise noted, the results are given in the m_h^{max} scenario, CARENA 13.

In $p\overline{p}$ and pp collisions the experiments search for a variety of processes, as explicitly specified for each entry. Limits on the A^0 mass arise from these direct searches, as well as from the relations valid in the minimal supersymmetric model between m_{A^0} and $m_{H_1^0}$. As discussed in the review on "Status of Higgs Boson Physics" in this Volume, these relations depend, via potentially large radiative corrections, on the mass of the t quark and on the supersymmetric parameters, in particular those of the stop sector. These indirect limits are weaker for larger t and $\tilde{t}$ masses. To include the radiative corrections to the Higgs masses, unless otherwise stated, the listed papers use theoretical predictions incorporating two-loop corrections and beyond (SLAVICH 21), and the results are given for the M_h^{125} benchmark scenario, see BAGNASCHI 19.

Mass Limits for heavy neutral Higgs bosons (H_2^0, A^0) in the MSSM

The limits rely on $pp \to H_2^0/A^0 \to \tau^+\tau^-$ and assume that H_2^0 and A^0 are (sufficiently) mass degenerate. The limits depend on $\tan\beta$.

[1] TUMASYAN 23S search for production of $H^0_2/A^0 \to \tau^+\tau^-$ by gluon fusion and b-associated prodution using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 13 for excluded regions in the m_{A^0}–$\tan\beta$ plane in M^{125}_h and M^{125}_{hEFT} MSSM scenarios. In both scenarios $m_{A^0} < 350$ GeV is excluded at 95% CL.

[2] AAD 20AA search for $H^0_2/A^0 \to \tau^+\tau^-$ produced by gluon fusion or b-associated production using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 2(c) for excluded region in the M^{125}_h scenario of MSSM. Values of $\tan\beta > 8$ (21) are excluded for $m_{A^0} = 1.0$ (1.5) TeV at 95%CL.

[3] CHEKHOVSKY 25C search for $H^0_2/A^0 \to b\overline{b}$ by b-associated prodution using 36.7–126.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 16–18 for excluded regions in the m_{A^0}–$\tan\beta$ plane in various MSSM scenarios.

[4] CHEKHOVSKY 25I search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH in the final states $\ell^+\ell^-\tau^+\tau^-$, assuming B($H \to \tau^+\tau^-$) of the SM, using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for excluded parameter region in M^{125}_{hEFT} MSSM scenario.

[5] AAD 24AP search for production of a heavy H^0_2 and A^0 decaying to $t\overline{t}$ in 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 13(b) for excluded parameter regions in hMSSM.

[6] AAD 24CB use ATLAS measurements from up to 139 fb^{-1} of H production cross sections and decays to constrain the MSSM Higgs sector. See their Figs. 22 and 23 for excluded regions in various MSSM scenarios.

[7] AAD 24H combine searches for a scalar resonance decaying to HH using up to 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV from AAD 22F, AAD 23Z, and AAD 22Y. See their Fig. 3 for the excluded region in the MSSM $M^{125}_{h,EFT}$ and $M^{125}_{h,EFT}(\widetilde{\chi})$ benchmark scenarios (where only the resonant H-exchange contribution has been taken into account in the signal modelling).

[8] AAD 20 combine measurements on H production and decay using data taken in years 2015–2017 (up to 79.8 fb^{-1}) of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 19 for excluded region in the hMSSM parameter space.

[9] AAD 20C combine searches for a scalar resonance decaying to HH in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV from AABOUD 19A, AABOUD 19O, AABOUD 18CQ, AABOUD 19T, AABOUD 18CW, and AABOUD 18BU. See their Fig. 7(b) for the excluded region in the hMSSM parameter space.

[10] AAD 20L search for b-associated production of H^0_2 decaying to $b\overline{b}$ in 27.8 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in hMSSM, m^{mod+}_h and m^{mod-}_h scenarios of MSSM.

[11] SIRUNYAN 20AC search for gluon-fusion and b-associated production of A^0 decaying to ZH in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for excluded regions in the M^{125}_{hEFT} and hMSSM scenarios of the MSSM.

[12] SIRUNYAN 20AF search for $H^0_2/A^0 \to t\overline{t}$ with one or two charged leptons in the final state using kinematic variables in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for excluded region in the hMSSM scenario of MSSM. Values of $\tan\beta$ below 1.0–1.5 are excluded for $m_{A^0} = 0.4$–0.75 TeV at 95%CL.

[13] SIRUNYAN 20Y search for gluon-fusion and vector-boson-fusion production of H^0_2 decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 8 and 9 for excluded regions in various MSSM scenarios.

[14] SIRUNYAN 19CR search for production of H^0_2/A^0 in gluon fusion and in association with a $b\overline{b}$ pair, decaying to $\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for the excluded region in the MSSM parameter space in the m^{mod+}_h and hMSSM scenarios.

[15] AABOUD 18G search for production of $H^0_2/A^0 \to \tau^+\tau^-$ by gluon fusion and b-associated prodution in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 10 for excluded regions in the m_{A^0}– $\tan\beta$ plane in several MSSM scenarios.

[16] SIRUNYAN 18A search for production of a scalar resonance decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 (lower) for excluded regions in the m_{A^0} – $\tan\beta$ plane in the hMSSM scenario.

[17] SIRUNYAN 18BP search for production of $H^0_2/A^0 \to b\overline{b}$ by b-associated prodution in 35.7 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H^0_2}$, $m_{A^0} = 0.3$–1.3 TeV, and Fig. 7 for excluded regions in the m_{A^0}– $\tan(\beta)$ plane in several MSSM scenarios.

[18] SIRUNYAN 18CX search for production of $H^0_{1,2}/A^0 \to \tau^+\tau^-$ by gluon fusion and b-associated prodution in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in the m_{A^0}– $\tan(\beta)$ plane in several MSSM scenarios.

[19] AABOUD 16AA search for production of a Higgs boson in gluon fusion and in association with a $b\overline{b}$ pair followed by the decay $A^0 \to \tau^+\tau^-$ in 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5(a, b) for limits on cross section times branching ratio for $m_{A^0} = 200$–1200 GeV, and Fig. 5(c, d) for the excluded region in the MSSM parameter space in the m^{mod+}_h and hMSSM scenarios.

[20] KHACHATRYAN 16A search for production of a Higgs boson in gluon fusion and in association with a $b\overline{b}$ pair followed by the decay $H^0_{1,2}/A^0 \to \mu^+\mu^-$ in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.3 fb^{-1} at $E_{cm} = 8$ TeV. See their Fig. 7 for the excluded region in the MSSM parameter space in the m^{mod+}_h benchmark scenario and Fig. 9 for limits on cross section times branching ratio.

[21] KHACHATRYAN 16P search for gluon fusion production of an H^0_2 decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ and an A^0 decaying to $ZH^0 \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 12 for excluded region in the $\tan\beta - \cos(\beta-\alpha)$ plane for $m_{H^0_2} = m_{A^0} = 300$ GeV.

[22] KHACHATRYAN 15AY search for production of a Higgs boson in association with a b quark in the decay $H^0_{1,2}/A^0 \to b\overline{b}$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV and combine with CHATRCHYAN 13AG 7 TeV data. See their Fig. 6 for the limits on cross section times branching ratio for $m_{A^0} = 100$–900 GeV and Figs. 7–9 for the excluded region in the MSSM parameter space in various benchmark scenarios.

[23] AAD 14AW search for production of a Higgs boson followed by the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ in 19.5–20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 11 for the limits on cross section times branching ratio and their Figs. 9 and 10 for the excluded region in the MSSM parameter space. For $m_{A^0} = 140$ GeV, the region $\tan\beta > 5.4$ is excluded at 95% CL in the m^{max}_h scenario.

[24] KHACHATRYAN 14M search for production of a Higgs boson in gluon fusion and in association with a b quark followed by the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ in 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. See their Figs. 7 and 8 for one- and two-dimensional limits on cross section times branching ratio and their Figs. 5 and 6 for the excluded region in the MSSM parameter space. For $m_{A^0} = 140$ GeV, the region $\tan\beta > 3.8$ is excluded at 95% CL in the m^{max}_h scenario.

[25] AAD 13O search for production of a Higgs boson in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ and $\mu^+\mu^-$ with 4.7–4.8 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and their Fig. 7 for the limits on cross section times branching ratio. For $m_{A^0} = 110$–170 GeV, $\tan\beta \gtrsim 10$ is excluded, and for $\tan\beta = 50$, m_{A^0} below 470 GeV is excluded at 95% CL in the m^{max}_h scenario.

[26] AAIJ 13T search for production of a Higgs boson in the forward region in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ in 1.0 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. See their Fig. 2 for the limits on cross section times branching ratio and the excluded region in the MSSM parameter space.

[27] CHATRCHYAN 13AG search for production of a Higgs boson in association with a b quark in the decay $H^0_{1,2}/A^0 \to b\overline{b}$ in 2.7–4.8 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and Fig. 5 for the limits on cross section times branching ratio. For $m_{A^0} = 90$–350 GeV, upper bounds on $\tan\beta$ of 18–42 at 95% CL are obtained in the m^{max}_h scenario with $\mu = +200$ GeV.

[28] AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.

[29] AALTONEN 12X search for associated production of a Higgs boson and a b quark in the decay $H^0_{1,2}/A^0 \to b\overline{b}$, with 2.6 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Table III and Fig. 15 for the limit on cross section times branching ratio and Figs. 17, 18 for the excluded region in the MSSM parameter space.

[30] ABAZOV 12G search for production of a Higgs boson in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ with 7.3 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV and combine with ABAZOV 11W and ABAZOV 11K. See their Figs. 4, 5, and 6 for the excluded region in the MSSM parameter space. For $m_{A^0} = 90$–180 GeV, $\tan\beta \gtrsim 30$ is excluded at 95% CL. in the m^{max}_h scenario.

[31] CHATRCHYAN 12K search for production of a Higgs boson in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ with 4.6 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. See their Fig. 3 and Table 4 for the excluded region in the MSSM parameter space. For $m_{A^0} = 160$ GeV, the region $\tan\beta > 7.1$ is excluded at 95% CL in the m^{max}_h scenario. Superseded by KHACHATRYAN 14M.

[32] ABAZOV 11K search for associated production of a Higgs boson and a b quark, followed by the decay $H^0_{1,2}/A^0 \to b\overline{b}$, in 5.2 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 5/Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for $\mu = -200$ GeV.

[33] ABAZOV 11W search for associated production of a Higgs boson and a b quark, followed by the decay $H^0_{1,2}/A^0 \to \tau\tau$, in 7.3 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.

[34] AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 2 for the limit on $\sigma \cdot$ B($H^0_{1,2}/A^0 \to \tau^+\tau^-$) for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.

Gauge & Higgs Boson Particle Listings

Neutral Higgs Bosons, Searches for

[35] ABDALLAH 08B give limits in eight *CP*-conserving benchmark scenarios and some *CP*-violating scenarios. See paper for excluded regions for each scenario. Supersedes ABDALLAH 04.

[36] SCHAEL 06B make a combined analysis of the LEP data. The quoted limit is for the m_h^{max} scenario with $m_t = 174.3$ GeV. In the *CP*-violating CPX scenario no lower bound on $m_{H_1^0}$ can be set at 95% CL. See paper for excluded regions in various scenarios. See Figs. 2–6 and Tabs. 14–21 for limits on $\sigma(ZH^0)\cdot B(H^0 \to b\overline{b}, \tau^+\tau^-)$ and $\sigma(H_1^0 H_2^0)\cdot B(H_1^0, H_2^0 \to b\overline{b}, \tau^+\tau^-)$.

[37] ACOSTA 05Q search for $H_{1,2}^0/A^0$ production in $p\overline{p}$ collisions at $E_{cm} = 1.8$ TeV with $H_{1,2}^0/A^0 \to \tau^+\tau^-$. At $m_{A^0} = 100$ GeV, the obtained cross section upper limit is above theoretical expectation.

[38] Search for $e^+e^- \to H_1^0 A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$, and $e^+e^- \to H_1^0 Z$. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 200 GeV, and $\mu = -200$ GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for m_t=175 GeV, and for the m_h^{max} scenario.

[39] ABBIENDI 04M exclude $0.7 < \tan\beta < 1.9$, assuming $m_t = 174.3$ GeV. Limits for other MSSM benchmark scenarios, as well as for *CP* violating cases, are also given.

[40] ABBIENDI 03G search for $e^+e^- \to H_1^0 Z$ followed by $H_1^0 \to A^0 A^0$, $A^0 \to c\overline{c}, gg$, or $\tau^+\tau^-$. In the no-mixing scenario, the region $m_{H_1^0} = 45$–85 GeV and $m_{A^0} = 2$–9.5 GeV is excluded at 95% CL.

[41] ACHARD 02H also search for the final state $H_1^0 Z \to 2A^0 q\overline{q}$, $A^0 \to q\overline{q}$. In addition, the MSSM parameter set in the "large-μ" and "no-mixing" scenarios are examined.

[42] AKEROYD 02 examine the possibility of a light A^0 with $\tan\beta < 1$. Electroweak measurements are found to be inconsistent with such a scenario.

[43] HEISTER 02 excludes the range $0.7 < \tan\beta < 2.3$. A wider range is excluded with different stop mixing assumptions. Updates BARATE 01C.

MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN EXTENDED HIGGS MODELS

This Section covers models which do not fit into either the Standard Model or its simplest minimal Supersymmetric extension (MSSM), leading to anomalous production rates, or nonstandard final states and branching ratios. In particular, this Section covers limits which may apply to generic two-Higgs-doublet models (2HDM), or to special regions of the MSSM parameter space where decays to invisible particles or to photon pairs are dominant (see the review on "Status of Higgs Boson Physics"). Concerning the mass limits for H^0 and A^0 listed below, see the footnotes or the comment lines for details on the nature of the models to which the limits apply.

The observed signal at about 125 GeV, see section "*H*", can be interpreted as one of the neutral Higgs bosons of an extended Higgs sector.

Mass Limits in General two-Higgs-doublet Models

[1] AAD 25AL search for production of H_2^0/A^0 in association with a $t\overline{t}$ pair, decaying to $t\overline{t}$, resulting in final states with one lepton or two opposite-sign leptons, using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in the parameter space of the type II 2HDM. Combined limits with AAD 23BG are shown in Fig. 11.

[2] CHEKHOVSKY 25C search for $H_2^0/A^0 \to b\overline{b}$ by b-associated production using 36.7–126.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 19 and 20 for excluded regions in the parameter space in Type II and flipped 2HDMs.

[3] HAYRAPETYAN 25I search for $A^0 \to ZH_2^0$ with $H_2^0 \to t\overline{t}$ using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 6 and 7 for excluded regions the 2HDM Type II.

[4] AAD 24AB search for gluon-fusion and $b\overline{b}$ associated production of A^0 decaying to $A^0 \to ZH_2^0$, in the final states $\ell^+\ell^- t\overline{t}$ and $\nu\overline{\nu}b\overline{b}$ using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 5 and 6 for limits on cross section times branching ratios in terms of two-Higgs-doublet models, and Fig. 7 for excluded model parameter space.

[5] AAD 24AP search for production of a heavy H_2^0 and A^0 decaying to $t\overline{t}$ in 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 13(a) for excluded parameter regions in a Type II two-Higgs-doublet model.

[6] AAD 24CB use ATLAS measurements from up to 139 fb^{-1} of H production cross sections and decays to constrain two Higgs doublet models. See their Figs. 19–21 for excluded regions of 2HDM parameter space.

[7] AAD 24H combine searches for a scalar resonance decaying to HH using up to 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV from AAD 22F, AAD 23Z, and AAD 22Y. See their Fig. 2 for the excluded region in the Type-I two-Higgs-doublet model parameter space (where only the resonant H-exchange contribution has been taken into account in the signal modelling).

[8] HAYRAPETYAN 24H search for H_2^0 and A^0 having flavor-violating couplings to tc or tu, produced in association with top quark(s), using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. For the interpretation of the data in terms of flavor-violating two-Higgs-doublet models, given in the range $m_{A^0} = 0.2$–1.0 TeV, see their Figs. 4, 5, and 6.

[9] AAD 23AD search for associated production of W/ZH_2^0 and gluon fusion production of A^0 decaying to ZH_2^0, with the decay chain $H_2^0 \to HH \to b\overline{b}b\overline{b}$, using 139 fb^{-1} of

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

pp collisions at E_{cm} = 13 TeV. See their Figs. 12 and 13 for excluded regions in Type-I and lepton-specific 2HDMs.

[10] AAD 23BG search for production of H_2^0/A^0 in association with a $t\bar{t}$ pair, decaying to $t\bar{t}$, resulting in final states with two same-sign leptons or three or more leptons, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 (corrected version in the erratum) for excluded regions in the parameter space of the type II 2HDM.

[11] AAD 23O search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to ZH in the final states $\nu\bar{\nu}b\bar{b}$ and $\ell^+\ell^-b\bar{b}$ using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 12 and 13 for excluded regions in the parameter space in various 2HDMs.

[12] AAD 21AF search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell'^+\ell'^-$ and $\ell^+\ell^-\nu\bar{\nu}$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 6 and 7 for excluded parameter regions of the 2HDM Type I and II.

[13] AAD 21AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to $ZH_2^0 \to \ell^+\ell^-b\bar{b}$ or $\ell^+\ell^-W^+W^-$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 10 and 14 for excluded regions in the parameter space of various 2HDMs.

[14] AAD 20 combine measurements on H^0 production and decay using data taken in years 2015–2017 (up to 79.8 fb^{-1}) of pp collisions at E_{cm} = 13 TeV. See their Fig. 18 for excluded regions in various 2HDMs.

[15] AAD 20L search for b-associated production of H_2^0 decaying to $b\bar{b}$ in 27.8 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 10 and 11 for excluded regions in the flipped two Higgs doublet model.

[16] SIRUNYAN 20AA search for $H_2^0 \to ZA^0$, $A^0 \to b\bar{b}$ or $A^0 \to ZH_2^0$, $H_2^0 \to b\bar{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 8 and 9 for excluded regions in the parameter space of Type-II two Higgs doublet model.

[17] SIRUNYAN 20Y search for gluon-fusion and vector-boson-fusion production of H_2^0 decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for excluded regions in Type I and II two Higgs doublet models.

[18] SIRUNYAN 19AE search for a pseudoscalar resonance produced in association with a $b\bar{b}$ pair, decaying to $\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for cross section limits for m_{A^0} = 25–70 GeV and comparison with some representative 2HDMs.

[19] SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or b associated production, decaying to $ZH^0 \to \ell^+\ell^-b\bar{b}$ ($\ell = e, \mu$) or $\nu\bar{\nu}b\bar{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 6 and 7 for excluded regions in the parameter space of various 2HDMs.

[20] AABOUD 18AH search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to $ZH_2^0 \to \ell^+\ell^-b\bar{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for excluded regions in the parameter space of various 2HDMs.

[21] AABOUD 18AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to ZH^0 in the final states $\nu\bar{\nu}b\bar{b}$ and $\ell^+\ell^-b\bar{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 7 and 8 for excluded regions in the parameter space in various 2HDMs.

[22] AABOUD 18BF search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$ and $\ell^+\ell^-\nu\bar{\nu}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 8 and 9 for excluded parameter regions in 2HDM Type I and II.

[23] AABOUD 18CE search for the process $pp \to H_2^0/A^0\,t\bar{t}$ followed by the decay $H_2^0/A^0 \to t\bar{t}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 12 for limits on cross section times branching ratio, and for lower limits on $\tan\beta$ for $m_{H_2^0}$, m_{A^0} = 0.4–1.0 TeV in the 2HDM type II.

[24] HALLER 18 perform global fits in the framework of two-Higgs-doublet models (type I, II, lepton specific, flipped). See their Fig. 8 for allowed parameter regions from fits to LHC H^0 measurements, Fig. 9 bottom and charm decays, Fig. 10 muon anomalous magnetic moment, Fig. 11 electroweak precision data, and Fig. 12 by combination of all data.

[25] SIRUNYAN 18BP search for production of $H_2^0/A^0 \to b\bar{b}$ by b-associated prodution in 35.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H_2^0}$, m_{A^0} = 0.3–1.3 TeV, and Figs. 8 and 9 for excluded regions in the parameter space of type-II and flipped 2HDMs.

[26] SIRUNYAN 18ED search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to ZH^0 in the final states $\nu\bar{\nu}b\bar{b}$ or $\ell^+\ell^-b\bar{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for excluded regions in the parameter space in Type I and II 2HDMs.

[27] AABOUD 17AN search for production of a heavy H_2^0 and/or A^0 decaying to $t\bar{t}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 3 and Table III for excluded parameter regions in Type II Two-Higgs-Doublet-Models.

[28] SIRUNYAN 17AX search for $A^0 b\bar{b}$ production followed by the decay $A^0 \to \mu^+\mu^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Limits are set in the range m_{A^0} = 25–60 GeV. See their Fig. 5 for upper limits on $\sigma(A^0 b\bar{b})\cdot B(A^0 \to \mu^+\mu^-)$.

[29] AAD 16AX search for production of a heavy H^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-\nu\bar{\nu}$, $\ell^+\ell^-q\bar{q}$, and $\nu\bar{\nu}q\bar{q}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 13 and 14 for excluded parameter regions in Type I and II models.

[30] KHACHATRYAN 16P search for gluon fusion production of an H_2^0 decaying to $H^0H^0 \to b\bar{b}\tau^+\tau^-$ and an A^0 decaying to $ZH^0 \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 11 for limits on $\tan\beta$ for m_{A^0} = 230–350 GeV.

[31] KHACHATRYAN 16W search for $A^0 b\bar{b}$ production followed by the decay $A^0 \to \tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 3 for upper limits on $\sigma(A^0 b\bar{b})\cdot B(A^0 \to \tau^+\tau^-)$.

[32] KHACHATRYAN 16Z search for $H_2^0 \to ZA^0$ followed by $A^0 \to b\bar{b}$ or $\tau^+\tau^-$, and $A^0 \to ZH_2^0$ followed by $H_2^0 \to b\bar{b}$ or $\tau^+\tau^-$, in 19.8 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 4 for cross section limits and Fig. 5 for excluded region in the parameter space.

[33] AAD 15BK search for production of a heavy H_2^0 decaying to H^0H^0 in the final state $b\bar{b}b\bar{b}$ in 19.5 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 15–18 for excluded regions in the parameter space.

[34] AAD 15S search for production of A^0 decaying to $ZH^0 \to \ell^+\ell^-b\bar{b}$, $\nu\bar{\nu}b\bar{b}$ and $\ell^+\ell^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4 and 5 for excluded regions in the parameter space.

[35] KHACHATRYAN 15BB search for H_2^0, $A^0 \to \gamma\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 10 for excluded regions in the two-Higgs-doublet model parameter space.

[36] KHACHATRYAN 15N search for production of A^0 decaying to $ZH^0 \to \ell^+\ell^-b\bar{b}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 5 for excluded regions in the $\tan\beta - \cos(\beta-\alpha)$ plane for m_{A^0} = 300 GeV.

[37] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to H^0W^\pm W^\mp$, H^0 decaying to $b\bar{b}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Table IV for limits in a two-Higgs-doublet model for $m_{H_2^0}$= 325–1025 GeV and m_{H^+}= 225–825 GeV.

[38] KHACHATRYAN 14Q search for $H_2^0 \to H^0H^0$ and $A^0 \to ZH^0$ in 19.5 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4 and 5 for limits on cross section times branching ratio for m_{H_2,A^0}= 260–360 GeV and their Figs. 7–9 for limits in two-Higgs-doublet models.

[39] AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 2 for the limit on $\sigma \cdot B(H_{1,2}^0/A^0 \to \tau^+\tau^-)$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.

[40] ABBIENDI 05A search for $e^+e^- \to H_1^0A^0$ in general Type-II two-doublet models, with decays H_1^0, $A^0 \to q\bar{q}$, gg, $\tau^+\tau^-$, and $H_1^0 \to A^0A^0$.

[41] ABDALLAH 05D search for $e^+e^- \to H^0Z$ and H^0A^0 with H^0, A^0 decaying to two jets of any flavor including gg. The limit is for SM H^0Z production cross section with $B(H^0 \to jj) = 1$.

[42] ABDALLAH 04O search for $Z \to b\bar{b}H^0$, $b\bar{b}A^0$, $\tau^+\tau^-H^0$ and $\tau^+\tau^-A^0$ in the final states $4b$, $b\bar{b}\tau^+\tau^-$, and 4τ. See paper for limits on Yukawa couplings.

[43] ABDALLAH 04O search for $e^+e^- \to H^0Z$ and H^0A^0, with H^0, A^0 decaying to $b\bar{b}$, $\tau^+\tau^-$, or $H^0 \to A^0A^0$ at E_{cm} = 189–208 GeV. See paper for limits on couplings.

[44] ABBIENDI 02D search for $Z \to b\bar{b}H_1^0$ and $b\bar{b}A^0$ with $H_1^0/A^0 \to \tau^+\tau^-$, in the range $4 < m_H < 12$ GeV. See their Fig. 8 for limits on the Yukawa coupling.

[45] ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{cm} \leq 189$ GeV. In addition to usual final states, the decays H_1^0, $A^0 \to q\bar{q}$, gg are searched for. See their Figs. 15,16 for excluded regions.

[46] ABBIENDI 99E search for $e^+e^- \to H^0A^0$ and H^0Z at E_{cm} = 183 GeV. The limit is with m_H=m_A in general two Higgs-doublet models. See their Fig. 18 for the exclusion limit in the m_H–m_A plane. Updates the results of ACKERSTAFF 98S.

[47] See Fig. 4 of ABREU 95H for the excluded region in the $m_{H^0} - m_{A^0}$ plane for general two-doublet models. For $\tan\beta > 1$, the region $m_{H^0}+m_{A^0} \lesssim 87$ GeV, $m_{H^0} < 47$ GeV is excluded at 95% CL.

[48] PICH 92 analyse H^0 with $m_{H^0} < 2m_\mu$ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and $\pi^\pm$, η rare decays are shown in Figs. 3,4. The considered mass region is not totally excluded.

Mass Limits for H^0 with Vanishing Yukawa Couplings

These limits assume that H^0 couples to gauge bosons with the same strength as the Standard Model Higgs boson, but has no coupling to quarks and leptons (this is often referred to as "fermiophobic").

Int. J. Mod. Phys. A 2026.41. Downloaded from worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use strictly not permitted, except for Open Access articles.

[4] ABAZOV 13G search for $H^0 \to WW^{(*)}$ in 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. A limit on cross section times branching ratio which corresponds to (2–9) times the expected cross section is given for m_{H^0} = 100–200 GeV at 95% CL.

[5] ABAZOV 13H search for $H^0 \to \gamma\gamma$ in 9.6 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[6] ABAZOV 13I search for H^0 production in the final state with one lepton and two or more jets plus missing E_T in 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The search is sensitive to WH^0, ZH^0 and vector-boson fusion Higgs production with $H^0 \to WW^{(*)}$. A limit on cross section times branching ratio which corresponds to (8–30) times the expected cross section is given in the range m_{H^0} = 100–200 GeV at 95% CL.

[7] ABAZOV 13J search for H^0 production in the final states $ee\mu$, $e\mu\mu$, $\mu\tau\tau$, and $e^{\pm}\mu^{\pm}$ in 8.6–9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The search is sensitive to WH^0, ZH^0 production with $H^0 \to WW^{(*)}$, $ZZ^{(*)}$, decaying to leptonic final states. A limit on cross section times branching ratio which corresponds to (2.4–13.0) times the expected cross section is given in the range m_{H^0} = 100–200 GeV at 95% CL.

[8] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[9] CHATRCHYAN 13AL search for $H^0 \to \gamma\gamma$ in 5.1 fb^{-1} and 5.3 fb^{-1} of pp collisions at E_{cm} = 7 and 8 TeV.

[10] AAD 12N search for $H^0 \to \gamma\gamma$ with 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV in the mass range m_{H^0} = 110–150 GeV.

[11] AALTONEN 12AN search for $H^0 \to \gamma\gamma$ with 10 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV in the mass range m_{H^0} = 100–150 GeV.

[12] CHATRCHYAN 12AO use data from CHATRCHYAN 12G, CHATRCHYAN 12E, CHATRCHYAN 12H, CHATRCHYAN 12I, CHATRCHYAN 12D, and CHATRCHYAN 12C.

[13] AALTONEN 09AB search for $H^0 \to \gamma\gamma$ in 3.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV in the mass range m_{H^0} = 70–150 GeV. Associated H^0W, H^0Z production and WW, ZZ fusion are considered.

[14] ABAZOV 08U search for $H^0 \to \gamma\gamma$ in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV in the mass range m_{H^0} = 70–150 GeV. Associated H^0W, H^0Z production and WW, ZZ fusion are considered. See their Tab. 1 for the limit on $\sigma \cdot B(H^0 \to \gamma\gamma)$, and see their Fig. 3 for the excluded region in the m_{H^0} — $B(H^0 \to \gamma\gamma)$ plane.

[15] SCHAEL 07 search for Higgs bosons in association with a fermion pair and decaying to WW^*. The limit is from this search and HEISTER 02L for a H^0 with SM production cross section.

[16] Search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq 209$ GeV. The limit is for a H^0 with SM production cross section.

[17] Updates ABREU 01F.

[18] ACHARD 03C search for $e^+e^- \to ZH^0$ followed by $H^0 \to WW^*$ or ZZ^* at E_{cm}= 200-209 GeV and combine with the ACHARD 02C result. The limit is for a H^0 with SM production cross section. For $B(H^0 \to WW^*) + B(H^0 \to ZZ^*) = 1$, $m_{H^0} > 108.1$ GeV is obtained. See fig. 6 for the limits under different BR assumptions.

[19] For $B(H^0 \to \gamma\gamma)$=1, m_{H^0} >117 GeV is obtained.

[20] ACHARD 02C search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq 209$ GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \to \gamma\gamma)$=1, m_{H^0} >114 GeV is obtained.

[21] AFFOLDER 01H search for associated production of a $\gamma\gamma$ resonance and a W or Z (tagged by two jets, an isolated lepton, or missing E_T). The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. See their Fig. 11 for limits with $B(H^0 \to \gamma\gamma) < 1$.

[22] ACCIARRI 00S search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at E_{cm}= 189 GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \to \gamma\gamma)$=1, $m_{H^0} > 98$ GeV is obtained. See their Fig. 5 for limits on $B(H \to \gamma\gamma)\cdot\sigma(e^+e^- \to Hf\overline{f})/\sigma(e^+e^- \to Hf\overline{f})$ (SM).

[23] BARATE 00L search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at E_{cm}= 88–202 GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \to \gamma\gamma)$=1, $m_{H^0} > 109$ GeV is obtained. See their Fig. 3 for limits on $B(H \to \gamma\gamma)\cdot\sigma(e^+e^- \to Hf\overline{f})/\sigma(e^+e^- \to Hf\overline{f})$ (SM).

[24] ABBIENDI 99O search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at 189 GeV. The limit is for a H^0 with SM production cross section. See their Fig. 4 for limits on $\sigma(e^+e^- \to H^0Z^0)\times B(H^0 \to \gamma\gamma)\times B(X^0 \to f\overline{f})$ for various masses. Updates the results of ACKERSTAFF 98Y.

[25] ABBOTT 99B search for associated production of a $\gamma\gamma$ resonance and a dijet pair. The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. Limits in the range of $\sigma(H^0 + Z/W)\cdot B(H^0 \to \gamma\gamma)$= 0.80–0.34 pb are obtained in the mass range m_{H^0}= 65–150 GeV.

[26] ABREU 99P search for $e^+e^- \to H^0\gamma$ with $H^0 \to b\overline{b}$ or $\gamma\gamma$, and $e^+e^- \to H^0q\overline{q}$ with $H^0 \to \gamma\gamma$. See their Fig. 4 for limits on $\sigma\times B$. Explicit limits within an effective interaction framework are also given.

Mass Limits for H^0 Decaying to Invisible Final States

These limits are for a neutral scalar H^0 which predominantly decays to invisible final states. Standard Model values are assumed for the couplings of H^0 to ordinary particles unless otherwise stated.

[1] AABOUD 19AI search for $H^0_{1,2}$ production by vector boson fusion and decay to invisible final states in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6(b) for limits on cross section times branching ratios for $m_{H^0_{1,2}}$ = 0.1–3 TeV.

[2] AAD 15BD search for $pp \to H^0WX$ and $pp \to H^0ZX$ with W or Z decaying hadronically and H^0 decaying to invisible final states in 20.3 fb^{-1} at E_{cm} = 8TeV. See their Fig. 6 for a limit on the cross section times branching ratio for m_{H^0} = 115–300 GeV.

[3] AAD 15BH search for events with a jet and missing E_T in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Limits on $\sigma(H'^0)$ B($H'^0 \to$ invisible) < (44–10) pb (95%CL) is given for $m_{H'^0}$ = 115–300 GeV.

[4] AAD 14BA search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle which decays to collimated pairs of e^+e^-, $\mu^+\mu^-$, or $\pi^+\pi^-$ plus invisible particles, in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 15 and 16 for limits on cross section times branching ratio.

[5] AAD 14O search for $pp \to H^0ZX$, $Z \to \ell\ell$, with H^0 decaying to invisible final states in 4.5 fb^{-1} at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. See their Fig. 3 for a limit on the cross section times branching ratio for m_{H^0} = 110–400 GeV.

[6] CHATRCHYAN 14B search for $pp \to H^0ZX$, $Z \to \ell\ell$ and $Z \to b\overline{b}$, and also $pp \to qqH^0X$ with H^0 decaying to invisible final states using data at E_{cm} = 7 and 8 TeV. See their Figs. 10, 11 for limits on the cross section times branching ratio for m_{H^0} = 100–400 GeV.

[7] AAD 13AG search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle which decays to $\mu^+\mu^-X'^0$, in 1.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 7 for limits on cross section times branching ratio.

[8] AAD 13AT search for H^0 production in the decay $H^0 \to X^0X^0$, where X^0 eventually decays to clusters of collimated e^+e^- pairs, in 2.04 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 3 for limits on cross section times branching ratio.

[9] CHATRCHYAN 13BJ search for H^0 production in the decay chain $H^0 \to X^0X^0$, $X^0 \to \mu^+\mu^-X'^0$ in 5.3 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 2 for limits on cross section times branching ratio.

[10] AAD 12AQ search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle which decays mainly to $b\overline{b}$ in the muon detector, in 1.94 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 3 for limits on cross section times branching ratio for m_{H^0} = 120, 140 GeV, m_{X^0} = 20, 40 GeV in the $c\tau$ range of 0.5–35 m.

[11] AALTONEN 12AB search for H^0 production in the decay $H^0 \to X^0X^0$, where X^0 eventually decays to clusters of collimated $\ell^+\ell^-$ pairs, in 5.1 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Cross section limits are provided for a benchmark MSSM model incorporating the parameters given in Table VI.

[12] AALTONEN 12U search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle with $c\tau \approx$ 1 cm which decays mainly to $b\overline{b}$, in 3.2 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Figs. 9 and 10 for limits on cross section times branching ratio for m_{H^0} = (130–170) GeV, m_{X^0} = 20, 40 GeV.

[13] ABBIENDI 10 search for $e^+e^- \to H^0Z$ with H^0 decaying invisibly. The limit assumes SM production cross section and B($H^0 \to$ invisible) = 1.

[14] ABBIENDI 07 search for $e^+e^- \to H^0Z$ with $Z \to q\overline{q}$ and H^0 decaying to invisible final states. The H^0 width is varied between 1 GeV and 3 TeV. A limit $\sigma \cdot B(H^0 \to$ invisible) < (0.07–0.57) pb (95%CL) is obtained at E_{cm} = 206 GeV for m_{H^0} = 60–114 GeV.

[15] Search for $e^+e^- \to H^0Z$ with H^0 decaying invisibly. The limit assumes SM production cross section and B($H^0 \to$ invisible) = 1.

[16] ACCIARRI 00M search for $e^+e^- \to ZH^0$ with H^0 decaying invisibly at E_{cm}=183–189 GeV. The limit assumes SM production cross section and B($H^0 \to$ invisible)=1. See their Fig. 6 for limits for smaller branching ratios.

Mass Limits for Light A^0

These limits are for a pseudoscalar A^0 in the mass range below $\mathcal{O}(10)$ GeV.

[1] AAD 25AT search for the decay $H \to ZA^0$, $Z \to \ell^+\ell^-$, A^0 decaying hadronically (gg or $q\overline{q}$), in 140 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for limits on B($H \to ZA^0$) with assumptions B($A^0 \to gg$) = 1 for m_{A^0} = 0.5–3.5 GeV, or B($A^0 \to q\overline{q}$) = 1 for m_{A^0} = 1.5–3.5 GeV. Supersedes AAD 20AE.

[2] ADACHI 23A search for flavor-changing τ decays $\tau \to eA^0$ and $\tau \to \mu A^0$, with A^0 invisible, using 62.8 fb^{-1} of e^+e^- collisions at E_{cm} = 10.58 GeV. Limits on B($\tau \to eA^0$)/B($\tau \to e\nu\nu$) in the range 1.1×10^{-3}–9.7×10^{-3} (95% CL) and B($\tau \to \mu A^0$)/B($\tau \to \mu\nu\nu$) in the range 0.7×10^{-3}–12.2×10^{-3} (95% CL) are given for m_{A^0} = 0–1.6 GeV. See their Fig. 2.

[3] TUMASYAN 23AR search for the decay $H \to A^0A^0$ with $A^0 \to \gamma\gamma$ (detected as a merged photonlike object) using 136 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Limits on B($H \to A^0A^0$)·B^2($A^0 \to \gamma\gamma$) in the range 0.9×10^{-3}–3.3×10^{-3} (95% CL) are given for m_{A^0} = 0.1–1.2 GeV. See their Fig. 2.

[4] ABLIKIM 22H search for the process $J/\psi \to A^0\gamma$ with A^0 decaying to $\mu^+\mu^-$ in 9×10^9 J/ψ events and give limits on B($J/\psi \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range 1.2×10^{-9}–7.78×10^{-7} (90% CL) for 0.212 GeV $\leq m_{A^0} \leq$ 3.0 GeV. See their Fig. 4.

[5] JIA 22 search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $\tau^+\tau^-$ or $\mu^+\mu^-$ in 158×10^6 $\Upsilon(2S)$ events and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \tau^+\tau^-$) in the range 3.8×10^{-6}–1.5×10^{-4} (90% CL) for m_{A^0} = 3.6–9.2 GeV, and B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range 3.1×10^{-7}–1.6×10^{-5} (90% CL) for m_{A^0} = 0.21–9.2 GeV. See their Fig. 4.

[6] AAD 20AE search for the decay $H^0 \to ZA^0$, $Z \to \ell^+\ell^-$, A^0 decaying hadronically ($A^0 \to gg$ or $s\overline{s}$), in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Limit on the product of production cross section and the $H^0 \to ZA^0$ branching ratio in the range 17–340 pb (95% CL) is given for m_{A^0} = 0.5–4.0 GeV, see their Table I.

[7] AABOUD 18AP search for the decay $H^0 \to A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10(b) for limits on B($H^0 \to A^0A^0$) in the range m_{A^0} = 1–2.5, 4.5–8 GeV, assuming a type-II two-doublet plus singlet model with tan(β) = 5.

[8] KHACHATRYAN 17AZ search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$, $\mu^+\mu^-b\overline{b}$, and $\mu^+\mu^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4, 5, and 6 for cross section limits in the range m_{A^0} = 5–62.5 GeV. See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[9] ABLIKIM 16E search for the process $J/\psi \to A^0\gamma$ with A^0 decaying to $\mu^+\mu^-$ and give limits on B($J/\psi \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range 2.8×10^{-8}–5.0×10^{-6} (90% CL) for 0.212 $\leq m_{A^0} \leq$ 3.0 GeV. See their Fig. 5.

[10] KHACHATRYAN 16F search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 8 for cross section limits for m_{A^0} = 4–8 GeV.

[11] LEES 15H search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $c\overline{c}$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to c\overline{c}$) in the range 7.4×10^{-5}–2.4×10^{-3} (90% CL) for 4.00 $\leq m_{A^0} \leq$ 8.95 and 9.10 $\leq m_{A^0} \leq$ 9.25 GeV. See their Fig. 6.

[12] LEES 13C search for the process $\Upsilon(2S, 3S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $\mu^+\mu^-$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3–9.7)\times10^{-6}$ (90% CL) for 0.212 $\leq m_{A^0} \leq$ 9.20 GeV. See their Fig. 5(e) for limits on the $b-A^0$ Yukawa coupling derived by combining this result with AUBERT 09Z.

[13] LEES 13L search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to gg or $s\overline{s}$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to gg$) between 1×10^{-6} and 2×10^{-2} (90% CL) for 0.5 $\leq m_{A^0} \leq$ 9.0 GeV, and B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to s\overline{s}$) between 4×10^{-6} and 1×10^{-3} (90%CL) for 1.5 $\leq m_{A^0} \leq$ 9.0 GeV. See their Fig. 4.

[14] LEES 13R search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $\tau^+\tau^-$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \tau^+\tau^-$) in the range $0.9–13\times10^{-5}$ (90% CL) for 3.6 $\leq m_{A^0} \leq$ 9.2 GeV. See their Fig. 4 for limits on the $b-A^0$ Yukawa coupling derived by combining this result with AUBERT 09P.

[15] ABLIKIM 12 searches for the process $\psi(3686) \to \pi\pi J/\psi$, $J/\psi \to A^0\gamma$ with A^0 decaying to $\mu^+\mu^-$. It gives mass dependent limits on B($J/\psi \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range 4×10^{-7}–2.1×10^{-5} (90% C.L.) for 0.212 $\leq m_{A^0} \leq$ 3.0 GeV. See their Fig. 2.

[16] CHATRCHYAN 12V search for A^0 production in the decay $A^0 \to \mu^+\mu^-$ with 1.3 fb^{-1} of pp collisions at E_{cm} = 7 TeV. A limit on $\sigma(A^0)$·B($A^0 \to \mu^+\mu^-$) in the range (1.5–7.5) pb is given for m_{A^0} = (5.5–8.7) and (11.5–14) GeV at 95% CL.

[17] AALTONEN 11P search in 2.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on B($t \to bH^+$) for 90 < m_{H^+} < 160 GeV.

[18] ABOUZAID 11A search for the decay chain $K_L \to \pi^0\pi^0A^0$, $A^0 \to \mu^+\mu^-$ and give a limit B($K_L \to \pi^0\pi^0A^0$) · B($A^0 \to \mu^+\mu^-$) < 1.0×10^{-10} at 90% CL for m_{A^0} = 214.3 MeV.

[19] The search was motivated by PARK 05.

[20] DEL-AMO-SANCHEZ 11J search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to invisible final states. They give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to$ invisible) in the range $(1.9–4.5)\times10^{-6}$ (90% CL) for 0 $\leq m_{A^0} \leq$ 8.0 GeV, and $(2.7–37)\times10^{-6}$ for 8.0 $\leq m_{A^0} \leq$ 9.2 GeV.

[21] LEES 11H search for the process $\Upsilon(2S, 3S) \to A^0\gamma$ with A^0 decaying hadronically and give limits on B($\Upsilon(2S, 3S) \to A^0\gamma$)·B($A^0 \to$ hadrons) in the range 1×10^{-6}–8×10^{-5} (90% CL) for 0.3 < m_{A^0} < 7 GeV. The decay rates for $\Upsilon(2S)$ and $\Upsilon(3S)$ are assumed to be equal up to the phase space factor. See their Fig. 5.

[22] ANDREAS 10 analyze constraints from rare decays and other processes on a light A^0 with $m_{A^0} < 2m_\mu$ and give limits on its coupling to fermions at the level of 10^{-4} times the Standard Model value.

[23] HYUN 10 search for the decay chain $B^0 \to K^{*0}A^0$, $A^0 \to \mu^+\mu^-$ and give a limit on B($B^0 \to K^{*0}A^0$) · B($A^0 \to \mu^+\mu^-$) in the range $(2.26–5.53)\times10^{-8}$ at 90%CL for m_{A^0} = 212–300 MeV. The limit for m_{A^0} = 214.3 MeV is 2.26×10^{-8}.

[24] HYUN 10 search for the decay chain $B^0 \to \rho^0A^0$, $A^0 \to \mu^+\mu^-$ and give a limit on B($B^0 \to \rho^0A^0$) · B($A^0 \to \mu^+\mu^-$) in the range $(1.73–4.51)\times10^{-8}$ at 90%CL for m_{A^0} = 212–300 MeV. The limit for m_{A^0} = 214.3 MeV is 1.73×10^{-8}.

[25] AUBERT 09P search for the process $\Upsilon(3S) \to A^0\gamma$ with $A^0 \to \tau^+\tau^-$ for 4.03 < m_{A^0} < 9.52 and 9.61 < m_{A^0} < 10.10 GeV, and give limits on B($\Upsilon(3S) \to A^0\gamma$)·B($A^0 \to \tau^+\tau^-$) in the range $(1.5–16)\times10^{-5}$ (90% CL).

[26] AUBERT 09Z search for the process $\Upsilon(2S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ for 0.212 < m_{A^0} < 9.3 GeV and give limits on B($\Upsilon(2S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3–8)\times10^{-6}$ (90% CL).

[27] AUBERT 09Z search for the process $\Upsilon(3S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ for 0.212 < m_{A^0} < 9.3 GeV and give limits on B($\Upsilon(3S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3–5)\times10^{-6}$ (90% CL).

[28] TUNG 09 search for the decay chain $K_L \to \pi^0\pi^0A^0$, $A^0 \to \gamma\gamma$ and give a limit on B($K_L \to \pi^0\pi^0A^0$) · B($A^0 \to \gamma\gamma$) in the range $(2.4–10.7)\times10^{-7}$ at 90%CL for m_{A^0} = 194.3–219.3 MeV. The limit for m_{A^0} = 214.3 MeV is 2.4×10^{-7}.

[29] LOVE 08 search for the process $\Upsilon(1S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ (for $m_{A^0} < 2m_\tau$) and $A^0 \to \tau^+\tau^-$. Limits on B($\Upsilon(1S) \to A^0\gamma$) · B($A^0 \to \ell^+\ell^-$) in the range 10^{-6}–10^{-4} (90% CL) are given.

[30] BESSON 07 give a limit B($\Upsilon(1S) \to \eta_b\gamma$) · B($\eta_b \to \tau^+\tau^-$) < 0.27% (95% CL), which constrains a possible A^0 exchange contribution to the η_b decay.

[31] PARK 05 found three candidate events for $\Sigma^+ \to p\mu^+\mu^-$ in the HyperCP experiment. Due to a narrow spread in dimuon mass, they hypothesize the events as a possible signal of a new boson. It can be interpreted as a neutral particle with $m_{A^0} = 214.3 \pm 0.5$ MeV and the branching fraction B($\Sigma^+ \to pA^0$)·B($A^0 \to \mu^+\mu^-$) = $(3.1^{+2.4}_{-1.9}\pm1.5)\times10^{-8}$.

[32] BALEST 95 give limits B($\Upsilon(1S) \to A^0\gamma$) ¡ 1.5×10^{-5} at 90% CL for m_{A^0} < 5 GeV. The limit becomes < 10^{-4} for m_{A^0} < 7.7 GeV.

[33] ANTREASYAN 90C give limits B($\Upsilon(1S) \to A^0\gamma$) ¡ 5.6×10^{-5} at 90% CL for m_{A^0} < 7.2 GeV. A^0 is assumed not to decay in the detector.

Other Mass Limits

We use a symbol H_1^0 if mass < 125 GeV or H_2^0 if mass > 125 GeV. The notation H is reserved for the 125 GeV particle.

[1] AAD 25AL search for production of H_2^0/A^0 in association with a $t\overline{t}$ pair, decaying to $t\overline{t}$, resulting in final states with one lepton or two opposite-sign leptons, using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for limits on cross section times branching ratios for $m_{H_2^0}$ and/or $m_{A^0} = 0.4$–1.0 TeV. Combined limits with AAD 23BG are shown in Fig. 10.

[2] AAD 25AN search for production of A^0 in association with a $t\overline{t}$ pair, in the decay $A^0 \to b\overline{b}$ using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for limits on cross section times branching ratio for $m_{A^0} = 12$–100 GeV. If the top Yukawa coupling is as strong as the one of the Standard Model Higgs and B($A^0 \to b\overline{b}$) = 1, the whole mass range is excluded at 95%CL.

[3] AAD 25AU search for the decay $H \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$, each tau pair decaying to hadrons + muon final states, in 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range $m_{A^0} = 4$–15 GeV, and Fig. 5 for the interpretation in terms of a model with two Higgs doublets plus a singlet.

[4] AAD 25AW search for the decay $H \to A^0A^0 \to b\overline{b}b\overline{b}$ in associated ZH production using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 14 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range $m_{A^0} = 12$–60 GeV.

[5] AAD 25AW search for the decay $H \to A_1^0A_2^0 \to b\overline{b}b\overline{b}$ and $H \to A_1^0A_2^0 \to A_1^0A_1^0A_1^0 \to b\overline{b}b\overline{b}b\overline{b}$ in associated ZH production using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 15 for limits on the product of production cross section (normalized to the SM) and branching ratios for several combinations of $m_{A_1^0}$ and $m_{A_2^0}$.

[6] AAD 25AY search for $H \to H_1^0H_1^0$ with hadronically decaying H_1^0 having a long lifetime resulting in displaced vertex, using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The case the parent particle has a different mass $H_{2/3}^0 \to H_1^0H_1^0$) are also examined. See their Figs. 12 and 13 for limits with decay length in the range 0.01–1000 m.

[7] AAD 25F search for $H_{1/2}^0 \to Z'Z'$ with $Z' \to \ell^+\ell^-$ using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on production cross section times branching ratios for $m_{H_1^0} = 40$–115 GeV, $m_{H_2^0} = 130$–800 GeV, and $m_{Z'} = 15$–300 GeV.

[8] AAD 25J search for production of H_3^0 decaying to H_2^0H, $H_2^0 \to HH$ in the $b\overline{b}b\overline{b}b\overline{b}$ final state, using 126 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 7 and 8 for limits on production cross section times branching ratios in the ranges $m_{H_3^0} = 325$–1500 GeV and $m_{H_2^0} = 250$–1000 GeV.

[9] AAD 25O search for $H_1^0 \to \gamma\gamma$ in 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 6(b), 8(b) and 9(b) for limits on cross section times branching ratio for $m_{H_1^0}$ = 66–110 GeV. Fig. 9(b) assumes Standard Model Higgs-like properties.

[10] AAD 25X search for the decay chain $H \to A^0A^0 \to \gamma\gamma\tau^+\tau^-$ in 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5(b) for limits on the product of branching ratios for $m_{A^0} = 10$–60 GeV, assuming SM-like production.

[11] ADAN 25 searches for $H \to A^0A^0 \to \mu^+\mu^-c\overline{c}$ using publicly available CMS data of 16.4 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See his Fig. 7 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range $m_{A^0} = 4$–11 GeV, and Fig. 8 for the interpretation in terms of a model with two Higgs doublets plus a singlet.

[12] CHEKHOVSKY 25C search for $H_2^0/A^0 \to b\overline{b}$ by b-associated prodution using 36.7–126.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 11–14 for limits on cross section times branching ratio for $m_{H_2^0}$, $m_{A^0} = 0.125$–1.8 TeV.

[13] CHEKHOVSKY 25D search for invisibly decaying $H_1^0/H_2^0/A^0$ produced in association with t or $t\overline{t}$, using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for masses between 50 and 500 GeV.

[14] CHEKHOVSKY 25I search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH in the final states $\ell^+\ell^-\tau^+\tau^-$, assuming B($H \to \tau^+\tau^-$) of the SM, using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{A^0} = 0.225$–1.0 TeV for the two production mechanisms, and Figs. 5, 6 for constraints on the combination of the two production mechanisms.

[15] CHEKHOVSKY 25J search for $A_2^0 \to HA_1^0$, A_1^0 escaping detection, using 101 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. In the framework of two Higgs doublet plus a singlet model, limits on signal strengths are given in their Figs. 3 and 4 with varying model parameters.

[16] CORTINA-GIL 25B search for the decay $K^+ \to \pi^+H_1^0$, with H_1^0 escaping detection or decaying to $\mu^+\mu^-$. See their Figs. 2, 3, and 6 for limits on the product of branching ratios for $m_{H_1^0} = 0$–0.33 GeV, and Fig. 9 for limits on the mixing with the Standard Model Higgs boson.

[17] HAYRAPETYAN 25A search for the decay $H_1^0 \to \gamma\gamma$ in 132 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H_1^0} = 70$–110 GeV.

[18] HAYRAPETYAN 25AP search for $H_3^0 \to HH_{1/2}^0$ with decays $H \to b\overline{b}$ and $H_{1/2}^0 \to \gamma\gamma$ using 132 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 5 and 6 for limits on cross section times branching ratio for $m_{H_3^0} = 0.24$–1.0 TeV and $m_{H_{1/2}^0} = 0.07$–0.8 TeV.

[19] HAYRAPETYAN 25C search for production of H_3^0 in the decay chain $H_3^0 \to H_1^0H_1^0$, $H_1^0 \to \gamma\gamma$ using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H_3^0} = 0.3$–3 TeV, $m_{H_1^0}/m_{H_3^0} = 0.005$–0.025.

[20] HAYRAPETYAN 25I search for $A^0 \to ZH_2^0$ with $H_2^0 \to t\overline{t}$ using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on production cross section times branching ratios for $m_{A^0} = 0.45$–2.1 TeV and $m_{H_2^0} = 0.35$–2.0 TeV.

[21] HAYRAPETYAN 25P search for A^0 decaying to invisible final states, produced in association with a $b\overline{b}$ pair, using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{A^0} = 50$–500 GeV and Fig. 8 for excluded parameter space, both in the two-Higgs-doublet plus singlet pseudoscalar model.

[22] AAD 24A search for the decay $H_2^0 \to Z\gamma$ with Z decaying to e^+e^- or $\mu^+\mu^-$ using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4 for limits on production cross section times branching ratios for $m_{H_2^0} = 0.22$–3.4 TeV.

[23] AAD 24AP search for production of a heavy H_2^0 or A^0 decaying to $t\overline{t}$ in 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 15 and 16 for limits on the Yukawa coupling for m_{A^0}, $m_{H_2^0} = 0.4$–1.4 TeV for different assumptions on width over mass.

[24] AAD 24BQ search for the decay chain $H \to A^0A^0 \to b\overline{b}\tau^+\tau^-$, produced by gluon fusion, vector boson fusion, or in association with a weak vector boson, in 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 10 for limits on the product of branching ratios in the range $m_{A^0} = 12$–60 GeV.

[25] AAD 24BV search for H_2^0 produced by vector-boson fusion, decaying to $HH \to b\overline{b}b\overline{b}$, using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for limits on the product of production cross section times branching ratios for $m_{H_2^0} = 1$–5 TeV.

[26] AAD 24BW search for production of H_3^0 decaying to H_2^0H, $H_2^0 \to W^+W^-$ or ZZ, and $H \to \gamma\gamma$ using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 6–8 for limits on production cross section times branching ratios in the ranges $m_{H_3^0} = 0.3$–1.0 TeV and $m_{H_2^0} = 0.17$–0.5 TeV.

[27] AAD 24BX search for production of H_4^0 decaying to $H_2^0H_3^0$, $H_2^0 \to$ invisible, and $H_3^0 \to ZZ \to 4\ell$, using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 (a), (b) for limits on production cross section times branching ratios in the ranges $m_{H_4^0} = 0.39$–1.3 TeV, $m_{H_3^0} = 0.22$–1.0 TeV, and $m_{H_2^0} = 160$ GeV.

[28] AAD 24BX search for production of A^0 decaying to H_2^0Z, $H_2^0 \to ZZ$, resulting in 4ℓ final states, using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 (c), (d) for limits on production cross section times branching ratios in the ranges $m_{A^0} = 0.32$–1.3 TeV and $m_{H_2^0} = 0.22$–1.0 TeV.

[29] AAD 24CA search for production of H_3^0 decaying to $H_{1,2}^0H$, $H_{1,2}^0 \to b\overline{b}$, and $H \to \gamma\gamma$ using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4 for limits on production cross section times branching ratios in the ranges $m_{H_3^0} = 0.17$–1.0 TeV and $m_{H_{1,2}^0} = 0.015$–0.5 TeV.

[30] AAD 24CD search for production of H_2^0 decaying to ZA, $A \to$ invisible, using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 8–12 for excluded parameter regions in two-Higgs-doublet plus singlet pseudoscalar model.

[31] AAD 24CF search for gluon-fusion production of A^0 decaying to $\tau^+\tau^-$ in 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio in the range $m_{A^0} = 20$–90 GeV, and Fig. 8 for A^0 coupling with the top quark.

[32] AAD 24CI search for production of H_2^0, A^0 decaying to invisible final states, in various channels including $t\overline{t}$ + missing E_T and $t\overline{t}t\overline{t}$, using up to 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 3 for cross section limits in a simplified model with fixed Dark Matter mass and couplings to quarks and Dark Matter.

[33] AAD 24CK combines published ATLAS data up to 139 fb^{-1} to constrain two-Higgs-doublet plus singlet pseudoscalar model with A_1^0 decaying to invisibly into Dirac Dark Matter final states. See their Figs. 4–9 for excluded parameter regions.

Gauge & Higgs Boson Particle Listings

Neutral Higgs Bosons, Searches for

[34] AAD 24H combine searches for a scalar resonance decaying to HH using up to 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV from AAD 22F, AAD 23Z, and AAD 22Y. See their Fig. 1 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.251–5.0 TeV.

[35] AAD 24K search for the decay $H \to ZA^0$ with $A^0 \to \gamma\gamma$ and $Z \to \ell^+\ell^-$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Merged $\gamma\gamma$ events as well as resolved ones are looked for. See their Fig. 3 for limits on the product of the branching ratios for m_{A^0} = 0.1–33 GeV.

[36] ADACHI 24F search for H_1^0, which couples preferentially to muon pairs, in the process $e^+e^- \to \mu^+\mu^- H_1^0 \to \mu^+\mu^-\mu^+\mu^-$ using 178 fb^{-1} of e^+e^- collisions at E_{cm} = 10.58 GeV. See their Fig. 13 (lower) for limits on cross section times branching ratio for $m_{H_1^0}$ = 0.212–9.0 GeV. Limits on the model parameter are given in Fig. 14 (lower).

[37] HAYRAPETYAN 24AA search for the decay chain $H \to A^0A^0 \to b\overline{b}b\overline{b}$, produced in association with $W^\pm$ or Z, in 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 3 for limits on the product of branching ratios in the range m_{A^0} = 15–60 GeV.

[38] HAYRAPETYAN 24AE search for $H_2^0 \to HH$ in the final state $b\overline{b}W^+W^-$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 19 (upper) for limit on the product of production cross section times branching ratios for $m_{H_2^0}$ = 0.25–0.9 TeV.

[39] HAYRAPETYAN 24AF search for $H \to A^0A^0$ in the final state $b\overline{b}\mu^+\mu^-$ and $b\overline{b}\tau^+\tau^-$ in 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 10, 11, and 12 for limits on the product of branching ratios in the range m_{A^0} = 12–60 GeV. Interpretation of the limits in terms of two Higgs doublet plus singlet models is given in their Figs. 13 and 14.

[40] HAYRAPETYAN 24AI search for $H \to H_1^0H_1^0$, with long-lived H_1^0 decaying in the muon detectors to $\gamma\gamma$, e^+e^-, $\pi^0\pi^0$, $\pi^+\pi^-$, K^+K^-, K^0K^0, $d\overline{d}$, $\tau^+\tau^-$, or $b\overline{b}$, using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 13–17 for limits on B($H \to H_1^0H_1^0$) in the mass range between 0.4 and 55 GeV for each of the decay modes.

[41] HAYRAPETYAN 24AJ search for production of a scalar resonance decaying to $\gamma\gamma$ in 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 3 (right) for limits on production cross section times branching ratio for $m_{H_2^0}$ = 0.6–5.0 TeV, and Fig. 4 (lower) for their dependence on the width.

[42] HAYRAPETYAN 24AZ search for pair production of A^0 decaying to $\mu^+\mu^-$ using 101–137 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for limits on cross section times branching ratio for m_{A^0} = 0.21–60 GeV.

[43] HAYRAPETYAN 24AZ search for H or $H_{1,2}^0$ decaying to $A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ using 101–137 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for limits on cross section times branching ratio for m_{A^0} = 0.5–2.7 GeV and several choices of $m_{H_{1,2}^0}$ in a NMSSM scenario.

[44] HAYRAPETYAN 24I search for the decay $H \to ZA^0$ with $A^0 \to \gamma\gamma$ and $Z \to \ell^+\ell^-$ in 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on the product of cross section times the branching ratios for m_{A^0} = 1–30 GeV.

[45] TUMASYAN 24A search for production of $H_{1,2}^0$ in association with W, Z, or $t\overline{t}$, decaying to e^+e^-, $\mu^+\mu^-$, or $\tau^+\tau^-$, using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 13 for limits on cross section times branching ratio for $m_{H_{1,2}^0}$ = 15–350 GeV. See also Figs. 16 and 17 for limits on the mixing with the Standard Model Higgs boson.

[46] TUMASYAN 24B search for $H_2^0 \to HH$ in the final state $\gamma\gamma b\overline{b}$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 (upper) for limit on the product of production cross section times branching ratios for $m_{H_2^0}$ = 0.26–1.0 TeV.

[47] TUMASYAN 24B search for production of H_3^0 decaying to $H_{1,2}^0H \to b\overline{b}\gamma\gamma$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on production cross section times branching ratios for $m_{H_3^0}$ = 0.3–1.0 TeV and $m_{H_{1,2}^0}$ = 0.09–0.8 TeV.

[48] AAD 23AD search for associated production of W/ZH_2^0 with the decay chain $H_2^0 \to HH \to b\overline{b}b\overline{b}$ using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–1000 GeV.

[49] AAD 23AD search for gluon fusion production of A^0 with the decay chain $A^0 \to ZH_2^0$, $H_2^0 \to HH \to b\overline{b}b\overline{b}$ using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10 for limits on cross section times branching ratios for m_{A^0} = 350–800 GeV and $m_{H_2^0}$ = 260–400 GeV.

[50] AAD 23AJ search for production of $H^\pm$ in association with a top quark, followed by $H^\pm \to W^\pm A^0$, $A^0 \to$ invisible, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10 for excluded parameter regions of 2HDM + CP-odd singlet model.

[51] AAD 23BD search for a top quark decaying to $qH_{1,2}^0$ (q = u, c), $H_{1,2}^0 \to b\overline{b}$, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for limits on production cross section times branching ratios for $m_{H_{1,2}^0}$ = 20–160 GeV.

[52] AAD 23BE search for associated production of H_2^0W and decay $H_2^0 \to W^+W^-$ assuming the presence of higher dimensional $H_2^0W^+W^-$ interactions, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for excluded parameter region of higher dimensional operators, and Fig. 7 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.3–1.5 TeV.

[53] AAD 23BG search for production of H_2^0/A^0 in association with a $t\overline{t}$ pair, decaying to $t\overline{t}$, resulting in final states with two same-sign leptons or three or more leptons, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 (corrected version in the erratum) for limits on cross section times branching ratios for $m_{H_2^0}$ and/or m_{A^0} = 0.4–1.0 TeV.

[54] AAD 23BW search for A^0 production in association with a $t\overline{t}$ pair, decaying to $\mu^+\mu^-$, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5(a) for limits on production cross section times branching ratio for m_{A^0} = 15–72 GeV.

[55] AAD 23BX search for production of $H \to \tau^+\tau^-$ with missing transverse momentum using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for interpretation of the data in terms of 2HDM + a model.

[56] AAD 23CA search for production of H_3^0 decaying to H_2^0H, $H_2^0 \to W^+W^-$ or ZZ, and $H \to \tau^+\tau^-$ using 140 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 4, 5 for limits on production cross section times branching ratios in the ranges $m_{H_3^0}$ = 0.5–1.5 TeV and $m_{H_2^0}$ = 0.2–0.5 TeV.

[57] AAD 23CR search for H_2^0 having flavor-violating couplings to tc or tu, produced in association with top quark(s), using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 14 for limits on production cross section times branching ratios for $m_{H_2^0}$ = 0.2–1.5 TeV with various assumptions on the flavor-changing couplings.

[58] AAD 23O search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH in the final states $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-b\overline{b}$ using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for limits on cross section times branching ratio for m_{A^0} = 0.22–2.0 TeV, and Fig. 11 for limits with both production components.

[59] AAD 23R search for the decay $A^0 \to \gamma\gamma$ in 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on cross section times branching ratio for m_{A^0} = 10–70 GeV.

[60] AAD 23U search for the decay $H_2^0 \to Z\gamma$ with Z decaying hadronically in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8(a) for limits on production cross section times branching ratios for $m_{H_2^0}$ = 1.0–6.8 TeV.

[61] AAD 23Z search for the decay chain $H_2^0 \to HH \to b\overline{b}\tau^+\tau^-$ using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10 for limits on the product of production cross section times branching ratios for $m_{H_2^0}$ = 0.251–1.6 TeV.

[62] HAYRAPETYAN 23C search for $H_{1,2}^0 \to e\mu$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on production cross section times branching ratio for $m_{H_{1,2}^0}$ = 110–160 GeV.

[63] HAYRAPETYAN 23G search for dimuon resonance in the mass range 1.1–2.6 or 4.2–7.9 GeV in 96.6 fb^{-1} of pp collisions at E_{cm} = 13 TeV, in inclusive and high p_T selections. See their Fig. 5 for cross section times branching ratio limits and Fig. 7 for mixing angle limits in two Higgs doublet plus singlet model (at 90% CL).

[64] TUMASYAN 23 search for production of H_3^0 decaying to $H_{1,2}^0H \to b\overline{b}b\overline{b}$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for limits on production cross section times branching ratios for $m_{H_3^0}$ = 0.9–4.0 TeV and $m_{H_{1,2}^0}$ = 60–600 GeV, and their interpretation in the NMSSM and the Two Real Singlet Model (TRSM).

[65] TUMASYAN 23M search for the decay chain $H \to A^0A^0 \to \gamma\gamma\gamma\gamma$ in 132 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for limits on cross section times branching ratio in the range m_{A^0} = 15–62 GeV.

[66] TUMASYAN 23O search for $H_2^0 \to HH$, each H decaying to either WW^* or $\tau^+\tau^-$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 14 (upper) for limit on the product of production cross section times branching ratios for $m_{H_2^0}$ = 0.25–1.0 TeV.

[67] TUMASYAN 23S search for gluon fusion and b-associated production of $H_{1,2}^0$ decaying to $\tau^+\tau^-$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10 for limits on production cross section times branching ratios for $m_{H_{1,2}^0}$ = 0.06–3.5 TeV.

[68] AAD 22A search for the decay chain $H \to A^0A^0 \to \mu^+\mu^-b\overline{b}$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for limits on the overall branching fraction in the range m_{A^0} = 16–62 GeV. See also Fig. 11 for limits without assuming A^0 is pseudoscalar.

[69] AAD 22D search for ZA^0 associate production with $Z \to \ell^+\ell^-$, A^0 decaying invisibly, in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for excluded regions in the mass parameter space of two Higgs doublet plus singlet (2HDM+A^0) model with a certain choice of the model parameters.

[70] AAD 22F search for gluon fusion production of H_2^0 decaying to $HH \to b\overline{b}b\overline{b}$ using 126–139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. B($H \to b\overline{b}$) = 0.582 is assumed. See their Fig. 14 for limit on the product of production cross section times branching ratios for $m_{H_2^0}$ = 0.251–5.0 TeV.

[71] AAD 22I search for ZH associate production with the decay chain $H \to \widetilde{\chi}_2^0\widetilde{\chi}_1^0$, $\widetilde{\chi}_2^0 \to A^0\widetilde{\chi}_1^0$, $A^0 \to b\overline{b}$, and $Z \to \ell^+\ell^-$, in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 3 and 4 for limits on the product of cross section times the branching ratios for m_{A^0} = 20–65 GeV with various choices of NMSSM model parameters.

[72] AAD 22J search for the decay $H \to ZA^0$ with $A^0 \to \mu^+\mu^-$ and $Z \to e^+e^-$, $\mu^+\mu^-$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV assuming SM gluon-gluon fusion production of the H. See their Fig. 17(b) for limits on the product of cross section times the branching ratios for m_{A^0} = 15–30 GeV.

[73] AAD 22J search for the decay $H \to A^0A^0$ with $A^0 \to \mu^+\mu^-$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV assuming SM gluon-gluon fusion production of the H in the range of m_{A^0} = 1–60 GeV . See their Fig. 14(b) for limits on the product of cross section times the branching ratios for m_{A^0} = 1.5–60 GeV (excluding ψ and Υ regions). The limit also applies to the decay $H \to H_1^0H_1^0$.

[74] AAD 22P search for invisibly decaying H_1^0, H_2^0 produced by vector boson fusion in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Limit on the product of cross section times branching ratio in the range 0.1–1 pb (95% CL) is given for the mass range 0.05–2 TeV. See their Fig. 14.

[75] AAD 22Y search for gluon fusion production of H_2^0 decaying to $HH \to b\overline{b}\gamma\gamma$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 15 for limit on the product of production cross section times branching ratios to HH for $m_{H_2^0}$ = 0.251–1.0 TeV.

[76] ABRATENKO 22A search for a singlet scalar boson H_1^0 having a small mixing with the SM Higgs boson in the decay chain $K^+ \to H_1^0\pi^+$, $H_1^0 \to \mu^+\mu^-$ from data corresponding to 7.01×10^{20} protons on NuMI target. See their Fig. 13 (right) and Table V for limits on the SM Higgs component of H_1^0 for $m_{H_1^0}$ = 212–279 MeV.

[77] TUMASYAN 22AK search for gluon-fusion production of H_3^0 decaying to $H_1^0 H_1^0 \to b\bar{b}b\bar{b}$ in 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H_3^0} = 1$–3 TeV, $m_{H_1^0} = 25$–100 GeV.

[78] TUMASYAN 22D search for production of an H_2^0 (denoted radion in the paper) in gluon fusion and vector boson fusion, decaying to W^+W^- in the final states $\ell\nu$ + hadrons, using 137 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H_2^0} = 1.0$–4.5 TeV.

[79] AAD 21AF search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell'^+\ell'^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4 for upper limits on cross section times branching ratio for $m_{H_2^0} = 0.2$–2.0 TeV assuming ggF or VBF with narrow width approximation, and Fig. 5 for upper limits on cross section times branching ratio for $m_{H_2^0} = 0.4$–2.0 TeV assuming ggF, and with several assumptions on its width.

[80] AAD 21AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH_2^0 \to \ell^+\ell^- b\overline{b}$ or $\ell^+\ell^- W^+W^-$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 9 and 13 for cross section limits for $m_{A^0} = 230$–800 GeV and $m_{H_2^0} = 130$–700 GeV.

[81] AAD 21AY search for production of a scalar resonance decaying to $\gamma\gamma$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5(a) for limits on fiducial cross section times branching ratio for $m_{H_2^0} = 0.16$–3 TeV with narrow width approximation, and Table 2 with several assumptions on the width.

[82] AAD 21AZ search for production of A_2^0 decaying to HA_1^0 followed by $H \to \gamma\gamma$, $A_1^0 \to$ invisible in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 10–12 for limits in terms of two-Higgs-doublet model plus singlet pseudoscalar and a fermionic Dark Matter particle.

[83] AAD 21BB search for production of A_2^0 by gluon fusion or associated $A_2^0 b\overline{b}$ production, decaying to HA_1^0 followed by $H \to b\overline{b}$, $A_1^0 \to$ invisible in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for limits in terms of two-Higgs-doublet plus singlet pseudoscalar model.

[84] AAD 21BE search for production of A_1^0 associated with a single top quark and either a light quark or a W boson, decaying to invisible final states, in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 13–15 for limits in terms of two-Higgs-doublet model plus singlet pseudoscalar, which is assumed to decay to a pair of Dark Matter particles.

[85] ABRATENKO 21 search for a singlet scalar boson H_1^0 having a small mixing with the SM Higgs boson in the decay chain $K^+ \to H_1^0\pi^+$, $H_1^0 \to e^+e^-$ from data corresponding to 1.93×10^{20} protons on NuMI target. See their Fig. 2 for limits on the SM Higgs component of H_1^0 for $m_{H_1^0} = 3$–210 MeV.

[86] SIRUNYAN 21A search for $H_2^0 \to ZA^0$ with $Z \to \ell^+\ell^-$, A^0 decaying invisibly, in 137 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for excluded regions in the mass parameter space of two Higgs doublet plus singlet model with a certain choice of the model parameters.

[87] TUMASYAN 21F search for gluon fusion production of H_3^0 decaying to $HH_{1,2}^0 \to \tau^+\tau^- b\overline{b}$ in 137 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 5 and 6 for limits on cross section times branching ratios for $m_{H_{1,2}^0} = 0.06$–2.8 TeV and $m_{H_3^0} = 0.24$–3.0 TeV.

[88] AAD 20AA search for $H_2^0/A^0 \to \tau^+\tau^-$ produced by gluon fusion or b-associated production using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 2(a), 2(b) for limits on the product of cross section and branching ratio for $m_{H_2^0}$, $m_{A^0} = 0.2$–2.5 TeV.

[89] AAD 20AI search for ZH production followed by the decay $H \to A^0A^0 \to b\overline{b}b\overline{b}$ in 36 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The search looks for collimated $A^0 \to b\overline{b}$ decays and is complementary to AABOUD 18BX. See their Fig. 10 for limits on the product of production cross section and branching ratios in the range $m_{A^0} = 15$–30 GeV.

[90] AAD 20AO search for gluon fusion production of H_2^0 decaying to $HH \to \tau^+\tau^- b\overline{b}$ (with hadronically decaying $\tau^+\tau^-$) using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. Limit on the product of production cross section times branching ratios in the range 28–817 fb (95% CL) is given for $m_{A^0} = 1.0$–3.0 TeV, see their Fig. 13.

[91] AAD 20C combine searches for a scalar resonance decaying to HH in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV from AABOUD 19A, AABOUD 19O, AABOUD 18CQ, AABOUD 19T, AABOUD 18CW, and AABOUD 18BU. See their Fig. 5(a) for limits on cross section times branching ratio for $m_{H_2^0} = 0.26$–3 TeV.

[92] AAD 20L search for b-associated production of H_2^0 decaying to $b\overline{b}$ in 27.8 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for limits on the product of cross section and branching ratio for $m_{H_2^0} = 0.45$–1.4 TeV.

[93] AAD 20X search for vector-boson-fusion production of H_2^0 decaying to HH using 126 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on the product of cross section and branching ratio for the assumptions of a narrow- and broad-width resonance.

[94] AAIJ 20AL search for dimuon resonance in the mass range 0.2–60 GeV in 5.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV, in inclusive and b quark associated production. Displaced decays are searched for for masses below 3 GeV. See their Figs. 7–9 for cross section limits and Fig. 10 for limits for mixing angle in two Higgs doublet plus singlet model (at 90% CL).

[95] SIRUNYAN 20 search for the decay $H \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ or $\tau^+\tau^-\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 10 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range $m_{A^0} = 4$–15 GeV.

[96] SIRUNYAN 20AA search for $H_2^0 \to ZA^0$, $A^0 \to b\overline{b}$ or $A^0 \to ZH_2^0$, $H_2^0 \to b\overline{b}$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on the product of cross section and branching ratio for $m_{H_2^0} = 0.12$–1 TeV and $m_{A^0} = 0.03$–1 TeV.

[97] SIRUNYAN 20AC search for gluon-fusion production of A^0 decaying to ZH in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on the product of cross section and branching ratios for $m_{A^0} = 220$–400 GeV.

[98] SIRUNYAN 20AD search for lepton-flavor violating decays $H_2^0 \to \mu\tau$, $e\tau$ of gluon-fusion-produced H_2^0 in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 (9) and Table 5 (6) for limits on production cross section times branching ratio for $m_{H_2^0} = 0.2$–0.9 TeV for the $\mu\tau$ ($e\tau$) final state.

[99] SIRUNYAN 20AF search for $H_2^0/A^0 \to t\overline{t}$ with one or two charged leptons in the final state using kinematic variables in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 5 and 6 for limits on top Yukawa coupling of H_2^0 and A^0 for $m_{H_2^0}$, $m_{A^0} = 0.4$–0.75 TeV for various width assumptions.

[100] SIRUNYAN 20AP search for the decay H or $H_2^0 \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ (for $m_{H_2^0} = 300$ GeV) with boosted final-state topology in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range $m_{A^0} = 3.6$–21 GeV, and Figs. 8 and 9 for its interpretation in terms of models with two Higgs doublets plus a singlet.

[101] SIRUNYAN 20Y search for gluon-fusion and vector-boson-fusion production of H_2^0 decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for limits on the product of cross section and branching ratio for $m_{H_2^0} = 0.2$–3 TeV.

[102] SIRUNYAN 20Z search for $H_{1,2}^0$ or A^0 production in association with a $t\overline{t}$ pair, decaying to e^+e^- or $\mu^+\mu^-$, in 137 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 12 for limits on production cross section times branching ratio for $m_{H_{1,2}^0}$, $m_{A^0} = 15$–75 GeV and 108–340 GeV.

[103] AABOUD 19A search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 27.5–36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9(a) for limits on cross section times branching ratios for $m_{H_2^0} = 0.26$–3 TeV.

[104] AABOUD 19AG search for the decay $H \to A^0A^0 \to \mu^+\mu^- b\overline{b}$ in 36.7 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 (a) for limits on the product of production cross section (normalized to the SM) and branching ratios in the range $m_{A^0} = 20$–60 GeV.

[105] AABOUD 19O search for a scalar resonance decaying to $HH \to b\overline{b}WW^*$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 12 (left) for limits on cross section times branching ratio for $m_{H_2^0} = 0.5$–3 TeV.

[106] AABOUD 19T search for a scalar resonance decaying to $HH \to WW^*WW^*$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H_2^0} = 260$–500 GeV, assuming SM decay rates for the H.

[107] AABOUD 19V combine published ATLAS data to constrain two-Higgs-doublet plus singlet pseudoscalar model with A_1^0 decaying to invisible final states. See their Fig. 19 for excluded parameter regions.

[108] AABOUD 19Y search for a narrow scalar resonance produced by gluon fusion or b associated production, decaying to $\mu^+\mu^-$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 4 and 5(a) for cross section limits for $m_{H_2^0} = 0.2$–1.0 TeV.

[109] AALTONEN 19 search for b associated production of a scalar particle decaying to $b\overline{b}$ in 5.4 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H_{1,2}^0} = 100$–300 GeV.

[110] SIRUNYAN 19 search for a narrow scalar resonance decaying to $HH \to \gamma\gamma b\overline{b}$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 (left) for limits on cross section times branching ratios for $m_{H_2^0} = 260$–900 GeV.

[111] SIRUNYAN 19AE search for a scalar resonance produced in association with a $b\overline{b}$ pair, decaying to $\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4 for cross section limits for $m_{A^0} = 25$–70 GeV.

[112] SIRUNYAN 19AN search for production of A_2^0 decaying to HA_1^0 followed by $H \to b\overline{b}$, $A_1^0 \to$ invisible in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV, in the mass range $m_{A_2^0} = 0.2$–1.6 TeV, $m_{A_1^0} = 0.15$–0.5 TeV. See their Fig. 6 for limits in terms of two-Higgs-doublet plus singlet pseudoscalar model.

[113] SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or b-associated production, decaying to $ZH \to \ell^+\ell^- b\overline{b}$ ($\ell = e$, μ) or $\nu\overline{\nu}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for cross section limits for $m_{A^0} = 0.22$–1.0 TeV.

[114] SIRUNYAN 19B search for gluon fusion production of narrow scalar resonance with large transverse momentum, decaying to $b\overline{b}$, in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 7 and 8 for limits on cross section times branching ratio for the resonance mass of 50–350 GeV.

[115] SIRUNYAN 19BB search for the decay $H_1^0 \to \gamma\gamma$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV and 35.9 fb^{-1} at $E_{cm} = 13$ TeV. See their Figs. 4–6 for limits on cross section times branching ratio for $m_{H_1^0} = 80$–110 GeV (some results in Fig. 5 for $m_{H_1^0} = 70$–110 GeV).

[116] SIRUNYAN 19BD search for the decay $H \to A^0A^0 \to \mu^+\mu^- b\overline{b}$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on the product of cross section times branching ratios in the range $m_{A^0} = 20$–62.5 GeV. See also their Figs. 6 and 7 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[117] SIRUNYAN 19BE combine searches for $H_2^0 \to HH$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV in various H decay modes, from SIRUNYAN 18A, SIRUNYAN 18AF, SIRUNYAN 18CW, SIRUNYAN 19, and SIRUNYAN 19H. See their Fig. 3 for limits on cross section times branching ratios for $m_{H_2^0} = 0.25$–3 TeV.

[118] SIRUNYAN 19BQ search for production of $H_{1,2}^0$ decaying to $A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_{1,2}^0} = 90$–150 GeV, $m_{A^0} = 0.25$–3.55 GeV.

Gauge & Higgs Boson Particle Listings

Neutral Higgs Bosons, Searches for

[119] SIRUNYAN 19CR search for production of H_2^0/A^0 in gluon fusion and in association with a $b\overline{b}$ pair, decaying to $\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for limits on cross section times branching ratio.

[120] SIRUNYAN 19H search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV, where one $b\overline{b}$ pair is resolved and the other not. Limits on cross section times branching ratios for $m_{H_2^0}$ = 0.75–1.6 TeV are obtained and combined with data from SIRUNYAN 18AF. See their Fig. 5 (right).

[121] AABOUD 18AA search for production of a scalar resonance decaying to $Z\gamma$, with Z decaying hadronically, in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8(a) for limits on cross section times branching ratio for $m_{H_2^0}$ = 1.0–6.8 TeV.

[122] AABOUD 18AG search for the decay $H \to A^0A^0 \to \gamma\gamma gg$ in 36.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 2 and Table 6 for cross section limits in the range m_{A^0} = 20–60 GeV.

[123] AABOUD 18AH search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH_2^0 \to \ell^+\ell^-b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for cross section limits for m_{A^0} = 230–800 GeV and $m_{H_2^0}$ = 130–700 GeV.

[124] AABOUD 18AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH in the final states $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for cross section limits for m_{A^0} = 0.2–2 TeV. See also AABOUD 18CC.

[125] AABOUD 18BF search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for upper limits on cross section times branching ratio for $m_{H_2^0}$ = 0.2–1.2 TeV assuming ggF or VBF with the NWA. See their Fig. 7 for upper limits on cross section times branching ratio for $m_{H_2^0}$ = 0.4–1.0 TeV assuming ggF, and with several assumptions on its width.

[126] AABOUD 18BU search for a narrow scalar resonance decaying to $HH \to \gamma\gamma WW^*$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–500 GeV.

[127] AABOUD 18BX search for associated production of WH or ZH followed by the decay $H \to A^0A^0 \to b\overline{b}b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for limits on cross section times branching ratios for m_{A^0} = 20–60 GeV. See also their Fig. 10 for the dependence of the limit on A^0 lifetime.

[128] AABOUD 18CQ search for a narrow scalar resonance decaying to $HH \to b\overline{b}\tau^+\tau^-$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 2 (above) for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–1000 GeV.

[129] AABOUD 18F search for production of a narrow scalar resonance decaying to W^+W^- and ZZ, followed by hadronic decays of W and Z, in 36.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5(c) for limits on cross section times branching ratio for $m_{H_2^0}$ = 1.2–3.0 TeV.

[130] AAIJ 18AM search for gluon-fusion production of $H_{1,2}^0$ decaying to $\mu\tau$ in 2 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_{1,2}^0}$ = 45–195 GeV.

[131] AAIJ 18AQ search for gluon-fusion production of a scalar particle A^0 decaying to $\mu^+\mu^-$ in 1.99 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 0.98 fb^{-1} at E_{cm} = 7 TeV. See their Fig. 4 for limits on cross section times branching ratio for m_{A^0} = 5.5–15 GeV (using the E_{cm} = 8 TeV data set).

[132] AAIJ 18AQ search for the decay $H \to A^0A^0$, with one of the A^0 decaying to $\mu^+\mu^-$, in 1.99 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 0.98 fb^{-1} at E_{cm} = 7 TeV. See their Fig. 5 (right) for limits on the product of branching ratios for m_{A^0} = 5.5–15 GeV (using the E_{cm} = 8 TeV data set).

[133] SIRUNYAN 18AF search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV, where both $b\overline{b}$ pairs are not resolved. See their Fig. 9 for limits on cross section times branching ratios for $m_{H_2^0}$ = 0.75–3 TeV.

[134] SIRUNYAN 18BA search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-q\overline{q}$, and $\ell^+\ell^-\nu\overline{\nu}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 10 and 11 for upper limits on cross section times branching ratio for $m_{H_2^0}$ = 0.13–3 TeV with several assumptions on its width and on the fraction of Vector-Boson-Fusion of the total production cross section.

[135] SIRUNYAN 18CW search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV, where both $b\overline{b}$ pairs are resolved. See their Fig. 9 for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–1200 GeV.

[136] SIRUNYAN 18DK search for production of a scalar resonance decaying to $Z\gamma$, with Z decaying to $\ell^+\ell^-$ or hadronically, in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.35–4 TeV for different assumptions on the width of the resonance.

[137] SIRUNYAN 18DT search for the decay $H \to A^0A^0 \to \tau^+\tau^-b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on the product of branching ratios in the range m_{A^0} = 15–60 GeV. See also their Fig. 8 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[138] SIRUNYAN 18DU search for production of a narrow scalar resonance decaying to $\gamma\gamma$ in 35.9 fb^{-1} (taken in 2016) of pp collisions at E_{cm} = 13 TeV. See their Fig. 3 (right) for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–5 TeV for several values of its width-to-mass ratio.

[139] SIRUNYAN 18ED search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH in the final states $\nu\overline{\nu}b\overline{b}$ or $\ell^+\ell^-b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for cross section limits for m_{A^0} = 0.8–2 TeV.

[140] SIRUNYAN 18EE search for the decay $H \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for limits on the product of branching ratios in the range m_{A^0} = 15–62.5 GeV, normalized to the SM production cross section. See also their Fig. 5 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[141] SIRUNYAN 18F search for a narrow scalar resonance decaying to $HH \to WWb\overline{b}$ or $ZZb\overline{b}$ in the final state $\ell\ell\nu\nu b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on cross section times branching ratios for $m_{H_2^0}$ = 250–900 GeV.

[142] AABOUD 17 search for production of a scalar resonance decaying to $Z\gamma$ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for the limits on cross section times branching ratio for $m_{H_2^0}$ = 0.25–3.0 TeV.

[143] AABOUD 17AP search for production of a scalar resonance decaying to $\gamma\gamma$ in 36.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4(a) for limits on fiducial cross section times branching ratio for $m_{H_2^0}$ = 0.2–2.7 TeV with narrow width approximation.

[144] AABOUD 17AW search for production of a scalar resonance decaying to $Z\gamma$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.25–2.4 TeV.

[145] KHACHATRYAN 17AZ search for the decay $H \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$, $\mu^+\mu^-b\overline{b}$, and $\mu^+\mu^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4, 5, and 6 for cross section limits in the range m_{A^0} = 5–62.5 GeV. See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[146] KHACHATRYAN 17D search for production of a scalar resonance decaying to $Z\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 2.7 fb^{-1} at E_{cm} = 13 TeV. See their Figs. 3 and 4 for the limits on cross section times branching ratio for $m_{H_2^0}$ = 0.2–2.0 TeV.

[147] KHACHATRYAN 17R search for production of a narrow scalar resonance decaying to $\gamma\gamma$ in 12.9 fb^{-1} (taken in 2016) of pp collisions at E_{cm} = 13 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–4.5 TeV for several values of its width-to-mass ratio. Limits from combination with KHACHATRYAN 16M are shown in their Figs. 4 and 6.

[148] SIRUNYAN 17CN search for a narrow scalar resonance decaying to $HH \to b\overline{b}\tau^+\tau^-$ in 18.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 5 (above) and Table II for limits on the cross section times branching ratios for $m_{H_2^0}$ = 0.3–1 TeV, and Fig. 6 (above) and Table III for the corresponding limits by combining with data from KHACHATRYAN 16BQ and KHACHATRYAN 15R.

[149] SIRUNYAN 17Y search for production of a scalar resonance decaying to $Z\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 2.7 fb^{-1} at E_{cm} = 13 TeV. See their Figs. 3, 4 and Table 3 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.7–3.0 TeV, and Fig. 5 for the corresponding limits for $m_{H_2^0}$ = 0.2–3.0 TeV from combination with KHACHATRYAN 17D data.

[150] AABOUD 16AB search for associated production of WH with the decay $H \to A^0A^0 \to b\overline{b}b\overline{b}$ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for limits on cross section times branching ratios for m_{A^0} = 20–60 GeV.

[151] AABOUD 16AE search for production of a narrow scalar resonance decaying to W^+W^- and ZZ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–3 TeV.

[152] AABOUD 16H search for production of a scalar resonance decaying to $\gamma\gamma$ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 12 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.2–2 TeV with different assumptions on the width.

[153] AABOUD 16I search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10(c) for limits on cross section times branching ratios for $m_{H_2^0}$ = 0.5–3 TeV.

[154] AAD 16AX search for production of a heavy H state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-\nu\overline{\nu}$, $\ell^+\ell^-q\overline{q}$, and $\nu\overline{\nu}q\overline{q}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig.12 for upper limits on $\sigma(H)$ B($H \to ZZ$) for m_H ranging from 140 GeV to 1000 GeV.

[155] AAD 16C search for production of a heavy H state decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 12, 13, and 16 for upper limits on $\sigma(H)$ B($H \to W^+W^-$) for m_H ranging from 300 GeV to 1000 or 1500 GeV with various assumptions on the total width of H.

[156] AAD 16L search for the decay $H \to A^0A^0 \to \gamma\gamma\gamma\gamma$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 4 (upper right) for limits on cross section times branching ratios (normalized to the SM H cross section) for m_{A^0} = 10–60 GeV.

[157] AAD 16L search for the decay $H_2^0 \to A^0A^0 \to \gamma\gamma\gamma\gamma$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 4 (lower right) for limits on cross section times branching ratios for $m_{H_2^0}$ = 600 GeV and m_{A^0} = 10–245 GeV, and Table 5 for limits for $m_{H_2^0}$= 300 and 900 GeV.

[158] AALTONEN 16C search for electroweak associated production of $H_1^0H^\pm$ followed by the decays $H^\pm \to H_1^0W^*$, $H_1^0 \to \gamma\gamma$ for $m_{H_1^0}$ = 10–105 GeV and $m_{H^\pm}$ = 30–300 GeV. See their Fig. 3 for excluded parameter region in a two-doublet model in which H_1^0 has no direct decay to fermions.

[159] KHACHATRYAN 16BG search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 6 for limits on the cross section times branching ratios for $m_{H_2^0}$ = 1.15–3 TeV.

[160] KHACHATRYAN 16BQ search for a resonance decaying to $HH \to \gamma\gamma b\overline{b}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 9 for limits on the cross section times branching ratios for $m_{H_2^0}$ = 0.26–1.1 TeV.

[161] KHACHATRYAN 16F search for the decay $H \to H_1^0H_1^0 \to \tau^+\tau^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 8 for cross section limits for $m_{H_1^0}$ = 4–8 GeV.

[162] KHACHATRYAN 16M search for production of a narrow resonance decaying to $\gamma\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 3.3 fb^{-1} at E_{cm} = 13 TeV. See their Fig. 3 (top) for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–4 TeV.

[163] KHACHATRYAN 16P search for gluon fusion production of an H_2^0 decaying to $HH \to b\overline{b}\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 8 (lower right) for cross section limits for $m_{H_2^0} = 260$–350 GeV.

[164] KHACHATRYAN 16P search for gluon fusion production of an A^0 decaying to $ZH \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 10 for cross section limits for $m_{H_2^0} = 220$–350 GeV.

[165] AAD 15BK search for production of a heavy H_2^0 decaying to HH in the final state $b\overline{b}b\overline{b}$ in 19.5 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 14(c) for $\sigma(H_2^0)$ B($H_2^0 \to HH$) for $m_{H_2^0} = 500$–1500 GeV with $\Gamma_{H_2^0} = 1$ GeV.

[166] AAD 15BZ search for the decay $H \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ ($m_H = 125$ GeV) in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 6 for limits on cross section times branching ratio for $m_{A^0} = 3.7$–50 GeV.

[167] AAD 15BZ search for a state H_2^0 via the decay $H_2^0 \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 6 for limits on cross section times branching ratio for $m_{H_2^0} = 100$–500 GeV and $m_{A^0} = 5$ GeV.

[168] AAD 15CE search for production of a heavy H_2^0 decaying to HH in the final states $b\overline{b}\tau^+\tau^-$ and $\gamma\gamma WW^*$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV and combine with data from AAD 15H and AAD 15BK. A limit $\sigma(H_2^0)$ B($H_2^0 \to HH$) $<$ 2.1–0.011 pb (95% CL) is given for $m_{H_2^0} = 260$–1000 GeV. See their Fig. 6.

[169] AAD 15H search for production of a heavy H_2^0 decaying to HH in the finalstate $\gamma\gamma b\overline{b}$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV.A limit of $\sigma(H_2^0)$ B($H_2^0 \to HH$) $<$ 3.5–0.7 pb is given for $m_{H_2^0} = 260$–500 GeV at 95% CL. See their Fig. 3.

[170] AAD 15S search for production of A^0 decaying to $ZH \to \ell^+\ell^-b\overline{b}$, $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 3 for cross section limits for $m_{A^0} = 200$–1000 GeV.

[171] KHACHATRYAN 15AW search for production of a heavy state H_2^0 of an electroweak singlet extension of the Standard Model via the decays of H_2^0 to W^+W^- and ZZ in up to 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 19.7 fb^{-1} at $E_{cm} = 8$ TeV in the range $m_{H_2^0} = 145$–1000 GeV. See their Figs. 8 and 9 for limits in the parameter space of the model.

[172] KHACHATRYAN 15BB search for production of a resonance H decaying to $\gamma\gamma$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_H = 150$–850 GeV.

[173] KHACHATRYAN 15N search for production of A^0 decaying to $ZH \to \ell^+\ell^-b\overline{b}$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 3 for limits on cross section times branching ratios for $m_{A^0} = 225$–600 GeV.

[174] KHACHATRYAN 15O search for production of a high-mass narrow resonance A^0 decaying to $ZH \to q\overline{q}\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 6 for limits on cross section times branching ratios for $m_{A^0} = 800$–2500 GeV.

[175] KHACHATRYAN 15R search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 17.9 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 5 (top) for limits on cross section times branching ratios for $m_{H_2^0} = 0.27$–1.1 TeV.

[176] AAD 14AP search for a second H state decaying to $\gamma\gamma$ in addition to the state at about 125 GeV in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_H = 65$–600 GeV.

[177] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to HW^\pm W^\mp$, H decaying to $b\overline{b}$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Table III for limits on cross section times branching ratio for $m_{H_2^0} = 325$–1025 GeV and $m_{H^+} = 225$–925 GeV.

[178] CHATRCHYAN 14G search for a second H state decaying to $WW^{(*)}$ in addition to the observed signal at about 125 GeV using 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.4 fb^{-1} at $E_{cm} = 8$ TeV. See their Fig. 21 (right) for cross section limits in the mass range 110–600 GeV.

[179] KHACHATRYAN 14P search for a second H state decaying to $\gamma\gamma$ in addition to the observed signal at about 125 GeV using 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. See their Figs. 27 and 28 for cross section limits in the mass range 110–150 GeV.

[180] AALTONEN 13P search for production of a heavy Higgs boson H'^0 that decays into a charged Higgs boson $H^\pm$ and a lighter Higgs boson H via the decay chain $H'^0 \to H^\pm W^\mp$, $H^\pm \to W^\pm H$, $H \to b\overline{b}$ in the final state $\ell\nu$ plus 4 jets in 8.7 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 4 for limits on cross section times branching ratio in the $m_{H^\pm} - m_{H'^0}$ plane for $m_H = 126$ GeV.

[181] CHATRCHYAN 13BJ search for H production in the decay chain $H \to A^0A^0$, $A^0 \to \mu^+\mu^-$ in 5.3 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. See their Fig. 2 for limits on cross section times branching ratio.

[182] AALTONEN 11P search in 2.7 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig.4 for limits on B($t \to bH^+$) for $90 < m_{H^+} < 160$ GeV.

[183] ABBIENDI 10 search for $e^+e^- \to ZH$ with the decay chain $H \to \tilde{\chi}_1^0\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \to \tilde{\chi}_1^0 + (\gamma$ or $Z^*)$, when $\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0$ are nearly degenerate. For a mass difference of 2 (4) GeV, a lower limit on m_H of 108.4 (107.0) GeV (95% CL) is obtained for SM ZH cross section and B($H \to \tilde{\chi}_1^0\tilde{\chi}_2^0$) = 1.

[184] SCHAEL 10 search for the process $e^+e^- \to HZ$ followed by the decay chain $H \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ with $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$ at $E_{cm} = 183$–209 GeV. For a HZZ coupling equal to the SM value, B($H \to A^0A^0$) = B($A^0 \to \tau^+\tau^-$) = 1, and $m_{A^0} =$ 4–10 GeV, m_H up to 107 GeV is excluded at 95% CL.

[185] ABAZOV 09V search for H production followed by the decay chain $H \to A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ or $\mu^+\mu^-\tau^+\tau^-$ in 4.2 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 3 for limits on $\sigma(H)$·B($H \to A^0A^0$) for $m_{A^0} = 3.6$–19 GeV.

[186] ABBIENDI 05A search for $e^+e^- \to H_1^0A^0$ in general Type-II two-doublet models, with decays H_1^0, $A^0 \to q\overline{q}$, gg, $\tau^+\tau^-$, and $H_1^0 \to A^0A^0$.

[187] ABBIENDI 04K search for $e^+e^- \to HZ$ with H decaying to two jets of any flavor including gg. The limit is for SM production cross section with B($H \to jj$) = 1.

[188] ABDALLAH 04 consider the full combined LEP and LEP2 datasets to set limits on the Higgs coupling to W or Z bosons, assuming SM decays of the Higgs. Results in Fig. 26.

[189] ACHARD 04B search for $e^+e^- \to HZ$ with H decaying to $b\overline{b}$, $c\overline{c}$, or gg. The limit is for SM production cross section with B($H \to jj$) = 1.

[190] ACHARD 04F search for H with anomalous coupling to gauge boson pairs in the processes $e^+e^- \to H\gamma$, e^+e^-H, HZ with decays $H \to f\overline{f}$, $\gamma\gamma$, $Z\gamma$, and W^*W at $E_{cm} =$ 189–209 GeV. See paper for limits.

[191] ABBIENDI 03F search for $H \to$ anything in $e^+e^- \to HZ$, using the recoil mass spectrum of $Z \to e^+e^-$ or $\mu^+\mu^-$. In addition, it searched for $Z \to \nu\overline{\nu}$ and $H \to e^+e^-$ or photons. Scenarios with large width or continuum H mass distribution are considered. See their Figs. 11–14 for the results.

[192] ABBIENDI 03G search for $e^+e^- \to H_1^0Z$ followed by $H_1^0 \to A^0A^0$, $A^0 \to c\overline{c}$, gg, or $\tau^+\tau^-$ in the region $m_{H_1^0} = 45$-86 GeV and $m_{A^0} = 2$-11 GeV. See their Fig. 7 for the limits.

[193] Search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq 209$ GeV. The limit is for a H with SM production cross section and B($H \to f\overline{f}$)=0 for all fermions f.

[194] For B($H \to \gamma\gamma$)=1, $m_H > 113.1$ GeV is obtained.

[195] HEISTER 02M search for $e^+e^- \to HZ$, assuming that H decays to $q\overline{q}$, gg, or $\tau^+\tau^-$ only. The limit assumes SM production cross section.

[196] ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{cm} \leq 189$ GeV. In addition to usual final states, the decays H_1^0, $A^0 \to q\overline{q}$, gg are searched for. See their Figs. 15,16 for excluded regions.

[197] ACCIARRI 00R search for $e^+e^- \to H\gamma$ with $H \to b\overline{b}$, $Z\gamma$, or $\gamma\gamma$. See their Fig. 3 for limits on $\sigma \cdot$ B. Explicit limits within an effective interaction framework are also given, for which the Standard Model Higgs search results are used in addition.

[198] ACCIARRI 00R search for the two-photon type processes $e^+e^- \to e^+e^-H$ with $H \to b\overline{b}$ or $\gamma\gamma$. See their Fig. 4 for limits on $\Gamma(H \to \gamma\gamma)$·B($H \to \gamma\gamma$or $b\overline{b}$) for m_H=70–170 GeV.

[199] GONZALEZ-GARCIA 98B use DØ limit for $\gamma\gamma$ events with missing E_T in $p\overline{p}$ collisions (ABBOTT 98) to constrain possible ZH or WH production followed by unconventional $H \to \gamma\gamma$ decay which is induced by higher-dimensional operators. See their Figs. 1 and 2 for limits on the anomalous couplings.

[200] KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no H_1^0ZZ coupling and obtain $m_{H_1^0} \gtrsim$ 5 GeV or $m_{A^0} \gtrsim 5$ GeV for tan$\beta > 50$. Other Higgs bosons are assumed to be much heavier.

[201] ALEXANDER 96H give B($Z \to H\gamma$)×B($H \to q\overline{q}$) $<$ 1–4$\times10^{-5}$ (95%CL) and B($Z \to H\gamma$)×B($H \to b\overline{b}$) $<$ 0.7–2 $\times10^{-5}$ (95%CL) in the range 20 $< m_H <$80 GeV.

Electroweak Constraints on the Standard Model Higgs Boson Mass

Here we list constraints on the mass of the Higgs boson derived from fits to precision electroweak observables, assuming the minimal Standard Model with a doublet Higgs field and three generations of fermions.

VALUE (GeV)	DOCUMENT ID		TECN
$\mathbf{90^{+21}_{-18}}$	[1] HALLER	18	RVUE
• • • We do not use the following data for averages, fits, limits, etc. • • •			
91^{+30}_{-23}	[2] BAAK	12	RVUE
94^{+25}_{-22}	[3] BAAK	12A	RVUE

129^{+74}_{-49}	[5] LEP-SLC	06	RVUE

[1] HALLER 18 make Standard Model fits to Z and neutral current parameters, m_t, m_W, and Γ_W measurements available in 2018. The direct mass measurement at the LHC is not used in the fit.

[2] BAAK 12 make Standard Model fits to Z and neutral current parameters, m_t, m_W, and Γ_W measurements available in 2010 (using also preliminary data). The quoted result is obtained from a fit that does not include the limit from the direct Higgs searches. The result including direct search data from LEP2, the Tevatron and the LHC is 120^{+12}_{-5} GeV.

[3] BAAK 12A make Standard Model fits to Z and neutral current parameters, m_t, m_W, and Γ_W measurements available in 2012 (using also preliminary data). The quoted result is obtained from a fit that does not include the measured mass value of the signal observed at the LHC and also no limits from direct Higgs searches.

[4] ERLER 10A makes Standard Model fits to Z and neutral current parameters, m_t, m_W measurements available in 2009 (using also preliminary data). The quoted result is obtained from a fit that does not include the limits from the direct Higgs searches. With direct search data from LEP2 and Tevatron added to the fit, the 90% CL (99% CL) interval is 115–148 (114–197) GeV.

[5] LEP-SLC 06 make Standard Model fits to Z parameters from LEP/SLC and m_t, m_W, and Γ_W measurements available in 2005 with $\Delta\alpha^{(5)}_{had}(m_Z) = 0.02758 \pm 0.00035$. The 95% CL limit is 285 GeV.

Charged Higgs Bosons ($H^\pm$ and $H^{\pm\pm}$), Searches for

CONTENTS:

$H^\pm$ (charged Higgs) mass limits for $m_{H^+} < m(top)$
$H^\pm$ (charged Higgs) mass limits for $m_{H^+} > m(top)$
$H^{\pm\pm}$ (doubly-charged Higgs boson) mass limits
– Limits for $H^{\pm\pm}$ with $T_3 = \pm 1$
– Limits for $H^{\pm\pm}$ with $T_3 = 0$

$H^\pm$ (charged Higgs) mass limits for $m_{H^+} < m(top)$

Unless otherwise stated, LEP limits assume $B(H^+ \to \tau^+\nu)+B(H^+ \to c\bar{s})=1$, and hold for all values of $B(H^+ \to \tau^+\nu_\tau)$, and assume H^+ weak isospin of $T_3=+1/2$. In the following, $\tan\beta$ is the ratio of the two vacuum expectation values in two-doublet models (2HDM).

The limits are also applicable to point-like technipions. For a discussion of techniparticles, see the Review of Dynamical Electroweak Symmetry Breaking in this Review.

Limits obtained at the LHC are given in the m_h^{mod-} benchmark scenario, see CARENA 13, and hold for all $\tan\beta$ values.

For limits obtained in hadronic collisions before the observation of the top quark, and based on the top mass values inconsistent with the current measurements, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review.

Searches in e^+e^- collisions at and above the Z pole have conclusively ruled out the existence of a charged Higgs in the region $m_{H^+} \lesssim 45$ GeV, and are meanwhile superseded by the searches in higher energy e^+e^- collisions at LEP. Results that are by now obsolete are therefore not included in this compilation, and can be found in a previous Edition (The European Physical Journal **C15** 1 (2000)) of this Review.

In the following, and unless otherwise stated, results from the LEP experiments (ALEPH, DELPHI, L3, and OPAL) are assumed to derive from the study of the $e^+e^- \to H^+H^-$ process. Limits from $b \to s\gamma$ decays are usually stronger in generic 2HDM models than in Supersymmetric models.

[1] AAD 15AF search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ in 19.5 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. Upper limits on B($t \to bH^+$) B($H^+ \to \tau\nu$) between 2.3×10^{-3} and 1.3×10^{-2} (95% CL) are given for m_{H^+} = 80–160 GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM. The region $m_{H^+} < 140$ GeV is excluded for tan$\beta > 1$ in the considered scenarios.

[2] KHACHATRYAN 15AX search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. Upper limits on B($t \to bH^+$) B($H^+ \to \tau\nu$) between 1.2×10^{-2} and 1.5×10^{-3} (95% CL) are given for m_{H^+} = 80–160 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM. The region $m_{H^+} < 155$ GeV is excluded for tan$\beta > 1$ in the considered scenarios.

[3] LEP 13 give a limit that refers to the Type II scenario. The limit for B($H^+ \to \tau\nu$) = 1 is 94 GeV (95% CL), and for B($H^+ \to cs$) = 1 the region below 80.5 as well as the region 83–88 GeV is excluded (95% CL). LEP 13 also search for the decay mode $H^+ \to A^0 W^*$ with $A^0 \to b\overline{b}$, which is not negligible in Type I models. The limit in Type I models is 72.5 GeV (95% CL) if $m_{A^0} > 12$ GeV.

[4] ABBIENDI 12 also search for the decay mode $H^+ \to A^0 W^*$ with $A^0 \to b\overline{b}$.

[5] AAD 25 combine AAD 23AH and AAD 24AD and derive limits on the isotriplet contribution to the gauge boson masses in the Georgi-Machacek model. See their Fig. 5(c).

[6] Charge conjugated states are also implied.

[7] AAD 25AI search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{s}$ using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for limits on the product of branching ratios for m_{H^+} = 60–168 GeV.

[8] AAD 25K search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7(b) for limits on the product of branching ratios for m_{H^+} = 60–160 GeV.

[9] AAD 25K search for H^+ production in association with top quark, in the decay mode $H^+ \to \tau^+\nu$, using 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7(a) for limits on cross section times branching ratios for m_{H^+} = 80–3000 GeV, and Fig. 8 for excluded regions in m_{H^+}–tanβ plane in hMSSM and M_h^{125} MSSM scenarios.

[10] AAD 25U search for H^+ production in association with tb, in the decay mode $H^+ \to W^+H$, $H \to b\overline{b}$ in 140 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 15 for limits on cross section times branching ratios for m_{H^+} = 0.25–3 TeV.

[11] HAYRAPETYAN 24AV search for production of scalar resonance decaying to $W^\pm\gamma$ with $W \to \ell\nu$ in 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for the mass range 0.3–2.0 TeV for a narrow and a broad width. Combined limits with TUMASYAN 22B are shown in Fig. 8.

[12] AAD 23AH search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to \ell^\pm\nu\ell^+\ell^-$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for limits on cross section times branching ratio in the Georgi-Machacek model for $m_{H^\pm}$ = 0.2–1.0 TeV, and also for limits on the triplet vacuum expectation value fraction.

[13] AAD 23BB search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{b}$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for limits on the product of branching ratios for m_{H^+} = 60–160 GeV.

[14] AAD 23BW search for $t \to bH^+$ from pair produced top quarks, with the decay chain $H^+ \to W^+A^0$, $A^0 \to \mu^+\mu^-$ using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5(b)-(d) for limits on the product of branching ratios for m_{H^+} = 120, 140, 160 GeV, and m_{A^0} = 15–72 GeV.

[15] TUMASYAN 23AV search for production of $H^\pm$ in association with a top quark, decaying to $H_2^0 W^\pm$, $H_2^0 \to \tau^+\tau^-$, using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for limits on production cross section times branching ratios for $m_{H^\pm}$ = 0.3–0.7 TeV and $m_{H_2^0}$ = 0.2 TeV.

[16] TUMASYAN 22B search for production of scalar resonance decaying to $W^\pm\gamma \to qq\gamma$ in 137 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for the mass range 0.7–6.0 TeV, assuming narrow width or $\Gamma/M = 0.05$.

[17] AAD 21V search for $\overline{t}bH^+$ associated production followed by $H^+ \to t\overline{b}$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for upper limits on cross section times branching ratio for m_{H^+} = 0.2–2 TeV. See also their Fig. 7 for the excluded region in the parameter space of the hMSSM and the following MSSM benchmark scenarios: M_h^{125}, $M_h^{125}(\tilde{\chi})$, $M_h^{125}(\tilde{\tau})$, M_h^{125}(alignment), $M_{h_1}^{125}$(CPV).

[18] SIRUNYAN 21W search for vector boson fusion production of H^+ decaying to $H^+ \to W^+Z \to \ell^+\nu\ell^+\ell^-$ in 137 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for limits on cross section times branching ratio for m_{H^+} = 0.2–3.0 TeV, and also for limits on the fraction of the triplet vev contribution to the W mass in the Georgi-Machacek model.

[19] AAD 20W search for dijet resonances in events with isolated leptons using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. As a byproduct, $H^+ \to t\overline{b}$ produced in association with $\overline{t}b$ is searched for. Limits on the product of cross section times branching ratio for m_{H^+} = 0.6–2 TeV are given in their Fig. 5(c).

[20] SIRUNYAN 20AO search for $H^+ \to t\overline{b}$ produced in association with $t(b)$ in all jet final states in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for limits on the product of cross section times branching ratio for m_{H^+} = 0.2–3 TeV. Limits for s-channel production are also given for m_{H^+} = 0.8–3 TeV. See also Fig. 7 for the corresponding limits in scenarios in the minimal supersymmetric standard model. Cross section limits from combined results with SIRUNYAN 20AV are given in Fig. 8.

[21] SIRUNYAN 20AV search for $H^+ \to t\overline{b}$ produced in association with $t(b)$ in final states with one or two leptons, in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on the product of cross section times branching ratio for m_{H^+} = 0.2–3 TeV, and their Fig. 6 for the corresponding limits in scenarios in the minimal supersymmetric standard model.

[22] SIRUNYAN 20BE search for $t \to bH^+$ followed by the decay $H^+ \to c\overline{s}$ in pair produced top quark events using 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. Limits on the branching ratio in the range 1.68–0.25% (95%CL) are given for m_{H^+} = 80–160 GeV, see their Fig. 4.

[23] SIRUNYAN 19AH search for H^+ in the decay of a pair-produced t quark, or in associated tbH^+ or nonresonant $b\overline{b}H^+W^-$ production, followed by $H^+ \to \tau^+\nu$, in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. Upper limits on cross section times branching ratio between 6 pb and 5 fb (95% CL) are given for m_{H^+} = 80–3000 GeV (including the non-resonant production near the top quark mass), see their Fig. 6 (left). See their Fig. 6 (right) for the excluded regions in the $m_h^{\text{mod}-}$ scenario of the MSSM.

[24] SIRUNYAN 19BP search for vector boson fusion production of H^+ decaying to $H^+ \to W^+Z \to \ell^+\nu\ell^+\ell^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for m_{H^+} = 0.3–2.0 TeV, and also for limits on the fraction of the triplet vev contribution to the W mass in the Georgi-Machacek model.

[25] SIRUNYAN 19CC search for $t \to bH^+$ from pair produced top quarks, with the decay chain $H^+ \to W^+A^0$, $A^0 \to \mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 2 for limits on the product of branching ratios for m_{A^0} = 15–75 GeV.

[26] SIRUNYAN 19CQ search for vector boson fusion production of H^+ decaying to $H^+ \to W^+Z \to \ell^+\nu q\overline{q}$ or $q\overline{q}\ell^+\ell^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for m_{H^+} = 0.6–2.0 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[27] AABOUD 18BW search for $\overline{t}bH^+$ associated production or the decay $t \to bH^+$, followed by $H^+ \to \tau^+\nu$, in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8(a) for upper limits on cross section times branching ratio for m_{H^+} = 90–2000 GeV, and Fig. 8(b) for limits on B($t \to bH^+$) B($H^+ \to \tau^+\nu$) for m_{H^+} = 90–160 GeV. See also their Fig. 9 for the excluded region in the hMSSM parameter space.

[28] AABOUD 18CD search for $\overline{t}bH^+$ associated production followed by $H^+ \to t\overline{b}$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for upper limits on cross section times branching ratio for m_{H^+} = 0.2–2 TeV. See also their Fig. 9 for the excluded region in the parameter space of the $m_h^{\text{mod}-}$ and hMSSM scenarios of the MSSM. The theory predictions overlaid to the experimental limits to determine the excluded m_{H^+} range are shown without their respective uncertainty band.

[29] AABOUD 18CH search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to \ell^\pm\nu\ell^+\ell^-$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^\pm}$ = 0.2–0.9 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[30] HALLER 18 give 95% CL lower limits on m_{H^+} of 590 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for B($b \to s\gamma$).

[31] SIRUNYAN 18DO search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{b}$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 3 for upper limits on B($t \to bH^+$) for m_{H^+} = 90–150 GeV assuming that B($H^+ \to c\overline{b}$) = 1 and B($t \to bH^+$) + B($t \to bW^+$) = 1.

[32] MISIAK 17 give 95% CL lower limits on m_{H^+} between 570 and 800 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for B($b \to s(d)\gamma$).

[33] SIRUNYAN 17AE search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to \ell^\pm\nu\ell^+\ell^-$ in 15.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^\pm}$ = 0.2–2.0 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[34] AABOUD 16A search for $t(b)$ $H^\pm$ associated production followed by $H^+ \to \tau^+\nu$ in 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. Upper limits on $\sigma(t(b)\ H^\pm)$ B($H^+ \to \tau\nu$) between 1.9 pb and 15 fb (95% CL) are given for m_{H^+} = 200–2000 GeV, see their Fig. 6. See their Fig. 7 for the excluded regions in the hMSSM scenario.

[35] AAD 16AJ search for $t(b)$ $H^\pm$ associated production followed by $H^\pm \to tb$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 6 for upper limits on $\sigma(t(b)\ H^\pm)$ B($H^+ \to tb$) for m_{H^+} = 200–600 GeV.

[36] AAD 16AJ search for $H^\pm$ production from quark-antiquark annihilation, followed by $H^\pm \to tb$, in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 10 for upper limits on $\sigma(H^\pm)$ B($H^+ \to tb$) for m_{H^+} = 400–3000 GeV.

[37] AAD 15AF search for $tH^\pm$ associated production followed by $H^\pm \to \tau^\pm\nu$ in 19.5 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. Upper limits on $\sigma(tH^\pm)$ B($H^+ \to \tau\nu$) between 760 and 4.5 fb (95% CL) are given for m_{H^+} = 180–1000 GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM.

[38] AAD 15M search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to q\overline{q}\ell^+\ell^-$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H^\pm}$ = 200–1000 GeV, and Fig. 3 for limits on thetriplet vacuum expectation value fraction in the Georgi-Machacek model.

[39] KHACHATRYAN 15AX search for $tH^\pm$ associated production followed by $H^\pm \to tb$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. Upper limits on $\sigma(tH^\pm)$ B($H^+ \to t\overline{b}$)

between 2.0 and 0.13 pb (95% CL) are given for m_{H^+} = 180–600 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.

[40] KHACHATRYAN 15AX search for $tH^\pm$ associated production followed by $H^\pm \to \tau^\pm\nu$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Upper limits on $\sigma(tH^\pm)$ B($H^+ \to \tau\nu$) between 380 and 25 fb (95% CL) are given for m_{H^+} = 180–600 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.

[41] KHACHATRYAN 15BF search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{s}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Upper limits on B($t \to bH^+$) B($H^+ \to c\overline{s}$) between 1.2×10^{-2} and 6.5×10^{-2} (95% CL) are given for m_{H^+} = 90–160 GeV.

[42] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to H^0 W^\pm W^\mp$, H^0 decaying to $b\overline{b}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Table III for limits on cross section times branching ratio for $m_{H_2^0}$= 325–1025 GeV and m_{H^+}= 225–925 GeV.

[43] AALTONEN 14A measure B($t \to b\tau\nu$) = 0.096 ± 0.028 using 9 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. For m_{H^+}= 80–140 GeV, this measured value is translated to a limit B($t \to bH^+$) < 0.059 at 95% CL assuming B($H^+ \to \tau^+\nu$) = 1.

[44] AAD 13AC search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{s}$ (flavor unidentified) in 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV. Upper limits on B($t \to bH^+$) between 0.05 and 0.01 (95%CL) are given for m_{H^+}=90–150 GeV and B($H^+ \to c\overline{s}$)=1.

[45] AAD 13V search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ through violation of lepton universality with 4.6 fb^{-1} of pp collisions at E_{cm} = 7 TeV. Upper limits on B($t \to bH^+$) between 0.032 and 0.044 (95% CL) are given for m_{H^+} = 90–140 GeV and B($H^+ \to \tau^+\nu$) = 1. By combining with AAD 12BH, the limits improve to 0.008 to 0.034 for m_{H^+} = 90–160 GeV. See their Fig. 7 for the excluded region in the m_h^{max} scenario of the MSSM.

[46] AAD 12BH search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ with 4.6 fb^{-1} of pp collisions at E_{cm} = 7 TeV. Upper limits on B($t \to bH^+$) between 0.01 and 0.05 (95% CL) are given for m_{H^+} = 90–160 GeV and B($H^+ \to \tau^+\nu$) = 1. See their Fig. 8 for the excluded region in the m_h^{max} scenario of the MSSM.

[47] CHATRCHYAN 12AA search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ with 2 fb^{-1} of pp collisions at E_{cm} = 7 TeV. Upper limits on B($t \to bH^+$) between 0.019 and 0.041 (95% CL) are given for m_{H^+} = 80–160 GeV and B($H^+ \to \tau^+\nu$)=1.

[48] AALTONEN 11P search in 2.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on B($t \to bH^+$) for $90 < m_{H^+} < 160$ GeV.

[49] DESCHAMPS 10 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays, $b \to s\gamma$, B, B_s mixings, and $Z \to b\overline{b}$. The limit holds irrespective of tanβ.

[50] AALTONEN 09AJ search for $t \to bH^+$, $H^+ \to c\overline{s}$ in $t\overline{t}$ events in 2.2 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Upper limits on B($t \to bH^+$) between 0.08 and 0.32 (95% CL) are given for m_{H^+} = 60–150 GeV and B($H^+ \to c\overline{s}$) = 1.

[51] ABAZOV 09AC search for $t \to bH^+$, $H^+ \to \tau^+\nu$ in $t\overline{t}$ events in 0.9 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Upper limits on B($t \to bH^+$) between 0.19 and 0.25 (95% CL) are given for m_{H^+} = 80–155 GeV and B($H^+ \to \tau^+\nu$) = 1. See their Fig. 4 for an excluded region in a MSSM scenario.

[52] ABAZOV 09AG measure $t\overline{t}$ cross sections in final states with ℓ + jets ($\ell = e, \mu$), $\ell\ell$, and $\tau\ell$ in 1 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV, which constrains possible $t \to bH^+$ branching fractions. Upper limits (95% CL) on B($t \to bH^+$) between 0.15 and 0.40 (0.48 and 0.57) are given for B($H^+ \to \tau^+\nu$) = 1 (B($H^+ \to c\overline{s}$) = 1) for m_{H^+} = 80–155 GeV.

[53] ABAZOV 09AI search for $t \to bH^+$ in $t\overline{t}$ events in 1 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Final states with ℓ + jets ($\ell = e, \mu$), $\ell\ell$, and $\tau\ell$ are examined. Upper limits on B($t \to bH^+$) (95% CL) between 0.15 and 0.19 (0.19 and 0.22) are given for B($H^+ \to \tau^+\nu$) = 1 (B($H^+ \to c\overline{s}$) = 1) for m_{H^+} = 80–155 GeV. For B($H^+ \to \tau^+\nu$) = 1 also a simultaneous extraction of B($t \to bH^+$) and the $t\overline{t}$ cross section is performed, yielding a limit on B($t \to bH^+$) between 0.12 and 0.26 for m_{H^+} = 80–155 GeV. See their Figs. 5–8 for excluded regions in several MSSM scenarios.

[54] ABAZOV 09P search for H^+ production by $q\overline{q}'$ annihilation followed by $H^+ \to t\overline{b}$ decay in 0.9 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Cross section limits in several two-doublet models are given for m_{H^+} = 180–300 GeV. A region with 20 $\lesssim \tan\beta \lesssim$ 70 is excluded (95% CL) for 180 GeV $\lesssim m_{H^+} \lesssim$ 184 GeV in type-I models.

[55] ABULENCIA 06E search for associated H^0W production in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. A fit is made for $t\overline{t}$ production processes in dilepton, lepton + jets, and lepton + τ final states, with the decays $t \to W^+b$ and $t \to H^+b$ followed by $H^+ \to \tau^+\nu$, $c\overline{s}$, $t^*\overline{b}$, or W^+H^0. Within the MSSM the search is sensitive to the region tanβ < 1 or > 30 in the mass range m_{H^+} = 80–160 GeV. See Fig. 2 for the excluded region in a certain MSSM scenario.

[56] ABDALLAH 04I search for $e^+e^- \to H^+H^-$ with $H^\pm$ decaying to $\tau\nu$, cs, or W^*A^0 in Type-I two-Higgs-doublet models.

[57] ABBIENDI 03 give a limit $m_{H^+} > 1.28\tan\beta$ GeV (95%CL) in Type II two-doublet models.

[58] ABAZOV 02B search for a charged Higgs boson in top decays with $H^+ \to \tau^+\nu$ at E_{cm}=1.8 TeV. For m_{H^+}=75 GeV, the region tan$\beta > 32.0$ is excluded at 95%CL. The excluded mass region extends to over 140 GeV for tanβ values above 100.

[59] BORZUMATI 02 point out that the decay modes such as $b\overline{b}W$, A^0W, and supersymmetric ones can have substantial branching fractions in the mass range explored at LEP II and Tevatron.

[60] ABBIENDI 01Q give a limit $\tan\beta/m_{H^+} < 0.53$ GeV^{-1} (95%CL) in Type II two-doublet models.

[61] BARATE 01E give a limit $\tan\beta/m_{H^+} < 0.40$ GeV^{-1} (90% CL) in Type II two-doublet models. An independent measurement of $B \to \tau\nu_\tau X$ gives $\tan\beta/m_{H^+} < 0.49$ GeV^{-1} (90% CL).

[62] GAMBINO 01 use the world average data in the summer of 2001 B($b \to s\gamma$) = (3.23 ± 0.42) × 10^{-4}. The limit applies for Type-II two-doublet models.

[63] AFFOLDER 00I search for a charged Higgs boson in top decays with $H^+ \to \tau^+\nu$ in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The excluded mass region extends to over 120 GeV for tanβ values above 100 and B($\tau\nu$) = 1. If B($t \to bH^+$) $\gtrsim$ 0.6, m_{H^+} up to 160 GeV is excluded. Updates ABE 97L.

[64] ABBOTT 99E search for a charged Higgs boson in top decays in $p\overline{p}$ collisions at E_{cm}=1.8 TeV, by comparing the observed $t\overline{t}$ cross section (extracted from the data assuming the dominant decay $t \to bW^+$) with theoretical expectation. The search is sensitive to regions of the domains tan$\beta \lesssim$1, 50 < m_{H^+}(GeV) $\lesssim$120 and tan$\beta \gtrsim$40, 50 < m_{H^+} (GeV) $\lesssim$160. See Fig. 3 for the details of the excluded region.

[65] ACKERSTAFF 99D measure the Michel parameters ρ, ξ, η, and $\xi\delta$ in leptonic τ decays from $Z \to \tau\tau$. Assuming e-μ universality, the limit $m_{H^+} > 0.97\tan\beta$ GeV (95%CL) is obtained for two-doublet models in which only one doublet couples to leptons.

[66] ACCIARRI 97F give a limit $m_{H^+} > 2.6\tan\beta$ GeV (90% CL) from their limit on the exclusive $B \to \tau\nu_\tau$ branching ratio.

[67] AMMAR 97B measure the Michel parameter ρ from $\tau \to e\nu\nu$ decays and assumes e/μ universality to extract the Michel η parameter from $\tau \to \mu\nu\nu$ decays. The measurement is translated to a lower limit on m_{H^+} in a two-doublet model $m_{H^+} > 0.97\tan\beta$ GeV (90% CL).

[68] COARASA 97 reanalyzed the constraint on the ($m_{H^\pm}$,tanβ) plane derived from the inclusive $B \to \tau\nu_\tau X$ branching ratio in GROSSMAN 95B and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.

[69] GUCHAIT 97 studies the constraints on m_{H^+} set by Tevatron data on $\ell\tau$ final states in $t\overline{t} \to (Wb)(Hb)$, $W \to \ell\nu$, $H \to \tau\nu_\tau$. See Fig. 2 for the excluded region.

[70] MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large $B_c \to \tau\nu_\tau$ background to $B_u \to \tau\nu_\tau$ decays. Stronger limits are obtained.

[71] STAHL 97 fit τ lifetime, leptonic branching ratios, and the Michel parameters and derive limit $m_{H^+} > 1.5\tan\beta$ GeV (90% CL) for a two-doublet model. See also STAHL 94.

[72] ALAM 95 measure the inclusive $b \to s\gamma$ branching ratio at $\Upsilon(4S)$ and give B($b \to s\gamma$)< 4.2×10^{-4} (95% CL), which translates to the limit $m_{H^+} > [244 + 63/(\tan\beta)^{1.3}]$ GeV in the Type II two-doublet model. Light supersymmetric particles can invalidate this bound.

[73] BUSKULIC 95 give a limit $m_{H^+} > 1.9\tan\beta$ GeV (90% CL) for Type-II models from $b \to \tau\nu_\tau X$ branching ratio, as proposed in GROSSMAN 94.

$H^\pm$ (charged Higgs) mass limits for $m_{H^+} >$ m(top)

Limits obtained at the LHC are given in the m_h^{mod-} benchmark scenario, see CARENA 13, and depend on the tanβ values.

>1103	95	[1] AABOUD	18BW	ATLS	tanβ = 60

[1] AABOUD 18BW search for $\overline{t}bH^+$ associated production in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See also their Fig. 9 for the excluded region in the hMSSM parameter space.

$H^{\pm\pm}$ (doubly-charged Higgs boson) mass limits

This section covers searches for a doubly-charged Higgs boson with couplings to lepton pairs. Its weak isospin T_3 is thus restricted to two possibilities depending on lepton chiralities: $T_3(H^{\pm\pm}) = \pm1$, with the coupling $g_{\ell\ell}$ to $\ell_L^-\ell_L'^-$ and $\ell_R^+\ell_R'^+$ ("left-handed") and $T_3(H^{\pm\pm}) = 0$, with the coupling to $\ell_R^-\ell_R'^-$ and $\ell_L^+\ell_L'^+$ ("right-handed"). These Higgs bosons appear in some left-right symmetric models based on the gauge group $SU(2)_L\times SU(2)_R\times U(1)$, the type-II seesaw model, and the Zee-Babu model. The two cases are listed separately in the following. Unless noted, one of the lepton flavor combinations is assumed to be dominant in the decay.

Limits for $H^{\pm\pm}$ with $T_3 = \pm1$

[1] AAD 23AI search for $H^{++}H^{--}$ production using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Decay branching ratios B($H^{++} \to \ell^+\ell'^+$) for the six flavor combinations are assumed to be equal, adding up to unity. If the $T_3 = 0$ states are degenerate with the $T_3 = \pm 1$ states, the limit becomes 1080 GeV.

[2] AABOUD 19K search for pair production of $H^{++}H^{--}$ followed by the decay $H^{\pm\pm} \to W^{\pm}W^{\pm}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The search is interpreted in a doublet-triplet extension of the scalar sector with a vev of 0.1 GeV, leading to B($H^{\pm\pm} \to W^{\pm}W^{\pm}$) = 1. See their Fig. 5 for limits on the cross section for $m_{H^{++}}$ between 200 and 700 GeV.

[3] See their Figs. 11(b) and 13 for limits with smaller branching ratios.

[4] AAD 15AG search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.

[5] AAD 15AP search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The limit assumes 100% branching ratio to the specified final state.

[6] CHATRCHYAN 12AU search for $H^{++}H^{--}$ production with 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 6 for limits including associated $H^{++}H^{-}$ production or assuming different scenarios.

[7] ABDALLAH 03 search for $H^{++}H^{--}$ pair production either followed by $H^{++} \to \tau^+\tau^+$, or decaying outside the detector.

[8] ABBIENDI 02C searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ (ℓ,ℓ' = e,μ,τ). The limit holds for ℓ=ℓ'=τ, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$.

[9] AAD 25 combine AAD 23AH and AAD 24AD and derive limits on the isotriplet contribution to the gauge boson masses in the Georgi–Machacek model. See their Fig. 5(c).

[10] AAD 24AD search for production of $H^{\pm\pm}$ by $W^{\pm}W^{\pm}$ fusion, in the decay to $W^{\pm}W^{\pm}$, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 12 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 0.2 and 3.0 TeV. Limits on the isotriplet contribution to the gauge-boson masses in the Georgi-Machacek model are also shown.

[11] AAD 21U search for pair production of $H^{++}H^{--}$ followed by the decay $H^{\pm\pm} \to W^{\pm}W^{\pm}$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The search is interpreted in a triplet extension of the SM Higgs sector with a triplet vev of 0.1 GeV, leading to B($H^{\pm\pm} \to W^{\pm}W^{\pm}$) = 1. See their Fig. 9(a) for limits on the cross section for $m_{H^{++}}$ between 200 and 600 GeV.

[12] AAD 21U search for associated production of $H^{\pm\pm}H^{\mp}$ followed by the decays $H^{\pm\pm} \to W^{\pm}W^{\pm}$, $H^{\pm} \to W^{\pm}Z$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. $H^{\pm\pm}$ and $H^{\pm}$ are assumed to be degenerate in mass within 5 GeV. The search is interpreted in a triplet extension of the SM Higgs sector with a triplet vev of 0.1 GeV, leading to B($H^{\pm\pm} \to W^{\pm}W^{\pm}$) = 1. See their Fig. 9(b) for limits on the cross section for $m_{H^{++}}$ between 200 and 600 GeV.

[13] SIRUNYAN 21W search for vector boson fusion production of $H^{\pm\pm}$ decaying to $H^{\pm\pm} \to W^{\pm}W^{\pm} \to \ell^{\pm}\nu\ell^{\pm}\nu$ in 137 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for limits on cross section times branching ratio for $m_{H^{++}}$ = 0.2–3.0 TeV.

[14] SIRUNYAN 19CQ search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^{\pm}W^{\pm} \to qq\ell\nu$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 0.6 and 2 TeV.

[15] SIRUNYAN 18CC search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^{\pm}W^{\pm}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 200 and 1000 GeV.

[16] KANEMURA 15 examine the case where H^{++} decays preferentially to $W^{(*)}W^{(*)}$ and estimate that a lower mass limit of $\sim$ 84 GeV can be derived from the same-sign dilepton data of AAD 15AG if H^{++} decays with 100% branching ratio to $W^{(*)}W^{(*)}$.

[17] KHACHATRYAN 15D search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^{\pm}W^{\pm}$ in 19.4 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H^{++}}$ between 160 and 800 GeV.

[18] KANEMURA 14 examine the case where H^{++} decays preferentially to $W^{(*)}W^{(*)}$ and estimate that a lower mass limit of $\sim$ 60 GeV can be derived from the same-sign dilepton data of AAD 12CY.

[19] AAD 13Y search for $H^{++}H^{--}$ production in a generic search of events with three charged leptons in 4.6 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The limit assumes 100% branching ratio to the specified final state.

[20] AAD 12AY search for $H^{++}H^{--}$ production with 1.6 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The limit assumes 100% branching ratio to the specified final state.

[21] AAD 12CQ search for $H^{++}H^{--}$ production with 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

[22] ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[23] AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[24] AALTONEN 08AA search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The limit assumes 100% branching ratio to the specified final state.

[25] ABAZOV 08V search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The limit is for B($H \to \mu\mu$) = 1. The limit is updated in ABAZOV 12A.

[26] AKTAS 06A search for single $H^{\pm\pm}$ production in ep collisions at HERA. Assuming that H^{++} only couples to $e^+\mu^+$ with $g_{e\mu}$ = 0.3 (electromagnetic strength), a limit $m_{H^{++}} > 141$ GeV (95% CL) is derived. For the case where H^{++} couples to $e\tau$ only the limit is 112 GeV.

[27] ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\overline{p}$ collisions. The limit is valid for $g_{\ell\ell'} < 10^{-8}$ so that the Higgs decays outside the detector.

[28] ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm} \to \mu^{\pm}\mu^{\pm}$. The limit is valid for $g_{\mu\mu} \gtrsim 10^{-7}$.

[29] ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \to e^{\mp}e^{\mp}H^{\pm\pm}$, and via t-channel exchange in $e^+e^- \to e^+e^-$. In the direct case, and assuming B($H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$) = 1, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} < 160$ GeV (see Fig. 6). In the second case, indirect limits on h_{ee} are set for $m_{H^{\pm\pm}} < 2$ TeV (see Fig. 8).

[30] GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210$ GeV if the Yukawa couplings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

[31] ASAKA 95 point out that H^{++} decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does not apply.

[32] ACTON 92M limit assumes $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.

[33] ACTON 92M from $\Delta\Gamma_Z$ <40 MeV.

[34] SWARTZ 90 assume $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ (any flavor). The limits are valid for the Higgs-lepton coupling g($H\ell\ell$) $\gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

[1] AAD 23AI search for $H^{++}H^{--}$ production using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Decay branching ratios B($H^{++} \to \ell^+\ell'^+$) for the six flavor combinations are assumed to be equal, adding up to unity.

[2] See their Figs. 12(b) and 14 for limits with smaller branching ratios.

[3] AAD 15AG search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.

[4] AAD 15AP search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The limit assumes 100% branching ratio to the specified final state.

[5] ABDALLAH 03 search for $H^{++}H^{--}$ pair production either followed by $H^{++} \to \tau^+\tau^+$, or decaying outside the detector.

[6] ACHARD 03F search for $e^+e^- \to H^{++}H^{--}$ with $H^{\pm\pm} \to \ell^{\pm}\ell'^{\pm}$. The limit holds for $\ell = \ell' = \tau$, and slightly different limits apply for other flavor combinations. The limit is valid for $g_{\ell\ell'} \gtrsim 10^{-7}$.

[7] ABBIENDI 02C searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ (ℓ,ℓ' = e,μ,τ). the limit holds for ℓ=ℓ'=τ, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$.

[8] AAD 12AY search for $H^{++}H^{--}$ production with 1.6 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The limit assumes 100% branching ratio to the specified final state.

[9] AAD 12CQ search for $H^{++}H^{--}$ production with 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

[10] ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[11] AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[12] ABAZOV 08V search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at E_{cm}= 1.96 TeV. The limit is for B($H \to \mu\mu$) = 1. The limit is updated in ABAZOV 12A.

[13] AKTAS 06A search for single $H^{\pm\pm}$ production in ep collisions at HERA. Assuming that H^{++} only couples to $e^+\mu^+$ with $g_{e\mu}$ = 0.3 (electromagnetic strength), a limit $m_{H^{++}} > 141$ GeV (95% CL) is derived. For the case where H^{++} couples to $e\tau$ only the limit is 112 GeV.

[14] ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\overline{p}$ collisions. The limit is valid for $g_{\ell\ell'} < 10^{-8}$ so that the Higgs decays outside the detector.

[15] ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm} \to \mu^{\pm}\mu^{\pm}$. The limit is valid for $g_{\mu\mu} \gtrsim 10^{-7}$.

[16] ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \to e^{\mp}e^{\mp}H^{\pm\pm}$, and via t-channel exchange in $e^+e^- \to e^+e^-$. In the direct case, and assuming B($H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$) = 1, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} < 160$ GeV (see Fig. 6). In the second case, indirect limits on h_{ee} are set for $m_{H^{\pm\pm}} < 2$ TeV (see Fig. 8).

[17] GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210$ GeV if the Yukawa couplings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

[18] ACTON 92M limit assumes $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.

[19] ACTON 92M from $\Delta\Gamma_Z$ <40 MeV.

[20] SWARTZ 90 assume $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ (any flavor). The limits are valid for the Higgs-lepton coupling g($H\ell\ell$) $\gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

New Heavy Bosons (W', Z', leptoquarks, etc.), Searches for

We list here various limits on charged and neutral heavy vector bosons (other than W's and Z's), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axigluons. The latest unpublished results are described in "W' Searches" and "Z' Searches" reviews. For recent searches on scalar bosons which could be identified as Higgs bosons, see the listings in the Higgs boson section.

CONTENTS:

Mass Limits for W' (Heavy Charged Vector Boson Other Than W) in Hadron Collider Experiments
W_R (Right-Handed W Boson) Mass Limits
Limit on W_L-W_R Mixing Angle ζ
Mass Limits for Z' (Heavy Neutral Vector Boson Other Than Z)
– Limits for Z'_{SM}
– Limits for Z_{LR}
– Limits for Z_χ
– Limits for Z_ψ
– Limits for Z_η
– Limits for other Z'
– Searches for Z' with Lepton-Flavor-Violating decays
Indirect Constraints on Kaluza-Klein Gauge Bosons
Mass Limits for Leptoquarks from Pair Production
Mass Limits for Leptoquarks from Single Production
Indirect Limits for Leptoquarks
Mass Limits for Diquarks
Mass Limits for g_A (axigluon) and Other Color-Octet Gauge Bosons
Mass Limits for Color-Octet Scalar Bosons
X^0 (Heavy Boson) Searches in Z Decays
Mass Limits for a Heavy Neutral Boson Coupling to e^+e^-
Search for X^0 Resonance in e^+e^- Collisions

W'-Boson Searches

MASS LIMITS for W' (Heavy Charged Vector Boson Other Than W) in Hadron Collider Experiments

Couplings of W' to quarks and leptons are taken to be identical with those of W. The following limits are obtained from $p\overline{p}$ or $pp \to W'X$ with W' decaying to the mode indicated in the comments. New decay channels (*e.g.*, $W' \to WZ$) are assumed to be suppressed. The most recent preliminary results can be found in the "W'-boson searches" review above.

[1] AAD 24T limit is for W' with SM-like coupling from pp collisions at $\sqrt{s}$ =1 3 TeV. Bosonic decays of W' and $W - W'$ interference are neglected. See their Fig. 7a for limits on $\sigma \cdot B$.

[2] HAYRAPETYAN 24X search for right-handed W' decaying to tb in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 7 for limits on $\sigma \cdot B$.

[3] AAD 23AH search for resonances produced through Drell-Yan and vector-boson-fusion processes in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 7 and Fig. 8 for limits on $\sigma \cdot B$. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$ produced mainly via Drell-Yan.

[4] AAD 23CC search for resonances decaying to tb in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for right-handed W' assuming a W' coupling equal to the SM W

coupling. The limit becomes $M_{W'} > 4200$ GeV for left-handed W'. See their Figs. 12 and 13 for limits on $\sigma \cdot B$.

[5] AAD 23L perform a generic search for resonances with events containing a Z decaying into e^+e^- or $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs. 6, 7, 8 for model independent limits on $\sigma \cdot B$ for Gaussian-shaped resonances. The limit above is for heavy-vector-triplet W' decaying to WZ with $g_V = 3$ as well as with $g_V = 1$.

[6] AAD 23O search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2950$ GeV for $g_V = 1$.

[7] TUMASYAN 23AP search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 4.8$ TeV assuming $M_{W'} = M_{Z'}$ and combining $W' \to WZ$, $W' \to WH$, $Z' \to WW$, $Z' \to ZH$ channels.

[8] TUMASYAN 23AP search for resonances decaying to WH in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 4.8$ TeV assuming $M_{W'} = M_{Z'}$ and combining $W' \to WZ$, $W' \to WH$, $Z' \to WW$, $Z' \to ZH$ channels.

[9] TUMASYAN 23AW search for SSM W' resonance decaying to $\tau\nu$ in pp collisions at $\sqrt{s} = 13$ TeV. W–W' intereference and bosonic decays of W' are not included. See their Fig. 6 for limits on $\sigma \cdot B$.

[10] TUMASYAN 22AC search for W' with SM-like couplings in pp collisions at $\sqrt{s} = 13$ TeV. The diboson decays of W' are assumed to be suppressed. See their Fig. 5 for limits on $\sigma \cdot B$.

[11] TUMASYAN 22D search for resonances produced through Drell-Yan and vector-boson-fusion processes in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on $\sigma \cdot B$. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$ produced mainly via Drell-Yan.

[12] TUMASYAN 22J search for resonances produced through Drell-Yan and vector-boson-fusion processes in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$, produced mainly via Drell-Yan. See their Fig. 9 for limits on $\sigma \cdot B$.

[13] TUMASYAN 22R search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' produced mainly via Drell-Yan. See their Fig. 8 for limits on $\sigma \cdot B$.

[14] SIRUNYAN 21Y search for resonances decaying to tb in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 2 for limits on $\sigma \cdot \mathrm{B}(W' \to tb)$.

[15] AAD 20AJ search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2900$ GeV for $g_V = 1$. See their Fig. 6 for limits on $\sigma \cdot B$.

[16] AAD 20AT search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3900$ GeV for $g_V = 1$. See their Fig. 13 for limits on $\sigma \cdot B$.

[17] AAD 20T search for W' with SM-like couplings in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 4(c) for limits on the product of the cross section, acceptance, and branching fraction.

[18] SIRUNYAN 20AI limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV.

[19] SIRUNYAN 20Q search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$.

[20] AABOUD 19E search for right-handed W' in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limit on on $\sigma \cdot B$.

[21] AAD 19C search for W' with SM-like couplings in pp collisions at $\sqrt{s} = 13$ TeV. Bosonic decays and $W - W'$ interference are neglected. The limits on e and μ separately are 6.0 and 5.1 TeV respectively. See their Fig. 2 for limits on $\sigma \cdot B$.

[22] AAD 19D search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3400$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 3800$ GeV and $M_{W'} > 3500$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 9 for limits on $\sigma \cdot B$.

[23] SIRUNYAN 19AY limits shown for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. $W - W'$ interference and bosonic decays of W' are not included. See their Fig. 5 for limits on $\sigma \cdot B$. Limits in the context of a nonuniversal gauge interaction are shown in Fig. 7. Model independent limits on $\sigma B A \epsilon$ can be seen in Fig. 8.

[24] SIRUNYAN 19CP present a statistical combinations of searches for W' decaying to pairs of bosons or leptons in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. If we assume $M_{W'} = M_{Z'}$, the limit becomes $M_{W'} > 4500$ GeV for $g_V = 3$ and $M_{W'} > 5000$ GeV for $g_V = 1$. See their Figs. 2 and 3 for limits on $\sigma \cdot B$.

[25] SIRUNYAN 19I search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2800$ GeV if we assume $M_{W'} = M_{Z'}$.

[26] AABOUD 18AF give the limit above for right-handed W' using pp collisions at $\sqrt{s} = 13$ TeV. These limits also exclude W bosons with left-handed couplings with masses below 2.9 TeV, at the 95% confidence level. $W' \to \ell\nu_R$ is assumed to be forbidden. See their Fig.5 for limits on $\sigma \cdot B$ for both cases of left- and right-handed W'.

[27] AABOUD 18AI search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2670$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2930$ GeV and $M_{W'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 5 for limits on $\sigma \cdot B$.

[28] AABOUD 18AK search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2800$ GeV for $g_V = 1$.

[29] AABOUD 18AL search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2900$ GeV for $g_V = 1$.

[30] AABOUD 18BG limit is for W' with SM-like couplings using pp collisions at $\sqrt{s} = 13$ TeV. Bosonic decays of W' and $W - W'$ interference are neglected. See Fig. 2 for limits on $\sigma \cdot B$.

[31] AABOUD 18CH search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2260$ GeV for $g_V = 1$.

[32] AABOUD 18F search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3000$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{W'} > 3500$ GeV and $M_{W'} > 3100$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.5 for limits on $\sigma \cdot B$.

[33] AABOUD 18K limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. $W - W'$ interference and bosonic decays of W' are not included. See their Fig. 4 for limit on $\sigma \cdot B$.

[34] SIRUNYAN 18 limit is for right-handed W' using pp collisions at $\sqrt{s} = 13$ TeV. $W' \to \ell\nu_R$ decay is assumed to be forbidden. The limit becomes $M_{W'} > 3.4$ TeV if $M_{\nu_R} \ll M_{W'}$. See their Fig. 5 for exclusion limits on W' models having both left- and right-handed couplings.

[35] SIRUNYAN 18AX search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. See their Fig.6 for limits on $\sigma \cdot$ B.

[36] SIRUNYAN 18AZ limit is derived for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. No interference with SM W process is considered. The bosonic decays are assumed to be negligible. See their Fig.6 for limits on $\sigma \cdot B$.

[37] SIRUNYAN 18BK search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $\mathrm{M}_{W'} > 3100$ GeV for $g_V = 1$.

[38] SIRUNYAN 18BO limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV.

[39] SIRUNYAN 18DJ search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2270$ GeV for $g_V = 1$.

[40] SIRUNYAN 18ED search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The limit above is for heavy-vector-triplet W' with $g_V = 3$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2900$ GeV and $M_{W'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively.

[41] SIRUNYAN 18P give this limit for a heavy-vector-triplet W' with $g_V = 3$. If they assume $M_{Z'} = M_{W'}$, the limit increases to $M_{W'} > 3800$ GeV.

[42] AABOUD 17AK search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit above is for a W' boson having axial-vector SM couplings and decaying to quarks with 75% branching fraction.

[43] AABOUD 17AO search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a W' in the heavy-vector-triplet model with $g_V = 3$. See their Fig.4 for limits on $\sigma \cdot B$.

[44] AABOUD 17B search for resonances decaying to HW ($H \to b\overline{b}$, $c\overline{c}$; $W \to \ell\nu$) in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 1750$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2310$ GeV and $M_{W'} > 1730$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.3 for limits on $\sigma \cdot B$.

[45] KHACHATRYAN 17J search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into τ and hypothetical heavy neutrino N_τ, with N_τ decaying into τjj. The quoted limit is for $M_{N_\tau} = M_{W_R}/2$. The limit becomes $M_{W_R} > 2350$ GeV (1630 GeV) for $M_{W_R}/M_{N_\tau} = 0.8$ (0.2). See their Fig. 4 for excluded regions in the $M_{W_R} - M_{N_\tau}$ plane.

[46] KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.

[47] KHACHATRYAN 17Z limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. The bosonic decays of W' and the interference with SM W process are neglected.

[48] SIRUNYAN 17A search for resonances decaying to WZ with $WZ \to \ell\nu q\overline{q}$, $q\overline{q}q\overline{q}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2000$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{W'} > 2400$ GeV and $M_{W'} > 2300$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.6 for limits on $\sigma \cdot B$.

[49] SIRUNYAN 17AK search for resonances decaying to WZ or HW in pp collisions at $\sqrt{s} = 8$ and 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2300$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2400$ GeV for both $g_V = 3$ and $g_V = 1$. See their Fig.1 and 2 for limits on $\sigma \cdot B$.

[50] SIRUNYAN 17H search for right-handed W' in pp collisions at $\sqrt{s} = 13$ TeV. W' is assumed to decay into τ and a heavy neutrino N, with N decaying to $\tau q\overline{q}$. The limit above assumes $\mathrm{M}_N = \mathrm{M}_{W'}/2$.

[51] SIRUNYAN 17I limit is for a right-handed W' using pp collisions at $\sqrt{s} = 13$ TeV. The limit becomes $M_{W'} > 2400$ GeV for $M_{\nu_R} \ll M_{W'}$.

[52] SIRUNYAN 17R search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. Mass regions $M_{W'} < 2370$ GeV and $2870 < M_{W'} < 2970$ GeV are excluded for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the excluded mass regions are $1000 < M_{W'} < 2500$ GeV and $2760 < M_{W'} < 3300$ GeV for $g_V = 3$; $1000 < M_{W'} < 2430$ GeV and $2810 < M_{W'} < 3130$ GeV for $g_V = 1$. See their Fig.5 for limits on $\sigma \cdot B$.

[53] AABOUD 16AE search for resonances decaying to VV ($V = W$ or Z) in pp collisions at $\sqrt{s} = 13$ TeV. Results from $\nu\nu qq$, $\nu\ell qq$, $\ell\ell qq$ and $qqqq$ final states are combined. The quoted limit is for a heavy-vector-triplet W' with $g_V = 3$ and $M_{W'} = M_{Z'}$.

[54] AABOUD 16V limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. The bosonic decays of W' and the interference with SM W process are neglected.

[55] AAD 16R search for $W' \to WZ$ in pp collisions at $\sqrt{s} = 8$ TeV. $\ell\nu\ell'\ell'$, $\ell\ell q\overline{q}$, $\ell\nu q\overline{q}$, and all hadronic channels are combined. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

[56] AAD 16S search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a W' having SM-like couplings to quarks.

[57] KHACHATRYAN 16AO limit is for a SM-like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit combines $t \to qqb$ and $t \to \ell\nu b$ events.

[58] KHACHATRYAN 16AP search for a resonance decaying to HW in pp collisions at $\sqrt{s} = 8$ TeV. Both H and W are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$.

[59] KHACHATRYAN 16BD search for resonance decaying to HW in pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit is for heavy-vector-triplet (HVT) W' with $g_V = 3$. The HVT model $m_{W'} = m_{Z'} > 1.8$ TeV is also obtained by combining $W'/Z' \to WH/ZH \to \ell\nu bb$, $qq\tau\tau$, $qqbb$, and $qqqqqq$ channels.

[60] KHACHATRYAN 16K search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.

[61] KHACHATRYAN 16L search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.

[62] KHACHATRYAN 16O limit is for W' having universal couplings. Interferences with the SM amplitudes are assumed to be absent.

[63] AAD 15AU search for W' decaying into the WZ final state with $W \to q\overline{q}'$, $Z \to \ell^+\ell^-$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[64] AAD 15AV limit is for a SM like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[65] AAD 15AZ search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to q\overline{q}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[66] AAD 15CP search for W' decaying into the WZ final state with $W \to q\overline{q}$, $Z \to q\overline{q}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[67] AAD 15R limit is for a SM like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[68] AAD 15V search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.

[69] KHACHATRYAN 15C search for W' decaying via WZ to fully leptonic final states using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = M_W M_Z/M^2_{W'}$.

[70] KHACHATRYAN 15T limit is for W' with SM-like coupling which interferes the SM W boson constructively using pp collisions at $\sqrt{s} = 8$ TeV. For W' without interference, the limit becomes > 3280 GeV.

[71] KHACHATRYAN 14O search for right-handed W_R in pp collisions at $\sqrt{s} = 8$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. The quoted limit is for $M_{\nu_{eR}} = M_{\nu_{\mu R}} = M_{W_R}/2$. See their Fig. 3 and Fig. 5 for excluded regions in the $M_{W_R} - M_\nu$ plane.

[72] AAD 25AX search for a narrow resonance decaying to a pair of large-radius-jets using a machine-learning approach. See their Fig. 7 for limits on $\sigma \cdot B$ obtained with different classifier feature sets.

[73] AAD 24AE search for resonances decaying to qq, tt, tb, VV, VH, $\ell\ell$, $\ell\tau$, $\tau\nu$, $\tau\tau$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. $M_{W'} = M_{Z'}$ is assumed. The limit becomes $M_{W'} > 5.8$ TeV for $g_V = 1$.

[74] AAD 24CM search for pair productions of dark pions $\pi^\pm_D \pi^0_D$ in $ttbb$ events of pp collisions at $\sqrt{s} = 13$ TeV. $\pi^\pm_D \to tb$ and $\pi^0_D \to tt$ decays are assumed. The production cross section is computed in a model with dark $\rho^\pm_D$ assuming dark isospin symmetry $m_{\rho^\pm_D} = m_{\rho^0_D}$, $m_{\pi^\pm_D} = m_{\pi^0_D}$. See their Fig. 12 for limits on the production cross sections.

[75] HAYRAPETYAN 24AV search for a spin-0 particle X decaying to $W\gamma$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on $\sigma \cdot B$.

[76] AAD 23BF search for W' decaying to WZ' in pp collisions at $\sqrt{s} = 13$ TeV. The mass difference between W' and Z' is assumed to be 250 GeV. See their Fig. 9(a) for limits on $\sigma \cdot B$ as a function of $M_{W'}$.

[77] AAD 23CG search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. See their Fig. 9 for limits in m_N–m_{W_R} plane.

[78] AAD 23CK search for a new resonance decaying to HX ($H \to b\overline{b}$, $X \to q\overline{q}'$) in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 12 for limits on $\sigma \cdot B$.

[79] AAD 23U search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 8(d) for the exclusion limit in $m_{W'} - \sigma \cdot B$ plane.

[80] TUMASYAN 22 search for KK excited W decaying in cascade to three W via a scalar radion R. See their Fig. 4 for limits in $M_{W'} - M_R$ plane.

[81] TUMASYAN 22AL search for resonances decaying to tB or bT with vector-like quarks B (T) subsequently decaying to bH or bZ (tH or tZ). See their Fig. 7 for limits on $\sigma \cdot B$.

[82] TUMASYAN 22B search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 5 for limits on $\sigma \cdot B$.

[83] TUMASYAN 22I search for KK excited W decaying in cascade to three W via a scalar radion R. See their Fig. 10 for limits in $M_{W'} - M_R$ plane.

[84] TUMASYAN 22P search for right handed W_R in pp collisiions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying to ℓjj. See their Fig. 7 for excluded regions in $M_{W_R} - M_N$ plane.

[85] AAD 20AD search for a narrow resonance decaying to a pair of large-radius-jets J_1 and J_2 employing a machine-learning procedure. See their Fig. 3 for limits on $\sigma \cdot B$ depending on assumptions about invariant masses for J_1, J_2, and J_1 J_2.

[86] AAD 20W search for W' decaying to WZ' in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5(b) for limits on $\sigma \cdot B$ as a function of $m_{Z'}$. The $W' \to WZ'$ branching fraction was chosen to be 0.5 and the mass difference between the W' and Z' was set to 250 GeV.

[87] AABOUD 19B search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying to ℓjj. See their Figs. 7 and 8 for excluded regions in $M_{W_R} - M_N$ plane.

[88] AABOUD 19BB search for right handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and a boosted hypothetical heavy neutrino N, with N decaying to ℓ and a large radius jet $j = q\overline{q}$. See their Fig. 7 for excluded regions in $M_{W_R} - M_N$ plane.

[89] SIRUNYAN 19V search for a new resonance decaying to a top quark and a heavy vector-like bottom partner B decaying to Hb (or a bottom quark and a heavy vector-like top partner T decaying to Ht) in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on $\sigma \cdot B$.

[90] AABOUD 18AA search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 9 for the exclusion limit in $M_{W'} - \sigma$B plane.

[91] AABOUD 18AD search for resonances decaying to HX ($H \to b\overline{b}$, $X \to q\overline{q}'$) in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs. 3–5 for limits on $\sigma \cdot B$.

[92] AABOUD 18CJ search for heavy-vector-triplet W' in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for model with $g_V = 3$ assuming $M_{W'} = M_{Z'}$. The limit becomes $M_{W'} > 5500$ GeV for model with $g_V = 1$.

[93] SIRUNYAN 18CV search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying to ℓjj. The quoted limit is for $M_N = M_{W_R}/2$. See their Fig. 6 for excluded regions in the $M_{W_R} - M_N$ plane.

[94] KHACHATRYAN 17U search for resonances decaying to HW ($H \to b\overline{b}$; $W \to \ell\nu$) in pp collisions at $\sqrt{s} = 13$ TeV. The limit on the heavy-vector-triplet model is $M_{Z'} = M_{W'} > 2$ TeV for $g_V = 3$, in which constraints from the $Z' \to HZ$ ($H \to b\overline{b}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) are combined. See their Fig.3 and Fig.4 for limits on $\sigma \cdot B$.

[95] AAD 15BB search for W' decaying into WH with $W \to \ell\nu$, $H \to b\overline{b}$. See their Fig. 4 for the exclusion limits in the heavy vector triplet benchmark model parameter space.

[96] AALTONEN 15C limit is for a SM-like right-handed W' assuming $W' \to \ell\nu$ decays are forbidden, using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. See their Fig. 3 for limit on $g_{W'}/g_W$.

[97] KHACHATRYAN 15V search new resonance decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.

[98] AAD 14AT search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 3a for the exclusion limit in $m_{W'} - \sigma B$ plane.

[99] AAD 14S search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to \ell\ell$ using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[100] KHACHATRYAN 14 search for W' decaying into WZ final state with $W \to q\overline{q}$, $Z \to q\overline{q}$ using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[101] KHACHATRYAN 14A search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to q\overline{q}$, or $W \to q\overline{q}$, $Z \to \ell\ell$. pp collisions data at $\sqrt{s}$=8 TeV are used for the search. See their Fig. 13 for the exclusion limit on the number of events in the mass−width plane.

[102] AAD 13AO search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to 2j$ using pp collisions at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[103] CHATRCHYAN 13AJ search for resonances decaying to WZ pair, using the hadronic decay modes of W and Z, in pp collisions at $\sqrt{s}$=7 TeV. See their Fig. 7 for the limit on the cross section.

[104] CHATRCHYAN 13AQ limit is for W' with SM-like coupling which interferes with the SM W boson using pp collisions at $\sqrt{s}$=7 TeV.

[105] CHATRCHYAN 13E limit is for W' with SM-like coupling which intereferes with the SM W boson using pp collisions at $\sqrt{s}$=7 TeV. For W' with right-handed coupling, the bound becomes >1850 GeV (>1910 GeV) if W' decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings are present, the limit becomes >1640 GeV.

[106] CHATRCHYAN 13U search for W' decaying to the WZ final state, with W decaying into jets, in pp collisions at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[107] The AAD 12AV quoted limit is for a SM-like right-handed W' using pp collisions at $\sqrt{s}$=7 TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[108] AAD 12BB use pp collisions data at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[109] AAD 12CK search for $pp \to tW'$, $W' \to \overline{t}q$ events in pp collisions. See their Fig. 5 for the limit on $\sigma \cdot B$.

[110] AAD 12CR use pp collisions at $\sqrt{s}$=7 TeV.

[111] AAD 12M search for right-handed W_R in pp collisions at $\sqrt{s} = 7$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. See their Fig. 4 for the limit in the m_N–$m_{W'}$ plane.

[112] AALTONEN 12N search for $p\overline{p} \to tW'$, $W' \to \overline{t}d$ events in $p\overline{p}$ collisions. See their Fig. 3 for the limit on $\sigma \cdot B$.

[113] CHATRCHYAN 12AR search for $pp \to tW'$, $W' \to \overline{t}d$ events in pp collisions. See their Fig. 2 for the limit on $\sigma \cdot B$.

[114] CHATRCHYAN 12BG search for right-handed W_R in pp collisions $\sqrt{s} = 7$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. See their Fig. 3 for the limit in the m_N–$m_{W'}$ plane.

[115] ABAZOV 11H use data from $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. The quoted limit is obtained assuming $W'WZ$ coupling strength is the same as the ordinary WWZ coupling strength in the Standard Model.

[116] ABAZOV 11L limit is for W' with SM-like coupling which interferes with the SM W boson, using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. For W' with right-handed coupling, the bound becomes >885 GeV (>890 GeV) if W' decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings present, the limit becomes >916 GeV.

[117] AALTONEN 10N use $p\overline{p}$ collision data at $\sqrt{s}$=1.96 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$. See their Fig. 4 for limits in mass-coupling plane.

[118] AALTONEN 09AC search for new particle decaying to dijets using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV.

[119] The ACOSTA 03B quoted limit is for $M_{W'} \gg M_{\nu_R}$, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV. For $M_{W'} < M_{\nu_R}$, $M_{W'}$ between 225 and 566 GeV is excluded.

[120] The quoted limit is obtained assuming $W'WZ$ coupling strength is the same as the ordinary WWZ coupling strength in the Standard Model, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV. See their Fig. 2 for the limits on the production cross sections as a function of the W' width.

[121] AFFOLDER 01I combine a new bound on $W' \to e\nu$ of 754 GeV, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV, with the bound of ABE 00 on $W' \to \mu\nu$ to obtain quoted bound.

[122] ABE 97G search for new particle decaying to dijets using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV.

[123] For bounds on W_R with nonzero right-handed mass, see Fig. 5 from ABACHI 96C.

[124] ABACHI 95E assume that the decay $W' \to WZ$ is suppressed and that the neutrino from W' decay is stable and has a mass significantly less $m_{W'}$.

[125] RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.

W_R (Right-Handed W Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89B, and COLANGELO 91. $g_R = g_L$ assumed. [Limits in the section MASS LIMITS for W' below are also valid for W_R if $m_{\nu_R} \ll m_{W_R}$.] Some limits assume manifest left-right symmetry, *i.e.*, the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 89B. Limits on the W_L-W_R mixing angle ζ are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] BUENO 11 limit is for manifest left-right symmetric model.

[2] CZAKON 99 perform a simultaneous fit to charged and neutral sectors.

[3] ALVES 24 limit quoted above is from $B(\pi \to e\nu)/B(\pi \to \mu\nu)$ assuming $m_{\nu_R} = 50$ MeV in vanishing $W_L - W_R$ mixing limit. $g_L = g_R$ is assumed. See their Fig. 2 for limits in $m_{\nu_R} - m_{W_R}$ plane.

[4] PRIEELS 14 limit is from $\mu^+ \to e^+\nu\overline{\nu}$ decay parameter ξ'', which is determined by the positron polarization measurement.

[5] WAUTERS 10 limit is from a measurement of the asymmetry parameter of polarized ^{60}Co β decays. The listed limit assumes no mixing.

[6] ZHANG 08 limit uses a lattice QCD calculation of the relevant hadronic matrix elements, while BEALL 82 limit used the vacuum saturation approximation.

[7] MELCONIAN 07 measure the neutrino angular asymmetry in β^+-decays of polarized ^{37}K, stored in a magneto-optical trap. Result is consistent with SM prediction and does not constrain the $W_L - W_R$ mixing angle appreciably.

[8] SCHUMANN 07 limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing is assumed.

[9] CYBURT 05 limit follows by requiring that three light ν_R's decouple when $T_{dec} > 140$ MeV. For different T_{dec}, the bound becomes $M_{W_R} > 3.3$ TeV $(T_{dec} / 140\ \text{MeV})^{3/4}$.

[10] THOMAS 01 limit is from measurement of β^+ polarization in decay of polarized ^{12}N. The listed limit assumes no mixing.

[11] ACKERSTAFF 99D limit is from τ decay parameters. Limit increase to 145 GeV for zero mixing.

[12] BARENBOIM 98 assumes minimal left-right model with Higgs of $SU(2)_R$ in $SU(2)_L$ doublet. For Higgs in $SU(2)_L$ triplet, m_{W_R} >1100 GeV. Bound calculated from effect of corresponding Z_{LR} on electroweak data through Z–Z_{LR} mixing.

[13] The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from K_L-K_S mass difference.

[14] STAHL 97 limit is from fit to τ-decay parameters.

[15] ALLET 96 measured polarization-asymmetry correlation in ^{12}N β^+ decay. The listed limit assumes zero L-R mixing.

[16] KUZNETSOV 95 limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94B.

[17] KUZNETSOV 94B limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed.

[18] BHATTACHARYYA 93 uses Z-Z' mixing limit from LEP '90 data, assuming a specific Higgs sector of $SU(2)_L \times SU(2)_R \times U(1)$ gauge model. The limit is for m_t=200 GeV and slightly improves for smaller m_t.

[19] SEVERIJNS 93 measured polarization-asymmetry correlation in ^{107}In β^+ decay. The listed limit assumes zero L-R mixing. Value quoted here is from SEVERIJNS 94 erratum.

[20] IMAZATO 92 measure positron asymmetry in $K^+ \to \mu^+\nu_\mu$ decay and obtain $\xi P_\mu > 0.990$ (90% CL). If W_R couples to $u\overline{s}$ with full weak strength (V^R_{us}=1), the result corresponds to m_{W_R} >653 GeV. See their Fig. 4 for m_{W_R} limits for general $|V^R_{us}|^2 = 1 - |V^R_{ud}|^2$.

[21] POLAK 92B limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ=0. Supersedes POLAK 91.

[22] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.

[23] COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.

[24] POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ=0. Superseded by POLAK 92B.

[25] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.

[26] LANGACKER 89B limit is for any ν_R mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.

[27] BALKE 88 limit is for $m_{\nu_{eR}} = 0$ and $m_{\nu_{\mu R}} \leq 50$ MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.

[28] JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point e^+ spectrum in the decay of the highly polarized μ^+.

[29] STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay e^+ spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.

[30] BERGSMA 83 set limit m_{W_2}/m_{W_1} >1.9 at CL = 90%.

[31] CARR 83 is TRIUMF experiment with a highly polarized μ^+ beam. Looked for deviation from $V-A$ at the high momentum end of the decay e^+ energy spectrum. Limit from previous world-average muon polarization parameter is m_{W_R} >240 GeV. Assumes a light right-handed neutrino.

[32] BEALL 82 limit is obtained assuming that W_R contribution to K_L^0–K_S^0 mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

Limit on W_L-W_R Mixing Angle ζ

Lighter mass eigenstate $W_1 = W_L \cos\zeta - W_R \sin\zeta$. Light ν_R assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

[1] ACKERSTAFF 99D limit is from τ decay parameters.

[2] CZAKON 99 perform a simultaneous fit to charged and neutral sectors.

[3] The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from K_L-K_S mass difference.

[4] MISHRA 92 limit is from the absence of extra large-x, large-y $\overline{\nu}_\mu N \to \overline{\nu}_\mu X$ events at Tevatron, assuming left-handed ν and right-handed $\overline{\nu}$ in the neutrino beam. The result gives $\zeta^2(1 - 2m^2_{W_1}/m^2_{W_2}) < 0.0015$. The limit is independent of ν_R mass.

[5] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed.

[6] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.

[7] First JODIDIO 86 result assumes $m_{W_R} = \infty$, second is for unconstrained m_{W_R}.

Z′-Boson Searches

MASS LIMITS for Z' (Heavy Neutral Vector Boson Other Than Z)

Limits for Z'_{SM}

Z'_{SM} is assumed to have couplings with quarks and leptons which are identical to those of Z, and decays only to known fermions. The most recent preliminary results can be found in the "Z'-boson searches" review above.

[1] HAYRAPETYAN 25M search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 4 for limits on $\sigma \cdot B$.

[2] TUMASYAN 23AF search for resonance decaying to $b\overline{b}$ in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 4 for limits on $\sigma \cdot B$.

[3] TUMASYAN 22AE set limits on Z' from the measurements of the forward-backward asymmetry in e^+e^- and $\mu^+\mu^-$ events in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for the sequential SM Z'. See their Fig. 6 for limits in mass-coupling plane.

[4] SIRUNYAN 21N search for resonance decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[5] AAD 20T search for resonances decaying to $b\overline{b}$ in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 7(b) for limits on the product of the cross section, acceptance, b-tagging efficiency, and branching fraction.

[6] SIRUNYAN 20AI search for resonances decaying into dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[7] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[8] AABOUD 18AB search for resonances decaying to $b\overline{b}$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[9] AABOUD 18G search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[10] SIRUNYAN 18BB search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig.5 for limits on the Z' coupling strengths with light quarks.

[11] SIRUNYAN 18BO search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[12] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[13] KHACHATRYAN 17H search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[14] KHACHATRYAN 17T search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8, 13 TeV.

[15] KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[16] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[17] KHACHATRYAN 15AE search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.

[18] KHACHATRYAN 15V search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV.

[19] AAD 14V search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.

[20] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 11 for limits in $M_{Z'} - \xi$ plane.

[21] AABOUD 16AA search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[22] AAD 15AM search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.

[23] AAD 13S search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[24] CHATRCHYAN 13A use pp collisions at $\sqrt{s}$=7 TeV.

[25] CHATRCHYAN 13AF search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV and 8 TeV.

[26] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[27] CHATRCHYAN 12O search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[28] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[29] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[30] The quoted limit assumes $g_{WWZ'}/g_{WWZ} = (M_W/M_{Z'})^2$. See their Fig. 4 for limits in mass-coupling plane.

[31] AALTONEN 09AC search for new particle decaying to dijets.

[32] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0026 < \theta < 0.0006$.

[33] ABDALLAH 06C use data $\sqrt{s}$ = 130–207 GeV.

[34] ACOSTA 05R search for resonances decaying to tau lepton pairs in $\overline{p}p$ collisions at $\sqrt{s}$ = 1.96 TeV.

[35] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00422 < \theta < 0.00091$. $\sqrt{s}$ = 91 to 207 GeV.

[36] ABAZOV 01B search for resonances in $p\overline{p} \to e^+e^-$ at $\sqrt{s}$=1.8 TeV. They find $\sigma \cdot B(Z' \to ee) < 0.06$ pb for $M_{Z'} > 500$ GeV.

[37] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.

[38] ABREU 00S uses LEP data at $\sqrt{s}$=90 to 189 GeV.

[39] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[40] ERLER 99 give 90%CL limit on the Z-Z' mixing $-0.0041 < \theta < 0.0003$. ρ_0=1 is assumed.

[41] ABE 97S find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.

[42] VILAIN 94B assume m_t = 150 GeV.

[43] ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes $B(Z' \to q\overline{q}) = 0.7$. See their Fig. 5 for limits in the $m_{Z'}$–$B(q\overline{q})$ plane.

[44] RIZZO 93 analyses CDF limit on possible two-jet resonances.

[45] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. They fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and m_Z = 91.13 ± 0.03 GeV.

Limits for Z_{LR}

Z_{LR} is the extra neutral boson in left-right symmetric models. $g_L = g_R$ is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by specific left-right symmetric models (see the Note on the W'). Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. Direct search bounds assume decays to Standard Model fermions only, unless noted.

[1] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0012 < \theta < 0.0004$.

[2] ABE 97S find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s} = 1.8$ TeV.

[3] TUMASYAN 23BE search for pair production of heavy Majorana neutrinos via the decay of a Z' boson in a final state with $\ell^+\ell^-$ and at least two jets. For cases with $m_N = M_{Z'}/4$, their 95% CL limits are $M_{Z'} > 3.59$ TeV (> 4.10 TeV) in the dielectron (dimuon) channel. See their Fig. 5 for limits on $\sigma \cdot B$.

[4] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 10 for limits in $M_{Z'} - \xi$ plane.

[5] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0013 < \theta < 0.0006$.

[6] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0028$. See their Fig. 14 for limit contours in the mass-mixing plane.

[7] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00098 < \theta < 0.00190$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.

[8] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.

[9] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[10] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[11] CHAY 00 also find $-0.0003 < \theta < 0.0019$. For g_R free, $m_{Z'} > 430$ GeV.

[12] ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_{LR} and Z_χ.

[13] CASALBUONI 99 discuss the discrepancy between the observed and predicted values of Q_W(Cs). It is shown that the data are better described in a class of models including the Z_{LR} model.

[14] CZAKON 99 perform a simultaneous fit to charged and neutral sectors. Assumes manifest left-right symmetric model. Finds $|\theta| < 0.0042$.

[15] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0009 < \theta < 0.0017$.

[16] ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in E_6.

[17] BARENBOIM 98 also gives 68% CL limits on the Z-Z' mixing $-0.0005 < \theta < 0.0033$. Assumes Higgs sector of minimal left-right model.

[18] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[19] VILAIN 94B assume $m_t = 150$ GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[20] RIZZO 93 analyses CDF limit on possible two-jet resonances.

[21] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. A specific Higgs sector is assumed. See also GRIFOLS 90D, RIZZO 91.

[22] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV. Bounds depend on assumed supernova core temperature.

Limits for Z_χ

Z_χ is the extra neutral boson in SO(10) $\to$ SU(5) $\times$ U(1)$_\chi$. $g_\chi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.

[2] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.

[3] HERBERMANN 25 limit is from Atacama Cosmology Telescope (ACT) DR6 limit on effective number of light neutrino species $\Delta N_{\rm eff} < 0.17$. See their Fig. 1 for limits in mass-coupling plane.

[4] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 9 for limits in $M_{Z'} - \xi$ plane.

[5] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.

[6] AAD 14V search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 8$ TeV.

[7] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV.

[8] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[9] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[10] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0011 < \theta < 0.0007$.

[11] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[12] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0016 < \theta < 0.0006$.

[13] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0031$. See their Fig. 14 for limit contours in the mass-mixing plane.

[14] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[15] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00099 < \theta < 0.00194$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.

[16] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino $\delta N_\nu < 1$. The quark-hadron transition temperature T_c=150 MeV is assumed. The limit with T_c=400 MeV is >4300 GeV.

[17] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.

[18] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0017$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[19] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[20] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 3 for limits in the mass-mixing plane.

[21] ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_{LR} and Z_χ.

[22] ROSNER 00 discusses the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_χ.

[23] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0020 < \theta < 0.0015$.

[24] ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in E_6.

[25] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[26] ABE 97S find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s} = 1.8$ TeV.

[27] Z-Z' mixing is assumed to be zero. $\sqrt{s} = 57.77$ GeV.

[28] VILAIN 94B assume $m_t = 150$ GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[29] FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos $\Delta N_\nu < 0.5$ and is valid for $m_{\nu_R} < 1$ MeV.

[30] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[31] Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that ν_R is light ($\lesssim 1$ MeV).

[32] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.

Limits for Z_ψ

Z_ψ is the extra neutral boson in $E_6 \to$ SO(10) $\times$ U(1)$_\psi$. $g_\psi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] SIRUNYAN 21N search for resonance decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[2] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[3] SIRUNYAN 18BB search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[4] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[5] KHACHATRYAN 17T search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8, 13 TeV.

[6] CHATRCHYAN 12O search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[7] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z')\cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 10 for limits in $M_{Z'} - \xi$ plane.

[8] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[9] KHACHATRYAN 15AE search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.

[10] AAD 14V search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.

[11] CHATRCHYAN 13AF search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV and 8 TeV.

[12] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[13] CHATRCHYAN 12M search for resonances decaying to e^+e^- or $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[14] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[15] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[16] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0019 < \theta < 0.0007$.

[17] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[18] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0018 < \theta < 0.0009$.

[19] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0027$. See their Fig. 14 for limit contours in the mass-mixing plane.

[20] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[21] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00129 < \theta < 0.00258$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s}$ = 91 to 207 GeV.

[22] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino δN_ν <1. The quark-hadron transition temperature T_c=150 MeV is assumed. The limit with T_c=400 MeV is >1100 GeV.

[23] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[24] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[25] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 3 for limits in the mass-mixing plane.

[26] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0013 < \theta < 0.0024$.

[27] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[28] ABE 97S find $\sigma(Z')\times B(e^+e^-,\mu^+\mu^-)$< 40 fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.

[29] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[30] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[31] Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that ν_R is light ($\lesssim$ 1 MeV).

[32] GRIFOLS 90D limit holds for $m_{\nu_R} \lesssim$ 1 MeV. See also RIZZO 91.

Limits for Z_η

Z_η is the extra neutral boson in E_6 models, corresponding to $Q_\eta = \sqrt{3/8}\ Q_\chi - \sqrt{5/8}\ Q_\psi$. $g_\eta = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption ρ=1 but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[2] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z')\cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 9 for limits in $M_{Z'} - \xi$ plane.

[3] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[4] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[5] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[6] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[7] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0023 < \theta < 0.0027$.

[8] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[9] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0047 < \theta < 0.0021$.

[10] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0092$. See their Fig. 14 for limit contours in the mass-mixing plane.

[11] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[12] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00447 < \theta <$0.00331. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s}$ = 91 to 207 GeV.

[13] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino δN_ν <1. The quark-hadron transition temperature T_c=150 MeV is assumed. The limit with T_c=400 MeV is >3300 GeV.

[14] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0024$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[15] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[16] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 3 for limits in the mass-mixing plane.

[17] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0062 < \theta < 0.0011$.

[18] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[19] ABE 97S find $\sigma(Z')\times B(e^+e^-,\mu^+\mu^-)$< 40 fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.

[20] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[21] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[22] These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) constrains Z' masses if ν_R is light ($\lesssim$ 1 MeV).

[23] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim$ 1 MeV. See also GRIFOLS 90D, RIZZO 91.

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

[1] HAYRAPETYAN 25AB search for Z' with nonuniversal fermion couplings produced via vector boson fusion (VBF) processes in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above assumes Z' couplings with first- and second-generation fermion are zero, and $g_{Z'WW} = (5.3 \times M_W/M_{Z'})^2$, $B(\tau^+\tau^-) = 0.5$. See their Fig. 2 for exclusion limits on $M_{Z'}$ under various model assumptions.

[2] HAYRAPETYAN 25Q search for resonances decaying to ZH in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. See their Fig. 6 for limits on $\sigma \cdot B$.

[3] AAD 23O search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2800$ GeV for $g_V = 1$.

[4] TUMASYAN 23AF search for resonance decaying to $b\overline{b}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 1$. See their Fig. 4 for limits on $\sigma \cdot B$.

[5] TUMASYAN 23AP search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 4.8$ TeV assuming $M_{W'} = M_{Z'}$ and combining $W' \to WZ$, $W' \to WH$, $Z' \to WW$, $Z' \to ZH$ channels.

[6] TUMASYAN 23AP search for resonances decaying to ZH in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 4.8$ TeV assuming $M_{W'} = M_{Z'}$ and combining $W' \to WZ$, $W' \to WH$, $Z' \to WW$, $Z' \to ZH$ channels.

[7] TUMASYAN 22D search for resonances produced through Drell-Yan and vector-boson-fusion processes in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on $\sigma \cdot B$. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$ produced mainly via Drell-Yan.

[8] SIRUNYAN 21X search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 3500$ GeV for $g_V = 1$.

[9] AAD 20AJ search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for $g_V = 1$. See their Fig. 6 for limits on $\sigma \cdot B$.

[10] AAD 20AM search for a resonance decaying to $t\overline{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a leptophobic top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. The limit becomes $M_{Z'} > 4700$ GeV for $\Gamma_{Z'}/M_{Z'} = 0.03$.

[11] AAD 20AT search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 3500$ GeV for $g_V = 1$. See their Fig. 14 for limits on $\sigma \cdot B$.

[12] SIRUNYAN 20Q search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$.

[13] AABOUD 19AS search for a resonance decaying to $t\overline{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. Limits are also set on Z' masses in simplified Dark Matter models.

[14] AAD 19D search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2900$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 3800$ GeV and $M_{Z'} > 3500$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 9 for limits on $\sigma \cdot B$.

[15] SIRUNYAN 19AA search for a resonance decaying to $t\overline{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a leptophobic top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$.

[16] SIRUNYAN 19CP present a statistical combinations of searches for Z' decaying to pairs of bosons or leptons in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. If we assume $M_{Z'} = M_{W'}$, the limit becomes $M_{Z'} > 4500$ GeV for $g_V = 3$ and $M_{Z'} > 5000$ GeV for $g_V = 1$. See their Figs. 2 and 3 for limits on $\sigma \cdot B$.

[17] SIRUNYAN 19I search for resonances decaying to ZW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2800$ GeV if we assume $M_{Z'} = M_{W'}$.

[18] AABOUD 18AB search for resonances decaying to $b\overline{b}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' with SM-like couplings to quarks. See their Fig. 6 for limits on $\sigma \cdot B$. Additional limits on a Z' axial-vector mediator in a simplified dark-matter model are shown in Fig. 7.

[19] AABOUD 18AI search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2650$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{Z'} > 2930$ GeV and $M_{Z'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 5 for limits on $\sigma \cdot B$.

[20] AABOUD 18AK search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2750$ GeV for $g_V = 1$.

[21] AABOUD 18B search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 1$. See their Fig.11 for limits on $\sigma \cdot B$.

[22] AABOUD 18BI search for a resonance decaying to $t\overline{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a top-color assisted TC Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. The limits for wider resonances are available. See their Fig. 14 for limits on $\sigma \cdot B$.

[23] AABOUD 18F search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 3500$ GeV and $M_{Z'} > 3100$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.5 for limits on $\sigma \cdot B$.

[24] SIRUNYAN 18ED search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit above is for heavy-vector-triplet Z' with $g_V = 3$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2900$ GeV and $M_{Z'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively.

[25] SIRUNYAN 18P give this limit for a heavy-vector-triplet Z' with $g_V = 3$. If they assume $M_{Z'} = M_{W'}$, the limit increases to $M_{Z'} > 3800$ GeV.

[26] AABOUD 17AK search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' boson having axial-vector coupling strength with quarks $g_q = 0.2$. The limit is 2100 GeV if $g_q = 0.1$.

[27] AABOUD 17AO search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a Z' in the heavy-vector-triplet model with $g_V = 3$. See their Fig.4 for limits on $\sigma \cdot B$.

[28] SIRUNYAN 17AK search for resonances decaying to WW or HZ in pp collisions at $\sqrt{s} = 8$ and 13 TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limits becomes $M_{Z'} > 2200$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2400$ GeV for both $g_V = 3$ and $g_V = 1$. See their Fig.1 and 2 for limits on $\sigma \cdot B$.

[29] SIRUNYAN 17Q search for a resonance decaying to $t\overline{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a resonance with relative width $\Gamma_{Z'} / M_{Z'} = 0.01$. Limits for wider resonances are available. See their Fig.6 for limits on $\sigma \cdot B$.

[30] SIRUNYAN 17R search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. Mass regions $M_{Z'} < 1150$ GeV and 1250 GeV $< M_{Z'} < 1670$ GeV are excluded for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the excluded mass regions are $1000 < M_{Z'} < 2500$ GeV and $2760 < M_{Z'} < 3300$ GeV for $g_V = 3$; $1000 < M_{Z'} < 2430$ GeV and $2810 < M_{Z'} < 3130$ GeV for $g_V = 1$. See their Fig.5 for limits on $\sigma \cdot B$.

[31] AAD 25AZ search for a narrow resonance decaying to $q\overline{q}$ in pp collisions at $\sqrt{s} = 13$ TeV, using trigger level analysis to enhance sensitivity in the low mass region. See their Fig. 9 for mass-coupling limits in the Z' mass range 375–1800 GeV.

[32] AAD 25BA set limits on Z' mediated dark Higgs scenarios with mass between 250–400 GeV and Z' masses $M_{Z'} < 2.3$ TeV. Dark Higgs s is assumed to decay into HH. See their Fig. 7 for limits in $M_{Z'} - M_s$ plane.

[33] AAD 25BB search for $\tau^+\tau^-$ production from s-channel Z' exchange via $b\overline{b}$ annhilation in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 12 for limits in mass-coupling plane.

[34] AAD 25C search for a dark Higgs model spin-1 mediator Z' in pp collisions at $\sqrt{s} = 13$ TeV using large $\not{E}_T$ and resonant $b\overline{b}$ production events. Z' decays to dark Higgs S and a pair of DM particles χ, and the dark Higgs S decays to $b\overline{b}$ subsequently. See their Fig. 3 for limits in $m_{Z'} - m_S$ plane.

[35] AAD 25F search a new scalar particle S in pp collisions at $\sqrt{s} = 13$ TeV. S decays to $Z'Z'$ with Z' subsequently decaying to $\ell^+\ell^-$. See their Fig. 5 for limits on $\sigma \cdot B$.

[36] AAD 25N search for Z' production in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into a pair of dark quarks $q_d\overline{q}_d$ with q_d generating semivisible jet topology upon decay. See their Fig. 8 for limits on $\sigma \cdot B$ as a function of $M_{Z'}$.

[37] AAD 25Q search for a low mass Z' produced in association with γ in pp collisions at $\sqrt{s} = 13$ TeV. The decay products of $Z' \to q\overline{q}$ are reconstructed as a single large-radius jet. See their Fig. 5 for exclusion limits in the $m_{Z'} - g_q$ plane in the mass range 20 GeV $< m_{Z'} < 200$ GeV.

[38] CHEKHOVSKY 25J search for "mono-Higgs" events produced from s-channel Z' exchange in pp collisions at $\sqrt{s} = 13$ TeV, in which the SM Higgs H is reconstructed through $H \to \tau^+\tau^-$. The limit quoted above is for a baryonic Z' model with $g_q = 0.25$, $g_\chi = 1.0$, $m_\chi = 1$ GeV.

[39] HAYRAPETYAN 25V search for resonances decaying to a pair of heavy, stable (long-lived), charged particles (HSCPs) in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above assumes doubly-charged HSCP τ' with $m_{\tau'} = 600$ GeV and Z'_ψ production cross section.

[40] AAD 24AA search for Z' production in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into a pair of dark quarks which hadronise into dark hadrons before promptly decaying back as SM particles. The dark pions are either assumed to decay directly to SM quarks or through dark photons. See their Fig. 7 for limits on $\sigma \cdot B$.

[41] AAD 24AE search for resonances decaying to qq, tt, tb, VV, VH, $\ell\ell$, $\ell\tau$, $\tau\nu$, $\tau\tau$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. $M_{Z'} = M_{W'}$ is assumed. The limit becomes $M_{Z'} > 5.8$ TeV for $g_V = 1$.

[42] AAD 24AY search for a low-mass leptophobic Z' produced in association of high p_T ISR photon or jet in pp collisions at $\sqrt{s} = 13$ TeV. The Z' coupling with quarks g_q is constrained below 0.07 for $250 < M_{Z'} < 650$ GeV. See their Fig. 8 for exclusion limit in the mass-coupling plane.

[43] AAD 24BJ search for top-philic Z' in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 9 for limits on $\sigma(pp \to t(\overline{t})\,Z') \cdot B(Z' \to t\overline{t})$.

[44] AAD 24BR search for $L_\mu - L_\tau$ Z' in 3μ final states in pp collisions at $\sqrt{s} = 13$ TeV. Limits are combined with previous search results in the 4μ final states reported in AAD 23X. See their Fig. 4 for limits in mass-coupling plane.

[45] AAD 24CD search for a DM simplified Z' produced in association with W or Z in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay invisibly. See their Fig. 13 for limits in $M_{Z'} - M_{DM}$ plane.

[46] AAD 24CI give a summary of searches for DM simplified Z' in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs. 6–11 for the limits.

[47] AAD 24CM search for pair productions of dark pions $\pi_D^+\pi_D^-$ in $ttbb$ events of pp collisions at $\sqrt{s} = 13$ TeV. $\pi_D^\pm \to tb$ decay is assumed. The production cross section is computed in a model with dark ρ_D^0 assuming dark isospin symmetry $m_{\rho_D^\pm} = m_{\rho_D^0}$, $m_{\pi_D^\pm} = m_{\pi_D^0}$. See their Fig. 12 for limits on the production cross sections.

[48] ABLIKIM 24G search for a muonphilic Z' and a muonphilic scalar X_0 in decays of $J/\psi \to \mu^+\mu^- +$ invisible. See their Fig. 3 for limits in the mass coupling plane.

[49] ADACHI 24F for a muonphilic Z' and a muonphilic scalar X_0 in $\mu^+\mu^-\mu^+\mu^-$ events of e^+e^- collisions at $\sqrt{s} = 10.58$ GeV. See their Fig. 14 for limits in mass-coupling plane.

[50] AKITA 24 limit is from no events of high-energy SN1987A neutrinos. The Z' coupling down to $g \sim 3 \times 10^{-10}$ is excluded for $M_{Z'} < 400$ MeV in the $L_\mu - L_\tau$ Z' model. See their Fig. 3 and Fig. 4 for exclusion limits in mass-coupling plane.

[51] ANDREEV 24 search for Z' production in μ-nucleus scattering. Z' is assumed to decay invisibly. See their Fig. 4 for limits in mass-coupling plane.

[52] ANDREEV 24B search for Z' production in $e^{\pm}$-nucleus scattering. Z' is assumed to decay invisibly. See their Fig. 4 for limits in mass-coupling plane.

[53] ANDREEV 24E search for Z' production in μ-nucleus scattering. Invisible decays of Z' are assumed. See their Fig. 17 and Fig. 19 for limits in mass-coupling plane for Z' masses from 0.001 to 1 GeV.

[54] BISWAS 24 search for leptophilic scalar X_0 produced in association with $\tau^+\tau^-$ in e^+e^- collisions near $\sqrt{s} = 10.58$ GeV. X_0 is assumed to decay into e^+e^- or $\mu^+\mu^-$. See their Fig. 7 for limits in mass-coupling plane.

[55] HAYRAPETYAN 24AZ search for Z' resonances produced via kinetic mixing parameter ϵ and decaying to $s_D\overline{s}_D$ in pp collisions at $\sqrt{s} = 13$ TeV. Both s_D and $\overline{s}_D$ are assumed to decay into $\mu^+\mu^-$. See their Fig. 7 for limits on $\epsilon^2 B(Z' \to s_D\overline{s}_D)B^2(s_D \to \mu^+\mu^-)$.

[56] HAYRAPETYAN 24G search for singly produced narrow resonances decaying to jjj in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 2 for limits on $\sigma \cdot B$.

[57] HAYRAPETYAN 24W search for $W^+W^- + \not{E}_T$ events in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into dark Higgs S ($\to W^+W^-$) and DM particles $\chi\chi$. See their Fig. 5 for exclusion limits on the production cross section.

[58] AAD 23BF search for a Dark Matter (DM) simplified Z' produced in association with W in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 9(c) for limits on $\sigma \cdot B$ as a function of $M_{Z'}$.

[59] AAD 23W set limits on a dark Higgs model with a spin-1 mediator Z' and a dark Higgs s. Dark Higgs s is assumed to decay into WW. See their Fig. 9 for limits in $M_{Z'} - M_s$ plane.

[60] AAD 23X set limits on $L_\mu - L_\tau$ of Z' using four-muon final states in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 7 for limits in mass-coupling plane.

[61] ADACHI 23B search for Z' produced in association with $\mu^+\mu^-$ and decaying invisibly in e^+e^- collisions at $\sqrt{s} = 10.58$ GeV. See their Fig. 3 and Fig. 4 for limits in mass-coupling plane.

[62] ADACHI 23F search for resonances decaying to $\tau^+\tau^-$ in $\mu^+\mu^-\tau^+\tau^-$ events in e^+e^- collisions at $\sqrt{s} = 10.58$ GeV. See their Fig. 3 for limits on $\sigma \cdot B$.

[63] HAYRAPETYAN 23D search for $\mu^+\mu^-$ resonance produced in association with one or more b-jets in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits in the mass-coupling plane of the B_3–L_2 Z' model.

[64] HAYRAPETYAN 23G search for spin-0 and spin-1 resonances decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 13$ TeV in the mass ranges of 1.1–2.6 GeV and 4.2–7.9 GeV. See their Fig. 5 for limits on $\sigma \cdot B$.

[65] LI 23I limits on light Z' couplings are dervied from the steller cooling bounds in the mass range of 10^4–10^6 eV. See their Fig. 4 for limits on dark photon, B–L, L_μ–L_τ, and L_e–$L_{\mu(\tau)}$ models.

[66] MANZARI 23 study supernova cooling induced by the emission of light dark fermions χ assumed to couple with leptons via a new massive vector boson Z'. See their Figs. 4 and 5 for limits in mass-coupling plane.

[67] AAD 22 search for $b\overline{b}Z'$ productions in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into $b\overline{b}$. See their Fig.4 for limits on $\sigma \cdot B$.

[68] AAD 22D search for DM mediator Z' produced in association with a Z boson in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay invisibly $Z' \to \chi\chi$. See their Fig. 4 for limits in $M_{Z'}$–M_χ plane.

[69] ANDREEV 22 search for missing energy in CERN NA64-e experiment. See their Fig. 7 for limits on couplings of $U(1)$ gauge $L_\mu - L_\tau$ Z' models, in the mass range of 1 MeV $< M_{Z'} <$ 600 MeV with the kinetic $Z' - \gamma$ mixing being determined by μ and τ loops.

[70] BONET 22 obtain limits on Z' coupling from ν-nucleus scattering data collected by the CONUS experiment at the nuclear power plant in Brokdorf. See their Fig. 5 for limits in mass-coupling plane.

[71] COLOMA 22 set limits on Z' coupling from ν-nucleus and ν-e scattering data collected by a Ge detector at the Dresden-II power reactor and the COHERENT experiment. See their Fig. 6 for limits in mass-coupling plane in the mass range of 1 keV $< M_{Z'} <$ 5 GeV.

[72] COLOMA 22A use Borexino Phase-II spectral data to constrain Z' couplings. See their Fig. 5 for limits in mass-coupling plane in the mass range of 10 keV $< M_{Z'} <$ 100 MeV.

[73] CZANK 22 search for Z' produced in association with $\mu^+\mu^-$ in e^+e^- collisions at and near Υ resonances. Z' is assumed to decay into $\mu^+\mu^-$. See their Fig. 8 for limits on $Z'\mu\mu$ couplings.

[74] TUMASYAN 22AA search for Z' production in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into two "semivisible" jets (SVJ), i.e., collimated mixtures of visible and invisible particles. See their Fig. 7 and 8 for limits on $\sigma \cdot B$.

[75] AAD 21AQ limits are for a $B - L$ gauge boson model derived from their measurements on four-lepton differential cross sections. See their Fig. 13 for exclusion limits on the $B - L$ breaking Higgs boson mass.

[76] AAD 21AZ search for DM mediator Z' produced in association with a SM Higgs boson in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay invisibly $Z' \to \chi\chi$. See their Fig.7 for limits in $M_{Z'} - M_\chi$ plane.

[77] AAD 21BB search for Z' productions in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into a SM Higgs boson H and an invisible particle A. See their Fig.7 for limits in $M_{Z'} - M_A$ plane.

[78] AAD 21D set limits on a dark Higgs model with a spin-1 mediator Z' and a scalar dark Higgs boson s. Dark Higgs s is assumed to decay into WW or ZZ. See their Fig.4 for limits in $M_{Z'} - M_s$ plane.

[79] AAD 21K search for $\gamma + \not{E}_T$ events in pp collision at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits on Z' particle invisibly decaying to $\chi\chi$.

[80] BURAS 21 performed global fit to leptophilic Z' models using a large number of observables.

[81] CADEDDU 21 obtain limits on Z' coupling $g_{Z'}$ from coherent ν-nucleus scattering data collected by COHERENT experiment. For limits in the $M_{Z'}$–$g_{Z'}$ plane, see their Figures 3 and 4 for the universal Z' model and Figures 5 and 6 for the $B - L$ model.

[82] COLARESI 21 obtain limits on Z' coupling from coherent ν-nucleus scattering data collected by a Ge detector at the Dresden-II power reactor. See their Fig.7 for limits in mass-coupling plane.

[83] KRIBS 21 set decay-agnostic limits on kinetic mixing parameter between $U(1)_Y$ field and new heavy abelian vector boson (dark photon) field using the HERA ep collision data. See their Fig. 3 for limits in mass-mixing plane.

[84] TUMASYAN 21D search for energetic jets + $\not{E}_T$ events in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into a pair of invisible particles $\chi\chi$. See their Fig. 7 for limits on signal strength in $M_{Z'} - M_\chi$ plane, and Fig. 8 for limits on signal strength in quark and dark matter coupling vs mediator mass.

[85] AAD 20AF search for resonances decaying to $H\gamma$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 1c for limits on $\sigma \cdot B$ for the mass range $0.7 < m_{Z'} < 4$ TeV.

[86] AAD 20T search for Dark Matter mediator Z' decaying invisibly or decaying to $q\overline{q}$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits in $M_{Z'} - g_q$ plane from the inclusive category. See their Fig. 7(a) for limits on the product of the cross section, acceptance, b-tagging efficiency, and branching fraction from the 2 b-tag category.

[87] AAD 20W search for a Dark Matter (DM) simplified model Z' produced in association with W in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits on Z' production cross section.

[88] AAIJ 20AL search for spin-0 and spin-1 resonances decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 13$ TeV in the mass regions $M_{Z'} < 60$ GeV, with non-negligible widths considered above 20 GeV. See their Figs. 7, 8, and 9 for limits on $\sigma \cdot B$.

[89] ADACHI 20 search for production of Z' in e^+e^- collisions. The Z' is assume to decay invisibly. See their Fig. 3 and Fig. 5 for limits on Z' coupling and $\sigma(e^+e^- \to e^\pm\mu^\mp Z')$.

[90] SIRUNYAN 20AI search for broad resonances decaying into dijets in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 11 for exclusion limits in mass-coupling plane.

[91] SIRUNYAN 20AQ search for a narrow resonance lighter than 200 GeV decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 3 for limits on Z' kinetic mixing coefficient.

[92] SIRUNYAN 20M search for a narrow resonance with a mass between 350 and 700 GeV in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig.3 for exclusion limits in mass-coupling plane.

[93] AABOUD 19AJ search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\overline{q}$ and produced in association with a high p_T photon. For a leptophobic axial-vector Z' in the mass region 250 GeV $< M_{Z'} <$ 950 GeV, the Z' coupling with quarks g_q is constrained below 0.18. See their Fig.2 for limits in $M_{Z'} - g_q$ plane.

[94] AABOUD 19D search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\overline{q}$ and produced in association with a high-p_T photon or jet. For a leptophobic axial-vector Z' in the mass region 100 GeV $< M_{Z'} <$ 220 GeV, the Z' coupling with quarks g_q is constrained below 0.23. See their Fig. 6 for limits in $M_{Z'} - g_q$ plane.

[95] AABOUD 19V search for Dark Matter simplified Z' decaying invisibly or decaying to fermion pair in pp collisions at $\sqrt{s} = 13$ TeV.

[96] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 4 for limits in the heavy vector triplet model couplings.

[97] LONG 19 uses the weak charge data of Cesium and proton to constrain mass of Z' in the 3-3-1 models.

[98] PANDEY 19 obtain limits on Z' induced neutrino non-standard interaction (NSI) parameter ϵ from LHC and IceCube data. See their Fig.2 for limits in $M_{Z'} - \epsilon$ plane, where $\epsilon = g_q\, g_\nu\, v^2 / (2\, M^2_{Z'})$.

[99] SIRUNYAN 19AL search for a new resonance decaying to a top quark and a heavy vector-like top partner in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on Z' production cross section.

[100] SIRUNYAN 19AN search for a Dark Matter (DM) simplified model Z' decaying to H DM DM in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 7 for limits on the signal strength modifiers.

[101] SIRUNYAN 19CB search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\overline{q}$. For a leptophobic Z' in the mass region 50–300 GeV, the Z' coupling with quarks g'_q is constrained below 0.2. See their Figs. 4 and 5 for limits on g'_q in the mass range 50 $< M_{Z'} <$ 450 GeV.

[102] SIRUNYAN 19CD search in pp collisions at $\sqrt{s}$=13 TeV for a leptophobic Z' produced in association of high p_T ISR photon and decaying to $q\overline{q}$. See their Fig. 2 for limits on the Z' coupling strength g'_q to $q\overline{q}$ in the mass range between 10 and 125 GeV.

[103] SIRUNYAN 19D search for a narrow neutral vector resonance decaying to $H\gamma$. See their Fig. 3 for exclusion limit in $M_{Z'} - \sigma \cdot B$ plane. Upper limits on the production of $H\gamma$ resonances are set as a function of the resonance mass in the range of 720–3250 GeV.

[104] AABOUD 18AA search for a narrow neutral vector boson decaying to $H\gamma$. See their Fig. 10 for the exclusion limit in $M_{Z'} - \sigma B$ plane.

[105] AABOUD 18CJ search for heavy-vector-triplet Z' in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for model with $g_V = 3$ assuming $M_{Z'} = M_{W'}$. The limit becomes $M_{Z'} > 5500$ GeV for model with $g_V = 1$.

[106] AABOUD 18N search for a narrow resonance decaying to $q\overline{q}$ in pp collisions at $\sqrt{s} =$ 13 TeV using trigger level analysis to improve the low mass region sensitivity. See their Fig. 5 for limits in the mass-coupling plane in the Z' mass range 450–1800 GeV.

[107] AAIJ 18AQ search for spin-0 and spin-1 resonances decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ and 8 TeV in the mass region near 10 GeV. See their Figs. 4 and 5 for limits on $\sigma \cdot B$.

[108] SIRUNYAN 18DR searches for $\mu^+\mu^-$ resonances produced in association with b-jets in the pp collision data with $\sqrt{s} = 8$ TeV and 13 TeV. An excess of events near $m_{\mu\mu} =$ 28 GeV is observed in the 8 TeV data. See their Fig. 3 for the measured fiducial signal cross sections at $\sqrt{s} = 8$ TeV and the 95% CL upper limits at $\sqrt{s} = 13$ TeV.

[109] SIRUNYAN 18G search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} =$ 13 TeV in the mass range 50–300 GeV. See their Fig.7 for limits in the mass-coupling plane.

[110] SIRUNYAN 18I search for a narrow resonance decaying to $b\overline{b}$ in pp collisions at $\sqrt{s} =$ 8 TeV using dedicated b-tagged dijet triggers to improve the sensitivity in the low mass region. See their Fig. 3 for limits on $\sigma \cdot B$ in the Z' mass range 325–1200 GeV.

[111] AABOUD 17B search for resonances decaying to HZ ($H \to b\overline{b}$, $c\overline{c}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 1490$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2310$ GeV and $M_{Z'} > 1730$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.3 for limits on $\sigma \cdot B$.

by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use strictly not permitted, except for Open Access articles.

[112] KHACHATRYAN 17AX search for lepto-phobic resonances decaying to four leptons in pp collisions at $\sqrt{s} = 8$ TeV.

[113] KHACHATRYAN 17U search for resonances decaying to HZ ($H \to b\overline{b}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) in pp collisions at $\sqrt{s} = 13$ TeV. The limit on the heavy-vector-triplet model is $M_{Z'} = M_{W'} > 2$ TeV for $g_V = 3$, in which constraints from the $W' \to HW$ ($H \to b\overline{b}$; $W \to \ell\nu$) are combined. See their Fig.3 and Fig.4 for limits on $\sigma \cdot B$.

[114] SIRUNYAN 17A search for resonances decaying to WW with $WW \to \ell\nu q\overline{q}$, $q\overline{q}q\overline{q}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 1600$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2400$ GeV and $M_{Z'} > 2300$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.6 for limits on $\sigma \cdot B$.

[115] SIRUNYAN 17AP search for resonances decaying into a SM-like Higgs scalar H and a light pseudo scalar A. A is assumed to decay invisibly. See their Fig.9 for limits on $\sigma \cdot B$.

[116] SIRUNYAN 17T search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV in the mass range 100–300 GeV. See their Fig.3 for limits in the mass-coupling plane.

[117] SIRUNYAN 17V search for a new resonance decaying to a top quark and a heavy vector-like top partner T in pp collisions at $\sqrt{s} = 13$ TeV. See their table 5 for limits on the Z' production cross section for various values of $M_{Z'}$ and M_T in the range of $M_{Z'} = 1500$–2500 GeV and $M_T = 700$–1500 GeV.

[118] AABOUD 16 search for a narrow resonance decaying into $b\overline{b}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' with SM-like couplings to quarks. See their Fig.6 for limits on $\sigma \cdot B$.

[119] AAD 16L search for $Z' \to a\gamma$, $a \to \gamma\gamma$ in pp collisions at $\sqrt{s} = 8$ TeV. See their Table 6 for limits on $\sigma \cdot B$.

[120] AAD 16S search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' having coupling strength with quark $g_q = 0.3$ and is taken from their Figure 3.

[121] KHACHATRYAN 16AP search for a resonance decaying to HZ in pp collisions at $\sqrt{s} = 8$ TeV. Both H and Z are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$.

[122] KHACHATRYAN 16E search for a leptophobic top-color Z' decaying to $t\overline{t}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes that $\Gamma_{Z'}/m_{Z'} = 0.012$. Also $m_{Z'} < 2.9$ TeV is excluded for wider topcolor Z' with $\Gamma_{Z'}/m_{Z'} = 0.1$.

[123] AAD 15AO search for narrow resonance decaying to $t\overline{t}$ using pp collisions at $\sqrt{s} = 8$ TeV. See Fig. 11 for limit on σB.

[124] AAD 15AT search for monotop production plus large missing E_T events in pp collisions at $\sqrt{s} = 8$ TeV and give constraints on a Z' model having $Z'u\overline{t}$ coupling. Z' is assumed to decay invisibly. See their Fig. 6 for limits on $\sigma \cdot B$.

[125] AAD 15CD search for decays of Higgs bosons to 4 ℓ states via Z' bosons, $H \to ZZ' \to 4\ell$ or $H \to Z'Z' \to 4\ell$. See Fig. 5 for the limit on the signal strength of the $H \to ZZ' \to 4\ell$ process and Fig. 16 for the limit on $H \to Z'Z' \to 4\ell$.

[126] KHACHATRYAN 15F search for monotop production plus large missing E_T events in pp collisions at $\sqrt{s} = 8$ TeV and give constraints on a Z' model having $Z'u\overline{t}$ coupling. Z' is assumed to decay invisibly. See Fig. 3 for limits on σB.

[127] KHACHATRYAN 15O search for narrow Z' resonance decaying to ZH in pp collisions at $\sqrt{s} = 8$ TeV. See their Fig. 6 for limit on σB.

[128] AAD 14AT search for a narrow neutral vector boson decaying to $Z\gamma$. See their Fig. 3b for the exclusion limit in $m_{Z'} - \sigma B$ plane.

[129] KHACHATRYAN 14A search for new resonance in the WW ($\ell\nu q\overline{q}$) and the ZZ ($\ell\ell q\overline{q}$) channels using pp collisions at $\sqrt{s}$=8 TeV. See their Fig.13 for the exclusion limit on the number of events in the mass-width plane.

[130] MARTINEZ 14 use various electroweak data to constrain the Z' boson in the 3-3-1 models.

[131] AAD 13AQ search for a leptophobic top-color Z' decaying to $t\overline{t}$. The quoted limit assumes that $\Gamma_{Z'}/m_{Z'} = 0.012$.

[132] CHATRCHYAN 13BM search for top-color Z' decaying to $t\overline{t}$ using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit is for $\Gamma_{Z'}/m_{Z'} = 0.012$.

[133] CHATRCHYAN 13AP search for top-color leptophobic Z' decaying to $t\overline{t}$ using pp collisions at $\sqrt{s}$=7 TeV. The quoted limit is for $\Gamma_{Z'}/m_{Z'} = 0.012$.

[134] AAD 12BV search for narrow resonance decaying to $t\overline{t}$ using pp collisions at $\sqrt{s}$=7 TeV. See their Fig. 7 for limit on $\sigma \cdot$ B.

[135] AAD 12K search for narrow resonance decaying to $t\overline{t}$ using pp collisions at $\sqrt{s}$=7 TeV. See their Fig. 5 for limit on $\sigma \cdot$ B.

[136] AALTONEN 12AR search for chromophilic Z' in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. See their Fig. 5 for limit on $\sigma \cdot$ B.

[137] AALTONEN 12N search for $p\overline{p} \to tZ'$, $Z' \to \overline{t}u$ events in $p\overline{p}$ collisions. See their Fig. 3 for the limit on $\sigma \cdot$ B.

[138] ABAZOV 12R search for top-color Z' boson decaying exclusively to $t\overline{t}$. The quoted limit is for $\Gamma_{Z'}/m_{Z'}$= 0.012.

[139] CHATRCHYAN 12AI search for $pp \to tt$ events and give constraints on a Z' model having $Z'\overline{u}t$ coupling. See their Fig. 4 for the limit in mass-coupling plane.

[140] Search for resonance decaying to $t\overline{t}$. See their Fig. 6 for limit on $\sigma \cdot$ B.

[141] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 4 for limit on $\sigma \cdot$ B.

[142] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 3 for limit on $\sigma \cdot$ B.

[143] CHATRCHYAN 11O search for same-sign top production in pp collisions induced by a hypothetical FCNC Z' at $\sqrt{s} = 7$ TeV. See their Fig. 3 for limit in mass-coupling plane.

[144] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 3 for limit on $\sigma \cdot$ B.

[145] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 2 for limit on $\sigma \cdot$ B.

[146] BARGER 03B use the nucleosynthesis bound on the effective number of light neutrino δN_ν. See their Figs. 4–5 for limits in general E_6 motivated models.

[147] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 2 for limits in general E_6-motivated models.

[148] CHO 98 study constraints on four-Fermi contact interactions obtained from low-energy electroweak experiments, assuming no Z-Z' mixing.

[149] Search for Z' decaying to dijets at $\sqrt{s}$=1.8 TeV. For Z' with electromagnetic strength coupling, no bound is obtained.

Searches for Z' with Lepton-Flavor-Violating decays

The following limits are obtained from $p\overline{p}$ or $pp \to Z'X$ with Z' decaying to the mode indicated in the comments.

	[12] ABULENCIA	06M	CDF	$Z' \to e\mu$

[1] HAYRAPETYAN 25AK search for a new particle with lepton-flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV in the mass range $110 < M_{Z'} < 500$ GeV. See their Fig. 15 for limits on $\sigma \cdot B$.

[2] CABARCAS 24 use constraints on the non-standard neutrino interactions reported by ANTARES and IceCube expreriments to constrain Z' models with $\mu\tau$ coupling. See their Figs. 1 and 2 for limits in mass-coupling plane.

[3] AAD 23CB search for a new particle with lepton-flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs.4, 5, and 6 for limits on $\sigma \cdot B$.

[4] TUMASYAN 23H search for a new particle with lepton-flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 4 for limits on $\sigma \cdot B$.

[5] AABOUD 18CM search for a new particle with lepton-flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs. 4, 5, and 6 for limits on $\sigma \cdot B$.

[6] SIRUNYAN 18AT search for a narrow resonance Z' decaying into $e\mu$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig.5 for limit on $\sigma \cdot B$ in the range of 600 GeV $< M_{Z'} <$ 5000 GeV.

[7] AABOUD 16P search for new particle with lepton flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs.2, 3, and 4 for limits on $\sigma \cdot B$.

[8] KHACHATRYAN 16BE search for new particle Z' with lepton flavor violating decay in pp collisions at$\sqrt{s} = 8$ TeV in the range of 200 GeV $< M_{Z'} <$ 2000 GeV. See their Fig.4 for limits on $\sigma \cdot B$ and their Table 5 for bounds on various masses.

[9] AAD 15O search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s} = 8$ TeV in the range of 500 GeV $< M_{Z'} <$ 3000 GeV. See their Fig. 2 for limits on σB.

[10] AAD 11H search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s} = 7$ TeV in the range of 700 GeV $< M_{Z'} <$ 1000 GeV. See their Fig. 3 for limits on $\sigma \cdot B$.

[11] AAD 11Z search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s} = 7$ TeV in the range 700 GeV $< M_{Z'} <$ 2000 GeV. See their Fig. 3 for limits on $\sigma \cdot B$.

[12] ABULENCIA 06M search for new particle Z' with lepton flavor violating decay in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV in the range of 100 GeV $< M_{Z'} <$ 800 GeV. See their Fig. 4 for limits in the mass-coupling plane.

Indirect Constraints on Kaluza-Klein Gauge Bosons

Bounds on a Kaluza-Klein excitation of the Z boson or photon in d=1 extra dimension. These bounds can also be interpreted as a lower bound on $1/R$, the size of the extra dimension. Unless otherwise stated, bounds assume all fermions live on a single brane and all gauge fields occupy the 4+d-dimensional bulk. See also the section on "Extra Dimensions" in the "Searches" Listings in this *Review*.

> 2.9	95	[6] MARCIANO	99	RVUE	Electroweak
> 2.5	95	[7] MASIP	99	RVUE	Electroweak
> 1.6	90	[8] NATH	99	RVUE	Electroweak
> 3.4	95	[9] STRUMIA	99	RVUE	Electroweak

[1] MUECK 02 limit is 2σ and is from global electroweak fit ignoring correlations among observables. Higgs is assumed to be confined on the brane and its mass is fixed. For scenarios of bulk Higgs, of brane-SU(2)$_L$, bulk-U(1)$_Y$, and of bulk-SU(2)$_L$, brane-U(1)$_Y$, the corresponding limits are > 4.6 TeV, > 4.3 TeV and > 3.0 TeV, respectively.

[2] Bound is derived from limits on $e\nu qq'$ contact interaction, using data from HERA and the Tevatron.

[3] Bound holds only if first two generations of quarks lives on separate branes. If quark mixing is not complex, then bound lowers to 400 TeV from Δm_K.

[4] See Figs. 1 and 2 of DELGADO 00 for several model variations. Special boundary conditions can be found which permit KK states down to 950 GeV and that agree with the measurement of Q_W(Cs). Quoted bound assumes all Higgs bosons confined to brane; placing one Higgs doublet in the bulk lowers bound to 2.3 TeV.

[5] Bound is derived from global electroweak analysis assuming the Higgs field is trapped on the matter brane. If the Higgs propagates in the bulk, the bound increases to 3.8 TeV.

[6] Bound is derived from global electroweak analysis but considering only presence of the KK W bosons.

[7] Global electroweak analysis used to obtain bound independent of position of Higgs on brane or in bulk.

[8] Bounds from effect of KK states on G_F, α, M_W, and M_Z. Hard cutoff at string scale determined using gauge coupling unification. Limits for d=2,3,4 rise to 3.5, 5.7, and 7.8 TeV.

[9] Bound obtained for Higgs confined to the matter brane with m_H=500 GeV. For Higgs in the bulk, the bound increases to 3.5 TeV.

See the related review(s):
Leptoquarks

MASS LIMITS for Leptoquarks from Pair Production

These limits rely only on the color or electroweak charge of the leptoquark.

[11] AAD 24O search for scalar leptoquarks decaying to $b\mu$ or $t\nu$. See their Fig. 3a for exclusion limit on M_{LQ} as function of B($b\mu$).

[12] AAD 24O search for scalar leptoquarks decaying to $t\mu$ or $b\nu$. See their Fig.4 a for exclusion limit on M_{LQ} as function of B($t\mu$).

[13] AAD 24O search for scalar leptoquarks decaying to be or $t\nu$. See their Fig. 3b for exclusion limit on M_{LQ} as function of B(be).

[14] AAD 24O search for scalar leptoquarks decaying to te or $b\nu$. See their Fig. 4b for exclusion limit on M_{LQ} as function of B(te).

[15] AAD 24O search for vector leptoquarks decaying to $t\nu$ or $b\tau$ with $\kappa = 1$. The limit becomes > 1580 GeV for $\kappa = 0$.

[16] AAD 24O search for vector leptoquarks decaying to $t\nu$ or $b\mu$ with $\kappa = 1$. The limit becomes > 1710 GeV for $\kappa = 0$.

[17] AAD 24O search for vector leptoquarks decaying to $t\nu$ or be with $\kappa = 1$. The limit becomes > 1620 GeV for $\kappa = 0$.

[18] HAYRAPETYAN 24O search for scalar leptoquarks decaying to $b\mu$. See their Fig. 7 for exclusion limit on leptoquark pair production cross section as function of M_{LQ}.

[19] HAYRAPETYAN 24O search for $\kappa = 1$ vector leptoquarks decaying to $b\mu$. The limit becomes $M_{LQ} > 2120$ GeV for $\kappa = 0$.

[20] HAYRAPETYAN 24Z search for scalar and vector leptoquarks decaying to $b\tau$ and produced through single, pair, and nonresonantly in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above assumes scalar leptoquarks with B($b\tau$) = 1 and leptoquark coupling strength $\lambda = 0$. See their Fig. 7 for limits in mass-coupling plane.

[21] HAYRAPETYAN 24Z search for scalar and vector leptoquarks decaying to $b\tau$ and produced through single, pair, and nonresonantly in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above assumes $\kappa = 1$ vector leptoquarks with B($b\tau$) = 1 and leptoquark coupling strength $\lambda = 0$. See their Fig. 8 for limits in mass-coupling plane and for limits with $\kappa = 0$.

[22] AAD 23BJ search for scalar leptoquarks decaying to $c\tau$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for exclusion limit on σ as function of M_{LQ}.

[23] AAD 23CF search for scalar and vector leptoquarks decaying to $b\tau$. The limit quoted above is for scalar leptoquark. See their Fig. 9 for limits on leptoquark pair production cross sections.

[24] AAD 23CF search for scalar and vector leptoquarks decaying to $b\tau$. The limit quoted above is for vector leptoquark with $\kappa = 1$. The limit becomes $M_{LQ} > 1650$ for vector leptoquark with $\kappa = 0$. See their Fig. 9 for limits on leptoquark pair production cross sections.

[25] AAD 23F search for scalar leptoquarks decaying to $t\nu$ and $b\mu$ in pp collisions at $\sqrt{s} =$ 13 TeV. See their Fig. 9 for exclusion contour in B($b\mu$)$-M_{LQ}$ plane.

[26] AAD 23F search for scalar leptoquarks decaying to $t\nu$ and be in pp collisions at $\sqrt{s} =$ 13 TeV. See their Fig. 9 for exclusion contour in B(be)$-M_{LQ}$ plane.

[27] AAD 23F search for scalar leptoquarks decaying to $t\mu$ and $b\nu$ in pp collisions at $\sqrt{s} =$ 13 TeV. See their Fig. 9 for exclusion contour in B($t\mu$)$-M_{LQ}$ plane.

[28] AAD 23F search for scalar leptoquarks decaying to te and $b\nu$ in pp collisions at $\sqrt{s} =$ 13 TeV. See their Fig. 9 for exclusion contour in B(te)$-M_{LQ}$ plane.

[29] AAD 23F search for $\kappa = 1$ (YM coupling) vector leptoquarks decaying to $t\nu$ and $b\mu$ in pp collisions at $\sqrt{s} = 13$ TeV. If $\kappa = 0$ (minimal coupling) is assumed, the limit becomes $M_{LQ} > 1710$ GeV. See their Fig. 10 for exclusion contour in B($b\mu$)$-M_{LQ}$ plane.

[30] AAD 23F search for $\kappa = 1$ (YM coupling) vector leptoquarks decaying to $t\nu$ and be in pp collisions at $\sqrt{s} = 13$ TeV. If $\kappa = 0$ (minimal coupling) is assumed, the limit becomes $M_{LQ} > 1620$ GeV. See their Fig. 10 for exclusion contour in B(be)$-M_{LQ}$ plane.

[31] TUMASYAN 22H search for scalar leptoquarks decaying to te. See their Fig. 27 for exclusion limit on leptoquark pair production cross section as function of M_{LQ}.

[32] TUMASYAN 22H search for scalar leptoquarks decaying to $t\mu$. See their Fig. 27 for exclusion limit on leptoquark pair production cross section as function of M_{LQ}.

[33] TUMASYAN 22H search for scalar leptoquarks decaying to $t\tau$. See their Fig. 27 for exclusion limit on leptoquark pair production cross section as function of M_{LQ}.

[34] AAD 21AG search for scalar leptoquarks decaying to te. See their Fig. 6 for exclusion limit on B(te) as function of M_{LQ}.

[35] AAD 21AG search for scalar leptoquarks decaying to $t\mu$. See their Fig. 6 for exclusion limit on B($t\mu$) as function of M_{LQ}.

[36] AAD 21AW search for scalar leptoquarks decaying to $b\tau$. See their Fig. 9 for exclusion contour in B($b\tau$)$-M_{LQ}$ plane.

[37] AAD 21AW search for scalar leptoquarks decaying to $t\tau$. See their Fig. 9 for exclusion contour in B($t\tau$)$-M_{LQ}$ plane.

[38] AAD 21AW search for $\kappa = 1$ vector leptoquarks decaying to $b\tau$. See their Fig. 10 for exclusion contour in B($b\tau$)$-M_{LQ}$ plane and for limit on $\kappa = 0$ vector leptoquarks.

[39] AAD 21S search for scalar leptoquarks decaying to $b\nu$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes B($b\nu$) = 1. For B($b\nu$) = 0.05, the limit becomes 400 GeV.

[40] AAD 21T search for scalar leptoquarks decaying to $t\tau$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes B($t\tau$) = 1. For B($t\tau$) = 0.5, the limit becomes 1220 GeV. See their Fig. 15b for limits on B($t\tau$) as a function of leptoquark mass.

[41] SIRUNYAN 21J search for scalar leptoquarks decaying to $t\tau$ and $b\nu$ in pp collisions at $\sqrt{s} = 13$ TeV.

[42] SIRUNYAN 21J search for vector leptoquarks decaying to $t\nu$ and $b\tau$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above assumes $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1290$ GeV.

[43] AAD 20AK search for scalar leptoquarks decaying to eq, eb, ec, μq, μb, μc. The quoted limit assumes B(eq) = 1. See their Fig. 9 for limits on B(eq), B(eb), B(ec), B(μq), B(μb), B(μc) as a function of leptoquark mass.

[44] AAD 20AK search for scalar leptoquarks decaying to eq, eb, ec, μq, μb, μc. The quoted limit assumes B(μq) = 1. See their Fig. 9 for limits on B(eq), B(eb), B(ec), B(μq), B(μb), B(μc) as a function of leptoquark mass.

[45] AAD 20S search for scalar leptoquarks decaying to $t\nu$ in pp collisions at $\sqrt{s} = 13$ TeV.

[46] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes scalar leptoquark with B(νb) = 1.

[47] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes scalar leptoquark with B(νt) = 1.

[48] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes scalar leptoquark with B(νq) = 1.

[49] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes vector leptoquark with B(νb) = 1 and $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1560$ GeV.

[50] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes vector leptoquark with B(νt) = 1 and $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1475$ GeV.

[51] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes vector leptoquark with B(νq) = 1 and $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1560$ GeV.

[52] AABOUD 19AX search for leptoquarks using $eejj$ events in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes B(eq) = 1.

[53] AABOUD 19AX search for leptoquarks using $\mu\mu jj$ events in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes B(μq) = 1.

[54] AABOUD 19X search for scalar leptoquarks decaying to $t\nu$ in pp collisions at $\sqrt{s} = 13$ TeV.

[55] AABOUD 19X search for scalar leptoquarks decaying to $b\tau$ in pp collisions at $\sqrt{s} = 13$ TeV.

[56] AABOUD 19X search for scalar leptoquarks decaying to $b\nu$ in pp collisions at $\sqrt{s} = 13$ TeV.

[57] AABOUD 19X search for scalar leptoquarks decaying to $t\tau$ in pp collisions at $\sqrt{s} = 13$ TeV.

[58] SIRUNYAN 19BI search for a pair of scalar leptoquarks decaying to $\mu\mu jj$ and to $\mu\nu jj$ final states in pp collisions at $\sqrt{s} = 13$ TeV. Limits are shown as a function of β where β is the branching fraction to a muon and a quark. For $\beta = 1.0$ (0.5) LQ masses up to 1530 (1285) GeV are excluded. See Fig. 9 for exclusion limits in the plane of β and LQ mass.

[59] SIRUNYAN 19BJ search for a pair of scalar leptoquarks decaying to $eejj$ and $e\nu jj$ final states in pp collisions at $\sqrt{s} = 13$ TeV. Limits are shown as a function of the branching fraction β to an electron and a quark. For $\beta = 1.0$ (0.5) LQ masses up to 1435 (1270) GeV are excluded. See Fig. 9 for exclusion limits in the plane of β and LQ mass.

[60] SIRUNYAN 19Y search for a pair of third generation scalar leptoquarks, each decaying to τ and a jet. Assuming B(τb) = 1, leptoquark masses below 1.02 TeV are excluded.

[61] SIRUNYAN 18CZ search for scalar leptoquarks decaying to τt in pp collisions at $\sqrt{s} =$ 13 TeV. The limit above assumes B(τt) = 1.

[62] SIRUNYAN 18EC set limits for scalar and vector leptoquarks decaying to μt, τt, and νb. The limit quoted above assumes scalar leptoquark with B(μt) = 1.

[63] SIRUNYAN 18EC set limits for scalar and vector leptoquarks decaying to μt, τt, and νb. The limit quoted above assumes vector leptoquark with all possible combinations of branching fractions to μt, τt, and νb.

[64] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with B($b\nu$) = 1. Vector leptoquarks with $\kappa = 1$ are excluded below masses of 1810 GeV.

[65] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with B($q\nu$) = 1. Vector leptoquarks with $\kappa = 1$ are excluded below masses of 1790 GeV.

[66] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with B(νt) = 1. Vector leptoquarks with $\kappa = 1$ are excluded below masses of 1780 GeV.

[67] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. $\kappa = 1$ and LQ$\rightarrow$ $b\nu$ are assumed.

[68] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. $\kappa = 1$ and LQ$\rightarrow$ $q\nu$ with q = u,d,s,c are assumed.

[69] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. $\kappa = 1$ and LQ$\rightarrow$ $t\nu$ are assumed.

[70] KHACHATRYAN 17J search for scalar leptoquarks decaying to τb using pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes B(τb) = 1.

[71] SIRUNYAN 17H search for scalar leptoquarks using $\tau\tau bb$ events in pp collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B(τb) = 1.

[72] AAD 16G search for scalar leptoquarks using $eejj$ events in collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(eq) = 1$.

[73] AAD 16G search for scalar leptoquarks using $\mu\mu jj$ events in collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(\mu q) = 1$.

[74] AAD 16G search for scalar leptoquarks decaying to $b\nu$. The limit above assumes $B(b\nu) = 1$.

[75] AAD 16G search for scalar leptoquarks decaying to $t\nu$. The limit above assumes $B(t\nu) = 1$.

[76] KHACHATRYAN 16AF search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes B(eq)= 1. For B(eq) = 0.5, the limit becomes 850 GeV.

[77] KHACHATRYAN 16AF search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 760 GeV.

[78] KHACHATRYAN 15AJ search for scalar leptoquarks using $\tau\tau tt$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(\tau t) = 1$.

[79] KHACHATRYAN 14T search for scalar leptoquarks decaying to τb using pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes B(τb) = 1. See their Fig. 5 for the exclusion limit as function of B(τb).

[80] SIRUNYAN 19BC search for scalar leptoquark (LQ) pair production in pp collisions at $\sqrt{s} = 13$ TeV. One LQ is assumed to decay to μq, while the other decays to dark matter pair and SM particles. See their Fig. 4 for limits in M_{LQ}–M_{DM} plane.

[81] AAD 13AE search for scalar leptoquarks using $\tau\tau bb$ events in pp collisions at $E_{\mathrm{cm}} =$ 7 TeV. The limit above assumes B(τb) = 1.

[82] CHATRCHYAN 13M search for scalar and vector leptoquarks decaying to τb in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above is for scalar leptoquarks with B(τb) = 1.

[83] AAD 12H search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(eq) = 1. For B(eq) = 0.5, the limit becomes 607 GeV.

[84] AAD 12O search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 594 GeV.

[85] CHATRCHYAN 12AG search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(eq) = 1. For B(eq) = 0.5, the limit becomes 640 GeV.

[86] CHATRCHYAN 12AG search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 650 GeV.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[87] CHATRCHYAN 12BO search for scalar leptoquarks decaying to νb in pp collisions at $\sqrt{s}$ = 7 TeV. The limit above assumes B(νb) = 1.

[88] AAD 11D search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at E_{cm} = 7 TeV.The limit above assumes B(eq) = 1. For B(eq) = 0.5, the limit becomes 319 GeV.

[89] AAD 11D search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at E_{cm} = 7 TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 362 GeV.

[90] ABAZOV 11V search for scalar leptoquarks using $e\nu jj$ events in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The limit above assumes B(eq) = 0.5.

[91] CHATRCHYAN 11N search for scalar leptoquarks using $e\nu jj$ events in pp collisions at E_{cm} = 7 TeV. The limit above assumes B(eq) = 0.5.

[92] KHACHATRYAN 11D search for scalar leptoquarks using $eejj$ events in pp collisions at E_{cm} = 7 TeV. The limit above assumes B(eq) = 1.

[93] KHACHATRYAN 11E search for scalar leptoquarks using $\mu\mu jj$ events in pp collisions at E_{cm} = 7 TeV. The limit above assumes B(μq) = 1.

[94] ABAZOV 10L search for pair productions of scalar leptoquark state decaying to νb in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The limit above assumes B(νb) = 1.

[95] ABAZOV 09 search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 270 GeV.

[96] ABAZOV 09AF search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The limit above assumes B(eq) = 1. For B(eq) = 0.5 the bound becomes 284 GeV.

[97] AALTONEN 08P search for vector leptoquarks using $\tau^+\tau^- b\overline{b}$ events in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Assuming Yang-Mills (minimal) couplings, the mass limit is >317 GeV (251 GeV) at 95% CL for B(τb) = 1.

[98] Search for pair production of scalar leptoquark state decaying to τb in $p\overline{p}$ collisions at E_{cm}= 1.96 TeV. The limit above assumes B(τb) = 1.

[99] Search for scalar leptoquarks using $\nu\nu jj$ events in $\overline{p}p$ collisions at E_{cm} = 1.96 TeV. The limit above assumes B(νq) = 1.

[100] ABAZOV 07J search for pair productions of scalar leptoquark state decaying to νb in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The limit above assumes B(νb) = 1.

[101] ABAZOV 06A search for scalar leptoquarks using $\mu\mu jj$ events in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV and 1.96 TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 204 GeV.

[102] ABAZOV 06L search for scalar leptoquarks using $\nu\nu jj$ events in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV and at 1.96 TeV. The limit above assumes B(νq) = 1.

[103] ABULENCIA 06T search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted limit assumes B(μq) = 1. For B(μq) = 0.5 or 0.1, the bound becomes 208 GeV or 143 GeV, respectively. See their Fig. 4 for the exclusion limit as a function of B(μq).

[104] ABAZOV 05H search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $\overline{p}p$ collisions at E_{cm} = 1.8 TeV and 1.96 TeV. The limit above assumes B(eq) = 1. For B(eq) = 0.5 the bound becomes 234 GeV.

[105] ACOSTA 05P search for scalar leptoquarks using $eejj$, $e\nu jj$ events in $\overline{p}p$ collisions at E_{cm} = 1.96TeV. The limit above assumes B(eq) = 1. For B(eq) = 0.5 and 0.1, the bound becomes 205 GeV and 145 GeV, respectively.

[106] ABBIENDI 03R search for scalar/vector leptoquarks in e^+e^- collisions at $\sqrt{s}$ = 189–209 GeV. The quoted limits are for charge $-4/3$ isospin 0 scalar-leptoquark with B(ℓq) = 1. See their table 12 for other cases.

[107] ABAZOV 02 search for scalar leptoquarks using $\nu\nu jj$ events in $\overline{p}p$ collisions at E_{cm}=1.8 TeV. The bound holds for all leptoquark generations. Vector leptoquarks are likewise constrained to lie above 200 GeV.

[108] ABAZOV 01D search for scalar leptoquarks using $e\nu jj$, $eejj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The limit above assumes B(eq)=1. For B(eq)=0.5 and 0, the bound becomes 204 and 79 GeV, respectively. Bounds for vector leptoquarks are also given. Supersedes ABBOTT 98E.

[109] ABBIENDI 00M search for scalar/vector leptoquarks in e^+e^- collisions at $\sqrt{s}$=183 GeV. The quoted limits are for charge $-4/3$ isospin 0 scalar-leptoquarks with B(ℓq)=1. See their Table 8 and Figs. 6–9 for other cases.

[110] ABBOTT 00C search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The limit above assumes B(μq)=1. For B(μq)=0.5 and 0, the bound becomes 180 and 79 GeV respectively. Bounds for vector leptoquarks are also given.

[111] AFFOLDER 00K search for scalar leptoquark using $\nu\nu cc$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The quoted limit assumes B(νc)=1. Bounds for vector leptoquarks are also given.

[112] AFFOLDER 00K search for scalar leptoquark using $\nu\nu bb$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The quoted limit assumes B(νb)=1. Bounds for vector leptoquarks are also given.

[113] ABBOTT 99J search for leptoquarks using $\mu\nu jj$ events in $p\overline{p}$ collisions at E_{cm}= 1.8TeV. The quoted limit is for a scalar leptoquark with B(μq) = B(νq) = 0.5. Limits on vector leptoquarks range from 240 to 290 GeV.

[114] ABBOTT 98E search for scalar leptoquarks using $e\nu jj$, $eejj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The limit above assumes B(eq)=1. For B(eq)=0.5 and 0, the bound becomes 204 and 79 GeV, respectively.

[115] ABBOTT 98J search for charge $-1/3$ third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. The quoted limit is for scalar leptoquark with B(νb)=1.

[116] ABE 98S search for scalar leptoquarks using $\mu\mu jj$ events in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. The limit is for B(μq)= 1. For B(μq)=B(νq)=0.5, the limit is > 160 GeV.

[117] GROSS-PILCHER 98 is the combined limit of the CDF and DØ Collaborations as determined by a joint CDF/DØ working group and reported in this FNAL Technical Memo. Original data published in ABE 97X and ABBOTT 98E.

[118] ABE 97F search for third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV. The quoted limit is for scalar leptoquark with B(τb) = 1.

[119] ABE 97X search for scalar leptoquarks using $eejj$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The limit is for B(eq)=1.

[120] Limit is for charge $-1/3$ isospin-0 leptoquark with B(ℓq) = 2/3.

[121] First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.

[122] Limits are for charge $-1/3$, isospin-0 scalar leptoquarks decaying to $\ell^- q$ or νq with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks.

[123] KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of de^+ and $u\overline{\nu}$ ($s\mu^+$ and $c\overline{\nu}$). See paper for limits for specific branching ratios.

[124] BARTEL 87B limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint B(X $\rightarrow$ $c\overline{\nu}_\mu$) + B(X $\rightarrow$ $s\mu^+$) = 1.

[125] BEHREND 86B assumed that a charge 2/3 spinless leptoquark, χ, decays either into $s\mu^+$ or $c\overline{\nu}$: B($\chi \rightarrow s\mu^+$) + B($\chi \rightarrow c\overline{\nu}$) = 1.

MASS LIMITS for Leptoquarks from Single Production

These limits depend on the q-ℓ-leptoquark coupling g_{LQ}. It is often assumed that $g^2_{LQ}/4\pi$=1/137. Limits shown are for a scalar, weak isoscalar, charge $-1/3$ leptoquark.

[1] AAD 25BN search for single production of a scalar leptoquark in pp collisions at $\sqrt{s}$ = 13 TeV and at $\sqrt{s}$ = 13.6 TeV. The quoted limit assumes leptoquark production in de collisions with coupling strength g_{de} = 1. Masses below 3.1 TeV, 4.3 TeV, and 2.8 TeV are excluded at 95% CL for g_{be} = 3.5, $g_{s\mu}$ = 3.5 and $g_{b\mu}$ = 3.5, respectively. See their Figs. 14–17 for exclusion limits in mass-coupling plane.

[2] HAYRAPETYAN 24C search for single production of scalar leptoquarks decaying to $q\tau^+$ (q = u, d, s, b) in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for a leptoquark produced in τu collisions and the leptoquark coupling strength λ = 1. See their Fig. 4 for limits in mass-coupling plane.

[3] HAYRAPETYAN 24C search for single production of scalar leptoquarks decaying to $q\tau^+$ (q = u, d, s, b) in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for a leptoquark produced in τd collisions and the leptoquark coupling strength λ = 1. See their Fig. 4 for limits in mass-coupling plane.

[4] HAYRAPETYAN 24Z search for scalar and vector leptoquarks decaying to $b\tau$ and produced through single, pair, and nonresonantly in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is derived solely from single production limit and assumes scalar leptoquark decaying to $b\tau$. The leptoquark coupling strength λ = 1 is assumed. See their Fig. 7 and Fig. 8 for combined limits in mass-coupling plane.

[5] AAD 23BZ search for single production of charge 4/3 scalar leptoquarks decaying to $b\tau^-$, and charge 2/3 vector leptoquarks decaying to $\overline{b}\tau^-$ in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above assumes a scalar leptoquark with B($b\tau$) = 1 and the leptoquark coupling strength λ = 1.0. The limit becomes M_{LQ} > 1530 GeV for λ = 2.5.

[6] SIRUNYAN 21J search for single production of charge $-1/3$ scalar leptoquarks decaying to $t\tau^-$ and $b\nu$, and charge 2/3 vector leptoquarks decaying to $t\nu$ and $b\tau^+$ in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above assumes a scalar leptoquark with B($t\tau$) = B($b\nu$) = 0.5 and the leptoquark coupling strength λ = 1.5. The limit becomes M_{LQ} > 750 GeV for λ = 2.5.

[7] SIRUNYAN 18BJ search for single production of charge 2/3 scalar leptoquarks decaying to τb in pp collisions at $\sqrt{s}$ = 13 TeV. The limit above assumes B(τb) = 1 and the leptoquark coupling strength λ = 1.

[8] KHACHATRYAN 16AG search for single production of charge $\pm 1/3$ scalar leptoquarks using eej events in pp collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B(eq) = 1 and the leptoquark coupling strength λ = 1.

[9] KHACHATRYAN 16AG search for single production of charge $\pm 1/3$ scalar leptoquarks using $\mu\mu j$ events in pp collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B(μq) = 1 and the leptoquark coupling strength λ = 1.

[10] ABRAMOWICZ 12A limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R. See their Figs. 12–17 and Table 4 for states with different quantum numbers.

[11] Limit from single production in Z decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes B(ℓq) = 2/3. The limit is 77 GeV if first and second leptoquarks are degenerate.

[12] AAD 22E leptoquarks decaying both to ue^- and $c\mu^-$ are constrained from the comparison of the production cross sections for $e^+\mu^-$ and $e^-\mu^+$ in pp collisions at $\sqrt{s}$ = 13 TeV. Scalar leptoquarks with M_{LQ} < 1880 GeV are excluded for $g^{eu} = g^{\mu c} = 1$.

[13] TUMASYAN 21D search for energetic jets + $\not{E}_T$ events in pp collisions at $\sqrt{s}$ = 13 TeV. The branching fraction for the decay of the leptoquark into an electron neutrino

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use strictly not permitted, except for Open Access articles.

and up quark is assumed to be 100% ($\beta = 0$). See their Fig. 12 for exclusion limits in mass-coupling plane.

[14] DEY 16 use the 2010-2012 IceCube PeV energy data set to constrain the leptoquark production cross section through the $\nu q \to$ LQ $\to \nu q$ process. See their Figure 4 for the exclusion limit in the mass-coupling plane.

[15] AARON 11A search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 2–3 and Tables 1–4 for detailed limits.

[16] The quoted limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R. See their Figs. 3–5 for limits on states with different quantum numbers.

[17] ABAZOV 07E search for leptoquark single production through qg fusion process in $p\overline{p}$ collisions. See their Fig. 4 for exclusion plot in mass-coupling plane.

[18] AKTAS 05B limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R. See their Fig. 3 for limits on states with different quantum numbers.

[19] CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs.6–10 and Tables 1–8 for detailed limits.

[20] CHEKANOV 03B limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R. See their Figs. 11–12 and Table 5 for limits on states with different quantum numbers.

[21] For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 4 and Fig. 5.

[22] CHEKANOV 02 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–7 and Tables 5–6 for detailed limits.

[23] For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 3.

[24] See their Fig. 14 for limits in the mass-coupling plane.

[25] BREITWEG 00E search for F=0 leptoquarks in e^+p collisions. For limits in mass-coupling plane, see their Fig. 11.

[26] ABREU 99G limit obtained from process $e\gamma \to LQ+q$. For limits on vector and scalar states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 4 and Table 2.

[27] For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 13 and Fig. 14. ADLOFF 99 also search for leptoquarks with lepton-flavor violating couplings. ADLOFF 99 supersedes AID 96B.

[28] DERRICK 97 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 5–8 and Table 1 for detailed limits.

[29] DERRICK 93 search for single leptoquark production in ep collisions with the decay eq and νq. The limit is for leptoquark coupling of electromagnetic strength and assumes B(eq) = B(νq) = 1/2. The limit for B(eq) = 1 is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

[1] AAD 25BB search for $\tau^+\tau^-$ production from t-channel LQ exchange in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 11 and Fig. 12 for limits in mass-coupling plane.

[2] HAYRAPETYAN 25AN use e^+e^- and $\mu^+\mu^-$ spectra in pp collisions at $\sqrt{s}$ = 13 TeV to set limits on t-channel LQ exchange amplitudes. See their Figs. 7–10 for limits in mass-coupling plane.

[3] AAD 24W search for leptoquark induced $\mu\tau qt$ (q = u, c) contact interaction in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 7b for limits in mass-coupling plane.

[4] CALABRESE 23 obtain limits on leptoquark coupling from coherent ν-nucleus scattering data collected by COHERENT experiment. See their Fig. 3 for limits in mass-coupling plane.

[5] TUMASYAN 23AW search for $\tau\nu$ events mediated by t-channel leptoquark exchange in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 10 for limits in mass-coupling plane.

[6] TUMASYAN 23S search for leptoquark induced $b\overline{b} \to \tau^+\tau^-$ process in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 12 for limits on a vector $b\tau$ leptoquark in mass-coupling plane.

[7] CRIVELLIN 21A set limits on coupling strengths of scalar and vector leptoquarks using $K \to \pi\nu\nu$, $K \to \pi e^+e^-$, $K^0 - \overline{K}^0$ and $D^0 - \overline{D}^0$ mixings, and weak neutral current measurements. See their Fig. 2 and Fig. 3 for the limits in mass-coupling plane.

[8] AEBISCHER 20 explain the B decay anomalies using four-fermion operator Wilson coefficients. See their Table 1. These Wilson coefficients may be generated by a U_1 vector leptoquark with U_1 transforming as $(3,1)_{2/3}$ under the SM gauge group. See their Figures 6, 7, 8 for the regions of the LQ parameter space which explains the B anomalies and avoids the indirect low energy constraints.

[9] DEPPISCH 20 limits on the lepton-number-violating higher-dimensional-operators are derived from $K \to \pi\nu\nu$ in the standard model effective field theory. These higher-dimensional-operators may be induced from leptoquark-exchange diagrams.

[10] ABRAMOWICZ 19 obtain a limit on $\lambda/M_{LQ} > 1.16$ TeV^{-1} for weak isotriplet spin-0 leptoquark S_1^L. We obtain the limit quoted above by converting the limit on λ/M_{LQ} for S_1^L assuming $\lambda = \sqrt{4\pi}$. See their Table 5 for the limits of leptoquarks with different quantum numbers. These limits are derived from bounds of eq contact interactions.

[11] MANDAL 19 give bounds on leptoquarks from τ-decays, leptonic dipole moments, lepton-flavor-violating processes, and K decays.

[12] ZHANG 18A give bounds on leptoquark induced four-fermion interactions from $D \to K\ell\nu$. The authors inform us that the shape parameter of the vector form factor in both the abstract and the conclusions of ZHANG 18A should be $r_{+1} = 2.16 \pm 0.07$ rather than ± 0.007. The numbers listed in their Table 7 are correct.

[13] BARRANCO 16 give bounds on leptoquark induced four-fermion interactions from $D \to K\ell\nu$ and $D_s \to \ell\nu$.

[14] KUMAR 16 gives bound on SU(2) singlet scalar leptoquark with chrge $-1/3$ from $K^0 - \overline{K}^0$ mixing, $K \to \pi\nu\overline{\nu}$, $K_L^0 \to \mu^+\mu^-$, and $K_L^0 \to \mu^\pm e^\mp$ decays.

[15] BESSAA 15 obtain limit on leptoquark induced four-fermion interactions from the ATLAS and CMS limit on the $\overline{q}q\overline{e}e$ contact interactions.

[16] SAHOO 15A obtain limit on leptoquark induced four-fermion interactions from $B_{s,d} \to \mu^+\mu^-$ for $\lambda \simeq O(1)$.

[17] SAKAKI 13 explain the $B \to D^{(*)}\tau\overline{\nu}$ anomaly using Wilson coefficients of leptoquark-induced four-fermion operators.

[18] KOSNIK 12 obtains limits on leptoquark induced four-fermion interactions from $b \to s\ell^+\ell^-$ decays.

[19] AARON 11C limit is for weak isotriplet spin-0 leptoquark at strong coupling $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds of eq contact interactions.

[20] DORSNER 11 give bounds on scalar, weak singlet, charge 4/3 leptoquark from K, B, τ decays, meson mixings, LFV, $g-2$ and $Z \to b\overline{b}$.

[21] AKTAS 07A search for lepton-flavor violation in ep collision. See their Tables 4–7 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

[22] SCHAEL 07A limit is for the weak-isoscalar spin-0 left-handed leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 35.

[23] SMIRNOV 07 obtains mass limits for the vector and scalar chiral leptoquark states from $K \to e\mu$, $B \to e\tau$ decays.

[24] CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs.6–10 and Tables 1–8 for detailed limits.

[25] ADLOFF 03 limit is for the weak isotriplet spin-0 leptoquark at strong coupling λ=$\sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds on $e^\pm q$ contact interactions.

[26] The bound is derived from B($B^0 \to e^\pm\mu^\mp$) $< 1.7 \times 10^{-7}$.

[27] CHEKANOV 02 search for lepton-flavor violation in ep collisions. See their Tables 1–4 for limits on lepton-flavor violating and four-fermion interactions induced by various leptoquarks.

[28] CHEUNG 01B quoted limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark with a coupling of electromagnetic strength. The limit is derived from bounds on contact interactions in a global electroweak analysis. For the limits of leptoquarks with different quantum numbers, see Table 5.

[29] ACCIARRI 00P limit is for the weak isoscalar spin-0 leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 4.

[30] ADLOFF 00 limit is for the weak isotriplet spin-0 leptoquark at strong coupling, λ=$\sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 2. ADLOFF 00 limits are from the Q^2 spectrum measurement of $e^+p \to e^+$X.

[31] BARATE 00I search for deviations in cross section and jet-charge asymmetry in $e^+e^- \to q\overline{q}$ due to t-channel exchange of a leptoquark at $\sqrt{s}$=130 to 183 GeV. Limits for other scalar and vector leptoquarks are also given in their Table 22.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[32] BARGER 00 explain the deviation of atomic parity violation in cesium atoms from prediction is explained by scalar leptoquark exchange.

[33] GABRIELLI 00 calculate various process with lepton flavor violation in leptoquark models.

[34] ZARNECKI 00 limit is derived from data of HERA, LEP, and Tevatron and from various low-energy data including atomic parity violation. Leptoquark coupling with electromagnetic strength is assumed.

[35] ABBIENDI 99 limits are from $e^+e^- \to q\overline{q}$ cross section at 130–136, 161–172, 183 GeV. See their Fig. 8 and Fig. 9 for limits in mass-coupling plane.

[36] ABE 98V quoted limit is from B($B_s \to e^\pm\mu^\mp$)$< 8.2\times10^{-6}$. ABE 98V also obtain a similar limit on $M_{LQ} > 20.4$ TeV from B($B_d \to e^\pm\mu^\mp$)$< 4.5\times10^{-6}$. Both bounds assume the non-canonical association of the b quark with electrons or muons under SU(4).

[37] ACCIARRI 98J limit is from $e^+e^- \to q\overline{q}$ cross section at $\sqrt{s}$= 130–172 GeV which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 4 and Fig. 5 for limits in the mass-coupling plane.

[38] ACKERSTAFF 98V limits are from $e^+e^- \to q\overline{q}$ and $e^+e^- \to b\overline{b}$ cross sections at $\sqrt{s}$ = 130–172 GeV, which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 21 and Fig. 22 for limits of leptoquarks in mass-coupling plane.

[39] DEANDREA 97 limit is for $\tilde{R}_2$ leptoquark obtained from atomic parity violation (APV). The coupling of leptoquark is assumed to be electromagnetic strength. See Table 2 for limits of the four-fermion interactions induced by various scalar leptoquark exchange. DEANDREA 97 combines APV limit and limits from Tevatron and HERA. See Fig. 1–4 for combined limits of leptoquark in mass-coupling plane.

[40] DERRICK 97 search for lepton-flavor violation in ep collision. See their Tables 2–5 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

[41] GROSSMAN 97 estimate the upper bounds on the branching fraction $B \to \tau^+\tau^-(X)$ from the absence of the B decay with large missing energy. These bounds can be used to constrain leptoquark induced four-fermion interactions.

[42] JADACH 97 limit is from $e^+e^- \to q\overline{q}$ cross section at $\sqrt{s}$=172.3 GeV which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 1 for limits on vector leptoquarks in mass-coupling plane.

[43] KUZNETSOV 95B use π, K, B, τ decays and μe conversion and give a list of bounds on the leptoquark mass and the fermion mixing matrix in the Pati-Salam model. The quoted limit is from $K_L \to \mu e$ decay assuming zero mixing.

[44] MIZUKOSHI 95 calculate the one-loop radiative correction to the Z-physics parameters in various scalar leptoquark models. See their Fig. 4 for the exclusion plot of third generation leptoquark models in mass-coupling plane.

[45] BHATTACHARYYA 94 limit is from one-loop radiative correction to the leptonic decay width of the Z. m_H=250 GeV, $\alpha_s(m_Z)$=0.12, m_t=180 GeV, and the electroweak strength of leptoquark coupling are assumed. For leptoquark coupled to $\overline{e}_L\, t_R$, $\overline{\mu}t$, and $\overline{\tau}t$, see Fig. 2 in BHATTACHARYYA 94B erratum and Fig. 3.

[46] DAVIDSON 94 gives an extensive list of the bounds on leptoquark-induced four-fermion interactions from π, K, D, B, μ, τ decays and meson mixings, *etc.* See Table 15 of DAVIDSON 94 for detail.

[47] KUZNETSOV 94 gives mixing independent bound of the Pati-Salam leptoquark from the cosmological limit on $\pi^0 \to \overline{\nu}\nu$.

[48] LEURER 94, LEURER 94B limits are obtained from atomic parity violation and apply to any chiral leptoquark which couples to the first generation with electromagnetic strength. For a nonchiral leptoquark, universality in $\pi_{\ell 2}$ decay provides a much more stringent bound.

[49] MAHANTA 94 gives bounds of P- and T-violating scalar-leptoquark couplings from atomic and molecular experiments.

[50] From $(\pi \to e\nu)/(\pi \to \mu\nu)$ ratio. SHANKER 82 assumes the leptoquark induced four-fermion coupling $4g^2/M^2\ (\overline{\nu}_{eL}\ u_R)\ (\overline{d}_L\, e_R)$with g=0.004 for spin-0 leptoquark and $g^2/M^2\ (\overline{\nu}_{eL}\ \gamma_\mu u_L)\ (\overline{d}_R\ \gamma^\mu e_R)$ with $g\simeq$ 0.6 for spin-1 leptoquark.

[1] SIRUNYAN 18BO search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[2] KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[3] KHACHATRYAN 16K search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[4] KHACHATRYAN 16L search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.

[5] KHACHATRYAN 15V search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV.

[6] CHATRCHYAN 13A search for new resonance decaying to dijets in pp collisions at $\sqrt{s}$ = 7 TeV.

[7] CHATRCHYAN 13AS search for new resonance decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV.

[8] CHATRCHYAN 11Y search for new resonance decaying to dijets in pp collisions at $\sqrt{s}$ = 7 TeV.

[9] KHACHATRYAN 10 search for new resonance decaying to dijets in pp collisions at $\sqrt{s}$ = 7 TeV.

[10] AALTONEN 09AC search for new narrow resonance decaying to dijets.

[11] ABE 97G search for new particle decaying to dijets.

[12] ABREU 94O limit is from $e^+e^- \to \overline{c}sc\,s$. Range extends up to 43 GeV if diquarks are degenerate in mass.

MASS LIMITS for g_A (axigluon) and Other Color-Octet Gauge Bosons

Axigluons are massive color-octet gauge bosons in chiral color models and have axial-vector coupling to quarks with the same coupling strength as gluons.

[1] SIRUNYAN 20AI search for resonances decaying into dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[2] SIRUNYAN 18BO search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[3] KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[4] KHACHATRYAN 16K search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[5] KHACHATRYAN 16L search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.

[6] KHACHATRYAN 15V search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV.

[7] KHACHATRYAN 17Y search for pair production of color-octet gauge boson g_A each decaying to 4j in pp collisions at $\sqrt{s}$ = 8 TeV.

[8] AAD 16W search for a new resonance decaying to a pair of b and B_H in pp collisions at $\sqrt{s}$ = 8 TeV. The vector-like quark B_H is assumed to decay to bH. See their Fig. 3 and Fig. 4 for limits on $\sigma \cdot B$.

[9] KHACHATRYAN 16E search for KK gluon decaying to $t\overline{t}$ in pp collisions at $\sqrt{s}$ = 8 TeV.

[10] KHACHATRYAN 15AV search for pair productions of neutral color-octet weak-triplet scalar particles (Θ^0), decaying to $b\overline{b}$, Zg or γg, in pp collisions at $\sqrt{s}$ = 8 TeV. The Θ^0 particle is often predicted in coloron (G', color-octet gauge boson) models and appear in the pp collisions through $G' \to \Theta^0\Theta^0$ decays. Assuming B($\Theta^0 \to b\overline{b}$) = 0.5, they give limits $m_{\Theta^0} > 623$ GeV (426 GeV) for $m_{G'} = 2.3\ m_{\Theta^0}$ ($m_{G'} = 5\ m_{\Theta^0}$).

[11] AALTONEN 13R search for new resonance decaying to $\sigma\sigma$, with hypothetical strongly interacting σ particle subsequently decaying to 2 jets, in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV, using data corresponding to an integrated luminosity of 6.6 fb^{-1}. For 50 GeV $< m_\sigma <$ $m_{g_A}/2$, axigluons in mass range 150–400 GeV are excluded.

[12] CHATRCHYAN 13A search for new resonance decaying to dijets in pp collisions at $\sqrt{s}$ = 7 TeV.

[13] CHATRCHYAN 13AS search for new resonance decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV.

[14] CHATRCHYAN 13AU search for the pair produced color-octet vector bosons decaying to $q\overline{q}$ pairs in pp collisions. The quoted limit is for B($g_A \to q\overline{q}$) = 1.

[15] ABAZOV 12R search for massive color octet vector particle decaying to $t\overline{t}$. The quoted limit assumes g_A couplings with light quarks are suppressed by 0.2.

[16] CHATRCHYAN 11Y search for new resonance decaying to dijets in pp collisions at $\sqrt{s}$ = 7 TeV.

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

[17] AALTONEN 10L search for massive color octet non-chiral vector particle decaying into $t\bar{t}$ pair with mass in the range 400 GeV < M < 800 GeV. See their Fig. 6 for limit in the mass-coupling plane.

[18] KHACHATRYAN 10 search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 7$ TeV.

[19] AALTONEN 09AC search for new narrow resonance decaying to dijets.

[20] CHOUDHURY 07 limit is from the $t\bar{t}$ production cross section measured at CDF.

[21] DONCHESKI 98 compare α_s derived from low-energy data and that from $\Gamma(Z \to \text{hadrons})/\Gamma(Z \to \text{leptons})$.

[22] ABE 97G search for new particle decaying to dijets.

[23] ABE 95N assume axigluons decaying to quarks in the Standard Model only.

[24] ABE 93G assume $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 10$.

[25] CUYPERS 91 compare α_s measured in Υ decay and that from R at PEP/PETRA energies.

[26] ABE 90H assumes $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 5$ ($\Gamma(g_A) = 0.09 m_{g_A}$). For $N = 10$, the excluded region is reduced to 120–150 GeV.

[27] ROBINETT 89 result demands partial-wave unitarity of $J = 0$ $t\bar{t} \to t\bar{t}$ scattering amplitude and derives a limit $m_{g_A} > 0.5\, m_t$. Assumes $m_t > 56$ GeV.

[28] ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution. $\Gamma(g_A) < 0.4\, m_{g_A}$ assumed. See also BAGGER 88.

[29] CUYPERS 88 requires $\Gamma(\Upsilon \to g g g_A) < \Gamma(\Upsilon \to g g g)$. A similar result is obtained by DONCHESKI 88.

[30] DONCHESKI 88B requires $\Gamma(\Upsilon \to g q \bar{q})/\Gamma(\Upsilon \to g g g) < 0.25$, where the former decay proceeds via axigluon exchange. A more conservative estimate of < 0.5 leads to $m_{g_A} > 21$ GeV.

MASS LIMITS for Color-Octet Scalar Bosons

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
none 400–1300	95	[1] AAD	25AL	ATLS	$pp \to S_8 S_8 X$, $S_8 \to t\bar{t}$
none 1800–3700	95	[2] SIRUNYAN	20AI	CMS	$pp \to S_8 X$, $S_8 \to gg$

		[4] KHACHATRY...	15AV	CMS	$pp \to \Theta^0 \Theta^0 \to b\bar{b} Z g$
none 150–287	95	[5] AAD	13K	ATLS	$pp \to S_8 S_8 X$, $S_8 \to 2$ jets

[1] AAD 25AL search for pair production of color-octet scalar particles in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above assumes the $S_8 t\bar{t}$ coupling parameter 0.1. See their Fig. 12 for limits on $\sigma \cdot B$.

[2] SIRUNYAN 20AI search for resonances decaying into dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes S_{8gg} coupling $k_s^2 = 1/2$.

[3] SIRUNYAN 18BO search for color octet scalar boson produced through gluon fusion process in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes S_{8gg} coupling $k_s^2 = 1/2$.

[4] KHACHATRYAN 15AV search for pair productions of neutral color-octet weak-triplet scalar particles (Θ^0), decaying to $b\bar{b}$, Zg or γg, in pp collisions at $\sqrt{s} = 8$ TeV. The Θ^0 particle is often predicted in coloron (G', color-octet gauge boson) models and appear in the pp collisions through $G' \to \Theta^0 \Theta^0$ decays. Assuming $B(\Theta^0 \to b\bar{b}) = 0.5$, they give limits $m_{\Theta^0} > 623$ GeV (426 GeV) for $m_{G'} = 2.3\, m_{\Theta^0}$ ($m_{G'} = 5\, m_{\Theta^0}$).

[5] AAD 13K search for pair production of color-octet scalar particles in pp collisions at $\sqrt{s} = 7$ TeV. Cross section limits are interpreted as mass limits on scalar partners of a Dirac gluino.

X^0 (Heavy Boson) Searches in Z Decays

Searches for radiative transition of Z to a lighter spin-0 state X^0 decaying to hadrons, a lepton pair, a photon pair, or invisible particles as shown in the comments. The limits are for the product of branching ratios.

[1] RAINBOLT 19 limits are from $B(Z \to \ell^+\ell^-\ell^+\ell^-)$. See their Figs. 5 and 6 for limits in mass-coupling plane.

[2] SIRUNYAN 19AZ search for $pp \to Z \to X^0\mu^+\mu^- \to \mu^+\mu^-\mu^+\mu^-$ events in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits on $\sigma(pp \to X^0\mu^+\mu^-) \cdot B(X^0 \to \mu^+\mu^-)$.

[3] BARATE 98U obtain limits on $B(Z \to \gamma X^0) B(X^0 \to \ell\bar{\ell}, q\bar{q}, gg, \gamma\gamma, \nu\bar{\nu})$. See their Fig. 17.

[4] See Fig. 4 of ACCIARRI 97Q for the upper limit on $B(Z \to \gamma X^0;\ E_\gamma > E_{\min})$ as a function of $E_{\min}$.

[5] ACTON 93E give $\sigma(e^+e^- \to X^0\gamma) \cdot B(X^0 \to \gamma\gamma) < 0.4$ pb (95%CL) for $m_{X^0} = 60 \pm 2.5$ GeV. If the process occurs via s-channel γ exchange, the limit translates to $\Gamma(X^0) \cdot B(X^0 \to \gamma\gamma)^2 < 20$ MeV for $m_{X^0} = 60 \pm 1$ GeV.

[6] ABREU 92D give $\sigma_Z \cdot B(Z \to \gamma X^0) \cdot B(X^0 \to \text{hadrons}) < (3\text{–}10)$ pb for $m_{X^0} =$ 10–78 GeV. A very similar limit is obtained for spin-1 X^0.

[7] ADRIANI 92F search for isolated γ in hadronic Z decays. The limit $\sigma_Z \cdot B(Z \to \gamma X^0) \cdot B(X^0 \to \text{hadrons}) < (2\text{–}10)$ pb (95%CL) is given for $m_{X^0} = 25$–85 GeV.

[8] ACTON 91 searches for $Z \to Z^* X^0$, $Z^* \to e^+e^-$, $\mu^+\mu^-$, or $\nu\bar{\nu}$. Excludes any new scalar X^0 with $m_{X^0} < 9.5$ GeV/c if it has the same coupling to ZZ^* as the MSM Higgs boson.

[9] ACTON 91B limits are for $m_{X^0} = 60$–85 GeV.

[10] ADEVA 91D limits are for $m_{X^0} = 30$–89 GeV.

[11] ADEVA 91D limits are for $m_{X^0} = 30$–86 GeV.

[12] AKRAWY 90J give $\Gamma(Z \to \gamma X^0) \cdot B(X^0 \to \text{hadrons}) < 1.9$ MeV (95%CL) for $m_{X^0} =$ 32–80 GeV. We divide by $\Gamma(Z) = 2.5$ GeV to get product of branching ratios. For nonresonant transitions, the limit is $B(Z \to \gamma q\bar{q}) < 8.2$ MeV assuming three-body phase space distribution.

MASS LIMITS for a Heavy Neutral Boson Coupling to e^+e^-

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
none 55–61		[1] ODAKA	89	VNS	$\Gamma(X^0 \to e^+e^-) \cdot B(X^0 \to \text{had.}) \gtrsim 0.2$ MeV

none 39.8–45.5		[5] ADEVA	84	MRKJ	$\Gamma(X^0 \to e^+e^-) = 10$ keV
>47.8	95	[5] ADEVA	84	MRKJ	$\Gamma(X^0 \to e^+e^-) = 4$ MeV
none 39.8–45.2		[5] BEHREND	84C	CELL	
>47	95	[5] BEHREND	84C	CELL	$\Gamma(X^0 \to e^+e^-) = 4$ MeV

[1] ODAKA 89 looked for a narrow or wide scalar resonance in $e^+e^- \to$ hadrons at $E_{cm} = 55.0$–60.8 GeV.

[2] DERRICK 86 found no deviation from the Standard Model Bhabha scattering at $E_{cm} =$ 29 GeV and set limits on the possible scalar boson e^+e^- coupling. See their figure 4 for excluded region in the $\Gamma(X^0 \to e^+e^-)$-m_{X^0} plane. Electronic chiral invariance requires a parity doublet of X^0, in which case the limit applies for $\Gamma(X^0 \to e^+e^-) =$ 3 MeV.

[3] ADEVA 85 first limit is from 2γ, $\mu^+\mu^-$, hadrons assuming X^0 is a scalar. Second limit is from e^+e^- channel. $E_{cm} = 40$–47 GeV. Supersedes ADEVA 84.

[4] BERGER 85B looked for effect of spin-0 boson exchange in $e^+e^- \to e^+e^-$ and $\mu^+\mu^-$ at $E_{cm} = 34.7$ GeV. See Fig. 5 for excluded region in the $m_{X^0} - \Gamma(X^0)$ plane.

[5] ADEVA 84 and BEHREND 84C have $E_{cm} = 39.8$–45.5 GeV. MARK-J searched X^0 in $e^+e^- \to$ hadrons, 2γ, $\mu^+\mu^-$, e^+e^- and CELLO in the same channels plus τ pair. No narrow or broad X^0 is found in the energy range. They also searched for the effect of X^0 with $m_X > E_{cm}$. The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for $\Gamma(X^0 \to e^+e^-) = 2$ MeV if X^0 is a spin-0 doublet. The second limit of BEHREND 84C was read off from their figure 2. The original papers also list limits in other channels.

Search for X^0 Resonance in e^+e^- Collisions

The limit is for $\Gamma(X^0 \to e^+e^-) \cdot B(X^0 \to f)$, where f is the specified final state. Spin 0 is assumed for X^0.

[2] Limit is for m_{X^0} around 60 GeV.
[3] ABREU 96T obtain limit as a function of m_{X^0}. See their Fig. 15.
[4] ADRIANI 92F give $\sigma_Z \cdot B(Z \to q\overline{q}X^0) \cdot B(X^0 \to \gamma\gamma)$<(0.75–1.5) pb (95%CL) for m_{X^0} = 10–70 GeV. The limit is 1 pb at 60 GeV.

Search for X^0 Resonance in WX^0 final state

VALUE (MeV)	DOCUMENT ID			TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
	[1] AALTONEN	13AA	CDF		$X^0 \to jj$
	[2] CHATRCHYAN	12BR	CMS		$X^0 \to jj$
	[3] ABAZOV	11I	D0		$X^0 \to jj$
	[4] ABE	97W	CDF		$X^0 \to b\overline{b}$

[1] AALTONEN 13AA search for X^0 production associated with W (or Z) in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The upper limit on the cross section $\sigma(p\overline{p} \to WX^0)$ is 2.2 pb for M_{X^0} = 145 GeV.
[2] CHATRCHYAN 12BR search for X^0 production associated with W in pp collisions at E_{cm} = 7 TeV. The upper limit on the cross section is 5.0 pb at 95% CL for m_{X^0} = 150 GeV.
[3] ABAZOV 11I search for X^0 production associated with W in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The 95% CL upper limit on the cross section ranges from 2.57 to 1.28 pb for X^0 mass between 110 and 170 GeV.
[4] ABE 97W search for X^0 production associated with W in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The 95%CL upper limit on the production cross section times the branching ratio for $X^0 \to b\overline{b}$ ranges from 14 to 19 pb for X^0 mass between 70 and 120 GeV. See their Fig. 3 for upper limits of the production cross section as a function of m_{X^0}.

Search for X^0 Resonance in Quarkonium Decays

Limits are for branching ratios to modes shown. Spin 1 is assumed for X^0.

See the related review(s):
Axions and Other Similar Particles

A^0 (Axion) MASS LIMITS from Astrophysics and Cosmology

These bounds depend on model-dependent assumptions (i.e. — on a combination of axion parameters).

VALUE (MeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
>0.2	BARROSO	82	ASTR	Standard Axion
>0.25	[1] RAFFELT	82	ASTR	Standard Axion
>0.2	[2] DICUS	78C	ASTR	Standard Axion
	MIKAELIAN	78	ASTR	Stellar emission
>0.3	[2] SATO	78	ASTR	Standard Axion
>0.2	VYSOTSKII	78	ASTR	Standard Axion

[1] Lower bound from 5.5 MeV γ-ray line from the sun.
[2] Lower bound from requiring the red giants' stellar evolution not be disrupted by axion emission.

A^0 (Axion) and Other Light Boson (X^0) Searches in Hadron Decays

Limits are for branching ratios.

		[54] ZHITNITSKII	79		Heavy axion

[1] ABLIKIM 25AV search for η decays to A^0 subsequently decaying to an electron positron pair in the BESIII detector. They set limits down to 3×10^{-3} on the relative branching fraction for the decay process compared to $\eta \to \pi^+\pi^- e^+e^-$ for axion masses between 5 and 200 MeV - see their Fig. 7 for mass-dependent limits.
[2] ADACHI 25AA search for axion-like particles produced from decays of B to K or K^* mesons in the Belle detector, with the axion-like particle subsequently decaying to two photons. See their Fig. 5 for mass-dependent limits on the axion coupling to the W boson in the mass range 0.16–4.5 GeV.
[3] ALRAHMAN 25 present a search for scalars and axions produced from the kaon decays that then decay to two muons using the ICARUS detector at Fermilab. In their Fig. 2, they present a constraint on axions with masses up to 350 MeV for a particular choice of gauge field and muon couplings. The quoted value is from their model-independent branching ratio limit shown in Fig. 3 at $c\tau_{A^0} = 200$ m.
[4] CORTINA-GIL 25B report a search for an invisibly decaying X^0 produced in decays of K^+ in the NA62 detector, for masses up to 260 MeV. The quoted branching ratio limit is for $K^+ \to \pi^+ X^0$ for an invisibly decaying X^0. See their Fig. 2 for mass-dependent limits.
[5] ABLIKIM 24AK search for η' decays to axions in the mass range 0 to 500 MeV using the BESIII detector at the Beijing Electron-Positron Collider. See Fig. 9b for mass-dependent limits.
[6] ABLIKIM 24G search for muonphilic vector or scalar X^0 particles with masses between 1 and 1000 MeV in J/ψ decays at the BESIII detector. See their Fig. 3 for mass-dependent limits on the scalar/vector couplings under three different models.
[7] ABLIKIM 24M search for η and η' decays to dark photons in the mass range 0 to 0.7 GeV using the BESIII detector at the Beijing Electron-Positron Collider. The quoted limit is for $\eta' \to \gamma X^0$. See Fig. 7 a and b for mass-dependent limits.
[8] CORTINA-GIL 24 use $K^+ \to \pi^+\gamma\gamma$ events in NA62 to constrain 210 to 350 MeV-mass axions coupled to gluons, which promptly decay to $\gamma\gamma$. See their Fig. 8 for mass-dependent limits.
[9] SADOVSKY 24 report results from the OKA collaboration on a missing-mass search for invisible axions in K^+ decays to pions. The quoted limit applies at $m_{A^0} \simeq 200$ MeV. See their Fig. 6 for mass-dependent limits up to 200 MeV.
[10] ADACHI 23K quoted limit is for $m_{X^0} \simeq 3$ GeV, $c\tau_{X^0} = 1$ cm, and the decay channel $X^0 \to e^+e^-$. See their Fig. 2 for limits with different lifetimes and decay channels, $X^0 \to \mu^+\mu^-$, $\pi^+\pi^-$, K^+K^-.
[11] ADACHI 23K quoted limit is for $m_{X^0} \simeq 2$ GeV, $c\tau_{X^0} = 1$ cm, and the decay channel $X^0 \to e^+e^-$. See their Fig. 2 for limits with different lifetimes and decay channels, $X^0 \to \mu^+\mu^-$, $\pi^+\pi^-$, K^+K^-.
[12] CORTINA-GIL 23B limit extends over 10–170 MeV in mass. Quoted limit is at 155 MeV.
[13] LEES 22B quoted limit is for $m_{A^0} = 3.9$ GeV, assuming the promptly decaying axion. Limits of $O(10^{-7})$ are obtained for $m_{A^0} = 0.175$–4.78 GeV. See their Figs.3 and 4 for mass and lifetime dependent limits.
[14] ABRATENKO 21 quoted limit is for $m_{X^0} = 150$ MeV and the lifetime $c\tau_{X^0} = 80$ m. See their Fig. 4 for the limits in the range of $m_{X^0} = 10$–210 MeV.
[15] CORTINA-GIL 21 quoted limit is for $m_{X^0} = 370$ MeV. Limits from $O(10^{-5})$ and $O(10^{-6})$ are obtained for $m_{X^0} = 10$–370 MeV (see their Fig. 7).
[16] CORTINA-GIL 21A quoted limit is for $m_{X^0} = 160$–250 MeV. Limits between 5×10^{-11} and 2×10^{-10} are obtained in the range of $m_{X^0} = 0$–110 and 154–260 MeV, assuming stable or invisibly decaying X^0. See their Fig. 4 for mass- and lifetime-dependent limits.
[17] CORTINA-GIL 21C quoted limit is for $m_{X^0} = 130$–140 MeV, and limits of 9×10^{-10}–6×10^{-7} are obtained in the mass range of $m_{X^0} = 110$–155 MeV, assuming X^0 escapes detection. See their Fig. 6 for mass- and lifetime-dependent limits.
[18] PARK 21 look for dark photons produced by decays of B^0 through off-shell Higgs-dark Higgs mixing. See their Fig. 5 for limits in the range of $m_{X^0} = 0.01$–2.62 GeV.
[19] AHN 19 is an update of AHN 17 from a new data set. See their Fig. 4 for the limits in the range of $m_{X^0} = 0$–250 MeV.
[20] AAIJ 17AQ limit is for $\tau_{X^0} = 10$ ps. See their Fig. 4 for limits in the range of $m_{X^0} = 250$–4700 MeV and $\tau_{X^0} = 0.1$–1000 ps.
[21] AHN 17 limit as a function of m_{X^0} from 0 to 250 MeV is provided in their Fig. 5.
[22] BATLEY 17 limit is for $m_{X^0} = 216$ MeV and $\tau_{X^0} \leq 10$ ps. See their Fig. 4(c) for limits in the range of $m_{X^0} = 211$–354 MeV and longer lifetimes.
[23] WON 16 look for a vector boson coupled to baryon number. Derived limits on $\alpha' < 10^{-3}$–10^{-2} for $m_{X^0} = 290$–520 MeV at 95% CL. See their Fig. 4 for mass-dependent limits.
[24] AAIJ 15AZ limit is for $\tau_{X^0} = 10$ ps and $m_{X^0} = 214$–4350 MeV. See their Fig. 4 for mass- and lifetime-dependent limits.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[25] ADLARSON 13 limits between 2.0×10^{-5} and 1.5×10^{-6} are obtained for m_{X^0} = 20–100 MeV (see their Fig. 8). Angular momentum conservation requires that X^0 has spin ≥ 1.

[26] BABUSCI 13B limit is for $B(\phi\to\eta X^0)\cdot B(X^0\to e^+e^-)$ and applies to $m_{X^0}=410$ MeV. It is derived by analyzing $\eta\to\pi^0\pi^0\pi^0$ and $\pi^-\pi^+\pi^0$. Limits between 1×10^{-6} and 2×10^{-8} are obtained for $m_{X^0}\leq 450$ MeV (see their Fig. 6).

[27] ARCHILLI 12 analyzed $\eta\to\pi^+\pi^-\pi^0$ decays. Derived limits on $\alpha'/\alpha < 2\times10^{-5}$ for m_{X^0} = 50–420 MeV at 90% CL. See their Fig. 8 for mass-dependent limits.

[28] GNINENKO 12A limit is for $B(\pi^0\to\gamma X^0)\cdot B(X^0\to e^+e^-)$ and applies for m_{X^0} = 90 MeV and $\tau_{X^0}\simeq 1\times10^{-8}$ sec. Limits between 10^{-8} and 2×10^{-15} are obtained for m_{X^0} = 3–120 MeV and $\tau_{X^0}=1\times10^{-11}$–1 sec. See their Fig. 3 for limits at different masses and lifetimes.

[29] GNINENKO 12B limit is for $B(\eta\to\gamma X^0)\cdot B(X^0\to e^+e^-)$ and applies for m_{X^0} = 100 MeV and $\tau_{X^0}\simeq 6\times10^{-9}$ sec. Limits between 10^{-5} and 3×10^{-14} are obtained for $m_{X^0}\lesssim 550$ MeV and $\tau_{X^0}=10^{-10}$–10 sec. See their Fig. 5 for limits at different mass and lifetime and for η' decays.

[30] ADLER 04 limit applies for a mass near 180 MeV. For other masses in the range m_{X^0} = 150–250 MeV the limit is less restrictive, but still improves ADLER 02C and ATIYA 93B.

[31] ANISIMOVSKY 04 bound is for m_{X^0}=0.

[32] ADLER 02C bound is for m_{X^0} <60 MeV. See Fig. 2 for limits at higher masses.

[33] The quoted limit is for m_{X^0} = 0–80 MeV. See their Fig. 5 for the limit at higher mass. The branching fraction limit assumes pure phase space decay distributions.

[34] ALTEGOER 98 looked for X^0 from π^0 decay which penetrate the shielding and convert to π^0 in the external Coulomb field of a nucleus.

[35] KITCHING 97 limit is for $B(K^+\to\pi^+X^0)\cdot B(X^0\to\gamma\gamma)$ and applies for $m_{X^0}\simeq 50$ MeV, $\tau_{X^0}<10^{-10}$ s. Limits are provided for $0<m_{X^0}<100$ MeV, $\tau_{X^0}<10^{-8}$ s.

[36] ADLER 96 looked for a peak in missing-mass distribution. This work is an update of ATIYA 93. The limit is for massless stable X^0 particles and extends to m_{X^0}=80 MeV at the same level. See paper for dependence on finite lifetime.

[37] AMSLER 94B and AMSLER 96B looked for a peak in missing-mass distribution.

[38] MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of X^0 decay modes. It applies to $\tau(X^0)>10^{-23}$ sec.

[39] ATIYA 93B looked for a peak in missing mass distribution. The bound applies for stable X^0 of m_{X^0}=150–250 MeV, and the limit becomes stronger (10^{-8}) for m_{X^0}=180–240 MeV.

[40] NG 93 studied the production of X^0 via $\gamma\gamma\to\pi^0\to\gamma X^0$ in the early universe at $T\simeq 1$ MeV. The bound on extra neutrinos from nucleosynthesis $\Delta N_\nu<0.3$ (WALKER 91) is employed. It applies to $m_{X^0}\ll 1$ MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier X^0.

[41] ALLIEGRO 92 limit applies for m_{X^0}=150–340 MeV and is the branching ratio times the decay probability. Limit is $<1.5\times10^{-8}$ at 99%CL.

[42] ATIYA 92 looked for a peak in missing mass distribution. The limit applies to m_{X^0}=0–130 MeV in the narrow resonance limit. See paper for the dependence on lifetime. Covariance requires X^0 to be a vector particle.

[43] BARABASH 92 is a beam dump experiment that searched for a light Higgs. Limits between 1×10^{-12} and 1×10^{-7} are obtained for $3<m_{X^0}<40$ MeV.

[44] Limits between 1×10^{-12} and 1 are obtained for $4<m_{X^0}<69$ MeV.

[45] Limits between 1×10^{-11} and 5×10^{-3} are obtained for $4<m_{X^0}<63$ MeV.

[46] Limits between 1×10^{-14} and 1 are obtained for $3<m_{X^0}<82$ MeV.

[47] MEIJERDREES 92 limit applies for $\tau_{X^0}=10^{-23}$–10^{-11} sec. Limits between 2×10^{-4} and 4×10^{-6} are obtained for m_{X^0} = 25–120 MeV. Angular momentum conservation requires that X^0 has spin ≥ 1.

[48] ATIYA 90B limit is for $B(K^+\to\pi^+X^0)\cdot B(X^0\to\gamma\gamma)$ and applies for $m_{X^0}=50$ MeV, $\tau_{X^0}<10^{-10}$ s. Limits are also provided for $0<m_{X^0}<100$ MeV, $\tau_{X^0}<10^{-8}$ s.

[49] KORENCHENKO 87 limit assumes $m_{A^0}=1.7$ MeV, $\tau_{A^0}\lesssim 10^{-12}$ s, and $B(A^0\to e^+e^-)=1$.

[50] EICHLER 86 looked for $\pi^+\to e^+\nu A^0$ followed by $A^0\to e^+e^-$. Limits on the branching fraction depend on the mass and and lifetime of A^0. The quoted limits are valid when $\tau(A^0)\gtrsim 3.\times10^{-10}$s if the decays are kinematically allowed.

[51] YAMAZAKI 84 looked for a discrete line in $K^+\to\pi^+$X. Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.

[52] ASANO 82 at KEK set limits for $B(K^+\to\pi^+X^0)$ for m_{X^0} <100 MeV as BR $<4.\times10^{-8}$ for $\tau(X^0\to n\gamma$'s$)>1.\times10^{-9}$ s, BR $<1.4\times10^{-6}$ for $\tau<1.\times10^{-9}$s.

[53] ASANO 81B is KEK experiment. Set $B(K^+\to\pi^+X^0)<3.8\times10^{-8}$ at CL = 90%.

[54] ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 (3 <m <40 MeV) contradicts experimental muon anomalous magnetic moments.

[1] ABLIKIM 23E obtained limits in the range of 8.3×10^{-8}–1.8×10^{-6} for 0.165 GeV $\leq m_{A^0}\leq$ 2.84 GeV. See their Fig. 5 for mass-dependent limits.

[2] JIA 22 limits between 3.1×10^{-7}–1.6×10^{-5} were obtained for 0.22 GeV $< m_{A^0} <$ 9.2 GeV. See their Fig. 4 for mass-dependent limits.

[3] ABLIKIM 16E limits between 2.8–495.3×10^{-8} were obtained for 0.212 GeV $< m_{A^0} <$ 3.0 GeV. See their Fig. 5 for mass-dependent limits.

[4] ABLIKIM 12 derived limits between 4×10^{-7}–2.1×10^{-5} for 0.212 GeV $< m_{A^0} <$ 3.0 GeV. See their Fig. 2(c) for mass-dependent limits.

[5] ANTREASYAN 90C assume that A^0 does not decay in the detector.

[6] The first DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 3\times10^{-13}$ s/MeV and $m_{A^0}<20$ MeV.

[7] The second DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 5\times10^{-13}$ s/MeV and $m_{A^0}<20$ MeV.

[8] The third DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} > 7\times10^{-12}$ s/MeV and $m_{A^0}<200$ MeV.

[9] EDWARDS 82 looked for $J/\psi\to\gamma A^0$ decays by looking for events with a single γ [of energy $\sim 1/2$ the $J/\psi(1S)$ mass], plus nothing else in the detector. The limit is inconsistent with the axion interpretation of the FAISSNER 81B result.

A^0 (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

		[7] AMALDI	85	CNTR	Ortho-positronium
		[8] CARBONI	83	CNTR	Ortho-positronium

[1] BADERTSCHER 02 looked for a three-body decay of ortho-positronium into a photon and two penetrating (neutral or milli-charged) particles.

[2] The ASAI 94 limit is based on inclusive photon spectrum and is independent of A^0 decay modes.

[3] The AKOPYAN 91 limit applies for a short-lived A^0 with $\tau_{A^0}<10^{-13}\ m_{A^0}$ [keV] s.

[4] ASAI 91 limit translates to $g^2_{A^0e^+e^-}/4\pi < 1.1\times10^{-11}$ (90% CL) for $m_{A^0}<800$ keV.

[5] The TSUCHIAKI 90 limit is based on inclusive photon spectrum and is independent of A^0 decay modes.

[6] ORITO 89 limit translates to $g^2_{A^0ee}/4\pi < 6.2\times10^{-10}$. Somewhat more sensitive limits are obtained for larger m_{A^0}: $B<7.6\times10^{-6}$ at 100 keV.

[7] AMALDI 85 set limits $B(A^0\gamma)$ / $B(\gamma\gamma\gamma)<(1$–$5)\times10^{-6}$ for m_{A^0} = 900–100 keV which are about 1/10 of the CARBONI 83 limits.

[8] CARBONI 83 looked for orthopositronium $\to A^0\gamma$. Set limit for A^0 electron coupling squared, $g(eeA^0)^2/(4\pi)<6.\times10^{-10}$–$7.\times10^{-9}$ for m_{A^0} from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from $g-2$ experiments.

A^0 (Axion) Search in Photoproduction

• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[1] ADHIKARI	22C	GLUX	m_{A^0} = 180–480, 600–720 MeV
	[2] BASSOMPIE...	95		$m_{A^0}=1.8\pm0.2$ MeV

[1] ADHIKARI 22C search for $A^0\to\gamma\gamma$ and $A^0\to\pi^+\pi^-\pi^0$ decays, and set limits of $f_{A^0}\lesssim$ 0.5–14 GeV at 90% CL. See their Fig. 4 for mass-dependent limits.

[2] BASSOMPIERRE 95 is an extension of BASSOMPIERRE 93. They looked for a peak in the invariant mass of e^+e^- pairs in the region $m_{e^+e^-}=1.8\pm0.2$ MeV. They obtained bounds on the production rate A^0 for $\tau(A^0)=10^{-18}$–10^{-9} sec. They also found an excess of events in the range $m_{e^+e^-}$ = 2.1–3.5 MeV.

A^0 (Axion) Production in Hadron Collisions

[1] AAD 25AN search for axion-like particle production in proton-proton collisions in association with single top and a W or top quark pair, with the subsequent A^0 decaying to $b\bar{b}$. They search for axion-like particles with masses between 12 and 100 GeV as shown in the mass-dependent limits on the production cross section times branching fraction in their Fig. 9.

[2] AAD 25AT set limits on the branching fraction of Higgs boson decays to a Z boson and a 0.5–3.5 GeV-mass axion-like particle decaying to either a gluon or quark pair. See their Fig. 4 for detailed limits.

[3] AAD 25AY set limits on long-lived axion-like particles produced in proton-proton collisions via an intermediate off-shell Z boson, with the axion-like particle decaying to a gluon pair in association with a lepton pair in the final state. See their Fig. 15 for limits on the Z + axion cross section multiplied by the axion-to-2-gluon branching ratio as a function of the proper decay length for the axion. They search across axion masses 0.1–40 GeV.

[4] CHEKHOVSKY 25 constrain the production of heavy axion-like particles via a search for $WZ\gamma$ events in proton-proton collisions recorded by the CMS detector. They consider a process in which an ALP is produced alongside a W, and then decays to a Z and γ. See Fig. 3 for mass-dependent limits on the branching ratio multiplied by the cross section (or in terms of the ALP energy scale) across the 110 to 400 GeV ALP mass region.

[5] AAD 24AT search for Higgs decays to axions, constraining the effective coupling to photons between 100 MeV and 62 GeV axion mass. Limit strength is dependent on the effective axion-Higgs coupling and is strongest at the highest mass. See their Fig. 8 for full limits.

[6] AAD 24BN search for the production of long-lived axion-like particles produced in proton-proton collisions at the ATLAS detector. See their Fig. 2 for cross-section limits on benchmark ALP masses between 40 and 55 GeV, as a function of their proper decay length. Limits are presented for both ALP production from $q\overline{q}$ in association with the production of a vector boson, and ALP production from top decays.

[7] AAD 24BZ set limits on photo-phobic axion-like particles with masses between 0.1 and 40 GeV that are radiated from vector bosons and decay into gluons. See their Figs. 11 and 12 for limits on the ALP couplings to W, Z and gluons. An erratum for this publication can be found at AAD 25BF, which impacts the ALP branching ratio limit plots: Figures 9(a) and 10(a).

[8] AAD 24CD search for the production of axion-like particles in association with a hadronically decaying W or Z and large missing transverse energy in proton-proton collisions at the ATLAS detector. See their Fig. 7 for upper limits on the vector boson coupling for an ALP mass of 1 MeV as a function of f_{A^0}.

[9] AAD 24K search for Higgs decays to a Z and an axion-like particle in the mass range 0.1 to 33 GeV. They constrain the axion coupling to photons. See Fig. 3b for mass-dependent limits, which also depend on the coupling of the Higgs to ZA^0.

[10] HAYRAPETYAN 24AZ present results from CMS's search for axion-like particles produced from Higgs decays then promptly decaying to a dimuon. See their Fig. 6 for limits on the effective ALP coupling to the SM-like Higgs.

[11] HAYRAPETYAN 24I report a search by CMS for an exotic Higgs decay to an axion-like particle and a Z, which decay to two photons and two leptons respectively. See Fig. 7 and 8 for mass-dependent limits on the cross-section for the process and the effective axion coupling in the mass range 1 to 30 GeV.

[12] TUMASYAN 24C reports results from the CMS and TOTEM collaborations' search for photon-photon fusion events in proton collisions and the subsequent diphoton events which may occur via the production of axions. Constraints on the axion to two-photon coupling are presented at the 10^{-5} GeV^{-1} level for axion masses between 500 and 2000 GeV.

[13] ACCIARRI 23 search for axions in the NuMI neutrino beam target, which are produced through mixings with mesons due to the coupling with gluons, and exclude f_{A^0} around tens of TeV for m_{A^0} = 0.2–0.9 GeV. They assume a slightly suppressed axion coupling to muons. See their Fig. 4 for the limits.

[14] BERTUZZO 23 employs an analysis analogous to ACCIARRI 23. They search for leptophilic axions primarily produced via $\tau \to \mu A^0$ and $\tau \to e A^0$, and exclude f_{A^0} around 1×10^6–6×10^7 GeV for m_{A^0} = 0.2–1.7 GeV. See their Fig. 2 for the limits.

[15] AAD 22J set upper limits for the cross sections of $H \to A^0A^0 \to 4\mu$ and $H \to ZA^0 \to 2\ell 2\mu$. See their Figs. 14 and 17 for the respective mass-dependent limits.

[16] TUMASYAN 22AH set the limits of $O(10^{-6})$ with respect to the product of the branching fractions of $H \to A^0A^0$ and $A^0 \to e^+e^-$, $\mu^+\mu^-$. They also derive limits on the effective axion couplings contributing to $H \to A^0A^0$ and $H \to ZA^0$. See their Figs. 5 and 7 for the limits.

[17] TUMASYAN 22R is analogous to GAVELA 20, and set a limit on the products of the axion couplings to gluons and Z bosons as $G_{AZZ}\, G_{Agg} < 6.64 \times 10^{-7}$ GeV^{-2} at 95% CL for f_{A^0} = 3 TeV and $m_{A^0} < 100$ GeV. Here we use $c_{\widetilde{G}} = G_{Agg}\, f_{A^0}/4$ and $c_{\widetilde{Z}} = G_{AZZ}\, f_{A^0}/4$ to translate their limits. They also set a limit on the product of the axion couplings to gluons and ZH. See their Fig. 9 for the f_{A^0}-dependent limits.

[18] AAD 21F look for axion production with an energetic jet and large missing p_T, and set a limit on the axion coupling to gluons, $c_{\widetilde{G}}/f_{A^0} < 8 \times 10^{-6}$ GeV^{-1} at 95 % CL for m_{A^0} = 1 MeV. Using $c_{\widetilde{G}} = \alpha_s/8\pi$, we interpret the limit as $f_{A^0} > 0.4$ TeV for $\alpha_s \simeq 0.08$.

[19] AAD 21K look for axion production with an energetic photon and large missing p_T, and set a limit on the axion coupling to a Z boson and photon, $G_{AZ\gamma} < 5.1 \times 10^{-4}$ GeV^{-1} at 95 % CL for m_{A^0} = 1 MeV and assuming $G_{A\gamma\gamma} = 0$.

[20] AAD 21N look for axion production using the measurement of light-by-light scattering based on Pb+Pb collision data. They set the limit on the axion-photon coupling, $G_{A\gamma\gamma} < 5.3 \times 10^{-5}$–$3.4 \times 10^{-4}$ GeV^{-1} at 95 % CL for m_{A^0} = 6–100 GeV. Here we use $\Lambda_a = {G_{A\gamma\gamma}}^{-1}$ to translate their limits. See their Fig. 9 for mass-dependent limits.

[21] CARRA 21 is analogous to GAVELA 20, and they use the differential cross sections for WW and $Z\gamma$ production measured with the ATLAS detector to set limits on the product of the axion couplings to gauge bosons as $G_{AWW}\, G_{Agg} < 6.2 \times 10^{-7}$ GeV^{-2} and $G_{AZ\gamma}\, G_{Agg} < 3.7 \times 10^{-7}$ GeV^{-2} at 95 % CL for $m_{A^0} \lesssim 100$ GeV.

[22] AAIJ 20AL look for a light new boson decaying into a pair of muons using the LHCb data with an integrated luminosity of 5.1 fb^{-1}, and set limits on the cross section over a range of m_{X^0} = 0.22–3 and 20–60 GeV. See Figs. 8 and 9 for mass-dependent limits.

[23] GAVELA 20 focus on the axion production as an s-channel off shell mediator, and use the Run 2 CMS public data to set limits on the product of the axion couplings to gluons and photons as well as Z bosons as $G_{A\gamma\gamma}\, G_{Agg} < 2.8 \times 10^{-7}$ GeV^{-2} and $G_{AZZ}\, G_{Agg} < 9.8 \times 10^{-7}$ GeV^{-2} for $m_{A^0} \lesssim 200$ GeV. See their Fig.3 for the limits.

[24] SIRUNYAN 19BQ look for the pair production of a new light boson decaying into a pair of muons, and set limits on the product of the production cross section times branching fraction to dimuons squared times acceptance over a range of m_{X^0} = 0.25–8.5 GeV. See the right panel of their Fig. 1 for mass-dependent limits.

[25] JAIN 07 claims evidence for $A^0 \to e^+e^-$ produced in ^{207}Pb collision on nuclear emulsion (Ag/Br) for $m(A^0) = 7 \pm 1$ or 19 ± 1 MeV and $\tau(A^0) \leq 10^{-13}$ s.

[26] AHMAD 97 reports a result of APEX Collaboration which studied positron production in ^{238}U+^{232}Ta and ^{238}U+^{181}Ta collisions, without requiring a coincident electron. No narrow lines were found for $250 < E_{e^+} < 750$ keV.

[27] LEINBERGER 97 (ORANGE Collaboration) at GSI looked for a narrow sum-energy e^+e^--line at $\sim$ 635 keV in ^{238}U+^{181}Ta collision. Limits on the production probability for a narrow sum-energy e^+e^- line are set. See their Table 2.

[28] GANZ 96 (EPOS II Collaboration) has placed upper bounds on the production cross section of e^+e^- pairs from ^{238}U+^{181}Ta and ^{238}U+^{232}Th collisions at GSI. See Table 2 for limits both for back-to-back and isotropic configurations of e^+e^- pairs. These limits rule out the existence of peaks in the e^+e^- sum-energy distribution, reported by an earlier version of this experiment.

[29] KAMEL 96 looked for e^+e^- pairs from the collision of ^{32}S (200 GeV/nucleon) and emulsion. No evidence of mass peaks is found in the region of sensitivity $m_{ee} > 2$ MeV.

[30] BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of e^+e^- or $\mu^+\mu^-$ from the produce A^0. See Fig. 5 for the excluded region in m_{A^0}-x plane. For the standard axion, $0.3 < x < 25$ is excluded at 95% CL. If combined with BLUEMLEIN 91, $0.008 < x < 32$ is excluded.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[31] MEIJERDREES 92 give $\Gamma(\pi^- p \to n A^0)\cdot B(A^0 \to e^+ e^-)/\Gamma(\pi^- p \to \text{all}) < 10^{-5}$ (90% CL) for $m_{A^0} = 100$ MeV, $\tau_{A^0} = 10^{-11}$–10^{-23} sec. Limits ranging from 2.5×10^{-3} to 10^{-7} are given for $m_{A^0} = 25$–136 MeV.

[32] BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for $A^0 \to e^+ e^-$, 2γ are found. Fig. 6 gives the excluded region in m_{A^0}-x plane ($x = \tan\beta = v_2/v_1$). Standard axion is excluded for $0.2 < m_{A^0} < 3.2$ MeV for most $x > 1$, 0.2–11 MeV for most $x < 1$.

[33] FAISSNER 89 searched for $A^0 \to e^+ e^-$ in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass $2m_e$–20 MeV is excluded. Lower limit on f_{A^0} of $\simeq 10^4$ GeV is given for $m_{A^0} = 2m_e$–20 MeV.

[34] DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass ~ 1.1, ~ 2.1, and ~ 9 MeV, lifetimes 10^{-16}–10^{-15} s decaying to $e^+ e^-$ and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A **A22** 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with π^0 Dalitz decay. DEBOER 89B is a reply which contests the criticism.

[35] EL-NADI 88 claim the existence of a neutral particle decaying into $e^+ e^-$ with mass 1.60 ± 0.59 MeV, lifetime $(0.15 \pm 0.01) \times 10^{-14}$ s, which is produced in heavy ion interactions with emulsion nuclei at ~ 4 GeV/c/nucleon.

[36] FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for $A^0 \to \gamma\gamma$. A standard axion decaying to 2γ is excluded except for a region $x \simeq 1$. Lower limit on f_{A^0} of 10^2–10^3 GeV is given for $m_{A^0} = 0.1$–1 MeV.

[37] BADIER 86 did not find long-lived A^0 in 300 GeV π^- Beam Dump Experiment that decays into $e^+ e^-$ in the mass range $m_{A^0} = (20$–$200)$ MeV, which excludes the A^0 decay constant $f(A^0)$ in the interval (60–600) GeV. See their figure 6 for excluded region on $f(A^0)$-m_{A^0} plane.

[38] BERGSMA 85 look for $A^0 \to 2\gamma$, $e^+ e^-$, $\mu^+ \mu^-$. First limit above is for $m_{A^0} = 1$ MeV; second is for 200 MeV. See their figure 4 for excluded region on f_{A^0}–m_{A^0} plane, where f_{A^0} is A^0 decay constant. For Peccei-Quinn PECCEI 77 A^0, $m_{A^0} < 180$ keV and $\tau > 0.037$ s. (CL = 90%). For the axion of FAISSNER 81B at 250 keV, BERGSMA 85 expect 15 events but observe zero.

[39] FAISSNER 83 observed 19 1-γ and 12 2-γ events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.

[40] FAISSNER 83B extrapolate SIN γ signal to LAMPF ν experimental condition. Resulting 370 γ's are not at variance with LAMPF upper limit of 450 γ's. Derived from LAMPF limit that $[d\sigma(A^0)/d\omega$ at $90^\circ] m_{A^0}/\tau_{A^0} < 14 \times 10^{-35}$ cm^2 sr^{-1} MeV ms^{-1}. See comment on FRANK 83B.

[41] FRANK 83B stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-A0 are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450 γ's. See comment on FAISSNER 83B.

[42] HOFFMAN 83 set CL = 90% limit $d\sigma/dt\, B(e^+ e^-) < 3.5 \times 10^{-32}$ cm^2/GeV^2 for $140 < m_{A^0} < 160$ MeV. Limit assumes $\tau(A^0) < 10^{-9}$ s.

[43] FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since 2-γ peak rate remarkably decreases if iron wall is set in front of the decay region.

[44] FAISSNER 81 see excess μe events. Suggest axion interactions.

[45] FAISSNER 81B is SIN 590 MeV proton beam dump. Observed 14.5 ± 5.0 events of 2γ decay of long-lived neutral penetrating particle with $m_{2\gamma} \lesssim 1$ MeV. Axion interpretation with η-A^0 mixing gives $m_{A^0} = 250 \pm 25$ keV, $\tau_{(2\gamma)} = (7.3 \pm 3.7) \times 10^{-3}$ s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83B, FRANK 83B, and BERGSMA 85. Also see in the next subsection ALEKSEEV 82B, CAVAIGNAC 83, and ANANEV 85.

[46] KIM 81 analyzed 8 candidates for $A^0 \to 2\gamma$ obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is $(0.86 \sim 5.6) \times 10^{-3}$ s depending on models. Faissner (private communication), says axion production underestimated and mass overestimated. Correct value around 200 keV.

[47] FAISSNER 80 is SIN beam dump experiment with 590 MeV protons looking for $A^0 \to e^+ e^-$ decay. Assuming $A^0/\pi^0 = 5.5 \times 10^{-7}$, obtained decay rate limit $20/(A^0$ mass) MeV/s (CL = 90%), which is about 10^{-7} below theory and interpreted as upper limit to $m_{A^0} < 2m_{e^-}$.

[48] JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events $[\sigma(\text{production})\sigma(\text{interaction}) < 7. \times 10^{-68}$ cm^4, CL = 90%]. Second limit is from nonobservation of axion decays into 2γ's or $e^+ e^-$, and for axion mass a few MeV.

[49] SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.

[50] BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either 2γ or $e^+ e^-$. No signal found. CL = 90% limits for model parameter(s) are given.

[51] COTEUS 79 is a beam dump experiment at BNL.

[52] DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distributions due to energy lost to weakly interacting particles.

[53] BELLOTTI 78 first value comes from search for $A^0 \to e^+ e^-$. Second value comes from search for $A^0 \to 2\gamma$, assuming mass $< 2m_{e^-}$. For any mass satisfying this, limit is above value$\times$(mass^{-4}). Third value uses data of PL 60B 401 and quotes $\sigma(\text{production})\sigma(\text{interaction}) < 10^{-67}$ cm^4.

[54] BOSETTI 78B quotes $\sigma(\text{production})\sigma(\text{interaction}) < 2. \times 10^{-67}$ cm^4.

[55] DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.

[56] MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).

[57] VYSOTSKII 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

A^0 (Axion) Searches in Reactor Experiments

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[1] CHANG	07		Primakoff or Compton
	[2] ALTMANN	95	CNTR	Reactor; $A^0 \to e^+ e^-$
	[3] KETOV	86	SPEC	Reactor, $A^0 \to \gamma\gamma$
	[4] KOCH	86	SPEC	Reactor; $A^0 \to \gamma\gamma$
	[5] DATAR	82	CNTR	Light water reactor
	[6] VUILLEUMIER	81	CNTR	Reactor, $A^0 \to 2\gamma$

[1] CHANG 07 looked for monochromatic photons from Primakoff or Compton conversion of axions from the Kuo-Sheng reactor due to axion coupling to photon or electron, respectively. The search places model-independent limits on the products $G_{A\gamma\gamma} G_{ANN}$ and $G_{Aee} G_{ANN}$ for $m(A^0)$ less than the MeV range.

[2] ALTMANN 95 looked for A^0 decaying into $e^+ e^-$ from the Bugey 5 nuclear reactor. They obtain an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma) \times B(A^0 \to e^+ e^-) < 10^{-16}$ for $m_{A^0} = 1.5$ MeV at 90% CL. The limit is weaker for heavier A^0. In the case of a standard axion, this limit excludes a mass in the range $2m_e < m_{A^0} < 4.8$ MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances Z^0 in the (m_{X^0}, f_{X^0}) plane.

[3] KETOV 86 searched for A^0 at the Rovno nuclear power plant. They found an upper limit on the A^0 production probability of 0.8 $[100$ keV$/m_{A^0}]^6 \times 10^{-6}$ per fission. In the standard axion model, this corresponds to $m_{A^0} > 150$ keV. Not valid for $m_{A^0} \gtrsim 1$ MeV.

[4] KOCH 86 searched for $A^0 \to \gamma\gamma$ at nuclear power reactor Biblis A. They found an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$ (CL=95%). Standard axion with $m_{A^0} = 250$ keV gives 10^{-5} for the ratio. Not valid for $m_{A^0} > 1022$ keV.

[5] DATAR 82 looked for $A^0 \to 2\gamma$ in neutron capture ($np \to d A^0$) at Tarapur 500 MW reactor. Sensitive to sum of $l = 0$ and $l = 1$ amplitudes. With ZEHNDER 81 $[(l = 0) - (l = 1)]$ result, assert nonexistence of standard A^0.

[6] VUILLEUMIER 81 is at Grenoble reactor. Set limit $m_{A^0} < 280$ keV.

A^0 (Axion) and Other Light Boson (X^0) Searches in Nuclear Transitions

Limits are for branching ratio.

[1] DERBIN 23 use a thallium garnet bolometric detector to search for the 8.4 keV solar axion line emitted from the M1 nuclear transition of ^{169}Tm. Their limits are equivalent to an upper bound on the KSVZ and DFSZ axion masses of 141 eV and 244 eV, respectively.

[2] DERBIN 02 looked for the axion emission in an M1 transition in ^{125m}Te decay. They looked for a possible presence of a shifted energy spectrum in gamma rays due to the undetected axion.

[3] DEBOER 97C reanalyzed the existent data on Nuclear M1 transitions and find that a 9 MeV boson decaying into $e^+ e^-$ would explain the excess of events with large opening angles. See also DEBOER 01 for follow-up experiments.

[4] TSUNODA 95 looked for axion emission when ^{252}Cf undergoes a spontaneous fission, with the axion decaying into $e^+ e^-$. The bound is for m_{A^0}=40 MeV. It improves to 2.5×10^{-5} for m_{A^0}=200 MeV.

[5] MINOWA 93 studied chain process, ^{139}Ce $\to {}^{139}$La* by electron capture and M1 transition of ^{139}La* to the ground state. It does not assume decay modes of A^0. The bound applies for $m_{A^0} < 166$ keV.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

[6] HICKS 92 bound is applicable for $\tau_{X^0} < 4 \times 10^{-11}$ sec.

[7] The ASANUMA 90 limit is for the branching fraction of X^0 emission per ^{241}Am α decay and valid for $\tau_{X^0} < 3 \times 10^{-11}$ s.

[8] The DEBOER 90 limit is for the branching ratio ^{8}Be* (18.15 MeV, 1^+) $\rightarrow$ ^{8}BeA^0, $A^0 \rightarrow e^+e^-$ for the mass range m_{A^0} = 4–15 MeV.

[9] The BINI 89 limit is for the branching fraction of ^{16}O*(6.05 MeV, 0^+) $\rightarrow$ ^{16}OX^0, $X^0 \rightarrow e^+e^-$ for m_X = 1.5–3.1 MeV. $\tau_{X^0} \lesssim 10^{-11}$ s is assumed. The spin-parity of X is restricted to 0^+ or 1^-.

[10] AVIGNONE 88 looked for the 1115 keV transition C* $\rightarrow$ CuA^0, either from $A^0 \rightarrow 2\gamma$ in-flight decay or from the secondary A^0 interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for $m_{A^0} < 1.1$ MeV.

[11] DATAR 88 rule out light pseudoscalar particle emission through its decay $A^0 \rightarrow e^+e^-$ in the mass range 1.02–2.5 MeV and lifetime range 10^{-13}–10^{-8} s. The above limit is for $\tau = 5 \times 10^{-13}$ s and $m = 1.7$ MeV; see the paper for the τ-m dependence of the limit.

[12] The limit is for the branching fraction of ^{16}O*(6.05 MeV, 0^+) $\rightarrow$ ^{16}OX^0, $X^0 \rightarrow e^+e^-$ against internal pair conversion for m_{X^0} = 1.7 MeV and $\tau_{X^0} < 10^{-11}$ s. Similar limits are obtained for m_{X^0} = 1.3–3.2 MeV. The spin parity of X^0 must be either 0^+ or 1^-. The limit at 1.7 MeV is translated into a limit for the X^0-nucleon coupling constant: $g^2_{X^0\,NN}/4\pi < 2.3 \times 10^{-9}$.

[13] The DOEHNER 88 limit is for m_{A^0} = 1.7 MeV, $\tau(A^0) < 10^{-10}$ s. Limits less than 10^{-4} are obtained for m_{A^0} = 1.2–2.2 MeV.

[14] SAVAGE 88 looked for A^0 that decays into e^+e^- in the decay of the 9.17 MeV $J^P = 2^+$ state in ^{14}N, 17.64 MeV state $J^P = 1^+$ in ^{8}Be, and the 18.15 MeV state $J^P = 1^+$ in ^{8}Be. This experiment constrains the isovector coupling of A^0 to hadrons, if m_{A^0} = (1.1 $\rightarrow$ 2.2) MeV and the isoscalar coupling of A^0 to hadrons, if m_{A^0} = (1.1 $\rightarrow$ 2.6) MeV. Both limits are valid only if $\tau(A^0) \lesssim 1 \times 10^{-11}$ s.

[15] Limits are for $\Gamma(A^0(1.8\text{ MeV}))/\Gamma(\pi\text{M1})$; i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of e^+e^- pairs. Valid for $\tau_{A^0} < 2 \times 10^{-11}$s. ^{6}Li isovector decay data strongly disfavor PECCEI 86 model I, whereas the ^{10}B and ^{14}N isoscalar decay data strongly reject PECCEI 86 model II and III.

[16] SAVAGE 86B looked for A^0 that decays into e^+e^- in the decay of the 9.17 MeV $J^P = 2^+$ state in ^{14}N. Limit on the branching fraction is valid if $\tau_{A^0} \lesssim 1. \times 10^{-11}$s for m_{A^0} = (1.1–1.7) MeV. This experiment constrains the iso-vector coupling of A^0 to hadrons.

[17] ANANEV 85 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% masses below 470 keV (Li* decay) and below $2m_e$ for deuteron* decay.

[18] CAVAIGNAC 83 at Bugey reactor exclude axion at any $m_{^{97}\text{Nb*decay}}$ and axion with m_{A^0} between 275 and 288 keV (deuteron* decay).

[19] ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% mass-ranges m_{A^0} <400 keV (Li* decay) and 330 keV <m_{A^0} <2.2 MeV. (deuteron* decay).

[20] LEHMANN 82 obtained $A^0 \rightarrow 2\gamma$ rate $< 6.2 \times 10^{-5}$/s (CL = 95%) excluding m_{A^0} between 100 and 1000 keV.

[21] ZEHNDER 82 used Gosgen 2.8GW light-water reactor to check A^0 production. No 2γ peak in Li*, Nb* decay (both single p transition) nor in n capture (combined with previous Ba* negative result) rules out standard A^0. Set limit m_{A^0} <60 keV for any A^0.

[22] ZEHNDER 81 looked for Ba* $\rightarrow$ A^0Ba transition with $A^0 \rightarrow 2\gamma$. Obtained 2γ coincidence rate $< 2.2 \times 10^{-5}$/s (CL = 95%) excluding m_{A^0} >160 keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.

[23] CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

A^0 (Axion) Limits from Its Electron Coupling

Limits are for $\tau(A^0 \rightarrow e^+e^-)$.

[1] ANDREEV 21 look for invisible decays of axions coupled to electrons, and set limits on $g_{Aee} < 4.6 \times 10^{-6}$–$3.1 \times 10^{-3}$ for $m_{A^0} = 10^{-3}$–1 GeV. This limits the axion contribution to the electron $g-2$ to an order of magnitude less than the current experimental uncertainty. See their Figs. 3 and 4 for mass-dependent limits.

[2] ANDREEV 21B set limits on g_{Aee} in the range of 6.3×10^{-6}–1.6×10^{-3} for m_{A^0} = 2–17 MeV at 90% CL. This excludes $6.6 \times 10^{-5} < g_{Aee} < 1 \times 10^{-4}$ at m_{A^0} = 16.7 MeV corresponding to the ATOMKI anomaly. See their Fig. 2 for mass-dependent limits.

[3] The listed BROSS 91 limit is for m_{A^0} = 1.14 MeV. B($A^0 \rightarrow e^+e^-$) = 1 assumed. Excluded domain in the τ_{A^0}–m_{A^0} plane extends up to $m_{A^0} \approx 7$ MeV (see Fig. 5). Combining with electron $g-2$ constraint, axions coupling only to e^+e^- ruled out for $m_{A^0} < 4.8$ MeV (90% CL).

[4] GUO 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with $g-2$ constraint, axions coupling only to e^+e^- are ruled out for $m_{A^0} < 2.7$ MeV (90% CL).

[5] BJORKEN 88 reports limits on axion parameters (f_A, m_A, τ_A) for $m_{A^0} < 200$ MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic electrons.

[6] BLINOV 88 assume zero spin, m = 1.8 MeV and lifetime $< 5 \times 10^{-12}$ s and find $\Gamma(A^0 \rightarrow \gamma\gamma)$B($A^0 \rightarrow e^+e^-$) < 2 eV (CL=90%).

[7] Assumes $A^0\gamma\gamma$ coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for $m_{A^0} < 15$ MeV.

[8] Uses electrons in hadronic showers from an incident 800 GeV proton beam. Limits for $m_{A^0} < 15$ MeV are shown in their figure 3.

[9] $m_{A^0} = 1.8$ MeV assumed. The excluded domain in the τ_{A^0}–m_{A^0} plane extends up to $m_{A^0} \approx 14$ MeV, see their figure 4.

[10] The limits are obtained from their figure 3. Also given is the limit on the $A^0\gamma\gamma$–$A^0e^+e^-$ coupling plane by assuming Primakoff production.

Search for A^0 (Axion) Resonance in Bhabha Scattering

The limit is for $\Gamma(A^0)$[B($A^0 \rightarrow e^+e^-$)]^2.

		[10] VONWIMMER..	87	CNTR	

[1] HALLIN 92 quote limits on lifetime, 8×10^{-14} – 5×10^{-13} sec depending on mass, assuming B($A^0 \rightarrow e^+e^-$) = 100%. They say that TSERTOS 91 overstated their sensitivity by a factor of 3.

[2] HENDERSON 92C exclude axion with lifetime τ_{A^0}=1.4×10^{-12} – 4.0×10^{-10} s, assuming B($A^0 \rightarrow e^+e^-$)=100%. HENDERSON 92C also exclude a vector boson with τ=1.4×10^{-12} – 6.0×10^{-10} s.

[3] WU 92 quote limits on lifetime > 3.3×10^{-13} s assuming B($A^0 \rightarrow e^+e^-$)=100%. They say that TSERTOS 89 overestimate the limit by a factor of $\pi/2$. WU 92 also quote a bound for vector boson, $\tau > 8.2 \times 10^{-13}$ s.

[4] WIDMANN 91 bound applies exclusively to the case B($A^0 \rightarrow e^+e^-$)=1, since the detection efficiency varies substantially as $\Gamma(A^0)_{\text{total}}$ changes. See their Fig. 6.

[5] JUDGE 90 excludes an elastic pseudoscalar e^+e^- resonance for 4.5×10^{-13} s < $\tau(A^0)$ < 7.5×10^{-12} s (95% CL) at m_{A^0} = 1.832 MeV. Comparable limits can be set for m_{A^0} = 1.776–1.856 MeV.

[6] See also TSERTOS 88B in references.

[7] The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88B, footnote 3.

[8] VANKLINKEN 88 looked for relatively long-lived resonance ($\tau = 10^{-10}$–10^{-12} s). The sensitivity is not sufficient to exclude such a narrow resonance.

[9] MAIER 87 obtained limits $R\Gamma \lesssim 60$ eV (100 eV) at $m_{A^0} \simeq 1.64$ MeV (1.83 MeV) for energy resolution $\Delta E_{\text{cm}} \simeq 3$ keV, where R is the resonance cross section normalized to that of Bhabha scattering, and $\Gamma = \Gamma^2_{ee}/\Gamma_{\text{total}}$. For a discussion implying that $\Delta E_{\text{cm}} \simeq 10$ keV, see TSERTOS 89.

[10] VONWIMMERSPERG 87 measured Bhabha scattering for E_{cm} = 1.37–1.86 MeV and found a possible peak at 1.73 with $\int \sigma dE_{\text{cm}} = 14.5 \pm 6.8$ keV·b. For a comment and a reply, see VANKLINKEN 88B and VONWIMMERSPERG 88. Also see CONNELL 88.

[1] IVANEZ-BALLESTEROS 25 set new bounds on majorons coupled to neutrinos using the 24 neutrino events from SN 1987A, based on a three-neutrino likelihood analysis including nonradiative neutrino decay in matter and the resulting distortion of the neutrino energy spectrum. See their Figs. 1–3 for bounds on the majoron-neutrino coupling as a function of the lightest neutrino mass.
[2] UNO 25 search for the production of a 0–1.6 GeV mass spin-0 particle in lepton-flavour violating tau decays at Belle II. See Fig. 4 for mass-dependent limits on the branching ratio of tau decays to X^0 and electrons or muons.
[3] ADACHI 23A set limits in the range of 1.1×10^{-3}–9.7×10^{-3} for $0 < m_{X^0} < 1.6$ GeV on B($\tau^- \to e^- X^0$)/B($\tau^- \to e^-\overline{\nu}_e\nu_\tau$). See their Fig. 2 for mass-dependent limits.
[4] ADACHI 23A set limits in the range of 7×10^{-4}–1.22×10^{-2} for $0 < m_{X^0} < 1.6$ GeV on B($\tau^- \to \mu^- X^0$)/B($\tau^- \to \mu^-\overline{\nu}_\mu\nu_\tau$). See their Fig. 2 for mass-dependent limits.
[5] FIORILLO 23 used data from Kamiokande-II and IMB on the neutrino flux from SN1987A to constrain the universal neutrino Majoron Yukawa coupling, g. They set an upper limit of $g\, m_{X^0} \lesssim 10^{-9}$ MeV for Majoron masses 100 eV $\lesssim m_{X^0} \lesssim$ 100 MeV, using neutrino coalescence as production of Majorons which then decay back to neutrinos. See their Fig. 1 for the mass-dependent limits.
[6] SANDNER 23 study Majoron production via neutrino inverse decay and use Planck data to constrain the neutrino Majoron Yukawa coupling to $g \lesssim 2\times10^{-13}$–$1\times10^{-12}$ for Majoron masses m_{X^0} = 1–10 eV. See their Fig. 1 for mass-dependent limits.
[7] COLOMA 22A used the spectral data of Borexino Phase II to constrain the neutrino non-standard interaction with electrons mediated by a scalar or a pseudoscalar. Limits on the universal coupling to neutrinos and electrons between 2×10^{-6} and 10^{-4} are obtained for $m_{X^0} \lesssim$ 30–40 MeV. See their Fig. 6 for mass-dependent limits.
[8] AGUILAR-AREVALO 21A quoted limit applies to m_{X^0} = 33.9 MeV. Limits between 4.3×10^{-6} and 7.5×10^{-5} are obtained for $0 < m_{X^0} <$ 33.9 MeV. The lifetime of X^0 is assumed to be long enough. See their Fig. 6 for mass-dependent limits.
[9] AGUILAR-AREVALO 21A quoted limit applies to m_{X^0} = 85 MeV. Limits between 5.2×10^{-8} and 1.4×10^{-6} are obtained for $0 < m_{X^0} <$ 120 MeV, which improve the limits of PICCIOTTO 88 by an order of magnitude. The lifetime of X^0 is assumed to be long enough. See their Fig. 4 for mass-dependent limits.
[10] AGUILAR-AREVALO 20 obtained limits of order 10^{-5} for m_{X^0} = 47.8–95.1 MeV. The quoted limit applies to m_{X^0} = 75 MeV. See their Fig. 1 for mass-dependent limits.
[11] BALDINI 20 obtained limits for m_{X^0} = 20–45 MeV and $\tau_{X^0} < 40$ ps, and supersedes BOLTON 88 for m_{X^0} = 20–40 MeV. See their Fig. 17 for mass-dependent limits.
[12] BAYES 15 limits are the average over m_{X^0} = 13–80 MeV for the isotropic decay distribution of positrons. See their Fig. 4 and Table II for the mass-dependent limits as well as the dependence on the decay anisotropy. In particular, they find a limit $< 58\times10^{-6}$ at 90% CL for massless familons and for the same asymmetry as normal muon decay, a case not covered by JODIDIO 86.
[13] LATTANZI 13 use WMAP 9 year data as well as X-ray and γ-ray observations to derive limits on decaying majoron dark matter. A limit on the decay width $\Gamma(X^0 \to \nu\overline{\nu}) < 6.4\times10^{-19}$ s^{-1} at 95% CL is found if majorons make up all of the dark matter.
[14] LESSA 07 consider decays of the form Meson $\to \ell\nu$Majoron and $\ell \to \ell'\nu\overline{\nu}$Majoron and use existing data to derive limits on the neutrino-Majoron Yukawa couplings $g_{\alpha\beta}$ (α,β=e,μ,τ). Their best limits are $|g_{e\alpha}|^2 < 5.5\times10^{-6}$, $|g_{\mu\alpha}|^2 < 4.5\times10^{-5}$, $|g_{\tau\alpha}|^2 < 5.5\times10^{-2}$ at CL = 90%.
[15] FARZAN 03 set limits on the neutrino Majoron Yukawa coupling, $|g_{ee}| < 4\times10^{-7}$, by considering the SN cooling due to the massless Majoron emission via neutrino coalescence. They also exclude values around 10^{-5} for both $g_{e\mu}$ and $g_{\mu\mu}$ using the process $\nu\nu \to X^0X^0$. See also their Figs. 3 and 4 for mass-dependent limits.
[16] DIAZ 98 studied models of spontaneously broken lepton number with both singlet and triplet Higgses. They obtain limits on the parameter space from invisible decay $Z \to H^0A^0 \to X^0X^0X^0X^0X^0$ and $e^+e^- \to ZH^0$ with $H^0 \to X^0X^0$.
[17] BOBRAKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (arion). A limit $x_e^2 < 2\times10^{-4}$ (95%CL) is found for the effective anomalous magneton parametrized as $x_e(G_F/8\pi\sqrt{2})^{1/2}$.
[18] ALBRECHT 90E limits are for B($\tau \to \ell X^0$)/B($\tau \to \ell\nu\overline{\nu}$). Valid for $m_{X^0} <$ 100 MeV. The limits rise to 7.1% (for μ), 5.0% (for e) for m_{X^0} = 500 MeV.
[19] ATIYA 90 limit is for m_{X^0} = 0. The limit B $< 1\times10^{-8}$ holds for $m_{X^0} <$ 95 MeV. For the reduction of the limit due to finite lifetime of X^0, see their Fig. 3.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

[20] BALKE 88 limits are for B($\mu^+ \to e^+ X^0$). Valid for $m_{X^0} < 80$ MeV and $\tau_{X^0} > 10^{-8}$ sec.

[21] BOLTON 88 limit corresponds to $F > 3.1 \times 10^9$ GeV, which does not depend on the chirality property of the coupling.

[22] CHANDA 88 find $v_T < 10$ MeV for the weak-triplet Higgs vacuum expectation value in Gelmini-Roncadelli model, and $v_S > 5.8 \times 10^6$ GeV in the singlet Majoron model.

[23] CHOI 88 used the observed neutrino flux from the supernova SN1987A to exclude the neutrino Majoron Yukawa coupling h in the range $2 \times 10^{-5} < h < 3 \times 10^{-4}$ for the interaction $L_{\rm int} = \frac{1}{2} i h \overline{\psi_\nu^c} \gamma_5 \psi_\nu \phi_X$. For several families of neutrinos, the limit applies for $(\Sigma h_i^4)^{1/4}$.

[24] PICCIOTTO 88 limit applies when $m_{X^0} < 55$ MeV and $\tau_{X^0} > 2$ns, and it decreases to 4×10^{-7} at $m_{X^0} = 125$ MeV, beyond which no limit is obtained.

[25] GOLDMAN 87 limit corresponds to $F > 2.9 \times 10^9$ GeV for the family symmetry breaking scale from the Lagrangian $L_{\rm int} = (1/F) \overline{\psi}_\mu \gamma^\mu (a + b\gamma_5)\, \psi_e \partial_\mu \phi_{X^0}$ with $a^2 + b^2 = 1$. This is not as sensitive as the limit $F > 9.9 \times 10^9$ GeV derived from the search for $\mu^+ \to e^+ X^0$ by JODIDIO 86, but does not depend on the chirality property of the coupling.

[26] Limits are for $\Gamma(\mu \to e X^0)/\Gamma(\mu \to e \nu \overline{\nu})$. Valid when $m_{X^0} =$ 0–93.4, 98.1–103.5 MeV.

[27] EICHLER 86 looked for $\mu^+ \to e^+ X^0$ followed by $X^0 \to e^+ e^-$. Limits on the branching fraction depend on the mass and and lifetime of X^0. The quoted limits are valid when $\tau_{X^0} \lesssim 3. \times 10^{-10}$ s if the decays are kinematically allowed.

[28] JODIDIO 86 corresponds to $F > 9.9 \times 10^9$ GeV for the family symmetry breaking scale with the parity-conserving effective Lagrangian $L_{\rm int} = (1/F)\, \overline{\psi}_\mu \gamma^\mu \psi_e \partial^\mu \phi_{X^0}$.

[29] BALTRUSAITIS 85 search for light Goldstone boson(X^0) of broken U(1). CL = 95% limits are B($\tau \to \mu^+ X^0$)/B($\tau \to \mu^+ \nu\nu$) <0.125 and B($\tau \to e^+ X^0$)/B($\tau \to e^+ \nu\nu$) <0.04. Inferred limit for the symmetry breaking scale is $m >$3000 TeV.

[30] The primordial heavy neutrino must decay into ν and familon, f_A, early so that the red-shifted decay products are below critical density, see their table. In addition, $K \to \pi f_A$ and $\mu \to e f_A$ are unseen. Combining these excludes $m_{{\rm heavy}\nu}$ between 5×10^{-5} and 5×10^{-4} MeV (μ decay) and $m_{{\rm heavy}\nu}$ between 5×10^{-5} and 0.1 MeV (K-decay).

Majoron Searches in Neutrinoless Double β Decay

Limits are for the half-life of neutrinoless $\beta\beta$ decay with a Majoron emission. No experiment currently claims any such evidence. Only the best or comparable limits for each isotope are reported.

[1] BERNATOWICZ 92 studied double-β decays of ^{128}Te and ^{130}Te, and found the ratio $\tau(^{130}\text{Te})/\tau(^{128}\text{Te}) = (3.52 \pm 0.11) \times 10^{-4}$ in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of ^{128}Te of $(7.7 \pm 0.4) \times 10^{24}$ year. We calculated 90% CL limit as $(7.7–1.28 \times 0.4{=}7.2) \times 10^{24}$.

[2] AUGIER 24 make use of 1.47 kg·yr of ^{100}Mo exposure of the CUPID-Mo scintillating cryogenic calorimeter, operated at the Laboratoire Souterrain de Modane to place a range of limits on the single Majoron mode of the $0\nu\beta\beta$ decay of ^{100}Mo. The range is due to the use of two different analysis strategies. Various limits on modes involving the emission of multiple Majorons are given too. The derived range of constraints on the Majoron-neutrino coupling constant is $g_{\nu\chi} < 4.0–8.5 \times 10^{-5}$, reflecting the variability of the used nuclear matrix elements and of the two data analysis strategies.

[3] AZZOLINI 23 use 9.95 kg·yr of data, collected by the CUPID-0 experiment, to place a limit on the single Majoron mode of the $0\nu\beta\beta$ decay of ^{82}Se. Various limits on modes involving the emission of multiple Majorons are given too. The resulting constraint on the Majoron-neutrino coupling constant is $g_{\nu\chi} < 1.8–4.4 \times 10^{-5}$. The range is due to the variability of the used nuclear matrix elements.

[4] AGOSTINI 22 use 32.8 kg·yr of GERDA phase 2 data to derive a limit of $g_{\nu\chi} < 1.8–4.4 \times 10^{-5}$ on the neutrino-Majoron coupling. The range reflects the author's evaluation of the spread of nuclear matrix elements.

[5] AL-KHARUSI 21 utilize the complete dataset of the EXO-200 experiment, corresponding to an exposure of 234 kg yr, to place a limit on the one Majoron mode of the neutrinoless double beta decay of ^{136}Xe. Several limits are reported, the one given here corresponds to a spectral index of 1, resulting in a limit of $g_{\nu\chi} < 0.4–0.9 \times 10^{-5}$ on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.

[6] ARNOLD 19 uses the NEMO-3 tracking calorimeter to determine limits for the Majoron emitting double beta decay, with spectral index n = 3. The limit corresponds to the range of the g_{ee} coupling of 0.013–0.035; dependimg on the nuclear matrix elements used.

[7] ARNOLD 18 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{ee} \rangle < 3.2–8.0 \times 10^{-5}$; the range corresponds to different nuclear matrix element calculations.

[8] AGOSTINI 15A analyze a 20.3 kg yr of data set of the GERDA calorimeter to determine $g_{\nu\chi} < 3.4–8.7 \times 10^{-5}$ on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.

[9] ARNOLD 15 use the NEMO-3 tracking calorimeter with 3.43 kg yr exposure to determine the limit on Majoron emission. The limit corresponds to $g_{\nu\chi} < 1.6–3.0 \times 10^{-4}$. The spread reflects different nuclear matrix elements. Supersedes ARNOLD 06.

[10] ALBERT 14A utilize 100 kg yr of exposure of the EXO-200 tracking calorimeter to place a limit on the $g_{\nu\chi} < 0.8–1.7 \times 10^{-5}$ on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.

[11] GANDO 12 use the KamLAND-Zen detector to obtain the limit on the $0\nu\chi$ decay with Majoron emission. It implies that the coupling constant $g_{\nu\chi} < 0.8–1.6 \times 10^{-5}$ depending on the nuclear matrix elements used.

[12] ARNOLD 11 use the NEMO-3 detector to obtain the reported limit on Majoron emission. It implies that the coupling constant $g_{\nu\chi} < 0.6–1.6 \times 10^{-4}$ depending on the nuclear matrix element used. Supercedes ARNABOLDI 03.

[13] ARGYRIADES 10 use the NEMO-3 tracking detector and ^{96}Zr to derive the reported limit. No limit for the Majoron electron coupling is given.

[14] ARGYRIADES 09 use ^{150}Nd data taken with the NEMO-3 tracking detector. The reported limit corresponds to $\langle g_{\nu\chi} \rangle < 1.7–3.0 \times 10^{-4}$ using a range of nuclear matrix elements that include the effect of nuclear deformation.

[15] ARNOLD 06 use ^{100}Mo data taken with the NEMO-3 tracking detector. The reported limit corresponds to $\langle g_{\nu\chi} \rangle < (0.4–1.8) \times 10^{-4}$ using a range of matrix element calculations. Superseded by ARNOLD 15.

[16] NEMO-3 tracking calorimeter is used in ARNOLD 06 . Reported half-life limit for ^{82}Se corresponds to $\langle g_{\nu\chi} \rangle < (0.66–1.9) \times 10^{-4}$ using a range of matrix element calculations. Supersedes ARNOLD 04.

[17] ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{\nu\chi} \rangle < (0.5–0.9)10^{-4}$ using the matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03. Superseded by ARNOLD 06.

[18] ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{\nu\chi} \rangle < (0.7–1.6)10^{-4}$ using the matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03.

[19] Supersedes ALESSANDRELLO 00. Array of TeO_2 crystals in high resolution cryogenic calorimeter. Some enriched in ^{130}Te. Derive $\langle g_{\nu\chi} \rangle < 17–33 \times 10^{-5}$ depending on matrix element.

[20] Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search.

[21] Limit for the $0\nu\chi$ decay with Majoron emission of ^{116}Cd using enriched $CdWO_4$ scintillators. $\langle g_{\nu\chi} \rangle < 4.6–8.1 \times 10^{-5}$ depending on the matrix element. Supersedes DANEVICH 00.

[22] Limit for the $0\nu2\chi$ decay of ^{116}Cd. Supersedes DANEVICH 00.

[23] BERNABEI 02D obtain limit for $0\nu\chi$ decay with Majoron emission of ^{136}Xe using liquid Xe scintillation detector. They derive $\langle g_{\nu\chi} \rangle < 2.0–3.0 \times 10^{-5}$ with several nuclear matrix elements.

[24] Replaces TANAKA 93. FUSHIMI 02 derive half-life limit for the $0\nu\chi$ decay by means of tracking calorimeter ELEGANT V. Considering various matrix element calculations, a range of limits for the Majoron-neutrino coupling is given: $\langle g_{\nu\chi} \rangle < (6.3–360) \times 10^{-5}$.

[25] ASHITKOV 01 result for $0\nu\chi$ of ^{100}Mo is less stringent than ARNOLD 00.

[26] DANEVICH 01 obtain limit for the $0\nu\chi$ decay with Majoron emission of ^{160}Gd using Gd_2SiO_5:Ce crystal scintillators.

[27] DANEVICH 01 obtain limit for the $0\nu2\chi$ decay with 2 Majoron emission of ^{160}Gd.

[28] ARNOLD 00 reports limit for the $0\nu\chi$ decay with Majoron emission derived from tracking calorimeter NEMO 2. Using ^{82}Se source: $\langle g_{\nu\chi} \rangle < 1.6 \times 10^{-4}$. Matrix element from GUENTHER 96.

[29] Using ^{96}Zr source: $\langle g_{\nu\chi} \rangle < 2.6 \times 10^{-4}$. Matrix element from ARNOLD 99.

[30] ARNOLD 00 reports limit for the $0\nu2\chi$ decay with two Majoron emission derived from tracking calorimeter NEMO 2.

[31] ARNOLD 98 determine the limit for $0\nu_\chi$ decay with Majoron emission of ^{82}Se using the NEMO-2 tracking detector. They derive $\langle g_{\nu_\chi} \rangle < 2.3–4.3 \times 10^{-4}$ with several nuclear matrix elements.

[32] LUESCHER 98 report a limit for the 0ν decay with Majoron emission of ^{136}Xe using Xe TPC. This result is more stringent than BARABASH 89. Using the matrix elements of ENGEL 88, they obtain a limit on $\langle g_{\nu\chi} \rangle$ of 2.0×10^{-4}.

[1] ASWATHI 25 use LIGO-VIRGO-KAGRA data from the black hole binary merger events GW231123 and GW190517 to search for evidence of the superradiant build-up of a cloud of bosons, which could act to spin down the black holes. They rule out two windows of axion masses, and present limits in terms of the inverse energy scale for an attractive quartic scalar interaction in Fig. 2, e.g. the axion decay constant. The quoted limits are taken from Fig. 2 for the conservative spin-down timescale of 100,000 years.

[2] ZIMMERMANN 25 place a lower bound on the mass an ultralight boson assumed to be all of the dark matter, by ensuring it is possible to have a dynamically self-consistent dark matter halo density profile for the observed Leo II dwarf spheroidal galaxy.

[3] BIANCHINI 24 report a new limit on the axion mass, testing for the existence of a thermally produced hot dark matter population using current cosmic microwave background and baryon acoustic oscillation data. This analysis presents a stronger limit than previous bounds, e.g. NOTARI 23.

[4] CHENG 23 employ an improved approximation of the boson cloud eigenfrequency to calculate the superradiance rate. They find that sensitivity depends on initial spin distribution and the merger timescale, and identify two preferred ranges for boson mass centered at 1.78×10^{-12} and 7.94×10^{-13} eV.

[5] DELLA-MONICA 23 consider the solitonic core implied by ultralight scalar dark matter in the centre of the Milky Way and the effect its presence would have on the precisely tracked orbits of the stars orbiting our galaxy's central supermassive black hole, Sagittarius A*.

[6] DERBIN 23 employ a thulium garnet crystal bolometer to search for the 8.4 keV solar axion line emitted from the M1 nuclear transition of thulium-169, ^{169}Tm. Mass bound applies to KSVZ axions, value for DFSZ is 244 eV.

[7] NOTARI 23 improved the evaluation of axion production from pion scatterings by using pion-pion scattering data and incorporating the momentum dependence of the Boltzmann equation. The limit is based on the Planck 2018, BAO, and Pantheon SN Ia data.

[8] ROGERS 23 use the CMB and BOSS galaxy-clustering data to set limits on the abundance of ultralight axion DM. They obtained $\Omega_{A^0} < 0.002$ for $m_{A^0} = 10^{-30}$–10^{-28} eV and set upper limits ranging from 0.002 to 0.07 for $m_{A^0} = 10^{-32}$–10^{-25} eV. See their Fig. 22 for mass-dependent limits.

[9] SMARRA 23 is the European Pulsar Timing Array's constraint on the contribution of ultralight DM to the DM density in our local galactic neighbourhood. Ultralight DM cannot saturate the known DM density of 0.3 GeV/cc for masses inside this mass interval of 10^{-24}–5×10^{-23} eV.

[10] XIA 23 is analogous to PORAYKO 18 and use the Fermi-LAT pulsar timing array. They set a bound on the local density as $\rho_{A^0} \lesssim 8$ GeV/cm^3 for $m_{A^0} \lesssim 10^{-23}$ eV at 95% CL, with weaker constraints up to 10^{-22} eV. See their Fig. 1 for the mass-dependent limits.

[11] LAGUE 22 used the BOSS galaxy-clustering data to set limits on the abundance of ultralight axion dark matter. When combined with the CMB data, they obtained $\Omega_{A^0}h^2 < 0.004$ for $m_{A^0} = 10^{-31}$–10^{-26} eV. See their Figs. 1 and 15 for mass-dependent limits.

[12] YUAN 22A use the data of Advanced LIGO and Advanced Virgo's first three observing runs to search for stochastic GW background produced by scalar bosonic clouds formed by the BH superradiant instability. They set the limit, taking into account all the unstable modes.

[13] BANIK 21 use the subhalo mass function inferred from the analyses of the GD-1 and Pal 5 stellar streams. The limit is strengthened to 2.2×10^{-21} eV when adding dwarf satellite counts.

[14] BAUMHOLZER 21 study the freeze-in production of axion dark matter through couplings to photons, and set the limit using Lyman-α forest data and the observed number of Milky Way subhalos.

[15] CROON 21 study the supernova cooling effect of the axion–muon coupling, taking account of semi-Compton scattering and muon-proton bremsstrahlung, as well as the loop-induced axion-photon coupling, and exclude the range of $g_{A\mu\mu} \simeq 7\times10^{-3}$–$2\times10^{-10}$ for $m_{A^0} < 0.5$ GeV. See their Fig. 8 for mass-dependent limits.

[16] FUJIKURA 21 use the EROS-2 survey and the Subaru HSC observation to set limits on spherically symmetric axion clumps, taking account of the finite lens and source size effects. $f_{A^0} \gtrsim 10^{12}$ GeV can be constrained depending on the fraction of the axion dark matter collapsed into clumps, and the clump densities. See their Figs. 7–10 for the limits.

[17] MARTINCAMALICH 21 considered axion emission from a supernova core through the Λ hyperon decay, and set the limit on B($\Lambda \to n A^0$) $\lesssim 8 \times 10^{-9}$, or equivalently, $f_{A^0}/C_{sd} \gtrsim 2.6 \times 10^{9}$ GeV in terms of the flavor-violating axion coupling to the down and strange quarks.

[18] NG 21 use the binary black holes reported by LIGO and Virgo to determine the black hole spin distribution at formation and the scalar boson mass simultaneously, neglecting the boson self-interaction.

[19] ROGERS 21 set the limit by using a framework involving Bayesian emulator optimization to accurately forward-model the Lyman-α flux power spectrum, and comparing this with small-scale data to constrain the predicted suppression of cosmic structure growth.

[20] TSUKADA 21 look for a stochastic GW background produced by extragalactic BH-hidden photon cloud systems through the superradiant instability. They assume a uniform spin distribution at birth of isolated BHs from 0 to 1.

[21] IRSIC 20 used the Lyman-α forest constraint on small-scale isocurvature perturbation to derive limits on the axion mass and decay constant, assuming that the axion makes up all dark matter in the post-inflationary scenario. See their Fig. 1 for other astrophysical limits as well as the limits on the case of the temperature-dependent axion mass.

[22] PODDAR 20 used the observed decay in orbital period of four compact binary systems to derive a limit on the emission of axions with $m_{A^0} < 1 \times 10^{-19}$ eV, assuming they couple to nucleons and the strong CP phase vanishes at the potential minimum. They exclude $f_{A^0} \lesssim 10^{11}$ GeV for such axions.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

[23] SCHUTZ 20 set a limit on fuzzy dark matter based on the existing limits for warm dark matter derived from the inferred subhalo mass function.

[24] SUN 20 look for quasimonochromatic gravitational waves emitted from boson clouds around the Cygnus X-1 black hole. The quoted limit assume the black hole age of 5×10^6 years. A mass range of 9.6–15.5 $\times 10^{-13}$ eV is disfavored when repeated induction of bosenova for string axions with decay constant $f_{A^0} \simeq 10^{15}$ GeV prevents the superradiance from being saturated.

[25] DAVOUDIASL 19 used the observed data of M87* by the Event Horizon Telescope to set the limit. A mass range of 0.85–4.6 $\times 10^{-21}$ eV is disfavored for a spin-1 boson.

[26] MARSH 19 considered heating of star clusters due to the stochastic oscillations of the core and granular quasiparticles in the outer halo. The limit was derived by requiring the survival of the old star cluster in Eridanus II, where the lower end is set by the validity of diffusion approximation. The effect of tidal stripping is also discussed for lower masses.

[27] PALOMBA 19 used the LIGO O2 dataset to derive limits on nearly monochromatic gravitational waves emitted by boson clouds formed around a stellar-mass black hole. They exclude boson masses in a range of 1.1×10^{-13} and 4×10^{-13} eV for high initial black hole spin, and 1.2×10^{-13} and 1.8×10^{-13} eV for moderate spin. See their Figs. 2 and 3 for limits based on various values of black hole initial spin, boson cloud age, and distance.

[28] CHANG 18 update axion bremsstrahlung emission rates in nucleon-nucleon collisions, shifting the excluded mass range to higher values. They rule out the hadronic axion with mass up to a few hundred eV, closing the hadronic axion window. See their Fig. 11 for results based on several different choices of the temperature and density profile of the proto-neutron star.

[29] PORAYKO 18 look for time-dependent oscillations in the gravitational potential generated by ultralight scalar dark matter, and set a bound on its local density as $\rho_{A^0} \lesssim 6$ GeV/cm^3 for $m_{A^0} \lesssim 10^{-23}$ eV at 95% CL. See their Fig. 4 for the limits.

[30] ARCHIDIACONO 13A is analogous to HANNESTAD 05A. The limit is based on the CMB temperature power spectrum of the Planck data, the CMB polarization from the WMAP 9-yr data, the matter power spectrum from SDSS-DR7, and the local Hubble parameter measurement by the Carnegie Hubble program.

[31] CADAMURO 11 use the deuterium abundance to show that the m_{A^0} range 0.7 eV – 300 keV is excluded for axions, complementing HANNESTAD 10.

[32] DERBIN 11A look for solar axions produced by Compton and bremsstrahlung processes, in the resonant excitation of ^{169}Tm, constraining the axion-electron $\times$ axion nucleon couplings.

[33] ANDRIAMONJE 10 search for solar axions produced from ^{7}Li (478 keV) and D$(p,\gamma)^3$He (5.5 MeV) nuclear transitions. They show limits on the axion-photon coupling for two reference values of the axion-nucleon coupling for $m_A < 100$ eV.

[34] This is an update of HANNESTAD 08 including 7 years of WMAP data.

[35] ANDRIAMONJE 09 look for solar axions produced from the thermally excited 14.4 keV level of ^{57}Fe. They show limits on the axion-nucleon $\times$ axion-photon coupling assuming $m_A < 0.03$ eV.

[36] DERBIN 09A look for Primakoff-produced solar axions in the resonant excitation of ^{169}Tm, constraining the axion-photon $\times$ axion-nucleon couplings.

[37] KEKEZ 09 look at axio-electric effect of solar axions in HPGe detectors. The one-loop axion-electron coupling for hadronic axions is used.

[38] This is an update of HANNESTAD 07 including 5 years of WMAP data.

[39] This is an update of HANNESTAD 05A with new cosmological data, notably WMAP (3 years) and baryon acoustic oscillations (BAO). Lyman-α data are left out, in contrast to HANNESTAD 05A and MELCHIORRI 07A, because it is argued that systematic errors are large. It uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component.

[40] MELCHIORRI 07A is analogous to HANNESTAD 05A, with updated cosmological data, notably WMAP (3 years). Uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component. Leaving out Lyman-α data, a conservative limit is 1.4 eV.

[41] HANNESTAD 05A puts an upper limit on the mass of hadronic axion because in this mass range it would have been thermalized and contribute to the hot dark matter component of the universe. The limit is based on the CMB anisotropy from WMAP, SDSS large scale structure, Lyman α, and the prior Hubble parameter from HST Key Project. A χ^2 statistic is used. Neutrinos are assumed not to contribute to hot dark matter.

[42] MOROI 98 points out that a KSVZ axion of this mass range (see CHANG 93) can be a viable hot dark matter of Universe, as long as the model-dependent $g_{A\gamma}$ is accidentally small enough as originally emphasized by KAPLAN 85; see Fig. 1.

[43] BORISOV 97 bound is on the axion-electron coupling $g_{ae} < 1 \times 10^{-13}$ from the photo-production of axions off of magnetic fields in the outer layers of neutron stars.

[44] KACHELRIESS 97 bound is on the axion-electron coupling $g_{ae} < 1 \times 10^{-10}$ from the production of axions in strongly magnetized neutron stars. The authors also quote a stronger limit, $g_{ae} < 9 \times 10^{-13}$ which is strongly dependent on the strength of the magnetic field in white dwarfs.

[45] KEIL 97 uses new measurements of the axial-vector coupling strength of nucleons, as well as a reanalysis of many-body effects and pion-emission processes in the core of the neutron star, to update limits on the invisible-axion mass.

[46] RAFFELT 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red giant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).

[47] ALTHERR 94 bound is on the axion-electron coupling $g_{ae} < 1.5 \times 10^{-13}$, from energy loss via axion emission.

[48] CHANG 93 updates ENGEL 90 bound with the Kaplan-Manohar ambiguity in $z = m_u/m_d$ (see the Note on the Quark Masses in the Quark Particle Listings). It leaves the window $f_A = 3\times10^5 – 3\times10^6$ GeV open. The constraint from Big-Bang Nucleosynthesis is satisfied in this window as well.

[49] BERSHADY 91 searched for a line at wave length from 3100–8300 Å expected from 2γ decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.

[50] KIM 91C argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an *upperbound* rather than a lowerbound.

[51] RAFFELT 91B argue that previous SN 1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.

[52] RESSELL 91 uses absence of any intracluster line emission to set limit.

[53] ENGEL 90 rule out $10^{-10} \lesssim g_{AN} \lesssim 10^{-3}$, which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to 2.5×10^{-3} eV $\lesssim m_{A^0} \lesssim 2.5 \times 10^4$ eV. The constraint is loose in the middle of the range, i.e. for $g_{AN} \sim 10^{-6}$.

[54] RAFFELT 90D is a re-analysis of DEARBORN 86.

[55] The region $m_{A^0} \gtrsim 2$ eV is also allowed.

[56] ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.

[57] MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2–4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 88B.

[58] RAFFELT 88B derives a limit for the energy generation rate by exotic processes in helium-burning stars $\epsilon < 100$ erg g^{-1} s^{-1}, which gives a firmer basis for the axion limits based on red giant cooling.

[59] RAFFELT 87 also gives a limit $g_{A\gamma} < 1 \times 10^{-10}$ GeV^{-1}.

[60] DEARBORN 86 also gives a limit $g_{A\gamma} < 1.4 \times 10^{-11}$ GeV^{-1}.

[61] RAFFELT 86 gives a limit $g_{A\gamma} < 1.1\times10^{-10}$ GeV^{-1} from red giants and $< 2.4\times10^{-9}$ GeV^{-1} from the sun.

[62] KAPLAN 85 says $m_{A^0} < 23$ eV is allowed for a special choice of model parameters.

[63] FUKUGITA 82 gives a limit $g_{A\gamma} < 2.3 \times 10^{-10}$ GeV^{-1}.

Search for Relic Invisible Axions

Limits are for the dimensionless quantity $[G_{A\gamma\gamma}/m_{A^0}]^2\rho_A$ where $G_{A\gamma\gamma}$ denotes the axion two-photon coupling, $L_{\rm int} = -\frac{G_{A\gamma\gamma}}{4}\phi_A F_{\mu\nu}\tilde{F}^{\mu\nu} = G_{A\gamma\gamma}\phi_A \mathbf{E}\cdot\mathbf{B}$, and ρ_A is the axion energy density near the earth, unless otherwise stated. Notice that for QCD axions $G_{A\gamma\gamma}/m_{A^0}$ does not depend on m_{A^0}. For the reference values $m_{A^0} = 1$ μeV, $G_{A\gamma\gamma} = 3.9 \times 10^{-16}$ GeV^{-1} (that would apply to KSVZ axions at that mass), and $\rho_A = 300$ MeV/cm^3 one finds $[G_{A\gamma\gamma}/m_{A^0}]^2\rho_A = 3.5 \times 10^{-43}$.

[1] AHYOUNE 25 report results from the RADES collaboration, where a custom resonant cavity was used with an 11.7 T dipole magnet. See their Fig. 9 for mass-dependent limits.

[2] BAE 25 present first results from the IBS Dark Matter Axion Group (DMAG), using the TM020 mode of a cylindrical resonant cavity haloscope. See their Fig. 4 for mass-dependent limits.

[3] BAI 25 present results from Phase II of the HAYSTAC resonant cavity haloscope search for axion dark matter. See their Fig. 3 for mass-dependent limits together with previous results.

[4] BRAGGIO 25 presents limits from a cavity haloscope search for axion dark matter. This experiment employed a single-photon counter to circumvent the Standard Quantum Limit and enhance the search speed. See their Fig. 5 for mass-dependent limits.

[5] CAROSI 25 reports the latest results from the ADMX collaboration, extending the exclusion of relic QCD axions between 1.1 and 1.3 GHz down to the DFSZ model line using a near-quantum-limited amplifier. Quoted limit is for the strongest point in the exclusion limit just below 5.4 μeV.

[6] GOODMAN 25 present a limit on QCD axion dark matter from an ADMX resonant cavity haloscope with a sensitivity reaching the DFSZ model line. See their Fig. 4 for the mass-dependent limit.

[7] HOSHINO 25 present a first limit on axion dark matter from the GigaBREAD experiment. They used a coaxial dish antenna haloscope design placed inside a 3.9 T solenoidal magnet. See their Fig. 3 for mass-dependent limits.

[8] PORAYKO 25 use the European Pulsar Timing Array dataset to place constraints on ultralight axion-like particles making up the dark matter halo of the galaxy. They look for the effect of interactions between the local dark matter ALP field and the radio photons emitted by the pulsars, which would induce an oscillating rotation of the plane of linear polarisation. See their Fig. 7 for mass-dependent limits.

[9] SANTOS-GARCIA 25 present results for a prototype setup of the MADMAX dielectric haloscope searching for axion dark matter to photon conversion in a 1.6 T dipole magnet. See their Fig. 4 for mass-dependent limits.

[10] SARDO-INFIRRI 25 report a result from the QUAX haloscope around 10.2 GHz, using a quantum-limited detection chain to achieve sensitivity to axions down to close to the KSVZ model. See their Fig. 4 for mass-dependent limits.

[11] AHN 24 is from the CAPP-MAX experiment with sensitivity to DFSZ axions. See Fig. 22 for mass-dependent limits.

[12] BAE 24 search for dark matter axions using a microwave cavity with a tunable TM020 mode, scanning around 5 GHz. See their Fig. 6 for mass-dependent limits.

[13] DAVYDOV 24 constrain ultralight axion-like particle dark matter via the oscillating birefringence effect induced by the local ALP field. Their constraint is based on polarimetric measurements of the HL Tauri protoplanetary disk. Their constraint is $g_{a\gamma} < 2.111\times10^{-12}$ GeV$^{-1}(m_a/10^{-22})$ eV.

[14] HEINZE 24 search for ALP dark matter using the LIDA experiment – a laser interferometric haloscope that can detect the axion-induced polarisation rotation of light. Quoted limit assumes a dark matter density of 0.4 GeV/cm^3. See their Fig. 2 for mass-dependent limits.

[15] KIM 24 report results from the CAPP-12T experiment searching for dark matter axions around 22 μeV down to the KSVZ level. See their Fig. 5 for mass-dependent limits.

[16] PANDEY 24 report first search from the ADBC haloscope – an optical bow-tie laser cavity searching for the oscillating birefringence effect due to axion dark matter coupled to the photon. See their Fig. 3 for mass-dependent limits.

[17] QUISKAMP 24 present results from Phase 1b of the ORGAN experiment, a high-frequency resonant axion haloscope in the 15–50 GHz range. See their Fig. 5 for mass-dependent limits.

[18] RETTAROLI 24 report results from the QUAX resonant cavity haloscope at 8.8 GHz. This extends their previous search around this mass range reported in ALESINI 19. See their Fig. 7 for mass-dependent limits.

[19] ADACHI 23D is analogous to ADE 21. They used POLARBEAR data, and take account of a stochastic local axion field amplitude with the time-averaged local axion density ρ_A = 0.3 GeV/cm^3. Limits are set at $G_{A\gamma\gamma} < 2.4\times10^{-11}$ GeV^{-1} ($m_{A^0}/10^{-21}$ eV), which is 2.2 times larger than the deterministic case. See Fig. 5 for mass-dependent limits.

[20] DI-VORA 23 searches for axions in a narrow mass window using an 8T haloscope and a travelling wave parametric amplifier to achieve noise close to the quantum limit. This is an improvement on their previous scan at the same mass, ALESINI 21. See Fig. 7 for mass-dependent limits and a comparison.

[21] JEWELL 23 is an update of BRUBAKER 17. See their Fig. 11 for the mass-dependent limits.

[22] JEWELL 23 correct an underestimation of intermediate frequency noise in BACKES 21. See their Fig. 11 for the mass-dependent limits.

[23] KIM 23 is an update of KWON 21 on the CAPP-PACE experiment. See their Fig. 4 for mass-dependent limits.

[24] OSHIMA 23 report first limits from the DANCE experiment. This experiment is based on a novel bow-tie cavity design that searches for the oscillating rotation of polarised laser light driven by the DM axion-photon mixing at low frequencies. See their Fig. 6 for mass-dependent limits.

[25] THOMSON 23 used an AC microwave cavity to search for dark matter axions. The axion signal is resonantly enhanced when the axion mass matches the difference between a cavity which is pumped with power and another resonant mode close in frequency that is used to read out the signal. See their Fig. 7 for the mass-dependent limits.

[26] YANG 23 extends the first phase of CAPP 18T to KSVZ axions between 4.8077 and 4.8181 GHz. They used an 18T high-temperature superconducting magnet haloscope. See their Fig. 5 for mass-dependent limits. Quoted value is for their limit derived with a Bayesian method.

[27] YI 23 is analogous to LEE 20A, using the CAPP-12TB haloscope. See their Fig. 4 for mass-dependent limits.

[28] YI 23A used the same data as YI 23, but instead of the standard halo model, they searched for axion dark matter in the Sagittarius tidal stream with a velocity v = 300 km/sec and a velocity dispersion δv = 20 km/sec. See their Fig. 4 for mass-dependent limits.

[29] ADE 22 is an update of ADE 21 based on the expanded data of the 2012–2015 observing seasons. See their Fig. 3 for mass-dependent limits over the extended mass range 1×10^{-23}–6×10^{-19} eV.

[30] ALESINI 22 is an update of ALESINI 21, using the TM030 mode of the cylindrical dielectric cavity. See their Fig. 8 for mass-dependent limits.

[31] BATTYE 22 is analogous to DARLING 20A, and use plasma ray tracing technique to analyze the propagation of radio photons converted from axion dark matter in the magnetosphere of PSR J1745-2900. The quoted limit assumes $\rho_A = 6.5\times10^4$ GeV/cm^3 in the vicinity of the magnetar. See their Fig. 1 for mass-dependent limits.

[32] CHANG 22 used a microwave cavity detector to search for dark matter axions. See Fig. 3 for the mass-dependent limits.

[33] FERGUSON 22 is analogous to ADE 21. They use the data of the SPT-3G's 2019 observing season. See their Fig. 5 for mass-dependent limits over the extended mass range 0.047–9.5×10^{-20} eV.

[34] LEE 22 is analogous to LEE 20A. They used an 18T high-temperature superconducting magnet haloscope. See their Fig. 5 for mass-dependent limits.

[35] QUISKAMP 22 is a 15.28 to 16.23 GHz microwave cavity haloscope with 11.5 T B-field. See Fig. 4 for mass-dependent limits.

[36] YOON 22 analyzed the data from LEE 22 and changed from a frequentist to a Bayesian method to set limits. See their Fig. 27 for mass-dependent limits.

[37] ZHOU 22 is analogous to DARLING 20A, and they use the data from the MeerKAT radio telescope's observation of the neutron star J0806.4-4123, which is 250 pc from Earth. See their Fig.3 for mass-dependent limits.

[38] ADE 21 looks for a time-variable global rotation of the CMB polarization induced by the harmonic oscillations of local axion-like dark matter and uses data from the 2012 observing season of the Keck Array, part of the BICEP program. The limits get 25% weaker for $m_{A^0} = 4.8\times10^{-20}$–$5.7\times10^{-19}$ eV. See their Eq. (80) and Fig. 6 for mass-dependent limits.

[39] ALESINI 21 is an update of ALESINI 19. See their Figs. 5 and 6 for the mass-dependent limits.

[40] BARTRAM 21A is analogous to DU 18. See their Fig.4 for mass-dependent limits.

[41] DEVLIN 21 use the superconducting resonant detection circuit of a cryogenic Penning trap with a single antiproton. See their Fig. 3 for mass-dependent limits.

[42] GRAMOLIN 21 use two detection channels, each consisting of two stacked toroids to look for the axion-induced oscillating magnetic field. The quoted limit applies at m_{A^0} = 0.02 neV. See their Fig. 4 for mass-dependent limits.

[43] KWON 21 is analogous to LEE 20A. They also obtain weaker limits in the range of m_{A^0} = 10.16–11.37 μeV. See their Fig. 4 for mass-dependent limits.

[44] MELCON 21 use a radio frequency cavity consisting of 5 sub-cavities coupled by inductive irises installed inside the CAST dipole magnet to look for higher axion masses. See their Fig. 9 for mass-dependent limits.

[45] SALEMI 21 is an update of OUELLET 19A. See their Fig. 4 for mass-dependent limits.

[46] THOMSON 21 use a resonant cavity supporting two spatially overlapping microwave modes, which is sensitive to the axion mass corresponding to the sum or difference of the two resonant frequencies. The original limit was retracted due to a sign error. See their Fig. 2 in the erratum for the corrected limits.

[47] YUAN 21 use polarimetric observations of Sgr A* taken by the Event Horizon Telescope to search for periodic oscillation of the polarization induced by axion dark matter, assuming a solitonic core near the Galactic center. They obtained limits in the range of $G_{A\gamma\gamma} = 8\times10^{-13}$–$3\times10^{-11}$ GeV^{-1}.

[48] BRAINE 20 is analogous to DU 18. See Fig. 4 for their mass-dependent limits.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

[49] CRISOSTO 20 used a resonant LC circuit to look for lighter axion dark matter. They obtained a similar, slightly weaker limit for m_{A^0} = 174.98–175.19 and 177.34–177.38 neV. See their Fig. 4 for mass-dependent limits.

[50] DARLING 20A use VLA data to look for radio-frequency radiation converted from axion dark matter in the magnetosphere of the Galactic Center magnetar PSR J1745–2900. They extended the results of DARLING 20, which used only data with the highest angular resolution, by adding sub-optimal data. They use $\rho_A = 6.5\times10^4$ GeV/cm^3 in the vicinity of the magnetar. See their Fig. 2 for mass-dependent limits.

[51] FOSTER 20 look for radio-frequency radiation converted from axion dark matter in the magnetic field around neutron stars. They use the observed data of isolated local neutron stars and in the Galactic center. The quoted limit applies to $m_{A^0} \simeq 7$ μeV. See their Fig. 2 for mass-dependent limits.

[52] JEONG 20 is analogous to LEE 20A, and they use a double-cell cavity to look for axions with mass > 10 μeV. See their Fig. 5 for mass-dependent limits.

[53] KENNEDY 20 is analogous to BRANCA 17, and they compare the frequency ratios of the Si cavity measured by a Sr optical lattice clock and by a H maser. Assuming the local density of moduli dark matter, $\rho_S = 0.3$ GeV/cm^3, they obtain a limit $G_{S\gamma\gamma} < 5.8\times10^{-24}$ GeV^{-1} at $m_{S^0} = 2\times10^{-19}$ eV. See their Fig. 2 for mass-dependent limits as well as limits on the modulus coupling to electrons.

[54] LEE 20A used a microwave cavity detector at the IBS/CAPP to search for dark matter axions. See Fig. 3 for the mass-dependent limits.

[55] ALESINI 19 used a superconducting resonant cavity made of NbTi to increase the quality factor. The limit applies to a mass range of 0.2 neV around $m_{A^0} = 37.5$ μeV.

[56] FUJITA 19 look for photon birefringence under the oscillating axion background using the polarimetric imaging observation of a protoplanetary disk, AB Aur. See their Fig. 2 for a more conservative limit taking account of possible systematic effects.

[57] OUELLET 19A look for the axion-induced oscillating magnetic field generated by a toroidal magnetic field. The quoted limit applies at $m_{A^0} = 8$ neV. See their Fig. 3 for the mass-dependent limits.

[58] BOUTAN 18 use a small high frequency cavity installed above the main ADMX cavity to look for heavier axion dark matter. See their Fig. 4 for mass-dependent limits.

[59] DU 18 is analogous to DUFFY 06. They upgraded a dilution refrigerator to reduce the system noise. The quoted limit is around $m_{A^0} = 2.69$ μeV for the boosted Maxwellian axion line shape. See Fig. 4 for their mass-dependent limits.

[60] ZHONG 18 is analogous to BRUBAKER 17. The quoted limit applies at $m_{A^0} = 23.76$ μeV. See Fig. 4 for their mass-dependent limits.

[61] BRANCA 17 look for modulations of the fine-structure constant and the electron mass due to moduli dark matter by using the cryogenic resonant-mass AURIGA detector. The limit on the assumed dilatonic coupling implies $G_{S\gamma\gamma} < 1.5\times10^{-24}$ GeV^{-1} for the scalar to two-photon coupling. See Fig. 5 for the mass-dependent limits.

[62] BRUBAKER 17 used a microwave cavity detector at the Yale Wright Laboratory to search for dark matter axions. See Fig. 3 for the mass-dependent limits.

[63] CHOI 17 used a microwave cavity detector with toroidal geometry. See Fig. 4 for their mass-dependent limits.

[64] MCALLISTER 17 used a high-frequency microwave cavity haloscope at 26.6 GHz in a 7 T magnetic field. See Fig. 4 for mass-dependent limits.

[65] HOSKINS 16 is analogous to DUFFY 06. See Fig. 12 for mass-dependent limits in terms of the local dark matter density.

[66] BECK 13 argues that dark-matter axions passing through Earth may generate a small observable signal in resonant S/N/S Josephson junctions. A measurement by HOFFMANN 04 [Physical Review **B70** 180503 (2004)] is interpreted in terms of subdominant dark matter axions with $m_{A^0} = 0.11$ meV.

[67] HOSKINS 11 is analogous to DUFFY 06. See Fig. 4 for the mass-dependent limit in terms of the local density.

[68] ASZTALOS 10 used the upgraded detector of ASZTALOS 04 to search for halo axions. See their Fig. 5 for the m_{A^0} dependence of the limit.

[69] DUFFY 06 used the upgraded detector of ASZTALOS 04, while assuming a smaller velocity dispersion than the isothermal model as in Eq. (8) of their paper. See Fig. 10 of their paper on the axion mass dependence of the limit.

[70] ASZTALOS 04 looked for a conversion of halo axions to microwave photons in magnetic field. At 90% CL, the KSVZ axion cannot have a local halo density more than 0.45 GeV/cm^3 in the quoted mass range. See Fig. 7 of their paper on the axion mass dependence of the limit.

[71] KIM 98 calculated the axion-to-photon couplings for various axion models and compared them to the HAGMANN 90 bounds. This analysis demonstrates a strong model dependence of $G_{A\gamma\gamma}$ and hence the bound from relic axion search.

[72] HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.

[73] WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagnetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with $[G_{A\gamma\gamma}/m_{A^0}]^2 = 2\times10^{-14}$ MeV^{-4} (the three generation DFSZ model) and $\rho_A = 300$ MeV/cm^3 that makes up galactic halos gives $(G_{A\gamma\gamma}/m_{A^0})^2\,\rho_A = 4\times10^{-44}$. Note that our definition of $G_{A\gamma\gamma}$ is $(1/4\pi)$ smaller than that of WUENSCH 89.

Invisible A^0 (Axion) Limits from Photon Coupling

Limits are for the modulus of the axion-two-photon coupling $G_{A\gamma\gamma}$ defined by $L = -G_{A\gamma\gamma}\phi_A \mathbf{E}\cdot\mathbf{B}$. For scalars S^0 the limit is on the coupling constant in $L = G_{S\gamma\gamma}\phi_S(\mathbf{E}^2-\mathbf{B}^2)$. The relation between $G_{A\gamma\gamma}$ and m_{A^0} is not used unless stated otherwise, i.e., many of these bounds apply to low-mass axion-like particles (ALPs), not to QCD axions.

< 7.7	$\times 10^{-7}$	99	[164] RUOSO	92		$m_{A^0} < 10^{-3}$ eV
< 2.5	$\times 10^{-6}$		[165] SEMERTZIDIS	90		$m_{A^0} < 7 \times 10^{-4}$ eV

[1] ABRAHAM 25 search for axions as a long-lived particle decaying into photons in the FASER detector at the LHC. They constrain models where the axion dominantly couples to W bosons. The quoted limit is from their Fig. 11, which shows the bound interpreted in terms of a coupling to photons, taking the value at a mass of 70 MeV where the constraint is strongest. Bounds on the axion-gluon coupling extend up to axion masses of up to 800 MeV.

[2] ADAMS 25C present a search for ALP-photon mixing imprinted on the gamma-ray spectrum of the flaring NGC 1275 radio galaxy at the centre of the Perseus cluster observed by the VERITAS observatory. They adopt the CLs method for reporting exclusion limits as shown in their Fig. 3. No point in the tested parameter space is excluded at or above 95% confidence. The quoted limit is reached at $m_{A^0} = 3.03 \times 10^{-7}$ eV.

[3] ALTENMULLER 25 primarily reports a new limit from the CAST helioscope on the product of the axion-photon and axion-electron coupling, but they also exploit the same analysis to set a new limit on the axion-photon coupling alone, although this is weaker than their previous limit in ALTENMULLER 24.

[4] CANDON 25 place bounds on heavy photon-coupled axion-like particles produced in the interiors of the stars in the starburst galaxy M82 and then decaying to two photons. This process would generate an X-ray flux peaking around 100 keV, which they search for using data from the NuSTAR space telescope. See their Fig. 2 for mass-dependent limits.

[5] CHEN 25 use data from X-ray satellites Chandra and eROSITA to search for the decays of axion-like particles produced by the Alpha Centauri binary system. Specifically, they consider the argument also used by BEAUFORT 23 in the case of the Sun, in which axions emitted with low speed from the star can build up in a gravitationally trapped 'basin' over the star's life. See their Fig. 3 for mass-dependent limits. The quoted value applies to the case where the axion-electron coupling is taken to be negligible.

[6] CHEN 25A constrain low-mass axion-like particles by searching for the imprints of axion-photon oscillations on the gamma-ray spectra of two active galactic nuclei measured by the Fermi and MAGIC gamma-ray telescopes. See their Fig. 11 for mass-dependent limits.

[7] CHEN 25B constrain low-mass axion-like particles by searching for the imprints of axion-photon oscillations on the gamma-ray spectra of several blazars observed by the Fermi gamma-ray telescope. See Figs. 2, 3 and 4 for mass-dependent limits.

[8] FONG 25 use early-release data from the eROSITA X-ray telescope's Final Equatorial Depth Survey to search for axion-like particle dark matter decaying to two photons in the Milky Way's dark matter halo. See their Fig. 7 for mass-dependent limits.

[9] GOLDSTEIN 25 place bounds on low mass axions mixing with photons over cosmological distances as they traverse large-scale structure, which would lead to an observable patchy screening effect in CMB anisotropy maps. See their Fig. 3 for mass-dependent limits. This bound is analogous to that placed on dark photons by MCCARTHY 24.

[10] HAYRAPETYAN 25Z places a bound on heavy axion-like particles coupled to photons via measurements of light-by-light scattering in ultraperipheral PbPb collisions at the CMS experiment. The bound is based on a search for diphoton events due to $\gamma\gamma \to a \to \gamma\gamma$ on top of the light-by-light scattering continuum. See Fig. 9 for mass-dependent limits on the axion-photon coupling.

[11] JANISH 25 use blank-sky observations of the James Webb Space Telescope to search for dark matter axions present in the galactic halo. eV-mass axions decaying into two photons would present an emission line in the infrared band. See their Fig. 2 for mass-dependent limits.

[12] KAR 25 use infrared to ultraviolet observations of the giant elliptical galaxy M87 to search for evidence of eV-scale axions decaying to two photons, assuming they make up the dark matter halo of the galaxy. See their Fig. 2, 3 and 4 for mass-dependent limits.

[13] KIRITA 25 presents a new result from the SAPPHIRES collaboration, namely a search for the production of axion-like particles in a quasi-parallel stimulated resonant photon-photon collider. See their Fig. 11 for mass-dependent limits.

[14] LI 25D search for evidence of axion-photon mixing imprinted on the gamma-ray spectrum of the flat-spectrum radio quasar Ton-599 detected by Fermi-LAT. See their Fig. 4 for mass-dependent limits.

[15] MIRZAKHANI 25 search for axion-like particles coupled to photons using the MINER reactor neutrino experiment. Their search assumes axions would be produced via Primakoff emission from the reactor photon flux, which can then decay to two photons or convert to a photon through the inverse Primakoff effect in the detector. See Fig. 10 for mass-dependent limits.

[16] NING 25 sets bounds on low-mass axion-like particle Primakoff emission by stars in the M87 and M82 starburst galaxies. They use data from the NuSTAR space telescope to search for evidence of the emitted axions converting into hard X-ray photons in the surrounding galactic magnetic fields. See Fig. 2 for mass-dependent limits.

Int. J. Mod. Phys. A 2026.41. Do [redacted] orldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re [redacted] strictly not permitted, except for Open Access articles.

[17] PARK 25 present a search for axion-like particles from the NEON reactor neutrino experiment. Axions would be produced by the large MeV photon flux from the reactor and subsequently scatter or decay to a photon pair in the detector. The quoted limit is at $m_{A^0} = 3$ MeV. See their Fig. 3 for mass-dependent limits.

[18] RUZ 25 use data from the NuSTAR X-ray telescope to search for solar axions converting into photons as they traverse the Sun's atmospheric magnetic field. For larger m_{A^0}, the limit becomes weaker due to loss of coherence in the conversion. See their Fig. 1 for mass-dependent limits.

[19] TODARELLO 25 use observations of dwarf spheroidal galaxies and galaxy clusters made by the Hubble Space Telescope to constrain axions decaying to two photons at UV wavelengths, assuming axions make up the dark matter halos of those astrophysical objects. See their Fig. 3 for mass-dependent limits.

[20] TROITSKY 25 searches for evidence of any anomalous cooling due to axion emission from red giants and helium-burning stars in seven globular clusters observed by the Gaia survey. A 3.3σ hint for anomalous cooling is found, which could be explained by a non-zero axion-photon coupling.

[21] YIN 25 use the WINERED spectrograph on the Magellan Clay Telescope to search for evidence of dark matter axions decaying into photons in the halos of the Leo V and Tucana II dwarf spheroidal galaxies. See their Fig. 1 for mass-dependent limits and the dependence on the assumed dark matter halo models.

[22] ZENG 25 place a bound on axions emitted by the Sun due to a nonzero axion-photon coupling using electronic recoil data collected by the PandaX detector. Electron recoil events are generated via the axion-photon coupling by the inverse Primakoff effect. The limit is independent of the axion mass up to around the core temperature of the Sun.

[23] ABLIKIM 24AD constrain the axion-photon coupling through radiative J/ψ decays in the BESIII detector at the Beijing electron-positron collider. See their Fig. 5 for mass-dependent limits.

[24] ALTENMULLER 24 report an extended search for solar axions using the CAST experiment. The experiment employed a new xenon-based microMEGAS detector - a pathfinder for the future International Axion Observatory (IAXO). This limit improves upon ANASTASSOPOULOS 17. See Fig. 4 for mass-dependent limits.

[25] DEV 24 use Fermi gamma-ray observations of the neutron star merger GW170817 to constrain the production and subsequent decay of high-mass axion-like particles. Constraint extends diagonally in mass-coupling space, reaching 7×10^{-12} GeV^{-1} at 100 MeV. See Fig. 4 for mass-dependent limits.

[26] DIAMOND 24 use multi-messenger observations of the neutron star merger GW170817 to constrain the production and radiative decay of axions in the event. Limits shown in their Fig. 3 extend diagonally in mass-coupling space.

[27] FORDHAM 24 use asteroseismology observations of a solar-like star, KIC 6933899, to constrain axion emission from its interior via the photon coupling. Bound applies to all axion masses up to around the core temperature of the star $\sim$ keV.

[28] GAO 24 constrain ALP-photon oscillations via their imprint on the gamma-ray spectrum of the blazar Mrk 421, as observed by MAGIC and Fermi-LAT. See their Fig. 5 for mass-dependent limits.

[29] GAO 24A constrain ALP-photon oscillations using the high-energy gamma-ray spectrum observed by LHAASO of the brightest gamma-ray burst so far detected, GRB 221009A. See their Fig. 5 for mass-dependent limits. The strength of the limit depends on the magnetic field of the host galaxy.

[30] GUO 24 search for axion dark matter decaying or converting into photons in the Coma Berenices dwarf galaxy using the radio telescope FAST. The quoted limit is for the case of axions decaying, including stimulated emission. See their Fig. 2 for mass-dependent limits.

[31] LI 24A constrain the imprint of ALP-photon oscillations on the TeV gamma-ray spectrum of the BL Lac blazar 1ES 1215+303 using VERITAS and Fermi-LAT data. See their Fig. 4 for mass-dependent limits.

[32] LI 24B constrain the imprint of ALP-photon oscillations on the very-high-energy gamma-ray spectrum of various galactic sources detected by the LHAASO air-shower array. Best limits are obtained from the Crab Nebula after combining several observations from different gamma-ray observatories in addition to LHAASO. See their Fig. 5 for mass-dependent limits.

[33] LI 24D search for evidence of axion-photon oscillations imprinted on the gamma-ray spectrum of the nearby BL Lac blazar Markarian 421. They set upper limits using data from Fermi-LAT and HAWC. The quoted limit applies for $m_{A^0} \simeq 3 \times 10^{-9}$ eV. See their Fig. 3 for mass-dependent limits.

[34] MANZARI 24 search for evidence of axions produced in SN1987A converting into gamma-rays that would have been detectable by the Solar Maximum Mission. This analysis improves upon previous studies of axion-photon conversion after SN1987A (e.g. HOOF 23) by including the magnetic field of the progenitor star. Quoted limit applies for masses below 0.1 neV and rises towards larger masses. See their Fig. 1 for mass-dependent limits.

[35] PANT 24 searches for the imprint of axion-photon oscillations in the very-high-energy gamma-ray spectrum of the quasar QSO B1420+326 observed by the MAGIC telescope. Three small disconnected regions of mass-coupling parameter space below 1 neV are ruled out. See Fig. 4 for the limits.

[36] PYBUS 24 report results from the GlueX detector, which has searched for the two-photon decay of heavy axions produced through the nuclear Primakoff effect due to a beam of photons incident on a Carbon target. See their Fig. 8 for mass-dependent limits.

[37] RAVENSBURG 24 search for heavy axions decaying to two photons using the recent nearby type-II supernova SN 2023ixf. Constraint extends diagonally downwards in mass-coupling space, see their Fig. 2 for full limits. Quoted limit is the most constraining point for the most conservative choices for supernova parameters.

[38] TODARELLO 24 search for axions decaying to two photons in the halos of Milky Way dwarf galaxies observed in the MUSE-Faint survey. This study improves upon an earlier one presented in REGIS 21. See their Fig. 5 for compiled mass-dependent limits.

[39] WANG 24A search for axions decaying into two photons assuming that they make up the dark matter halos of galaxies. They use data from the Dark Energy Spectroscopic Instrument, searching for the axion decay line in optical wavelengths with their Bright Galaxy and Luminous Red Galaxy samples. See their Fig. 8 for mass-dependent limits on the axion to photon decay rate. Their constraint is quoted as a 5σ detection limit.

[40] BATTYE 23 look for dark-matter axions falling into pulsar magnetospheres and converting into narrow radio lines. Unlike the earlier FOSTER 22 they search for evidence of conversion in the time-domain signal of a single pulsar, using 1 hour of MeerKAT data on the pulsar PSR J2144-3933. The quoted limit applies to an assumed magnetic field of 2×10^{12} G and a dark matter density of 0.45 GeV/cm^3.

[41] BEAUFORT 23 extends DEROCCO 22 who searched for the X-ray decay of axions that build up in the gravitational well of the Sun over its lifetime, the 'solar basin'. They use data from NuSTAR and SphinX telescopes and extends the previous study by accounting for the axion production via photon coalescence.

[42] BERNAL 23 use gamma-ray data from 739 blazars observed by FermiLAT and 38 blazars by Cherenkov observatories. They estimate optical depth, subtract the astrophysical component, and attribute the residual to axion two-photon decay. The quoted limit is for $m_{A^0} \simeq 25$ eV. See their Fig. 3 for the mass-dependent limits.

[43] CAPOZZI 23 use Planck CMB and Lyman-α observations to set limits on early energy injection by decaying dark matter axions that would affect CMB anisotropies and the reionisation history of the Universe. The quoted limit applies to $m_{A^0} = 100$ eV and the reionization model of Fauchere-Giguere. See Fig. 4 for mass-dependent constraints from different reionization models.

[44] CAPOZZI 23A search for axions produced in electromagnetic showers in proton beam dumps and fixed target experiments. In this case, they reinterpret MiniBoone data. Quoted limit applies at 100 MeV but the limit does not extend to arbitrarily large couplings. See Fig. 7 for mass-dependent limits.

[45] DAVIES 23 is analogous to AJELLO 16, and use the Fermi-LAT data from three quasars (3C454.3, CTA 102, and 3C279), considering the blazer jets as the regions where the axion-photon oscillations occur. See Fig. 8 for the mass-dependent limits.

[46] DIAMOND 23 demonstrate that a window of decaying 10-MeV-mass ALP parameter space previously thought to be excluded by the lack of gamma-ray emission from the SN 1987A explosion is actually unconstrained because of the formation of a fireball that would prevent decay photons from escaping. They nevertheless re-exclude this window by considering the non-detection of the sub-MeV emission by the Pioneer Venus Orbiter. The quoted limit is at $m_{A^0} = 56$ MeV. See their Fig. 2 for mass-dependent limits.

[47] FILZINGER 23 searched for oscillations in the fine structure constant induced by dilaton-like dark matter by measuring the frequency ratio between the E3 and E2 transitions of ^{171}Yb$^+$. They assume the local dark matter density $\rho_S = 0.4$ GeV/cm^3. The quoted limit is set at $m_{S^0} \simeq 4 \times 10^{-23}$ eV. See their Fig. 4 for the limits over $m_{S^0} = 1 \times 10^{-24}$–$1 \times 10^{-17}$ eV.

[48] HOOF 23 consider axions emitted from SN1987A converting to gamma rays in Galactic magnetic fields, using temporal information of the Solar Maximum Mission data. They set a limit $G_{A\gamma\gamma} \lesssim 5 \times 10^{-12}$ for masses $m_{A^0} \lesssim 2 \times 10^{-10}$ eV. See left panel in Fig. 3 for mass-dependent limits.

[49] HOOF 23 look for gamma rays resulting from the decay of axions produced from SN1987A, using the Solar Maximum Mission data. See right panel in Fig. 3 for mass-dependent limits.

[50] JACOBSEN 23 search for the imprints of axion-photon mixing on the TeV spectra of several blazars using data from the HAWC air shower detector.

[51] LI 23H look for gamma-ray spectral irregularities induced by axion-photon oscillations from AGN VER J0521+211, using the Fermi-LAT and VERITAS data. See their Fig. 4 for mass-dependent limits.

[52] NOORDHUIS 23 places strong constraints on the axion-photon coupling over a broad mass window using the fact that the polar cap regions of pulsars can generate a population of axions, which would then convert into an observable outgoing radio flux in the presence of the neutron star's B-field. They search for this signal in 27 pulsars and set mass-dependent limits shown in their Fig. 2.

[53] PANT 23 study the effect of axion-photon oscillations on the gamma-ray spectrum from the extragalactic neutrino source, TXS 0506+056. The quoted limit is at $m_{A^0} \simeq 2.7 \times 10^{-7}$ eV. See their Fig. 2 for mass-dependent limits.

[54] SHERRILL 23 search for scalar dilaton-like dark matter via oscillations in the fundamental constants. Their most competitive constraint is on the scalar photon coupling (Fig. 6, upper panel) that affects the fine-structure constant, which they extract using an optical-to-optical clock comparison between ^{171}Yb$^+$ and ^{87}Sr. Quoted limit applies at the smallest mass in their search window for this case of 10^{-20} eV.

[55] SULAI 23 looked for ultralight axion dark matter using the "Earth as a transducer" concept over the 0.5 to 5 Hz frequency range. They situate several magnetometers at magnetically quiet places and search for spatially-correlated magnetic field patterns induced by axion dark matter interacting in the effective cavity formed between the Earth's surface and the ionosphere. See their Fig. 12 for mass-dependent limits in context. This limit extends to higher-frequencies than their previous limit using archival geomagnetic field data collected by the SuperMAG collaboration, see ARZA 22

[56] YAO 23 study an optical circular polarization in blazers induced by the axion-photon mixing. The quoted limit assumes the transverse magnetic field at the jet's emission site, with $B_T = 1$ G, and this limit inversely scales with B_T. See their Fig. 3 for the limits' dependence on B_T and electron density.

[57] ZHANG 23A searched for oscillations in the fine structure constant induced by dilaton-like dark matter by measuring the frequencies of a hyperfine-structure transition in ^{87}Rb and an electronic transition in ^{164}Dy, and by comparing them with that of a quartz oscillator. They assume the local dark matter density $\rho_S \simeq 0.4$ GeV/cm^3. The quoted limit is set at $m_{S^0} \simeq 1 \times 10^{-17}$ eV. See their Fig. 3 for the limits over $m_{S^0} = 1 \times 10^{-17}$–$8.3 \times 10^{-13}$ eV.

[58] APRILE 22B is an update of APRILE 20 based on a similar solar axion modeling to DENT 20A and GAO 20. They exclude the XENON1T excess found in APRILE 20. The quoted limit holds for small g_{Aee}. See Fig. 6 for correlation between $G_{A\gamma\gamma}$ and g_{Aee}.

[59] ARNQUIST 22 is analogous to AVIGNONE 98, and supersedes ANASTASSOPOULOS 17 for $m_{A^0} \gtrsim 1.2$ eV.

[60] ARZA 22 search for low-mass axions as dark matter using the Earth as a transducer for axion-photon conversion. The concept works because the region between the Earth and the ionosphere forms an insulating cavity that parametrically enhances the axion signal by the radius of the Earth. The result is an oscillating and spatially correlated magnetic field induced via the interaction between axion dark matter and the geomagnetic field, which they searched for using archival magnetometer field data over 20 years compiled by the SuperMAG collaboration. Quoted limit applies for masses 3–4×10^{-17} eV, see Fig. 1 for mass-dependent limits.

[61] BERNAL 22 explored the possibility that the excess in the cosmic optical background measured by New Horizonss Long Range Reconnaisance Imager was due to axion dark matter decaying into monoenergetic photons. See their Fig. 2 for the axion-photon coupling to explain the excess.

[62] CALORE 22 update CALORE 20 by evaluating axion fluxes from progenitors of various masses and performing a template-based analysis using 12 years of Fermi-LAT data in the energy range from 50 MeV to 500 GeV. See their Fig. 10 for mass-dependent limits.

[63] CAPUTO 22 study the effect of energy deposition by radiative decay of axions produced via the Primakoff process and photon coalescence in the supernova core, and set the

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

limits by the radiative energy deposition $< 10^{50}$ erg and progenitor radius $= 5 \times 10^{13}$ cm. The quoted limit is at $m_{A^0} = 150$ MeV. See their Fig. 2 for mass-dependent limits.

[64] CASTILLO 22 update CAPUTO 19 using the polarization measurements of the Crab Pulsar by the QUIJOTE MFI instrument and 20 Galactic pulsars from the PPTA project. See their Table 1 for the assumed local axion energy density ρ_A for each pulsar and their Fig. 7 for the mass-dependent limits in the range of 3×10^{-23} eV $\leq m_{A^0} \leq 10^{-19}$ eV.

[65] DEROCCO 22 uses the NuSTAR data to search for monochromatic X-ray lines produced by the decay of solar axions trapped on bound orbits. The quoted limit applies to $m_{A^0} \simeq$ 9 keV. They also derive limits in the plane of g_{Aee} and $G_{A\gamma\gamma}$. See their Figs. 2 and 4 for mass-dependent limits.

[66] DESSERT 22A look for an axion-induced linear polarization using data from multiple magnetic white dwarf stars. See their Figs. 1 and 8 for the mass-dependent limits.

[67] ECKNER 22 set limits by using sub-PeV diffuse gamma-ray data from HAWC and Tibet ASγ by assuming that gamma rays produced simultaneously with high-energy neutrinos from extragalactic sources suggested by IceCube are converted to axions in the magnetic field at the source and reconverted to gamma rays in the Galactic magnetic field. See their Fig. 4 for mass-dependent limits.

[68] FOSTER 22 is an update of FOSTER 20 in the list of limits on relic invisible axions. They search for axion-photon transitions generated by neutron stars in the Galactic center region. They use improved population models of the Galactic center neutron stars and a Navarro-Frenk-White (NFW) model of the galactic dark matter distribution. The quoted limit applies to $m_{A^0} \simeq$ 17–25 μeV. See their Fig. 1 for mass-dependent limits.

[69] KIRITA 22 update HOMMA 21 by increasing the laser energy and developing a background discrimination method using the beam cross-section dependence of the background originated from optical elements. The quoted limits applies to $m_{A^0} = 0.18$ eV. See their Fig. 11 for mass-dependent limits.

[70] LANGHOFF 22 set limits by considering the freeze-in production of axions coupled only to photons. The quoted limit applies to $m_{A^0} = 2$ MeV for the reheating temperature equal to 5 MeV. See their Fig. 1 for mass-dependent limits.

[71] LI 22 is analogous to LI 21B, and use the spectra of the blazar FSRQ 4C+21.35 measured by MAGIC, VERITAS, and Fermi-LAT. The quoted limit applies to $m_{A^0} \simeq 8 \times 10^{-10}$ eV. See their Fig. 1 for mass-dependent limits.

[72] LI 22C is analogous to LI 21B, and use the spectra of the blazars Mrk 421 and PG 1553+113 measured by MAGIC and Fermi-LAT. The quoted limit applies to $m_{A^0} \simeq 1 \times 10^{-8}$ eV. See their Fig. 4 for mass-dependent limits.

[73] LUCENTE 22 developed a method to correctly incorporate the effects of axions decaying into photons inside the core of horizontal-branch stars. They update CARENZA 20 by evaluating axion energy transfer in the range of axion mean free path where the diffusive energy transport and free streaming approximations are not applicable. See their Fig. 1 for the limits.

[74] BASU 21 searched for birefringence induced by axion dark matter using multiple images of the polarized source in the strongly gravitationally lensed system CLASS B1152+199. They assume the axion makes up all dark matter, and used the axion density in the emitting region, $\rho_A = 20$ GeV/cm^3. Limits between 9.2×10^{-11}–7.7×10^{-8} GeV^{-1} are obtained for $m_{A^0} = 3.6 \times 10^{-21}$–$4.6 \times 10^{-18}$eV. See their Fig. 2 for mass-dependent limits.

[75] BI 21 look for the gamma-ray spectral distortions induced by axion-photon oscillations in the presence of the Galactic magnetic field, using the measurements of sub-PeV gamma-rays from the Crab Nebula by the Tibet ASγ and HAWC experiments, together with MAGIC and HEGRA gamma-ray data. See their Fig. 3 for mass-dependent limits.

[76] DOLAN 21A study the effect of axion production on the evolution of asymptotic giant branch stars, and use the white-dwarf initial-final mass relation to set the limits. See their Fig. 1 for mass-dependent limits.

[77] GUO 21 is analogous to AJELLO 16, and use the Fermi-LAT and H.E.S.S. II measurements of PG 1553+113 and PKS 2155-304. See their Fig. 6 for mass-dependent limits.

[78] HOMMA 21 look for the production of axion resonance states and their subsequent stimulated decays by combining linearly polarized creation laser pulses and circularly polarized inducing laser pulses. The quoted limit is at $m_{A^0} \simeq 0.178$ eV. See their Fig. 14 for mass-dependent limits.

[79] LI 21B is analogous to AJELLO 16, and use the spectra of the blazar Mrk 421 measured by ARGO-YBJ and Fermi-LAT. They consider ALP-photon mixing in the magnetic fields of both the blazar jet and the Galaxy. The quoted limit applies to $m_{A^0} \simeq 1 \times 10^{-9}$ eV. See their Fig. 5 for mass-dependent limits.

[80] LLOYD 21 is analogous to FORTIN 18, and set limits on the product of the axion couplings to photons and nucleons as $g_{ANN}\, G_{A\gamma\gamma} \lesssim 4.6 \times 10^{-19}$ GeV^{-1} for $m_{A^0} \lesssim 10^{-5}$ eV by using the quiescent soft gamma-ray flux upper limits in five magnetars. We use $g_{ANN} = G_{AN}\, 2m_N$ to translate their limits. See their Table II and Fig. 3 for the limits.

[81] REGIS 21 look for monochromatic photons from axion decay, using the MUSE spectroscopic data on the Leo T dwarf spheroidal galaxy. They assume that axions make up all of dark matter and use the integrated dark matter density along the line of sight determined by observations.

[82] XIAO 21 use X-ray data from Betelgeuse to look for signals from axions produced in the stellar core that were converted to X-rays by the Galactic magnetic field. See their Fig. 1 for the mass-dependent limit.

[83] ABUDINEN 20 look for the process $e^+e^- \to \gamma A^0$ ($A^0 \to \gamma\gamma$) and set upper limits of around 10^{-3} over the mass range. The quoted limit is at $m_{A^0} = 0.3$ GeV. See their Fig. 5 for mass dependent limits.

[84] BANERJEE 20A look for axions produced from high-energy bremsstrahlung photons through the Primakoff effect with the electric field of the target nuclei. They exclude $G_{A\gamma\gamma} = 2 \times 10^{-4}$–$5 \times 10^{-2}$ GeV^{-1} for $m_{A^0} < 55$ MeV. See their Fig. 5 for mass-dependent limits.

[85] BUEHLER 20 look for the γ-ray transparency due to axion-photon oscillations using high-energy photon events from 79 sources in the Second Fermi-LAT Catalog of High-Energy Sources. The quoted limit is for the intergalactic magnetic field strength and coherence length of $B = 1$ nG and $s = 1$ Mpc. See their Figs. 4 and 5 for mass-dependent limits and for different magnetic-field parameters.

[86] CALORE 20 use the isotropic diffuse γ-ray background measured by the Fermi-LAT to constrain the γ-ray flux converted in the Galactic magnetic field from axions produced from past core-collapse supernovae. They also derive a limit on a heavier axion with $m_{A^0} \gtrsim$ keV decaying into two photons of $G_{A\gamma\gamma} \lesssim 5 \times 10^{-11}$ GeV^{-1} for $m_{A^0} = 5$ keV. See their Figs. 5 and 7 for the limits as well as limits in the presence of axion-nucleon couplings.

[87] CARENZA 20 extend the globular cluster bound of AYALA 14 to heavier masses ($m_{A^0} \leq$ a few 100 keV) by taking account of the coalescence process $\gamma + \gamma \to A^0$ as well as the decay of the ALP inside the stellar core. See their Fig.4 for mass-dependent limits.

[88] DENT 20A is analogous to GAO 20. The quoted limit is from their arXiv:2006.15118v3 (v2 is their published version), using the relativistic Hartree-Fock form factor. The limit is up to two times weaker than the published one. See Fig. 4 in their arXiv version 3 for the correlation between $G_{A\gamma\gamma}$ and g_{Aee} corresponding to the excess reported in APRILE 20.

[89] DEPTA 20 correct the underestimated D abundance in MILLEA 15, and derive robust cosmological bounds by allowing the reheating temperature, $N_{\rm eff}$, and neutrino chemical potential to vary. See their Fig. 6 for mass-dependent limits.

[90] DESSERT 20A use the NuSTAR data of the Quintuplet and Westerlund 1 super star clusters to look for X-rays converted in the Galactic magnetic field from the axions produced in stellar cores. See their Fig. 3 for the mass-dependent limits.

[91] ESTEBAN 20 show that the two anomalous ANITA events can be explained by the reflected radio pulses that are resonantly produced in the ionosphere via axion-photon conversion for $m_{A^0} \lesssim 1 \times 10^{-7}$ eV , if an axion clump passes the Earth about once a month. See their Fig.5 for the region consistent with this interpretation for different values of the axion density inside the clumps.

[92] GAO 20 correct the limit of APRILE 20 by including inverse Primakoff scattering in the XENON1T detector. The quoted limit is from their arXiv:2006.14598v4 (v3 is their published version), taking account of the atomic form factor of Xe as pointed out in ABE 20J. The limit is weaker by a factor of 1.5–2 than the published one. See Fig. 3 in their arXiv version 4 for correlation between $G_{A\gamma\gamma}$ and g_{Aee} corresponding to the excess reported in APRILE 20.

[93] KOROCHKIN 20 assume the axion makes up all dark matter, and look for a dip in the observed gamma-ray spectrum of the blazer 1ES 1218+304 by Fermi/LAT and VERITAS due to the extragalactic background light produced by the axion decay. Their analysis favors nonzero axion-induced absorption with $G_{A\gamma\gamma} = 3 \times 10^{-11}$–$2 \times 10^{-10}$ GeV^{-1} over a range of $m_{A^0} = 2$–18 eV. See their Fig. 1 for mass-dependent limits between $0.25 < m_{A^0} < 25$ eV.

[94] LUCENTE 20A study the SN 1987A energy-loss argument on the axion-like particle production. In addition to the Primakoff process, they take account of photon coalescence as well as gravitational trapping that become relevant at $m_{A^0} > 100$ MeV. See their Fig. 12 for the mass-dependent limit.

[95] MEYER 20 look for prompt γ-rays converted in the Galactic magnetic fields from axions produced via the Primakoff process in a sample of 20 extragalactic core-collapse supernovae. The limits assume a progenitor mass of 10 times the solar mass and certain models for the optical emission and the galactic magnetic field. See their Figs. 2 and 6 in the erratum for mass- and model-dependent limits.

[96] YAMAMOTO 20 look for X-ray photons converted by the Earth's magnetic field from the axions produced by the two-body decay of dark matter, and set the limits by using the Suzaku data. The quoted limit is for the monochromatic X-ray line from the galactic dark matter with lifetime $\tau = 4.32 \times 10^{17}$ sec. They also derive limits on the continuum spectrum from the extragalactic component. See their Fig. 7 for the limits.

[97] ALONI 19 used the data collected by the PRIMEX experiment to derive a limit based on a data-driven method. See their Fig. 2 for mass-dependent limits.

[98] CAPUTO 19 look for an oscillating variation of the polarization angle of the pulsar J0437-4715, where they assume the local axion energy density $\rho_A = 0.3$ GeV/cm^3. See their Fig. 2 for mass-dependent limits for 5×10^{-24} eV $\leq m_{A^0} \leq 2 \times 10^{-19}$ eV.

[99] FEDDERKE 19 look for a uniform reduction of the CMB polarization at large scales, which is induced by the oscillating axion background during CMB decoupling. The quoted limit is based on the assumption that axions make up all of the dark matter. See their Fig. 3 for mass-dependent limits for $m_{A^0} = 10^{-22}$–10^{-19} eV.

[100] IVANOV 19 look for the axion-induced periodic changes in the polarization angle of parsec-scale jets in active galactic nuclei observed by the MOJAVE program, where they use the axion energy density $\rho_A = 20$ GeV/cm^3. See their Fig. 6 for mass-dependent limits for 5×10^{-23} eV $\leq m_{A^0} \leq 1.2 \times 10^{-21}$ eV.

[101] LIANG 19 look for spectral irregularities in the spectrum of 10 bright H.E.S.S. sources in the Galactic plane, assuming photon-ALP mixing in the Galactic magnetic fields. See their Fig. 2 for mass-dependent limits with different Galactic magnetic field models.

[102] FORTIN 18 studied the conversion of axion-like particles produced in the core of a magnetar to hard X-rays in the magnetosphere. See their Fig. 5 for mass-dependent limits with different values of the magnetar core temperature.

[103] JAECKEL 18 study axions produced through the Primakoff process from SN 1987A, which subsequently decay into photon pairs. See their Fig. 1 for the mass-dependent limits in the range of $m_{A^0} = 0.01$–100 MeV.

[104] YAMAJI 18 search for axions with an x-ray LSW at Spring-8, using the Laue-case conversion in a silicon crystal. They also obtain $G_{A\gamma\gamma} < 4.2 \times 10^{-3}$ GeV^{-1} for $m_{A^0} < 10$ eV. See their Fig. 5 for mass-dependent limits.

[105] ZHANG 18 look for spectral irregularities in the spectrum of PKS 2155-304 measured by Fermi LAT, assuming photon-ALP mixing in the intercluster and Galactic magnetic fields. See their Figs. 2 and 3 for mass-dependent limits with different values of the intercluster magnetic field parameters.

[106] ADE 17 look for cosmic birefringence from axion-like particles using CMB polarization data taken by the BICEP2 and Keck Array experiments. They set a limit $G_{A\gamma\gamma} H_I < 7.2 \times 10^{-2}$ at 95 %CL for $m_{A^0} < 10^{-28}$ eV, where H_I is the Hubble parameter during inflation.

[107] ANASTASSOPOULOS 17 looked for solar axions by the CAST axion helioscope in the vacuum phase, and supersedes ANDRIAMONJE 07.

[108] DOLAN 17 update existing limits on $G_{A\gamma\gamma}$ for axion-like particles. The limits from the proton beam dump experiments in their Fig. 2 contained an error, and the corrected version is shown in Fig. 1 of DOLAN 21.

[109] INADA 17 search for axions with an x-ray LSW at Spring-8. See their Fig. 4 for mass-dependent limits.

[110] KOHRI 17 attributed to axion-photon oscillations the excess of cosmic infrared background observed by the CIBER experiment. See their Fig. 5 for the region preferred by their scenario.

[111] MARSH 17 is similar to WOUTERS 13, using Chandra observations of M87. See their Fig. 6 for mass-dependent limits.

[112] TIWARI 17 use observed limits of the cosmic distance-duality relation to constrain the photon–ALP mixing based on 3D simulations of the magnetic field configuration. The quoted value is for the averaged magnetic field of 1nG with a coherent length of 1 Mpc. See their Fig. 5 for mass-dependent limits.
[113] AJELLO 16 look for irregularities in the energy spectrum of the NGC1275 measured by Fermi LAT, assuming photon-ALP mixing in the intra-cluster and Galactic magnetic fields. See their Fig. 2 for mass-dependent limits.
[114] DELLA-VALLE 16 look for the birefringence induced by axion-like particles. See their Fig. 14 for mass-dependent limits.
[115] DELLA-VALLE 16 look for the dichroism induced by axion-like particles. See their Fig. 14 for mass-dependent limits.
[116] JAECKEL 16 use the LEP data of $Z \to 2\gamma$ and $Z \to 3\gamma$ to constrain the ALP production via $e^+e^- \to Z \to A^0\gamma\,(A^0 \to \gamma\gamma)$, assuming the ALP coupling with two hypercharge bosons. See their Fig. 4 for mass-dependent limits.
[117] LEEFER 16 derived limits by using radio-frequency spectroscopy of dysprosium and atomic clock measurements. See their Fig. 1 for mass-dependent limits as well as limits on Yukawa-type couplings of the scalar to the electron and nucleons.
[118] ANASTASSOPOULOS 15 search for solar chameleons with CAST and derived limits on the chameleon coupling to photons and matter. See their Fig. 12 for the exclusion region.
[119] ARIK 15 is analogous to ARIK 09, and search for solar axions for m_{A^0} around 0.2 and 0.4 eV. See their Figs. 1 and 3 for the mass-dependent limits.
[120] Based on OSQAR photon regeneration experiment. See their Fig. 6 for mass-dependent limits on scalar and pseudoscalar bosons.
[121] BRAX 15 derived limits on conformal and disformal couplings of a scalar to photons by searching for a chaotic absorption pattern in the X-ray and UV bands of the Hydra A galaxy cluster and a BL lac object, respectively. See their Fig. 8.
[122] HASEBE 15 look for an axion via a four-wave mixing process at quasi-parallel colliding laser beams. They also derived limits on a scalar coupling to photons $G_{S\gamma\gamma} < 2.62 \times 10^{-4}$ GeV^{-1} at $m_{S^0} = 0.15$ eV. See their Figs. 11 and 12 for mass-dependent limits.
[123] MILLEA 15 is similar to CADAMURO 12, including the Planck data and the latest inferences of primordial deuterium abundance. See their Fig. 3 for mass-dependent limits.
[124] VANTILBURG 15 look for harmonic variations in the dyprosium transition frequency data, induced by coherent oscillations of the fine-structure constant due to dilaton-like dark matter, and set the limits, $G_{S\gamma\gamma} < 6\times10^{-27}$ GeV^{-1} at $m_{S^0} = 6\times10^{-23}$ eV. See their Fig. 4 for mass-dependent limits between $1\times10^{-24} < m_{S^0} < 1\times10^{-15}$ eV.
[125] VINYOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations. See their Fig. 9.
[126] ARIK 14 is similar to ARIK 11. See their Fig. 2 for mass-dependent limits.
[127] AYALA 14 derived the limit from the helium-burning lifetime of horizontal-branch stars based on number counts in globular clusters.
[128] DELLA-VALLE 14 use the new PVLAS apparatus to set a limit on vacuum magnetic birefringence induced by axion-like particles. See their Fig. 6 for the mass-dependent limits.
[129] EJLLI 14 set limits on a product of primordial magnetic field and the axion mass using CMB distortion induced by resonant axion production from CMB photons. See their Fig. 1 for limits applying specifically to the DFSZ and KSVZ axion models.
[130] PUGNAT 14 is analogous to EHRET 10. See their Fig. 5 for mass-dependent limits on scalar and pseudoscalar bosons.
[131] REESMAN 14 derive limits by requiring effects of axion-photon interconversion on gamma-ray spectra from distant blazars to be no larger than errors in the best-fit optical depth based on a certain extragalactic background light model. See their Fig. 5 for mass-dependent limits.
[132] ABRAMOWSKI 13A look for irregularities in the energy spectrum of the BL Lac object PKS 2155–304 measured by H.E.S.S. The limits depend on assumed magnetic field around the source. See their Fig. 7 for mass-dependent limits.
[133] ARMENGAUD 13 is analogous to AVIGNONE 98. See Fig. 6 for the limit.
[134] BETZ 13 performed a microwave-based light shining through the wall experiment. See their Fig. 13 for mass-dependent limits.
[135] FRIEDLAND 13 derived the limit by considering blue-loop suppression of the evolution of red giants with 7–12 solar masses.
[136] MEYER 13 attributed to axion-photon oscillations the observed excess of very high-energy γ-rays with respect to predictions based on extragalactic background light models. See their Fig.4 for mass-dependent lower limits for various magnetic field configurations.
[137] WOUTERS 13 look for irregularities in the X-ray spectrum of the Hydra cluster observed by Chandra. See their Fig. 4 for mass-dependent limits.
[138] CADAMURO 12 derived cosmological limits on $G_{A\gamma\gamma}$ for axion-like particles. See their Fig. 1 for mass-dependent limits.
[139] PAYEZ 12 derive limits from polarization measurements of quasar light (see their Fig. 3). The limits depend on assumed magnetic field strength in galaxy clusters. The limits depend on assumed magnetic field and electron density in the local galaxy supercluster.
[140] ARIK 11 search for solar axions using ^{3}He buffer gas in CAST, continuing from the ^{4}He version of ARIK 09. See Fig. 2 for the exact mass-dependent limits.
[141] ALPS is a photon regeneration experiment. See their Fig. 4 for mass-dependent limits on scalar and pseudoscalar bosons.
[142] AHMED 09A is analogous to AVIGNONE 98.
[143] ARIK 09 is the ^{4}He filling version of the CAST axion helioscope in analogy to INOUE 02 and INOUE 08. See their Fig. 7 for mass-dependent limits.
[144] CHOU 09 use the GammeV apparatus in the afterglow mode to search for chameleons, (pseudo)scalar bosons with a mass depending on the environment. For pseudoscalars they exclude at 3σ the range 2.6×10^{-7} GeV$^{-1} < G_{A\gamma\gamma} < 4.2\times10^{-6}$ GeV^{-1} for vacuum m_{A^0} roughly below 6 meV for density scaling index exceeding 0.8.
[145] GONDOLO 09 use the all-flavor measured solar neutrino flux to constrain solar interior temperature and thus energy losses.
[146] LIPSS photon regeneration experiment, assuming scalar particle S^0. See Fig. 4 for mass-dependent limits.
[147] CHOU 08 perform a variable-baseline photon regeneration experiment. See their Fig. 3 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06.
[148] FOUCHE 08 is an update of ROBILLIARD 07. See their Fig. 12 for mass-dependent limits.
[149] INOUE 08 is an extension of INOUE 02 to larger axion masses, using the Tokyo axion helioscope. See their Fig. 4 for mass-dependent limits.
[150] ZAVATTINI 08 is an upgrade of ZAVATTINI 06, see their Fig. 8 for mass-dependent limits. They now exclude the parameter range where ZAVATTINI 06 had seen a positive signature.
[151] ANDRIAMONJE 07 looked for Primakoff conversion of solar axions in 9T superconducting magnet into X-rays. Supersedes ZIOUTAS 05.
[152] ROBILLIARD 07 perform a photon regeneration experiment with a pulsed laser and pulsed magnetic field. See their Fig. 4 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06 with a CL exceeding 99.9%.
[153] ZAVATTINI 06 propagate a laser beam in a magnetic field and observe dichroism and birefringence effects that could be attributed to an axion-like particle. This result is now excluded by ROBILLIARD 07, ZAVATTINI 08, and CHOU 08.
[154] INOUE 02 looked for Primakoff conversion of solar axions in 4T superconducting magnet into X ray.
[155] MORALES 02B looked for the coherent conversion of solar axions to photons via the Primakoff effect in Germanium detector.
[156] BERNABEI 01B looked for Primakoff coherent conversion of solar axions into photons via Bragg scattering in NaI crystal in DAMA dark matter detector.
[157] ASTIER 00B looked for production of axions from the interaction of high-energy photons with the horn magnetic field and their subsequent re-conversion to photons via the interaction with the NOMAD dipole magnetic field.
[158] MASSO 00 studied limits on axion-proton coupling using the induced axion-photon coupling through the proton loop and CAMERON 93 bound on the axion-photon coupling using optical rotation. They obtained the bound $g_p^2/4\pi < 1.7\times10^{-9}$ for the coupling $g_p\overline{p}\gamma_5 p\phi_A$.
[159] AVIGNONE 98 result is based on the coherent conversion of solar axions to photons via the Primakoff effect in a single crystal germanium detector.
[160] Based on the conversion of solar axions to X-rays in a strong laboratory magnetic field.
[161] Experiment based on proposal by MAIANI 86.
[162] Experiment based on proposal by VANBIBBER 87.
[163] LAZARUS 92 experiment is based on proposal found in VANBIBBER 89.
[164] RUOSO 92 experiment is based on the proposal by VANBIBBER 87.
[165] SEMERTZIDIS 90 experiment is based on the proposal of MAIANI 86. The limit is obtained by taking the noise amplitude as the upper limit. Limits extend to $m_{A^0} = 4\times10^{-3}$ where $G_{A\gamma\gamma} < 1\times10^{-4}$ GeV^{-1}.

Limit on Invisible A^0 (Axion) Electron Coupling

The limit is for $g_{Aee}\,\phi_A\,\overline{e}(i\gamma_5)e$, or equivalently, the dipole-dipole potential $-\frac{g^2_{Aee}}{16\pi m^2_e}((\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2) - 3(\boldsymbol{\sigma}_1\cdot\boldsymbol{n})(\boldsymbol{\sigma}_2\cdot\boldsymbol{n}))/r^3$ where $\boldsymbol{n}=\boldsymbol{r}/r$ and the sign of the potential was corrected based on DAIDO 17.

[1] ALBAKRY 25 report a search with the SuperCDMS detector for axion-like particle dark matter absorption on silicon. See their Fig. 4 for mass-dependent limits.

[2] APRILE 25A presents results from a search with XENONnT for axion-like particle dark matter absorption on electrons in liquid xenon. See their Fig. 5 for mass-dependent limits.

[3] LI 25 search for MeV-mass axion-like particles coupled to electrons making up the dark matter halo of the galaxy that could be absorbed by liquid xenon in the PandaX detector. The local density $\rho_A = 0.3$ GeV/cm^3 is assumed. The quoted limit is at $m_{A^0} = 150$ keV. See their Fig. 3 for mass-dependent limits.

[4] MIRZAKHANI 25 search for axion-like particles coupled to electrons using the MINER reactor neutrino experiment. Their search assumes the axions would be produced via Compton scattering of the reactor photon flux, which then either decay to an electron-positron pair or undergo inverse Compton scattering in the detector. See Fig. 10 for mass-dependent limits.

[5] MONTEFALCONE 25 place bounds on axion-like particle dark matter coupled to electrons using Planck CMB data. They search for the effects of anomalous energy injection on CMB anisotropies due to electron-loop induced ALP decays to two photons. See their Fig. 6 for mass-dependent limits.

[6] PARK 25 present a search for axion-like particles from the NEON reactor neutrino experiment. Axions would be produced through the Compton scattering of electrons with the large MeV photon flux from the reactor and then subsequently scatter or decay to an electron-positron pair in the detector. The quoted limit is at $m_{A^0} = 1.02$ MeV. See their Fig. 3 for mass-dependent limits.

[7] TROITSKY 25 sets a bound on axions coupled to electrons through their cooling effect on red giants and helium-burning stars in seven globular clusters observed by the Gaia survey. The bound is independent of the axion mass up to approximately values close to the stellar core temperatures.

[8] ZENG 25 place a bound on axions emitted by the Sun due to a nonzero axion-electron coupling using electronic recoil data collected by the PandaX detector. The limit is independent of the axion mass up to around the core temperature of the Sun.

[9] ZENG 25 place a bound on keV-scale axion-like particles making up the halo of the galaxy by searching for electron recoil events in the PandaX detector. See Fig. 3(e) for mass-dependent limits.

[10] AGOSTINI 24A report a search for axion-like particle dark matter absorption and dark Compton scattering on germanium, generating electron events in the GERDA experiment. The quoted limit is at $m_{A^0} = 150$ keV. See their Fig. 7 for mass-dependent limits.

[11] ARNQUIST 24 use the MAJORANA DEMONSTRATOR to search for high-mass axion-like particle dark matter absorption by Germanium. See Fig. 5 for mass-dependent limits.

[12] AALBERS 23A look for solar axions from the ABC processes. See their Fig. 6 for the limits.

[13] AALBERS 23A look for absorption of axion dark matter. The quoted limit is for $m_{A^0} \simeq 1.4$ keV. The local density $\rho_A = 0.3$ GeV/cm^3 is assumed. See their Fig. 7 for mass-dependent limits.

[14] ADHIKARI 23 is an update of ADHIKARI 19B.

[15] ADHIKARI 23A look for absorption and Compton-like processes of axion dark matter. The quoted limit is for $m_{A^0} \simeq 37$ keV. See their Fig. 4 for mass-dependent limits.

[16] AGNES 23A look for absorption of axion dark matter. The quoted limit is for $m_{A^0} \simeq 0.25$ keV. The local density $\rho_A = 0.3$ GeV/cm^3 is assumed. See their Fig. 2 for mass-dependent limits.

[17] APRILE 23B look for an absorption signal of axions within ± 500 seconds of the GW signals, including the neutron star merger GW170817. They set a 90% CL upper limit on the product of coincident fluence and cross section of axions to be less than 10^{-29} cm^2/cm^2 in the recoil energy range of 5.5–210 keV$_{ee}$.

[18] CAPOZZI 23A search for axions produced in electromagnetic showers in proton beam dumps and fixed target experiments. In this case, they reinterpret MiniBoone data. Quoted limit applies at 1 MeV. See Fig. 8 for mass-dependent limits.

[19] WADEKAR 23 use the Leo T dwarf galaxy's interstellar medium to derive limits, requiring the heating rate from axion dark matter absorption into hydrogen atoms and two-photon decay to be less than the astrophysical cooling rate. See Fig. 2 for limits over $m_{A^0} = 1$–100 keV, which loosen for lighter masses.

[20] APRILE 22 extend APRILE 19D to lower masses by removing the background of ionization signals correlated with high-energy events. The quoted limit applies to $m_{A^0} = 0.1$ keV. See their Fig. 15 for mass-dependent limits.

[21] APRILE 22B is an update of APRILE 20, and set the limit, $g_{Aee} \lesssim 9 \times 10^{-15}$–$3 \times 10^{-13}$. The quoted limit applies to $m_{A^0} = 2$ keV. They exclude the XENON1T excess found in APRILE 20. See their Fig. 6 for mass-dependent limits.

[22] APRILE 22B is an update of APRILE 20. They exclude the XENON1T excess found in APRILE 20. The quoted limit holds for small $G_{A\gamma\gamma}$. See their Fig. 6 for correlation between g_{Aee} and $G_{A\gamma\gamma}$.

[23] DESSERT 22 is an update of DESSERT 19. They used the Chandra observation of the magnetic white dwarf RE J0317-853 to look for converted X-rays in the magnetosphere from axions produced in the core through electron bremsstrahlung. They obtained the limit, $g_{Aee} \cdot G_{A\gamma\gamma} < 1.3 \times 10^{-25}$ GeV^{-1} at 95% CL for $m_{A^0} \lesssim 10^{-5}$ eV. See their Fig. 1 for mass-dependent limits.

[24] IKEDA 22 look for magnons excited by dark matter axions, using data taken with a hybrid quantum system consisting of a superconducting qubit and a spherical ferrimagnetic crystal. The quoted limit assumes the local dark matter density $\rho_A = 0.45$ GeV/cm^3 and the velocity $v = 220$ km/sec. See their Fig. 4 for the limits.

[25] LANGHOFF 22 set limits by considering the freeze-in production of axions coupled to electrons without anomalous coupling to photons. The quoted limit applies to $m_{A^0} = 15$ MeV for the reheating temperature equal to 5 MeV. See their Fig. 2 for mass-dependent limits.

[26] WANG 22C use the spin-amplifier based on hyperpolarized ^{129}Xe to set limits on the product of the axion couplings to electrons and nucleons as $g_{Aee}\, g_{Ann} < 4 \times 10^2$ (95 % CL) at $m_{A^0} = 0.1$ meV. Here g_{Ann} is the dimensionless axion-neutron coupling. See their Fig. 4 for the mass-dependent limits.

[27] XIAO 22 extend XIAO 21 in the list of photon coupling limits by including the production of axions from Compton and bremsstrahlung processes, and set limits on the product of the axion couplings to electrons and photons as $G_{A\gamma\gamma}\, g_{Aee} < 0.4$–$2.8 \times 10^{-24}$ GeV^{-1} (95 % CL) for $m_{A^0} < 3.5 \times 10^{-11}$eV. See their Fig. 5 for the limits. They are comparable to those of DESSERT 19 and more restrictive than the CAST bounds of BARTH 13.

[28] CALORE 21 consider the production of axions from Galactic and extragalactic SNe via nucleon-nucleon bremsstrahlung and their subsequent decay into electron-positron pairs, and exclude the range of $g_{Aee} \simeq 10^{-19}$–10^{-11} at $g_{App} = 10^{-9}$ for $m_{A^0} = 3$–30 MeV. See their Fig. 7 for the limits.

[29] LUCENTE 21 study the axion production in a supernova via electron-proton bremsstrahlung and electron-positron fusion, and exclude the range of $g_{Aee} \simeq 2 \times 10^{-9}$–$5.5 \times 10^{-7}$ for masses less than 1 MeV. See their Fig. 12 for the mass-dependent limits extending up to 150 MeV. This limit was corrected in the erratum.

[30] AGOSTINI 20 is analogous to AHMED 09A. The quoted limit applies to $m_{A^0} = 150$ keV. Their limits in their Fig. 3 were later found to be incorrect due to an error of their Eqs. (1) and (2). See Fig. 3 in AGOSTINI 22A for the corrected limits.

[31] AMARAL 20 use a second-generation SuperCDMS high-voltage eV-resolution detector to set limits on dark-matter axion absorption. The quoted limit is for $m_{A^0} \simeq 17$ eV. The local density $\rho_A = 0.3$ GeV/cm^3 is assumed. See their Fig. 3 for mass-dependent limits.

[32] APRILE 20 is an update of APRILE 17B where they look for an absorption signal of axion dark matter. They obtained the limit, $g_{Aee} \lesssim 2 \times 10^{-14}$–$1 \times 10^{-12}$ at 90%CL for $m_{A^0} = 1$–200 keV. They also found an excess over known backgrounds, which favors the mass $m_{A^0} = 2.3 \pm 0.2$ keV with a $3\,\sigma$ significance. See their Fig. 10 for mass-dependent limits.

[33] APRILE 20 look for solar axions from the ABC interactions, the Primakoff conversion, and the 14.4 keV M1 transition of ^{57}Fe, and set limits on g_{Aee}, $G_{A\gamma\gamma}$, g_{ANN}, and their products. An excess is observed at low energies between 2 and 3 keV. See their Fig.8 for correlation between the couplings. The quoted limit applies to the case of vanishing $G_{A\gamma\gamma}$ and g_{ANN}.

[34] ARALIS 20 is analogous to AHMED 09A. The quoted limit applies to $m_{A^0} = 0.3$ keV. The limits at masses above 3 keV in their Fig. 9 was later found to be incorrect due to an error in their analysis. See Fig. 2 in erratum for the corrected limits.

[35] CAPOZZI 20 obtains a limit on the axion-electron coupling from the brightness of the tip of the red-giant branch in ω Centauri. A similar limit of $< 1.6 \times 10^{-13}$ is obtained in NGC 4258.

[36] CRESCINI 20 is an update of CRESCINI 18. They assume a local axion dark matter density, $\rho_A = 0.3$ GeV/cm^3. See their Fig.4 for the limits.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

[37] GHOSH 20A study thermal production of axion via coupling to leptons in the early universe and estimate its contribution to $\Delta N_{\rm eff}$. The quoted limit is for $\Delta N_{\rm eff} < 0.5$. See their Fig. 7 for their mass-dependent limits.

[38] STRANIERO 20 is analogous to CAPOZZI 20, with 22 galactic globular clusters used to derive the limit.

[39] WANG 20A is an update of LIU 17A. See their Fig. 9.

[40] WANG 20A is an update of LIU 17A. They assume a local axion dark matter density, $\rho_A = 0.3$ GeV/cm^3. See their Fig. 10 for limits between $0.185 < m_{A^0} < 10$ keV.

[41] ADHIKARI 19B is analogous to LIU 17A.

[42] APRILE 19D is analogous to APRILE 17B, but they use only ionization signals. The quoted limit applies to $m_{A^0} = 0.7$ keV. See their Fig. 5(e) for mass-dependent limits.

[43] DESSERT 19 used the Suzaku observations of a magnetic white dwarf (RE J0317-853) to look for X-ray signatures converted from axions in the surrounding magnetic fields. They obtained the limit, $g_{Aee} \cdot G_{A\gamma\gamma} < 1.6 \times 10^{-24}$ GeV^{-1} at 95%CL for $m_{A^0} \lesssim 10^{-5}$ eV. See their Fig. 2 for mass-dependent limits.

[44] TERRANO 19 look for the axion-induced oscillating magnetic field acting on the electron spin, using data taken with a rotating torsion pendulum containing polarized electrons. The quoted limit applies to $m_{A^0} = 10^{-23}$–10^{-18} eV and assumes a local axion dark matter density, $\rho_A = 0.45$ GeV/cm^3. See their Fig. 5 for mass-dependent limits.

[45] ABE 18F is an update of ABE 14F. The quoted limit applies to $m_{A^0} = 60$ keV. See their Fig. 5 for mass-dependent limits.

[46] ARMENGAUD 18 is analogous to LIU 17A.

[47] ARMENGAUD 18 is analogous to AHMED 09A. See the left panel of Fig. 5 for mass-dependent limits.

[48] CRESCINI 18 look for collective excitations of the electron spins caused by dark matter axions. The quoted limit assumes the local dark matter density, $\rho_A = 0.45$ GeV/cm^3.

[49] FICEK 18 use the measurements of the hyperfine structure of antiprotonic helium to constrain a dipole-dipole potential between electron and antiproton. See their Fig. 3 for limits on various spin- and velocity-dependent potentials.

[50] ABGRALL 17 is analogous to AHMED 09A using the MAJORANA DEMONSTRATOR. See their Fig. 2 for limits between $6 \text{ keV} < m_{A^0} < 97$ keV.

[51] AKERIB 17B is analogous to LIU 17A.

[52] AKERIB 17B is analogous to AHMED 09A. See their Fig. 7 for mass-dependent limits.

[53] APRILE 17B is analogous to AHMED 09A. They found a bug in their code and needed to correct the limits in Fig. 7 of APRILE 14B. See their Fig. 1 for the corrected limits between $1 \text{ keV} < m_{A^0} < 40$ keV.

[54] FICEK 17 look for spin-dependent interactions between electrons by comparing precision spectroscopic measurements in ^{4}He with theoretical calculations. See their Fig. 1 for limits up to $m_{A^0} = 10$ keV.

[55] FU 17A is analogous to LIU 17A. See their Fig. 3 for mass-dependent limits.

[56] FU 17A is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.

[57] LIU 17A is analogous to AHMED 09A. See their Fig. 9 for limits between $0.25 \text{ keV} < m_{A^0} < 20$ keV.

[58] LIU 17A look for solar axions produced from Compton, bremsstrahlung, atomic-recombination and deexcitation channels, and set a limit for $m_{A^0} < 1$ keV.

[59] LUO 17 use a recent measurement of the dipole-dipole interaction between two iron atoms at the nanometer scale and set a limit for $m_{A^0} < 1$ keV. See their Fig. 3 for mass-dependent limits.

[60] BATTICH 16 is analogous to CORSICO 16 and used the pulsating DB white dwarf PG 1351+489.

[61] CORSICO 16 studied the cooling rate of the pulsating DA white dwarf L19-2 based on an asteroseismic model.

[62] YOON 16 look for solar axions with the axio-electric effect in CsI(Tl) crystals and set a limit for $m_{A^0} < 1$ keV.

[63] TERRANO 15 used a torsion pendulum and rotating attractor with 20-pole electron-spin distributions. See their Fig. 4 for a mass-dependent limit up to $m_{A^0} = 500$ μeV.

[64] ABE 14F set limits on the axioelectric effect in the XMASS detector assuming the pseudoscalar constitutes all the local dark matter. See their Fig. 3 for limits between $m_{A^0} = 40$–120 keV.

[65] APRILE 14B look for solar axions using the XENON100 detector.

[66] APRILE 14B is analogous to AHMED 09A. Their Fig. 7 was later found to be incorrect due to a bug in their code. See Fig. 1 in APRILE 17B for the corrected limits.

[67] DERBIN 14 is an update of DERBIN 13 with a BGO scintillating bolometer. See their Fig. 3 for mass-dependent limits.

[68] MILLER-BERTOLAMI 14 studied the impact of axion emission on white dwarf cooling in a self-consistent way.

[69] ABE 13D is analogous to DERBIN 12, using the XMASS detector.

[70] ARMENGAUD 13 is similar to AALSETH 11. See their Fig. 10 for limits between $3 \text{ keV} < m_{A^0} < 100$ keV.

[71] ARMENGAUD 13 is similar to DERBIN 12, and take account of axio-recombination and axio-deexcitation effects. See their Fig. 12 for mass-dependent limits.

[72] BARTH 13 search for solar axions produced by axion-electron coupling, and obtained the limit, $g_{Aee} \cdot G_{A\gamma\gamma} < 8.1 \times 10^{-23}$ GeV^{-1} at 95%CL.

[73] DERBIN 13 looked for 5.5 MeV solar axions produced in $pd \to {}^3\text{He}\, A^0$ in a BGO detector through the axioelectric effect. See their Fig. 4 for mass-dependent limits.

[74] HECKEL 13 studied the influence of 2 or 4 stationary sources each containing 6.0×10^{24} polarized electrons, on a rotating torsion pendulum containing 9.8×10^{24} polarized electrons. See their Fig. 4 for mass-dependent limits.

[75] VIAUX 13A constrain axion emission using the observed brightness of the tip of the red-giant branch in the globular cluster M5.

[76] CORSICO 12 attributed the excessive cooling rate of the pulsating white dwarf R548 to emission of axions with $g_{Aee} \simeq 4.8 \times 10^{-13}$.

[77] DERBIN 12 look for solar axions with the axio-electric effect in a Si(Li) detector. The solar production is based on Compton and bremsstrahlung processes.

[78] AALSETH 11 is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.

[79] AHMED 09A assume keV-mass pseudoscalars are the local dark matter and constrain the axio-electric effect in the CDMS detector. See their Fig. 5 for mass-dependent limits.

[80] DAVOUDIASL 09 use geophysical constraints on Earth cooling by axion emission.

[81] These experiments measured induced magnetization of a bulk material by the spin-dependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor. The sign of the limit set by CHUI 93 is opposite to that of the axion-mediated dipole-dipole potential.

[82] These experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either of them. The limits reflect the corrected sign of the dipole-dipole potential.

[83] WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.

Invisible A^0 (Axion) Limits from Nucleon Coupling

Limits are for the axion mass in eV.

[1] ALONSO-GONZALEZ 25 use Super-Kamiokade data to search for the diffuse flux of axion-like particles produced in galactic core-collapse supernovae via the interaction with protons in the detector, $A^0 p \to p\gamma$. They set bounds on axion-proton couplings between a minimum and maximum of 2×10^{-5}–2×10^{-4} up to axion masses of 70 MeV, see their Fig. 4. ALONSO-GONZALEZ 25A details an erratum for this publication.

[2] ARIAS-ARAGON 25 use Borexino data to search for axion-induced pair production and inverse Compton scattering due to the flux of 5.5 MeV axions from proton-deuteron fusion in the Sun. They constrain the combination of axion-electron and axion-nucleon couplings for $m_{A^0} \lesssim 1$ MeV as shown in their Fig. 4.

[3] BASILICO 25 use Borexino data to search for the flux of 5.5 MeV axions produced through proton-deuteron fusion in the Sun, which can lead to detectable signals in the detector through axion decay to two photons, Primakoff and Compton conversion to photons, and the liberation of electrons through the axio-electric effect. They set bounds on the product of the axion-electron and axion-nucleon couplings, and the product of the axion-photon and axion-nucleon couplings, for $m_{A^0} < 1$ MeV.

[4] GENG 25 use a public electron recoil dataset from the XENONnT collaboration to search for events caused by the flux of 14.4 keV axions produced in M1 transitions of ^{57}Fe nuclei in the solar interior. They set limits on the product of the axion-photon and axion-nucleon couplings and the product of the axion-electron and axion-nucleon couplings for axion masses below 14.4 keV.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[5] WALTER 25 report results from a demonstrator for the CASPEr-Gradient experiment, which in this case used proton nuclear magnetic resonance spectroscopy of methanol to search for axion-like particle dark matter coupled to protons. They are sensitive in a narrow window around an ALP mass of 5.576741 neV. See their Fig. 3 for mass-dependent limits.

[6] ZHANG 25A set limits on dark matter axion-like particles coupled to nucleons in the 1×10^{-24}–5×10^{-21} eV mass range by reanalyzing data from a Helium-3/Xenon-129 comagnetometer experiment originally performed to test for Lorentz and CPT violations. See their Fig. 3 for mass-dependent limits.

[7] LELLA 24 update constraints on the axion-proton coupling from supernova 1987A based on the SN cooling argument (including a treatment of the trapping regime) as well as the non-observation of any coincident axion-induced events in the Kamiokande II neutrino detector. They exclude QCD axion models above 0.01 eV, and axion-like particles in a window that extends up to 300 MeV. See their Fig. 3 for mass-dependent limits.

[8] SU 24 search for an axion-mediated dipole-dipole force between two separated spin-polarized samples of ^{129}Xe gas. They set limits on the axion-neutron coupling for axion masses between 3.2 and 24.3 μeV. See their Fig. 4(b) for mass-dependent limits.

[9] KARANTH 23 utilized an in-plane polarized deuteron beam in a storage ring to constrain the axion-induced oscillating EDM of the deuteron for $m_{A^0} = 0.496$–0.502 neV. Assuming axions account for all dark matter with $\rho_A \simeq 0.55$ GeV/cm^3, they derived constraints on axion couplings to the deuteron EDM operator, gluons, and the deuteron spin. For detailed limits, see their Figs. 19–21.

[10] LEE 23 analyzed data from a K–^{3}He comagnetometer, accounting for stochastic effects, to limit the axion-neutron coupling $g_{Ann} < 2.4\times10^{-10}$ GeV^{-1} at 95% CL for m_{A^0} = 0.4–4 feV. They assumed axions form all dark matter with a density of 0.3 GeV/cm^3. See their Fig. 5 for the limits.

[11] BUSCHMANN 22 studied the axion emission from five neutron stars with ages $\sim 10^5$–10^6 years, comparing the simulation with axions to age and luminosity measurements. The mass bound assumes the KSVZ axion model with $C_p = -0.47$ and $C_n = -0.02$. See their Fig. 3 for the limits on the DFSZ axion model.

[12] GAVRILYUK 22 look for solar axions from the ABC interactions with the experimental setup similar to GAVRILYUK 15. The mass bound assumes the KSVZ axion model, $S = 0.5$, and $m_u/m_d = 0.56$.

[13] SCHULTHESS 22 look for a time-oscillating neutron EDM caused by the coupling between axion dark matter and gluons, using a Ramsey-type apparatus for a cold neutron beam. See their Fig. 4 for limits in the range of $m_{A^0} = 10^{-19}$–4×10^{-12} eV.

[14] AYBAS 21 limits the axion couplings to the nucleon EDM and the nucleons as $g_{ANN\gamma} < 9.5\times10^{-4}$ GeV^{-2} and $g_{ANN}/2m_N < 0.28$ GeV^{-1} (95 % CL) for $m_{A^0} = 162$–166 neV, based on a measurement of ^{207}Pb solid-state NMR in a polarized ferroelecrtric crystal. Here m_N is the nucleon mass and g_{ANN} is the dimensionless axion-nucleon coupling. They assume that axions make up all the dark matter with $\rho_A \simeq 0.46$ GeV/cm^3. See their Fig. 3 for the limits.

[15] BHUSAL 21 looked for 5.5 MeV solar axions produced by $pd \to {}^3\mathrm{He}\,A^0$ through the axion-induced dissociation of deuterons by using SNO data, and set a limit on the isovector axion-nucleon coupling, $|g^3_{aN}| < 2\times10^{-5}$ GeV^{-1}, which is equivalent to $|g_{Ann} - g_{App}| < 4\times10^{-5}$ in terms of the dimensionless axion-nucleon couplings.

[16] JIANG 21 use the spin-amplifier based on hyperpolarized ^{129}Xe gas to set limits on the axion couplings to nucleons as $g_{ANN}/2m_N < 3.2\times10^{-9}$ GeV^{-1} (95 % CL) at $m_{A^0} = 52.94$ feV, and comparable limits in the mass range of 8.3–744 feV. Here m_N is the nucleon mass and g_{ANN} is the dimensionless axion-nucleon coupling. They assume that axions make up all the dark matter with $\rho_A \simeq 0.4$ GeV/cm^3. See their Fig. 4b for the limits.

[17] ROUSSY 21 look for a time-oscillating EDM of molecular ions HfF$^+$ induced by axion dark matter couplings to gluons. See their Fig. 3 for limits in the range of $m_{A^0} = 10^{-22}$–10^{-15} eV.

[18] ZHANG 21B use the gravitational waves from the binary neutron star inspiral GW170817 to look for a type of axion whose mass is suppressed due to cancellation with additional contributions. They exclude $1.6\times10^{16} < f_A < 10^{18}$ GeV at 3 σ for $m_{A^0} \lesssim 10^{-13}$ eV. See their Fig. 1 for mass-dependent limits.

[19] ABDELHAMEED 20 look for the resonant excitation of ^{169}Tm (8.41 keV) by solar axions produced via the Primakoff effect. The mass bound assumes the KSVZ axion model, $S = 0.5$, and $m_u/m_d = 0.56$. They set a limit on the product of axion couplings to photons and nucleons as $G_{A\gamma\gamma} \cdot g_{App} < 1.44\times10^{-14}$ GeV^{-1} (90 % CL).

[20] ABDELHAMEED 20 look for the resonant excitation of ^{169}Tm (8.41 keV) by solar axions produced via the axion-electron coupling. They set a limit on the product of axion couplings to electrons and nucleons as $g_{Aee} \cdot g_{App} < 2.81\times10^{-16}$ (90 % CL).

[21] APRILE 20 look for solar axions from the ABC interactions, the Primakoff conversion, and the 14.4 keV M1 transition of ^{57}Fe. An excess is observed at low energies between 2 and 3 keV. See their Fig.8 for correlation between the couplings.

[22] KLIMCHITSKAYA 20 use the measurement of the Casimir force between a Au-coated microsphere and a SiC plate to constrain the force due to two-axion exchange for 17.8 $< m_{A^0} <$ 100 eV. See their Fig. 2 for mass-dependent limits.

[23] WANG 20A is an update of LIU 17A. The limit assumes the DFSZ axion. See their Fig. 7 for the limit on product of axion couplings to electrons and nucleons.

[24] LEINSON 19 is analogous to BEZNOGOV 18, but estimating the axion luminosity based on the Tolman's analytic solution to the Einstein equations of spherical fluids in hydrostatic equilibrium. The dimensionless axion-neutron coupling is constrained as $g_{Ann} < 1.0\times10^{-10}$.

[25] LLOYD 19 is analogous to BERENJI 16. They highlight that the limit obtained with this technique strongly depends on the assumed NS core temperature.

[26] SMORRA 19 look for spin-precession effects from ultra-light axion dark matter in the $\overline{p}$ spin-flip resonance data. Assuming $\rho_A = 0.4$ GeV/cm^3, they constrain the dimensionless axion-antiproton coupling as $g_{A\overline{p}\overline{p}} < 2$–$9$ at 95% CL for $m_{A^0} = 2\times10^{-23}$–$4\times10^{-17}$ eV. See the right panel of their Fig. 3.

[27] WU 19 look for axion-induced time-oscillating features of the NMR spectrum of acetonitrile-2-^{13}C. Assuming $C_p = C_n$ and $\rho_A = 0.4$ GeV/cm^3, they constrain the dimensionless axion-nucleon coupling as $g_{ANN} < 6\times10^{-5}$ for $m_{A^0} = 10^{-21}$–1.3×10^{-17} eV. Note that the limits for $m_{A^0} < 10^{-21}$ eV in their Fig. 3(a) should be weaker than those for heavier masses. See ADELBERGER 19 and WU 19C on this issue.

[28] AKHMATOV 18 is an update of GAVRILYUK 15.

[29] ARMENGAUD 18 is analogous to ALESSANDRIA 13. The quoted limit assumes the DFSZ axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.

[30] BEZNOGOV 18 constrain the axion-neutron coupling by assuming that thermal evolution of the hot neutron star HESS J1731-347 is dominated by the lowest possible neutrino emission. The quoted limit assumes the KSVZ axion with the effective Peccei-Quinn charge of the neutron $C_n = -0.02$. The dimensionless axion-neutron couling is constrained as $g_{Ann} < 2.8\times10^{-10}$.

[31] GAVRILYUK 18 look for the resonant excitation of ^{83}Kr (9.4 keV) by solar axions produced via the Primakoff effect. The mass bound assumes $m_u/m_d = 0.56$ and $S = 0.5$.

[32] HAMAGUCHI 18 studied the axion emission from the neutron star in Cassiopeia A based on the minimal cooling scenario which explains the observed rapid cooling rate. The quoted limit corresponds to $f_A > 5\times10^8$ GeV obtained for the KSVZ axion with $C_p = -0.47$ and $C_n = -0.02$.

[33] ABEL 17 look for a time-oscillating neutron EDM and an axion-wind spin-precession effect respectively induced by axion dark matter couplings to gluons and nucleons. See their Fig. 4 for limits in the range of $m_{A^0} = 10^{-24}$–10^{-17} eV.

[34] ABGRALL 17 limit assumes the hadronic axion model used in ALESSANDRIA 13. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.

[35] FU 17A look for the 14.4 keV ^{57}Fe solar axions. The limit assumes the DFSZ axion model. See their Fig. 3 for mass-dependent limits on the axion-electron coupling. Notice that in this figure the DFSZ and KSVZ lines should be interchanged.

[36] KLIMCHITSKAYA 17A use the differential measurement of the Casimir force between a Ni-coated sphere and Au and Ni sectors of the structured disc to constrain the axion coupling to nucleons for 2.61 meV $< m_{A^0} <$ 0.9 eV. See their Figs. 1 and 2 for mass dependent limits.

[37] LIU 17 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 6(b) for the limit on product of axion couplings to electrons and nucleons.

[38] BERENJI 16 used the Fermi LAT observations of neutron stars to look for photons from axion decay. They assume the effective Peccei-Quinn charge of the neutron $C_n = 0.1$ and a neutron-star core temperature of 20 MeV.

[39] GAVRILYUK 15 look for solar axions emitted by the M1 transition of ^{83}Kr (9.4 keV). The mass bound assumes $m_u/m_d = 0.56$ and $S = 0.5$.

[40] KLIMCHITSKAYA 15 use the measurement of differential forces between a test mass and rotating source masses of Au and Si to constrain the force due to two-axion exchange for $1.7\times10^{-3} < m_{A^0} < 0.9$ eV. See their Figs. 1 and 2 for mass dependent limits.

[41] BEZERRA 14 use the measurement of the thermal Casimir-Polder force between a Bose-Einstein condensate of ^{87}Rb atoms and a SiO_2 plate to constrain the force mediated by exchange of two pseudoscalars for 0.1 meV $< m_{A^0} <$ 0.3 eV. See their Fig. 2 for the mass-dependent limit on pseudoscalar coupling to nucleons.

[42] BEZERRA 14A is analogous to BEZERRA 14. They use the measurement of the Casimir pressure between two Au-coated plates to constrain pseudoscalar coupling to nucleons for 1×10^{-3} eV $< m_{A^0} <$ 15 eV. See their Figs. 1 and 2 for the mass-dependent limit.

[43] BEZERRA 14B is analogous to BEZERRA 14. BEZERRA 14B use the measurement of the normal and lateral Casimir forces between sinusoidally corrugated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for 1 eV $< m_{A^0} <$ 20 eV. See their Figs. 1–3 for mass-dependent limits.

[44] BEZERRA 14C is analogous to BEZERRA 14. They use the measurement of the gradient of the Casimir force between Au- and Ni-coated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for 3×10^{-5} eV $< m_{A_0} <$ 1 eV. See their Figs. 1, 3, and 4 for the mass-dependent limits.

[45] BLUM 14 studied effects of an oscillating strong CP phase induced by axion dark matter on the primordial ^{4}He abundance. See their Fig. 1 for mass-dependent limits.

[46] LEINSON 14 attributes the excessive cooling rate of the neutron star in Cassiopeia A to axion emission from the superfluid core, and found $C_n^2\, m^2_{A^0} \simeq 5.7\times10^{-6}$ eV^2, where C_n is the effective Peccei-Quinn charge of the neutron.

[47] ALESSANDRIA 13 used the CUORE experiment to look for 14.4 keV solar axions produced from the M1 transition of thermally excited ^{57}Fe nuclei in the solar core, using the axio-electric effect. The limit assumes the hadronic axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.

[48] ARMENGAUD 13 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 8 for the limit on product of axion couplings to electrons and nucleons.

[49] BELLI 12 looked for solar axions emitted by the M1 transition of ^{7}Li* (478 keV) after the electron capture of ^{7}Be, using the resonant excitation ^{7}Li in the LiF crystal. The mass bound assumes $m_u/m_d = 0.55$, $m_u/m_s = 0.029$, and the flavor-singlet axial vector matrix element $S = 0.4$.

[50] BELLINI 12B looked for 5.5 MeV solar axions produced in the $pd \to {}^3\mathrm{He}\,A^0$.The limit assumes the hadronic axion model. See their Figs. 6 and 7 for mass-dependent limits on productsof axion couplings to photons, electrons, and nucleons.

[51] DERBIN 11 looked for solar axions emitted by the M1 transition of thermally excited ^{57}Fe nuclei in the Sun, using their possible resonant capture on ^{57}Fe in the laboratory. The mass bound assumes $m_u/m_d = 0.56$ and the flavor-singlet axial vector matrix element $S = 3F - D \simeq 0.5$.

[52] BELLINI 08 consider solar axions emitted in the M1 transition of ^{7}Li* (478 keV) and look for a peak at 478 keV in the energy spectra of the Counting Test Facility (CTF), a Borexino prototype. For $m_{A^0} <$ 450 keV they find mass-dependent limits on products of axion couplings to photons, electrons, and nucleons.

[53] ADELBERGER 07 use precision tests of Newton's law to constrain a force contribution from the exchange of two pseudoscalars. See their Fig. 5 for limits on the pseudoscalar coupling to nucleons, relevant for m_{A^0} below about 1 meV.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

Axion Limits from *T*-violating Medium-Range Forces

The limit is for the coupling $g = g_p\, g_s$ in a *T*-violating potential between nucleons, nucleon and electron, or electrons of the form $V = \frac{g\hbar^2}{8\pi m_p}(\boldsymbol{\sigma}\cdot\hat{\boldsymbol{r}})\,(\frac{1}{r^2}+\frac{1}{\lambda r})\,e^{-r/\lambda}$, where g_s and g_p are dimensionless scalar and pseudoscalar coupling constants, m_p is the fermion mass with the pseudoscalar coupling (whereas the mass m_s of the fermion with the scalar coupling does not explicitly appear), and $\lambda = \hbar/(m_A c)$ is the range of the force.

[1] AYRES 23 at PSI use their neutron EDM setup to look for a mm to micron-range spin-dependent force between ultracold spin-polarized neutrons stored in vacuum and the unpolarised nucleons in the surrounding apparatus. They constrain a nucleon-neutron monopole-dipole interaction parameterised by the coupling $g_s^N g_p^n$. They set a limit of $g_s^N g_p^n < 10^{-20}$ (95% CL) for a 1 meV mass axion, see Fig. 6.

[2] PODDAR 23 search for long-range monopole-dipole forces between the polarized population of electrons inside the Earth and the unpolarised nucleons in the Sun, which would affect the precession of orbital perihelion. However, the most competitive limit is obtained by combining the monopole-monopole force constraints on g_s^N from planetary precession with the strongest stellar bound on the pseudoscalar electron coupling (g_p^e), shown in Fig. 5.

[3] ZHANG 23 look for changes of the ratio of precession frequencies between ^{129}Xe and ^{131}Xe as the bias field is flipped in Earth's gravitational field after Earth roation effect is subtracted. They find $g_p^n g_s^N < 1\times10^{-26}$–$3.7\times10^{-36}$ for $\lambda = 0.3$–1×10^{10} m. See their Fig. 4 for limits as a function of λ.

[4] CRESCINI 22 is an update of CRESCINI 17, and find $g_p^e g_s^N \leq 5.7\times10^{-32}$ and $g_p^e g_s^e \leq 1.6\times10^{-31}$ for $\lambda \gtrsim 10$ cm at 95% CL. See their Fig. 4 for limits as a function of λ.

[5] FENG 22 look for changes of the ratio of precession frequencies between ^{129}Xe and ^{131}Xe when a BGO crystal is positioned near the atomic cell. They find $g_p^n g_s^N < 2\times10^{-20}$–$3\times10^{-24}$ for $\lambda = 0.11$–0.55 mm. See their Fig. 4 for limits as a function of λ.

[6] AFACH 21 look for axion domain walls coupled to atomic spins by using the global network of optical magnetometers. Assuming that the axion domain walls make up all dark matter, they exclude the effective decay constant below 4×10^5 GeV for m_{A^0} in the range of 10^{-15}–10^{-11} eV. See their Fig. 4 for the mass-dependent limits.

[7] DZUBA 18 used atomic EDM measurements to derive limits on the product of the pseudoscalar coupling to nucleon and the scalar coupling to electron, which improved on the laboratory bounds for $m_{A^0} > 0.01$ eV. See their Fig. 1 for mass-dependent limits.

[8] STADNIK 18 used atomic and molecular EDM experiments to derive limits on the product of the pseudoscalar couplings to electron and the scalar coupling to nucleon and electron. See their Fig. 2 for mass-dependent limits, which improved on the laboratory bounds for $m_{A^0} > 0.01$ eV.

[9] CRESCINI 17 use the QUAX-$g_p g_s$ experiment to look for variation of a paramagnetic GSO crystal magnetization when rotating lead disks are positioned near the crystal, and find $g = g_p^e g_s^N < 4.3\times10^{-30}$ for $\lambda = 0.1$–0.2 m at 95% CL. See their Fig. 6 for limits as a function of λ.

[10] AFACH 15 look for a change of spin precession frequency of ultracold neutrons when a magnetic field with opposite directions is applied, and find $g < 2.2\times10^{-27}\ (\mathrm{m}/\lambda)^2$ at 95% CL for $1\ \mu\mathrm{m} < \lambda < 5$ mm. See their Fig. 3 for their limits.

[11] STADNIK 15 studied proton and neutron spin contributions for nuclei and derive the limits $g < 10^{-28}$–10^{-23} for $\lambda > 3\times10^{-4}$ m using the data of TULLNEY 13. See their Figs. 1 and 2 for λ-dependent limits.

[12] TERRANO 15 used a torsion pendulum and rotating attractor, and derived a restrictive limit on the product of the pseudoscalar coupling to electron and the scalar coupling to nucleons, $g < 9\times10^{-29}$–5×10^{-26} for $m_{A^0} < 1.5$–$400\ \mu$eV. See their Fig. 5 for mass-dependent limits.

[13] BULATOWICZ 13 looked for NMR frequency shifts in polarized ^{129}Xe and ^{131}Xe when a zirconia rod is positioned near the NMR cell, and find $g < 1\times10^{-19}$–1×10^{-24} for $\lambda = 0.01$–1 cm. See their Fig. 4 for their limits.

[14] CHU 13 look for a shift of the spin precession frequency of polarized ^{3}He in the presence of an unpolarized mass, in analogy to YOUDIN 96. See Fig. 3 for limits on g in the approximate m_{A^0} range 0.02–2 meV.

[15] TULLNEY 13 look for a shift of the precession frequency difference between the colocated ^{3}He and ^{129}Xe in the presence an unpolarized mass, and derive limits $g < 3\times10^{-29}$–2×10^{-22} for $\lambda > 3\times10^{-4}$ m. See their Fig. 3 for λ-dependent limits.

[16] RAFFELT 12 show that the pseudoscalar couplings to electron and nucleon and the scalar coupling to nucleon are individually constrained by stellar energy-loss arguments and searches for anomalous monopole-monopole forces, together providing restrictive constraints on g. See their Figs. 2 and 3 for results.

[17] HOEDL 11 use a novel torsion pendulum to study the force by the polarized electrons of an external magnet. In their Fig. 3 they show restrictive limits on g in the approximate m_{A^0} range 0.03–10 meV.

[18] PETUKHOV 10 use spin relaxation of polarized ^{3}He and find $g < 3\times10^{-23}\ (\mathrm{cm}/\lambda)^2$ at 95% CL for the force range $\lambda = 10^{-4}$–1 cm.

[19] SEREBROV 10 use spin precession of ultracold neutrons close to bulk matter and find $g < 2\times10^{-21}\ (\mathrm{cm}/\lambda)^2$ at 95% CL for the force range $\lambda = 10^{-4}$–1 cm.

[20] IGNATOVICH 09 use data on depolarization of ultracold neutrons in material traps. They show λ-dependent limits in their Fig. 1.

[21] SEREBROV 09 uses data on depolarization of ultracold neutrons stored in material traps and finds $g < 2.96\times10^{-21}\ (\mathrm{cm}/\lambda)^2$ for the force range $\lambda = 10^{-3}$–1 cm and $g < 3.9\times10^{-22}\ (\mathrm{cm}/\lambda)^2$ for $\lambda = 10^{-4}$–10^{-3} cm, each time at 95% CL, significantly improving on BAESSLER 07.

[22] BAESSLER 07 use the observation of quantum states of ultracold neutrons in the Earth's gravitational field to constrain g for an interaction range 1 μm–a few mm. See their Fig. 3 for results.

[23] HECKEL 06 studied the influence of unpolarized bulk matter, including the laboratory's surroundings or the Sun, on a torsion pendulum containing about 9×10^{22} polarized electrons. See their Fig. 4 for limits on g as a function of interaction range.

[24] NI 99 searched for a *T*-violating medium-range force acting on paramagnetic Tb F_3 salt. See their Fig. 1 for the result.

[25] POSPELOV 98 studied the possible contribution of *T*-violating Medium-Range Force to the neutron electric dipole moment, which is possible when axion interactions violate *CP*. The size of the force among nucleons must be smaller than gravity by a factor of $2\times10^{-10}\ (1\,\mathrm{cm}/\lambda_A)$, where $\lambda_A = \hbar/m_A c$.

[26] YOUDIN 96 compared the precession frequencies of atomic ^{199}Hg and Cs when a large mass is positioned near the cells, relative to an applied magnetic field. See Fig. 3 for their limits.

[27] RITTER 93 studied the influence of bulk mass with polarized electrons on an unpolarized torsion pendulum, providing limits in the interaction range from 1 to 100 cm.

[28] VENEMA 92 looked for an effect of Earth's gravity on nuclear spin-precession frequencies of ^{199}Hg and ^{201}Hg atoms.

[29] WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine resonances in stored ^{9}Be$^+$ ions using nuclear magnetic resonance.

Hidden Photons: Kinetic Mixing Parameter Limits

Limits are on the kinetic mixing parameter χ which is defined by the Lagrangian

$$L = -\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu} - \tfrac{1}{4}F'_{\mu\nu}F'^{\mu\nu} - \tfrac{\chi}{2}F_{\mu\nu}F'^{\mu\nu} + \frac{m_{\gamma'}^2}{2}A'_\mu A'^\mu,$$

where A_μ and A'_μ are the photon and hidden-photon fields with field strengths $F_{\mu\nu}$ and $F'_{\mu\nu}$, respectively, and $m_{\gamma'}$ is the hidden-photon mass.

[1] ABLIKIM 25CL search for kinetically mixed dark photons using the BESIII detector. They use the sample J/ψ events collected to measure the transition form factor of the η meson. Limits are derived on the branching ratio for $\eta \to \gamma\gamma'$, $\gamma' \to e^+e^-$ and presented in terms of mass-dependent limits on the kinetic mixing parameter in Fig. 7.

[2] ALBAKRY 25 report a search with the SuperCDMS detector for hidden photon dark matter absorption on silicon. See their Fig. 4 for mass-dependent limits.

[3] AN 25 search for dark photon dark matter resonantly converting into photons in the solar corona plasma, leading a signal detectable by the STEREO and Parker Solar Probe spacecraft. See their Fig. 2 for mass-dependent limits.

[4] ANDREEV 25 present the first hidden photon limits from the NA64e experiment using a 70 GeV positron beam. They set constraints on an invisibly decaying hidden photon that kinetically mixes with the photon. See Fig. 14 for various mass-dependent limits, noting the assumed parameter values for the dark gauge coupling and dark matter mass.

[5] APRILE 25A present results from a search with XENONnT for dark photon dark matter absorption on electrons in liquid xenon. See their Fig. 5 for mass-dependent limits.

[6] ASWATHI 25 use LIGO-VIRGO-KAGRA data from the black hole binary merger events GW231123 and GW190517 to search for evidence of the superradiant build-up of a cloud of vector bosons, which could act to spin down the black holes. They set lower limits on the dark photon kinetic mixing and present mass-dependent limits in Fig. 2.

[7] BAUDIS 25 presents results from the QROCODILE experiment which uses a superconducting nanowire single photon detector to search for low-mass dark matter. Fig. 2 shows mass-dependent constraints on hidden photon absorption.

[8] BLOCH 25 present results from a search for single-electron events in the SENSEI low-mass dark matter detector. See their Fig. 4 for mass-dependent limits on dark photon absorption.

[9] CAPUTO 25 present a new bound on dark photon emission from core-collapse supernovae. They consider the cooling effect of resonant dark photon production behind the shock wave which, if too excessive, can potentially prevent the explosion. In the case of SN1987A, this consideration supersedes the standard supernova cooling argument and leads to a bound that is strongest in the sub-MeV mass region. See their Fig. 2 for mass-dependent limits.

[10] CHOI 25 place bounds on a dark matter model using the NEON reactor neutrino experiment. They explore a scenario in which the high flux of photons from the nuclear reactor leads to a flux of dark photons; those dark photons can then decay into dark matter particles in the detector that scatter on electrons. See their Fig. 3 for mass-dependent bounds on the dark photon mediator, obtained for the dark matter mass $m_{\gamma'}/3$ and the hidden gauge coupling $\alpha_D = 0.1$.

[11] CORTINA-GIL 25A search for kinetically mixed hidden photons decaying to hadronic final states in the NA62 beam dump. Quoted limit applies around 0.8 GeV, but does not extend to arbitrarily large kinetic mixing. See their Fig. 7 for mass-dependent limits combining this hadronic analysis and the dilepton channel reported in CORTINA-GIL 24A.

[12] CORTINA-GIL 25B report limits on an invisibly decaying dark photon produced in the decays of K^+ and π^0 in the NA62 detector. See their Fig. 8 for mass-dependent limits.

[13] EGGE 25 search for dark photon dark matter using the prototype setup of the MADMAX dielectric disk haloscope. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 4 for mass-dependent limits.

[14] LI 25 search for MeV-mass dark photons making up the dark matter halo of the galaxy that could be absorbed by liquid xenon in the PandaX detector. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. The quoted limit is at $m_{\gamma'} = 150$ keV. See their Fig. 3 for mass-dependent limits.

[15] LINDEN 25 extend limits on dark photons as a dark matter candidate at masses below the electron pair creation threshold. They search for evidence of dark photon-to-three-photon decays using data from the INTEGRAL space telescope. See their Fig. 4 for mass-dependent limits.

[16] MELO-GALINDO 25 search for evidence of mixing between standard model and dark photons imprinted on the TeV gamma-ray spectra of the Crab Nebula and gamma-ray source MGRO J1908+06, using data from HAWC and LHAASO. See their Figs. 3–6 for mass-dependent limits for both sources and under various model assumptions.

[17] MIRASOLA 25 search for evidence of superradiant clouds of dark photons surrounding black holes, which are expected to produce pulsating radio emissions, and continuous gravitational wave signals that could be observed by LIGO-Virgo-KAGRA. Their bound disfavours dark photons within a specific range of masses and kinetic mixing parameters between 10^{-9}–10^{-7}, subject to uncertainties about the black hole population and details about the cloud's radio emission. See their Fig. 5.

[18] ROMERO-JORGE 25 set limits on kinetically-mixed dark photons produced through various decays in heavy-ion collisions and then decaying to dileptons. They incorporate a range of heavy ion data from across the SIS, RHIC and LHC. They present various mass-dependent limits in their Fig. 7 for different choices for the dark photon "surplus" – the maximum permissible increase in a dilepton yield from dark photons compared to the Standard Model yield.

[19] TROST 25 use VLT/UVES observations of the quasar HE0940-1050 to search for resonant conversion of dark photon dark matter into photons, which would heat the intergalactic medium and imprint on the quasar's Lyman-alpha forest spectrum. See their Fig. 7 for mass-dependent limits.

[20] ZENG 25 place a bound on keV-scale dark photons making up the halo of the galaxy by searching for electron recoil events in the PandaX detector. See Fig. 3(f) for mass-dependent limits.

[21] ZHAO 25 use a flux-tunable resonant cavity to search for dark photon dark matter in a narrow frequency window around 5.69 GHz, performing microwave single photon detection using a transmon qubit. The quoted limit assumes a local dark matter density of $\rho_{\gamma'} = 0.45$ GeV/cm^3

[22] ZHAO 25A use a single-site, two-sensor array of commercial scalar optically pumped magnetometers to search for dark photon dark matter converting into photons. The relevant observable signal appears in this low-mass regime due to the action of the Earth's ionosphere as transducer. See their Fig. 4 for mass-dependent limits.

[23] AAD 24AS search for hidden photons resulting from Higgs decays in the Falkowski-Ruderman-Volansky-Zupan model. See Fig. 7 for mass-dependent limits, value shown taken from the most constraining point at 10 GeV mass. The limits do not extend to arbitrarily high values of the kinetic mixing, stopping between 10^{-4} and 10^{-7} at the lower and upper end of the mass range respectively. The limit is also dependent on the branching fraction for Higgs decays resulting in dark photons.

[24] ABRATENKO 24A search for dark trident scattering at a neutrino beam using the MicroBooNE detector. Events involve a pair of particles $\chi\overline{\chi}$ produced from π^0 or η decays mediated by a dark photon, these particles then scatter off Argon in the detector and can produce an additional dark photon which then decays. See Fig. 7 for mass-dependent limits under three possible scenarios for the χ particle.

[25] ABREU 24 look for hidden photons produced from the pp collision in the decay channel $\gamma' \to e^+e^-$, and exclude at 90% CL the region of $\chi = 4\times10^{-6}$–2×10^{-4} and $m_{\gamma'}$ = 10–80 MeV, with the newly excluded region near the higher values of χ. See their Fig. 7 for mass-dependent limits.

[26] ADACHI 24C follows KOTAKA 23 of the DOSUE-RR collaboration, searching for hidden photon dark matter conversion using a millimetre-wave receiver and a radioshielding box. See Fig. 11 for mass dependent limits.

[27] AGOSTINI 24A report a search for dark photon dark matter absorption and dark Compton scattering on germanium, generating electron events in the GERDA experiment. The quoted limit is at $m_{A^0} = 150$ keV. See their Fig. 7 for mass-dependent limits.

[28] AGRAWAL 24 search for hidden photon dark matter via stimulated emission of a photon from a microwave cavity prepared in a non-classical state by a superconducting qubit.

[29] ANDREEV 24A perform a missing-energy search in the NA64 detector to look for an MeV-scale hidden photon mediator to a stable fermionic dark sector particle. See Fig. 3 for mass-dependent limits.

[30] ANDREEV 24E report results from the NA64μ beam dump experiment, employing a high-intensity muon beam. They set limits on the kinetic mixing parameter of an invisibly decaying hidden photon. See their Fig. 19 for mass-dependent limits.

[31] ARAMBURO-GARCIA 24 search for evidence of resonant conversion of regular photons into dark photons within the inter-galactic medium using the expected imprint on the CMB anisotropies. Quoted limit is for their "conservative" approach – see their Fig. 5 for mass-dependent limits.

[32] ARNQUIST 24 use the MAJORANA DEMONSTRATOR to search for keV-mass hidden photon dark matter absorption by Germanium. See Fig. 5 for mass-dependent limits.

[33] CERVANTES 24 use a superconducting radio frequency cavity at the SQMS Centre (Fermilab) to search for hidden photon dark matter at 1.3 GHz. See their Fig. 3 for limits in context.

[34] CORTINA-GIL 24A report results from the NA62 beam dump experiment, searching for production and decays of dark photons to lepton pairs. Quoted limit applies around 300 MeV, but does not extend to arbitrarily high kinetic mixing. See their Fig. 4 for mass-dependent limits

[35] DOLAN 24 constrain anomalous cooling of globular cluster stars due to the emission of hidden photons. Best limit is taken from the envelope of limits from the R parameter, R2 parameter and Tip of the Red Giant branch. This study includes hidden photon emission in stellar evolution simulation and so supersedes red giant bound in AN 20.

[36] HE 24 present results from the APEX collaboration. They look for hidden photon dark matter using a radio frequency cavity at 7.139 GHz. See their Fig. 4 for mass-dependent limits.

[37] KNIRCK 24 search for hidden photon dark matter using GigaBREAD, a broadband haloscope operating at room temperature that uses a parabolic reflector and a horn antenna. See their Fig. 4 for mass-dependent limits.

[38] LEVINE 24 search for hidden photon dark matter using Dark E-Field Radio, a broadband haloscope consisting of an E-field antenna inside a shielded room. This is a continuation of their experiment previously reported in GODFREY 21. See their Fig. 12 for mass-dependent limits.

[39] LIU 24 constrain hidden photon dark matter over a broad mass range using the very high-energy gamma-ray spectrum of blazars Mrk 501 and Mrk 421. See their Fig. 4 for mass-dependent limits which also depend on the density profiles of the host halos of the blazars. Quoted limit is for the case where the host halos have an NFW profile in Fig. 6.

[40] MCCARTHY 24 search for evidence of photons converting into hidden photons as they traverse large-scale structure, which would lead to a patchy-screening effect observable in CMB anisotropy maps. See their Fig. 3 for mass-dependent limits. This analysis improves upon a similar study by ARAMBURO-GARCIA 24 – see the note added in MCCARTHY 24.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

Int. J. Mod. Phys. A 2026.41. Downloaded from www.worldscientific.com by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[41] TANG 24 present results from a hidden photon dark matter search at 1.3 GHz with SHANHE, a tunable superconducting radio frequency cavity. See their Fig. 3 for mass-dependent limits.

[42] YAN 24A use data from the JUNO probe to constrain hidden photons via the way they would modify Jupiter's magnetic field. See their Fig. 7 for mass-dependent limits.

[43] AAD 23BO look for rare decays of the Z boson, $Z \to \gamma' + H'$, with dark Higgs decaying into a pair of hidden photons, assuming that at least two of the hidden photons decay into e^+e^- or $\mu^+\mu^-$. The quoted limit assumes the hidden fine structure constant $\alpha_D = 0.1$ and the dark Higgs mass ranging 20 to 70 GeV. See their Fig.5 for the mass-dependent limits.

[44] AAD 23I look for exotic decays of the SM-like Higgs boson, $H \to \gamma'\gamma'$ with hidden photons decaying into displaced lepton or light quark pairs, and set limits on the kinetic mixing within 1×10^{-4}–1×10^{-8} for the given mass range. The quoted limit is for $m_{A^0} \simeq 13$ GeV with a branching fraction of 0.1 for the Higgs decaying into hidden photon pairs. See their Fig. 13 for the mass-dependent limits.

[45] AAD 23T is analogous to AAD 22S, but using the ZH production mode, and set the upper limit on the branching ratio B($H \to \gamma\gamma'$) within 0.0219–0.0252 (95% CL).

[46] AALBERS 23A look for an absorption of hidden photon dark matter. The quoted limit is for $m_{\gamma'} = 1.4$ keV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 7 for mass-dependent limits.

[47] ABLIKIM 23AF look for invisible decays of hidden photons produced in the reaction $e^+e^- \to \gamma\gamma'$. They set limits within the 1.6×10^{-3}–5.7×10^{-3}. See their Fig. 3 for mass-dependent limits.

[48] ABUDINEN 23B look for hidden photons in the dark Higgsstrahlung process, $e^+e^- \to \gamma' H'$ ($\gamma' \to \mu^+\mu^-$) with H' being invisible. They set upper limits on the product of the kinetic mixing and the hidden gauge coupling, $\chi^2\cdot\alpha_D$, in the range of 1.7×10^{-8}–2×10^{-6} at 90% CL for a 1 GeV dark Higgs mass. See their Fig. 3 for the mass-dependent limits.

[49] ADHIKARI 23 look for the annual modulation signal induced by solar flux of hidden photons. See their Fig. 10 for mass-dependent limits.

[50] ADHIKARI 23A look for absorption and Compton-like processes of hidden photon dark matter. The quoted limit is for $m_{\gamma'} \simeq 12$ keV. Limits between 6×10^{-14}–3×10^{-11} are obtained. See their Fig. 4 for mass-dependent limits.

[51] ADRIAN 23 is an update of ADRIAN 18, and use the data from the 2016 engineering run at 2.3 GeV. The quoted limit is at $m_{\gamma'} \simeq 74$ MeV. See their Fig. 28 for the mass-dependent limits.

[52] AGNES 23A look for an absorption of hidden photon dark matter. The quoted limit is for $m_{\gamma'} = 0.03$ keV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 2 for mass-dependent limits.

[53] AN 23A look for absorption of hidden photon dark matter at radio telescopes, setting limits based on data from the FAST telescope. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 1 for mass-dependent limits.

[54] ANDREEV 23 is an update of ANDREEV 21 and ANDREEV 21A. The quoted limit applies to $m_{\gamma'} = 1$ MeV. See their Fig. 3 for mass-dependent limits.

[55] BAJJALI 23 look for hidden photon dark matter by using a 12–18 GHz dish antenna at U. Hamburg that is sensitive to vertically aligned hidden photon polarizations. They assume a local density of $\rho_{\gamma'} = 0.3$ GeV/cm^3. See their Figure 12 for mass-dependent limits in the range of $m_{\gamma'} = 50$–$75\ \mu eV$ under the assumption of randomly aligned hidden photon polarizations, defined as "1 sigma sensitivity". The run is labelled BRASS-p.

[56] CORTINA-GIL 23C NA62 beam dump experiment searches for hidden photons decaying to $\mu^+\mu^-$, extending their previous search CORTINA-GIL 19. The quoted limit applies at 300 MeV but does not extend to arbitrarily large kinetic mixing parameters. See Fig. 4 for mass-dependent limits.

[57] HAYRAPETYAN 23G search for kinetically mixed hidden photons in proton-proton collisions at the LHC that would generate a narrow peak in the mass spectrum of dimuon events. The mass window between 2.6 and 4.2 GeV is left unconstrained to avoid J/ψ and $\psi(2S)$ resonances. Mass dependent limits given in their Fig. 6.

[58] KOTAKA 23 is an update of TOMITA 20, and set limits $\chi < 0.3$–2×10^{-10} for the quoted mass range. The local density $\rho_{\gamma'} = 0.39$ GeV/cm^3 is assumed. See their Fig. 5 for mass-dependent limits.

[59] LI 23I set cooling bounds on the emission of hidden photons from the Sun, red giant, and horizontal branch stars, including emission of both the transverse and longitudinal modes. Cooling bounds are computed assuming a static model as opposed to considering the impact on stellar evolution. The result is comparable to earlier estimates of the same bound e.g. REDONDO 13. Limit applies at the most constraining mass around 200 eV for the solar bound.

[60] RAMANATHAN 23 look for hidden photon dark matter using a gold-plated copper dish antenna cooled to 20 mK. The local density $\rho_{\gamma'} = 0.45$ GeV/cm^3 is assumed. Limits between 7.9×10^{-13} and 3.81×10^{-12} are obtained. See their Fig. 5 for mass-dependent limits.

[61] ROMANENKO 23 employed two superconducting radio frequency cavities with a high quality factor, optimized for detecting the longitudinal polarization of the hidden photon. The quoted limit is set at $m_{\gamma'} \simeq 5\mu$eV. See their Fig. 4 for the mass-dependent limits.

[62] XIA 23 is analogous to WU 22A and use the Fermi-LAT pulsar timing array. They set a bound on the local density as $\rho_{\gamma'} \lesssim 7$ GeV/cm^3 for $m_{\gamma'} \lesssim 10^{-23}$ eV at 95% CL, with weaker constraints up to 10^{-22} eV. See their Fig. 1 for the mass-dependent limits.

[63] AAD 22J look for exotic decays of the SM-like Higgs boson, $H \to \gamma'\gamma' \to 4\ell$ and $H \to Z\gamma' \to 4\ell$, and set limits on the kinetic mixing and the Higgs portal coupling. See their Figs. 19 and 20 for the mass-dependent limits.

[64] AAD 22S look for decays of a Higgs boson into γ and γ' using the VBF production mode, and set the upper limit on the branching ratio at 0.018 (95% CL) for the 125 GeV Higgs boson. For the quoted mass range, the signal acceptance changes by less than 1%.

[65] APRILE 22 is analogous to AN 20, and their limit was corrected in the erratum to this paper: APRILE 24B. They set limits $\chi < 2\times10^{-12}$ (eV/$m_{\gamma'}$) for $m_{\gamma'} < 3$ eV (90% C.L.). For $m_{\gamma'} > 3$ eV, see Fig. 1 of APRILE 24B.

[66] APRILE 22 extend APRILE 19 to lower masses by removing the background of ionization signals correlated with high-energy events. The quoted limit applies to $m_{\gamma'} = 0.09$ keV. See their Fig. 15 for mass-dependent limits.

[67] APRILE 22B is an update of APRILE 20, and set limits $\chi \lesssim 5\times10^{-17}$–$2\times10^{-13}$. The quoted limit applies to $m_{\gamma'} = 1$ keV. They exclude the XENON1T excess found in APRILE 20. See their Fig. 6 for mass-dependent limits.

[68] BATTAGLIERI 22 is analogous to BATELL 14, and derived limits from the electron beam dump experiment at Jefferson Lab (BDX-MINI). Limits at the level of 7×10^{-5}–1×10^{-2} are obtained for the dark matter mass $m_{\gamma'}/3$ and the hidden gauge coupling $\alpha_D = 0.1$. See their Fig. 11.

[69] BOLTON 22 use the Ly-α forest at $z \simeq 0.1$ as a calorimeter for heating in the intergalactic medium by the resonant conversion of hidden photon dark matter to photons, which is assumed to be responsible for the tension between the predicted and observed Ly-α absorption linewidths.

[70] CERVANTES 22 use a dielectrically loaded Fabry-Perot open cavity to look for hidden photon dark matter. The local density $\rho_{\gamma'} = 0.45$ GeV/cm^3 is assumed. See their Fig. 5 for mass-dependent limits.

[71] CHILES 22 look for hidden photon dark matter by using a layered dielectric target and a superconducting nanowire single-photon detector. The local density $\rho_{\gamma'} = 0.4$ GeV/cm^3 is assumed. See their Fig. 4 for mass-dependent limits.

[72] HOCHBERG 22 update HOCHBERG 19. The quoted limit applies to $m_{A^0} \simeq 11$ eV. See their Fig. 5 for mass-dependent limits.

[73] LEES 22 look for a hidden fermion-fermion bound state decaying into three hidden photons, which subsequently decay into e^+e^-, $\mu^+\mu^-$, or $\pi^+\pi^-$. For the bound-state mass in the range of 0.05–9.5 GeV, limits at the level of 5×10^{-5}–1×10^{-3} are obtained. See their Fig. 6 for mass-dependent limits.

[74] LU 22 derive the limit by studying the effect of photons oscillating into hidden photons on the surface luminosity of the neutron star RX J1856.6-3754.

[75] MANENTI 22 look for hidden photon dark matter by using a multilayer dielectric haloscope. Limits between 6.86×10^{-11} and 5×10^{-8} are obtained for $m_{\gamma'} \simeq 1.1$–3.1 eV. See their Fig. 11 for mass-dependent limits.

[76] THOMAS 22 improved KRIBS 21 by taking account of the changes in the parton distribution functions due to the inclusion of hidden photons. The quoted limit is at $m_{\gamma'} \simeq 4$ GeV. Limits in the range of 3×10^{-2}–9×10^{-2} are obtained for $m_{\gamma'} = 1$–80 GeV. See their Fig. 1 for the limits.

[77] TUMASYAN 22AH look for exotic decays of the SM-like Higgs boson, $H \to Z\gamma' \to 4\ell$, and set limits on the Higgs portal coupling. See their Fig. 6 for the limits.

[78] TUMASYAN 22N look for exotic decays of the SM-like Higgs boson, $H \to \gamma'\gamma'$ ($\gamma' \to \mu^+\mu^-$), and set limits on the branching fraction product. See their Fig. 7 for mass- and lifetime-dependent limits.

[79] WU 22A look for direction-dependent oscillations in the gravitational potential generated by ultralight hidden photon dark matter, and set a bound on its local density as $\rho_{\gamma'} \lesssim 5$ GeV/cm^3 for $m_{\gamma'} \lesssim 10^{-23}$ eV at 95% CL.

[80] ANDREEV 21 is analogous to BANERJEE 18A. The quoted limit applies to $m_{\gamma'} = 1$ MeV. See their Fig. 3 for mass-dependent limits.

[81] ANDREEV 21A extends the limits of BANERJEE 19 by taking account of production through the resonant annihilation of secondary positrons with atomic electrons. The quoted limit is at $m_{\gamma'} = 0.23$ GeV, assuming the fermion dark matter of mass $m_{\gamma'}/3$ and the hidden gauge coupling $\alpha_D = 0.1$. See their Fig.3 for mass-dependent limits.

[82] BI 21 look for the gamma-ray spectral attenuation due to scattering with hidden photons constituting all dark matter, using the measurements of sub-PeV gamma-rays from the Crab Nebula by the Tibet ASγ and HAWC experiments, together with MAGIC and HEGRA gamma-ray data. See their Fig. 4 for mass-dependent limits.

[83] CAZZANIGA 21 look for semi-visible decays of hidden photons, $\gamma' \to \chi_1\chi_2$ ($\chi_2 \to \chi_1 e^+e^-$), where χ_1 and χ_2 are hidden fermions. They exclude $3\times10^{-5} \lesssim \chi \lesssim 2\times10^{-2}$ assuming the hidden gauge coupling $\alpha_D = 0.1$, and the fermion masses $m_{\chi_1} = m_{\gamma'}/3$, $(m_{\chi_2} - m_{\chi_1})/m_{\chi_1} = 0.4$. See their Fig. 4 for mass-dependent limits.

[84] DIXIT 21 look for hidden photon dark matter by using a superconducting transmon qubit dispersively coupled to a high Q storage cavity. The local density $\rho_{\gamma'} = 0.4$ GeV/cm^3 is assumed. See their Fig.4 for mass-dependent limits.

[85] GHOSH 21 use existing haloscope axion search limits to set limits on hidden photon dark matter, considering the polarization of hidden photons. The quoted limit is at $m_{\gamma'} \simeq 3$ μeV. See their Fig. 1 for mass-dependent limits.

[86] GODFREY 21 look for hidden photon dark matter by using a wideband antenna, and set 5σ limits on χ. The local density $\rho_{\gamma'} = 0.38$ GeV/cm^3 is assumed. See their updated Fig. 12 in arXiv:2101.02805v4 for mass-dependent limits in the range of $m_{\gamma'} = 0.207$–1.24 μeV.

[87] KOPYLOV 21A is an update of KOPYLOV 19, but use Ne gas instead of Ar. The quoted limit applies to $m_{\gamma'} = 12$ eV. See their Fig. 4 for mass-dependent limits.

[88] KRIBS 21 used the HERA data on neutral current deep inelastic ep scattering to derive the limits, which become weaker for heavier masses. See their Fig. 3 for mass-dependent limits.

[89] SCHMIDT 21 use the microscopic Parton-Hadron-String Dynamics approach to extract limits by comparing the theoretically calculated dilepton spectra with the HADES data on the search for $\gamma' \to e^+e^-$. See their Fig. 5 for the mass-dependent limits for various allowed surplus of the hidden photon contribution over the standard model yield.

[90] TSAI 21 update the limits from the CHARM and NuCal experiments, taking account of additional production channels from proton bremsstrahlung and η meson decays, respectively. Limits between 3×10^{-8} and 1×10^{-4} are obtained for $0.01 < m_{\gamma'} < 0.8$ GeV (see their Fig. 1).

[91] AAIJ 20C look for hidden photons produced from the pp collision in the decay channel $\gamma' \to \mu^+\mu^-$. For prompt decaying hidden photons, limits at the level of 10^{-4}–10^{-3} are obtained for $m_{\gamma'} = 0.214$–30 GeV. See their Fig. 2 for mass-dependent limits.

[92] AAIJ 20C look for hidden photons produced from the pp collision in the decay channel $\gamma' \to \mu^+\mu^-$. For hidden photons with lifetimes of order ps, limits at the level of 10^{-5} are obtained for $m_{\gamma'} = 218$–315 MeV. See their Fig. 4 for mass-dependent limits.

[93] ABLIKIM 20AB search for $J/\psi \to \eta'\gamma'$ ($\gamma' \to \gamma\pi^0$), and set the upper limit on the product branching fraction of order 10^{-7}. See their Fig. 7 for mass-dependent limits.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

[94] AGOSTINI 20 is analogous to ABE 14F. The quoted limit applies to $m_{\gamma'} = 150$ keV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. Their limits in their Fig. 3 were later found to be incorrect due to an error of their Eqs. (1) and (2). See Fig. 3 in AGOSTINI 22A for the corrected limits.

[95] AMARAL 20 use a second-generation SuperCDMS high-voltage eV-resolution detector to set limits on dark-matter hidden photon absorption. The quoted limit is for $m_{\gamma'} \simeq 17$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 3 for mass-dependent limits.

[96] AN 20 updates the direct detection limit of AN 13C on solar flux of hidden photons; $\chi < 1.6\times10^{-12}$ (eV/$m_{\gamma'}$) for $m_{\gamma'} < 6$ eV (90% C.L.). For $m_{\gamma'} > 6$ eV, see their Fig. 1 for mass-dependent limits.

[97] ANDRIANAVALOMAHEFA 20 is analogous to SUZUKI 15, but uses a mirror that is about one order of magnitude larger than in similar studies in the past. Limits at the level of 10^{-12} are obtained for $m_{\gamma'} = 2.5$–7 eV. See their Fig.23 and Table III for mass-dependent limits.

[98] APRILE 20 is analogous to ABE 14F, and set limits $\chi \lesssim 10^{-16}$–10^{-12}. The quoted limit applies to $m_{\gamma'} = 1$ keV. They also found an excess over known backgrounds, which favors the mass $m_{\gamma'} = 2.3 \pm 0.2$ keV with a 3 σ significance. See their Fig. 10 for mass-dependent limits.

[99] ARALIS 20 is analogous to ABE 14F. The quoted limit applies to $m_{\gamma'} = 0.1$ keV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. The limits at masses above 3 keV in their Fig. 10 was later found to be incorrect due to an error in their analysis. See Fig. 3 in erratum for the corrected limits.

[100] ARGUELLES 20 examine hidden-photon production in atmospheric cosmic-ray showers and its decay in IceCube and Super-Kamiokande. The quoted limit assumes a lifetime of $c\tau = 0.1$ km. See their Fig. 16 for mass- and lifetime-dependent limits.

[101] ARNAUD 20 look for the absorption signal of hidden photon dark matter in a Ge detector. The quoted limit applies to $m_{\gamma'} \simeq 9$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 3 for mass-dependent limits.

[102] BANERJEE 20 is an update of BANERJEE 18. They exclude $8.2\times10^{-5} \lesssim \chi \lesssim 1\times10^{-2}$ for $m_{\gamma'} = 1.5$–24 MeV. In particular, they exclude $\chi = 1.2\times10^{-4}$–6.8×10^{-4} for the 16.7 MeV gauge boson. See their Fig. 5 for mass-dependent limits.

[103] BARAK 20 is analogous to AGUILAR-AREVALO 19A, and look for hidden photon dark matter by using the Skipper CCD. The quoted limit applies to $m_{\gamma'} = 12.8$ eV. See their Fig. 4 for mass-dependent limits.

[104] KRASNIKOV 20 showed that the limit of BANERJEE 20 combined with the measured anomalous magnetic moment of the electron exclude the 16.7 MeV gauge boson suggested by the ATOMKI (KRASZNAHORKAY 16) experiment if it has pure vector or axial-vector interactions.

[105] SHE 20 look for solar hidden photons. The quoted limit applies to $m_{\gamma'} = 180$ eV. See their Fig. 4 for mass-dependent limits.

[106] SHE 20 look for hidden photon dark matter and set limits $\chi < 1.3\times10^{-15}$–2.8×10^{-14} for the quoted mass range. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 6 for mass-dependent limits.

[107] SIRUNYAN 20AQ look for a narrow resonance decaying into a pair of muons. For $m_{\gamma'} < 45$ GeV, they use dedicated high-rate dimuon triggers to reduce the muon transverse momentum thresholds. The quoted limit applies to $m_{\gamma'} = 50$ GeV, and limits of order 10^{-3} are obtained for the quoted mass range. See their Fig. 3 for mass-dependent limits.

[108] TOMITA 20 look for hidden photon dark matter using a planar metal plate and cryogenic receiver and set limits $\chi < 1.8$–4.3×10^{-10} for the quoted mass range. The local density $\rho_{\gamma'} = 0.39$ GeV/cm^3 is assumed. See their Fig. 7 for mass-dependent limits.

[109] WANG 20A is analogous to ABE 14F. The quoted limit applies to $m_{\gamma'} = 185$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 11 for mass-dependent limits.

[110] AABOUD 19G look for $h \to \gamma'\gamma'$ ($\gamma' \to \mu^+\mu^-$) and exclude a kinetic mixing around 10^{-9}–10^{-8} for B($h \to \gamma'\gamma'$) = 0.01 and 0.1. See their Fig. 9 for mass-dependent limits.

[111] ABLIKIM 19A look for $J/\psi \to \gamma'\eta$ ($\gamma' \to e^+e^-$). Limits between 6×10^{-3} and 5×10^{-2} are obtained (see their Fig. 8).

[112] ABLIKIM 19H look for $J/\psi \to \gamma'\eta'$ ($\gamma' \to e^+e^-$). Limits between 3.4×10^{-3} and 2.6×10^{-2} are obtained. See their Fig. 5 for mass-dependent limits.

[113] AGUILAR-AREVALO 19A look for the absorption signal of hidden photon dark matter by using a CCD. The quoted limit applies to $m_{\gamma'} = 17$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 4 for mass-dependent limits.

[114] APRILE 19D is analogous to ABE 14F. The quoted limit applies to $m_{\gamma'} = 0.7$ keV. See their Fig. 5(f) for mass-dependent limits.

[115] BANERJEE 19 is an update of BANERJEE 18A. The quoted limit is at $m_{\gamma'} = 1$ MeV. See their Fig. 3 for mass-dependent limits.

[116] BHOONAH 19 examine heating of Galactic Center gas clouds by hidden photon dark matter. The quoted limit applies to $m_{\gamma'} \simeq 10^{-12}$ eV. See their Fig. 2 for mass-dependent limits.

[117] BRUN 19 is analogous to SUZUKI 15. The limit is derived under an assumption that hidden photons constitute the local dark matter density $\rho_{\gamma'} = 0.3$ GeV/cm^3.

[118] CORTINA-GIL 19 look for an invisible hidden photon in the reaction $K^+ \to \pi^+\pi^0$ ($\pi^0 \to \gamma\gamma'$). The quoted limit applies to $m_{\gamma'} = 62.5$–65 MeV. See their Figs. 6 and 7 for mass-dependent limits.

[119] DANILOV 19 examined the hidden photon production in nuclear reactors, correctly taking account of the effective photon mass in the reactor and detector. The limit gets weaker for $m_{\gamma'}$ less than the effective photon mass in proportion to $1/m_{\gamma'}^2$. See their Fig. 1 for mass-dependent limits.

[120] HOCHBERG 19 look for the absorption signal of hidden photon dark matter by using superconducting-nanowire single-photon detectors. The quoted limit applies to $m_{\gamma'} \simeq 1$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 4 for mass-dependent limits.

[121] KOPYLOV 19 look for hidden-photon dark matter using a counter with an aluminum cathode and derive limits assuming it constitute all the local dark matter. The quoted limit applies to $m_{\gamma'} = 12$ eV. See their Fig. 7 for mass-dependent limits.

[122] KOVETZ 19 examine heating of the early Universe plasma by hidden photon dark matter, and derive the limits by requiring that the cosmic mean 21 cm brightness temperature relative to the CMB temperature satisfy $T_{21} > -100$ mK. The quoted limit applies to $m_{\gamma'} \simeq 2\times10^{-14}$ eV. See their Fig. 3 for mass-dependent limits.

[123] NGUYEN 19 look for hidden photon dark matter with a resonant cavity, and set limits $\sim10^{-12}$ for $m_{\gamma'} = 0.2$–2.07μeV. The quoted limit applies to $m_{\gamma'} = 1.3$ μeV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 19 for mass-dependent limits.

[124] ABE 18F is an update of ABE 14F. The quoted limit applies to $m_{\gamma'} \simeq 40$ keV. See their Fig. 5 for mass-dependent limits.

[125] ADRIAN 18 look for a hidden photon resonance in the reaction $e^- Z \to e^- Z\gamma'$ ($\gamma' \to e^+e^-$). The quoted limit applies to $m_{\gamma'} = 40$ MeV. See their Fig. 4 for mass-dependent limits.

[126] ANASTASI 18B look for a hidden photon resonance in the reaction $e^+e^- \to \gamma'\gamma$ ($\gamma' \to \mu^+\mu^-$). The quoted limit is obtained by combining the result of ANASTASI 16 and it applies to $m_{\gamma'} \simeq 519$–987 MeV. See their Fig. 9 for mass-dependent limits.

[127] ARMENGAUD 18 is analogous to ABE 14F. The quoted limits applies to $m_{\gamma'} = 1.6$ keV. See the right panel of Fig. 5 for mass-dependent limits.

[128] BANERJEE 18 look for hidden photons produced in the reaction $e^- Z \to e^- Z\gamma'$ ($\gamma' \to e^+e^-$), and exclude $9.2\times10^{-5} \lesssim \chi \lesssim 1\times10^{-2}$ for $m_{\gamma'} = 1$–23 MeV. They also set a limit on the electron coupling to a 16.7 MeV gauge boson suggested by the ATOMKI (KRASZNAHORKAY 16) experiment. See their Fig. 3 for mass-dependent limits.

[129] BANERJEE 18A look for invisible decays of hidden photons produced in the reaction $e^- Z \to e^- Z\gamma'$. The quoted limit is at $m_{\gamma'} = 1$ MeV. See their Fig. 15 for mass-dependent limits.

[130] KNIRCK 18 is analogous to SUZUKI 15. See their Fig. 5 for mass-dependent limits.

[131] ABGRALL 17 is analogous to ABE 14F using the MAJORANA DEMONSTRATOR. See their Fig. 3 for limits between 6 keV $< m_{\gamma'} <$ 97 keV.

[132] ABLIKIM 17AA look for $e^+e^- \to \gamma\gamma'$ ($\gamma' \to e^+e^-$ or $\mu^+\mu^-$). Limits between 10^{-3} and 10^{-4} are obtained (see their Fig. 3).

[133] ANGLOHER 17 is analogous to ABE 14F. The quoted limit is at $m_{\gamma'} = 0.7$ keV. See their Fig. 8 for mass-dependent limits.

[134] BANERJEE 17 look for invisible decays of hidden photons produced in the reaction $e^- Z \to e^- Z\gamma'$. The quoted limit applies to $m_{\gamma'} = 2$ MeV. See their Fig. 3 for mass-dependent limits.

[135] CHANG 17 examine the hidden photon emission from SN1987A, including the effects of finite temperature and density on χ and obtain limits χ ($m_{\gamma'}$/MeV) $\lesssim 3\times10^{-9}$ for $m_{\gamma'} < 15$ MeV and $\chi \lesssim 10^{-9}$ for $m_{\gamma'} = 15$–120 MeV.

[136] DUBININA 17 look for $\mu^+ \to e^+\overline{\nu}_\mu\nu_e\gamma'$ ($\gamma' \to e^+e^-$) in a nuclear photoemulsion. The quoted limit applies to $m_{\gamma'} = 1.1$ MeV. Limits between 4.5×10^{-3} and 10^{-2} are obtained (see their Fig. 3).

[137] LEES 17E look for invisible decays of hidden photons produced in the reaction $e^+e^- \to \gamma\gamma'$. See their Fig. 5 for limits in the mass range $m_{\gamma'} \leq 8$ GeV.

[138] AAD 16AG look for hidden photons promptly decaying into collimated electrons and/or muons, assuming that they are produced in the cascade decays of squarks or the Higgs boson. See their Fig. 10 and Fig.13 for their limits on the cross section times branching fractions.

[139] ANASTASI 16 look for the decay $\gamma' \to \pi^+\pi^-$ in the reaction $e^+e^- \to \gamma\gamma'$. Limits between 4.3×10^{-3} and 4.4×10^{-4} are obtained for 527 $< m_{\gamma'} <$ 987 MeV (see their Fig. 9).

[140] KHACHATRYAN 16 look for $\gamma' \to \mu^+\mu^-$ in a dark SUSY scenario where the SM-like Higgs boson decays into a pair of the visible lightest neutralinos with mass 10 GeV, both of which decay into γ' and a hidden neutralino with mass 1 GeV. See the right panel in their Fig. 2.

[141] AAD 15CD look for $H \to Z\gamma' \to 4\ell$ with the ATLAS detector at LHC and find $\chi < 4$–17×10^{-2} for $m_{\gamma'} = 15$–55 GeV. See their Fig. 6.

[142] ADARE 15 look for a hidden photon in π^0, $\eta^0 \to \gamma e^+e^-$ at the PHENIX experiment. See their Fig. 4 for mass-dependent limits.

[143] AN 15A derived limits from the absence of ionization signals in the XENON10 and XENON100 experiments, assuming hidden photons constitute all the local dark matter. Their best limit is $\chi < 1.3\times10^{-15}$ at $m_{\gamma'} = 18$ eV. See their Fig. 1 for mass-dependent limits.

[144] ANASTASI 15 look for a production of a hidden photon and a hidden Higgs boson with the KLOE detector at DAΦNE, where the hidden photon decays into a pair of muons and the hidden Higgs boson lighter than $m_{\gamma'}$ escape detection. See their Figs. 6 and 7 for mass-dependent limits on a product of the hidden fine structure constant and the kinetic mixing.

[145] ANASTASI 15A look for the decay $\gamma' \to e^+e^-$ in the reaction $e^+e^- \to e^+e^-\gamma$. Limits between 1.7×10^{-3} and 1×10^{-2} are obtained for $m_{\gamma'} = 5$–320 MeV (see their Fig. 7).

[146] BATLEY 15A look for $\pi^0 \to \gamma\gamma'$ ($\gamma' \to e^+e^-$) at the NA48/2 experiment. Limits between 4.2×10^{-4} and 8.8×10^{-3} are obtained for $m_{\gamma'} = 9$–120 MeV (see their Fig. 4).

[147] JAEGLE 15 look for the decay $\gamma' \to e^+e^-, \mu^+\mu^-$, or $\pi^+\pi^-$ in the dark Higgstrahlung channel, $e^+e^- \to \gamma' H'$ ($H' \to \gamma'\gamma'$) at the BELLE experiment. They set limits on a product of the branching fraction and the Born cross section as well as a product of the hidden fine structure constant and the kinetic mixing. See their Figs. 3 and 4.

[148] KAZANAS 15 set limits by studying the decay of hidden photons $\gamma' \to e^+e^-$ inside and near the progenitor star of SN1987A. See their Fig. 6 for mass-dependent limits.

Int. J. Mod. Phys. A 2026.41. Downloaded from worldscientific.com
by KARLSRUHE INSTITUTE OF TECHNOLOGY on 10/26/26. Re-use and distribution is strictly not permitted, except for Open Access articles.

[149] SUZUKI 15 looked for hidden-photon dark matter with a dish antenna and derived limits assuming they constitute all the local dark matter. Their limits are $\chi < 6\times10^{-12}$ for $m_{\gamma'} = 1.9$–4.3 eV. See their Fig. 7 for mass-dependent limits.

[150] VINYOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations, and set the limits $\chi m_{\gamma'} < 1.8\times10^{-12}$ eV for $m_{\gamma'} = 3\times10^{-5}$–8 eV. See their Fig. 11.

[151] ABE 14F look for the photoelectric-like interaction in the XMASS detector assuming the hidden photon constitutes all the local dark matter. Limits between 2×10^{-13} and 1×10^{-12} are obtained, where the relation $\chi^2 = \alpha'/\alpha$ is used to translate the original bound on the ratio of the hidden and EM fine-structure constants. See their Fig. 3 for mass-dependent limits.

[152] AGAKISHIEV 14 look for hidden photons $\gamma' \to e^+e^-$ at the HADES experiment, and set limits on χ for $m_{\gamma'} = 0.02$–0.6 GeV. See their Fig. 5 for mass-dependent limits.

[153] BABUSCI 14 look for the decay $\gamma' \to \mu^+\mu^-$ in the reaction $e^+e^- \to \mu^+\mu^-\gamma$. Limits between 4×10^{-3} and 9.0×10^{-4} are obtained for 520 MeV $< m_{\gamma'} <$ 980 MeV (see their Fig. 7).

[154] BATELL 14 derived limits from the electron beam dump experiment at SLAC (E-137) by searching for events with recoil electrons by sub-GeV dark matter produced from the decay of the hidden photon. Limits at the level of 10^{-4}–10^{-1} are obtained for $m_{\gamma'} = 10^{-3}$–1 GeV, depending on the dark matter mass and the hidden gauge coupling (see their Fig. 2).

[155] BLUEMLEIN 14 analyzed the beam dump data taken at the U-70 accelerator to look for γ'-bremsstrahlung and the subsequent decay into muon pairs and hadrons. See their Fig. 4 for mass-dependent excluded region.

[156] FRADETTE 14 studied effects of decay of relic hidden photons on BBN and CMB to set constraints on very small values of the kinetic mixing. See their Figs. 4 and 7 for mass-dependent excluded regions.

[157] LEES 14J look for hidden photons in the reaction $e^+e^- \to \gamma\gamma'$ ($\gamma' \to e^+e^-, \mu^+\mu^-$). Limits at the level of 10^{-4}–10^{-3} are obtained for 0.02 GeV $< m_{\gamma'} <$ 10.2 GeV. See their Fig. 4 for mass-dependent limits.

[158] MERKEL 14 look for $\gamma' \to e^+e^-$ at the A1 experiment at the Mainz Microtron (MAMI). See their Fig. 3 for mass-dependent limits.

[159] AN 13B examined the stellar production of hidden photons, correcting an important error of the production rate of the longitudinal mode which now dominates. See their Fig. 2 for mass-dependent limits based on solar energy loss.

[160] AN 13C use the solar flux of hidden photons to set a limit on the atomic ionization rate in the XENON10 experiment. They find $\chi\, m_{\gamma'} < 3\times10^{-12}$ eV for $m_{\gamma'} < 1$ eV. See their Fig. 2 for mass-dependent limits.

[161] DIAMOND 13 analyzed the beam dump data taken at the SLAC millicharge experiment to constrain a hidden photon invisibly decaying into lighter long-lived particles, which undergo elastic scattering off nuclei in the detector. Limits between 8×10^{-4}–2×10^{-2} are obtained. The quoted limit is applied when the dark gauge coupling is set equal to the electromagnetic coupling. See their Fig.4 for mass-dependent limits.

[162] GNINENKO 13 used the data taken at the SINDRUM experiment to constrain the decay, $\pi^0 \to \gamma\gamma'$ ($\gamma' \to e^+e^-$) to derive limits. See their Fig. 2 for their mass-dependent excluded region.

[163] HORVAT 13 look for hidden-photo-electric effect in HPGe detectors induced by solar hidden photons. See their Fig. 3 for mass-dependent limits.

[164] INADA 13 search for hidden photons using an intense X-ray beamline at SPring-8. See their Fig. 4 for mass-dependent limits.

[165] MIZUMOTO 13 look for solar hidden photons. See their Fig. 5 for mass-dependent limits.

[166] PARKER 13 look for hidden photons using a cryogenic resonant microwave cavity. See their Fig.5 for mass-dependent limits.

[167] PARKER 13 derived a limit for the hidden photon CDM with a randomly oriented hidden photon field.

[168] REDONDO 13 examined the solar emission of hidden photons including the enhancement factor for the longitudinal mode pointed out by AN 13B, and also updated stellar-energy loss arguments. See their Fig.3 for mass-dependent limits, including a review of the currently best limits from other arguments.

[169] GNINENKO 12A obtained bounds on $B(\pi^0 \to \gamma\gamma') \cdot B(\gamma' \to e^+e^-)$ from the NOMAD and PS191 neutrino experiments, and derived limits between 8×10^{-8}–2×10^{-4}. See their Fig.4 for mass-dependent excluded regions.

[170] GNINENKO 12B used the data taken at the CHARM experiment to constrain the decay, $\eta(\eta') \to \gamma\gamma'$ ($\gamma' \to e^+e^-$), and derived limits between 1×10^{-7}–1×10^{-4}. See their Fig.4 for mass-dependent excluded region.

[171] ABRAHAMYAN 11 look for $\gamma' \to e^+e^-$ in the electron-nucelon fixed-target experiment at the Jefferson Laboratory (APEX). See their Fig. 5 for mass-dependent limits.

[172] BLUEMLEIN 11 analyzed the beam dump data taken at the U-70 accelerator to look for $\pi^0 \to \gamma\gamma'$ ($\gamma' \to e^+e^-$). See their Fig. 5 for mass-dependent limits.

[173] BJORKEN 09 analyzed the beam dump data taken at E137, E141, and E774 to constrain a hidden photon produced by bremsstrahlung, subsequently decaying into e^+e^-, and derived limits between 10^{-7} and 10^{-2}. See their Fig. 1 for mass-dependent excluded region.

[174] BJORKEN 09 required the energy loss in the γ' emission from the core of SN1987A not to exceed 10^{53} erg/s, and derived limits between 5×10^{-9} and 2×10^{-6}. See their Fig. 1 for mass-dependent excluded region.

$J = \frac{1}{2}$

e MASS (atomic mass units u)

The primary determination of an electron's mass comes from measuring the ratio of the mass to that of a nucleus, so that the result is obtained in u (atomic mass units). The conversion factor to MeV is more uncertain than the mass of the electron in u; indeed, the recent improvements in the mass determination are not evident when the result is given in MeV. In this datablock we give the result in u, and in the following datablock in MeV.

VALUE (10^{-6} u)		DOCUMENT ID		TECN	COMMENT
548.5799090441 ± 0.0000000097		MOHR	25	RVUE	2022 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •					
548.579909065	±0.000000016	TIESINGA	21	RVUE	2018 CODATA value
548.579909070	±0.000000016	MOHR	16	RVUE	2014 CODATA value
548.57990946	±0.00000022	MOHR	12	RVUE	2010 CODATA value
548.57990943	±0.00000023	MOHR	08	RVUE	2006 CODATA value

548.579903	±0.000013	COHEN	87	RVUE	1986 CODATA value

[1] BEIER 02 compares Larmor frequency of the electron bound in a $^{12}C^{5+}$ ion with the cyclotron frequency of a single trapped $^{12}C^{5+}$ ion.
[2] FARNHAM 95 compares cyclotron frequency of trapped electrons with that of a single trapped $^{12}C^{6+}$ ion.

e MASS

The mass is known more precisely in u (atomic mass units) than in MeV. The conversion is: 1 u = 931.494 103 72(29) MeV/c^2 (2022 CODATA value, MOHR 25). The conversion error dominates the uncertainty of the masses given below.

$< 8 \times 10^{-9}$	90	[1] FEE	93	CNTR	Positronium spectroscopy
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$< 4 \times 10^{-23}$	90	[2] DOLGOV	14		From photon mass limit
$< 4 \times 10^{-8}$	90	CHU	84	CNTR	Positronium spectroscopy

[1] FEE 93 value is obtained under the assumption that the positronium Rydberg constant is exactly half the hydrogen one.
[2] DOLGOV 14 result is obtained under the assumption that any mass difference between electron and positron would lead to a non-zero photon mass. The PDG 12 limit of 1×10^{-18} eV on the photon mass is in turn used to derive the value quoted here.

$|q_{e^+} + q_{e^-}|/e$

A test of CPT invariance. See also similar tests involving the proton.

$< 4 \times 10^{-8}$	[1] HUGHES	92	RVUE	
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$< 2 \times 10^{-18}$	[2] SCHAEFER	95	THEO	Vacuum polarization
$< 1 \times 10^{-18}$	[3] MUELLER	92	THEO	Vacuum polarization

[1] HUGHES 92 uses recent measurements of Rydberg-energy and cyclotron-frequency ratios.
[2] SCHAEFER 95 removes model dependency of MUELLER 92.
[3] MUELLER 92 argues that an inequality of the charge magnitudes would, through higher-order vacuum polarization, contribute to the net charge of atoms.

[1] FAN 23 report the most accurate measurement of the electron magnetic moment. A one-electron quantum cyclotron is used. We do not propagate at the moment this measurement to the fine structure and other physical constants. When discrepancies in the independent determinations of alpha are resolved, the new measurement uncertainty of 0.13 ppt is available for precise tests for BSM physics.
[2] MOHR 08 average is dominated by ODOM 06.
[3] Superseded by HANNEKE 08 per private communication with Gerald Gabrielse.
[4] This VANDYCK 87 reault is for a positron. We do not take it into account for the average to avoid the assumption of CPT invariance.

$(g_{e^+} - g_{e^-}) / g_{average}$

A test of CPT invariance.

e, μ

e^- MEAN LIFE / BRANCHING FRACTION

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review **D45** S1 (1992), p. VI.10).

Most of these experiments are one of three kinds: Attempts to observe (a) the 255.5 keV gamma ray produced in $e^- \to \nu_e \gamma$, (b) the (K) shell x ray produced when an electron decays without additional energy deposit, e.g., $e^- \to \nu_e \overline{\nu}_e \nu_e$ ("disappearance" experiments), and (c) nuclear de-excitation gamma rays after the electron disappears from an atomic shell and the nucleus is left in an excited state. The last can include both weak boson and photon mediating processes. We use the best $e^- \to \nu_e \gamma$ limit for the Summary Tables.

Note that we use the mean life rather than the half life, which is often reported.

μ

$J = \frac{1}{2}$

μ MASS (atomic mass units u)

The muon's mass is obtained from the muon-electron mass ratio as determined from the measurement of Zeeman transition frequencies in muonium ($\mu^+ e^-$ atom). Since the electron's mass is most accurately known in u, the muon's mass is also most accurately known in u. The conversion factor to MeV has approximately the same relative uncertainty as the mass of the muon in u. In this datablock we give the result in u, and in the following datablock in MeV.

μ MASS

The mass is known more precisely in u (atomic mass units) than in MeV. The conversion is: 1 u = 931.494 103 72(29) MeV/c^2 (2022 CODATA value, MOHR 25). The conversion error contributes significantly to the uncertainty of the masses given below.

μ/p MAGNETIC MOMENT RATIO

This ratio is used to obtain a precise value of the muon mass and to reduce experimental muon Larmor frequency measurements to the muon magnetic moment anomaly. Measurements with an error > 0.00001 have been omitted. By convention, the minus sign on this ratio is omitted. CODATA values were fitted using their selection of data, plus other data from multiparameter fits.

Muon Anomalous Magnetic Moment

μ MAGNETIC MOMENT ANOMALY

The parity-violating decay of muons in a storage ring is observed. The difference frequency ω_a between the muon spin precession and the orbital angular frequency $(e/m_\mu c)\langle B\rangle$ is measured, as is the free proton NMR frequency ω_p, thus determining the ratio $R=\omega_a/\omega_p$. Given the magnetic moment ratio $\lambda=\mu_\mu/\mu_p$ (from hyperfine structure in muonium), $(g-2)/2 = R/(\lambda-R)$.

$\mu_\mu/(e\hbar/2m_\mu) - 1 = (g_\mu - 2)/2$

[1] AGUILLARD 25 combined their value with the previous independent BNL measurement of BENNETT 06.
[2] AGUILLARD 25 quote the combined value from all RUNS 1–6 (at 127 ppm precision). For the 2020–2023 data (Runs 4, 5, 6) alone AGUILLARD 25 measure a value of $(11659207.10 \pm 1.62) \times 10^{-10}$ (at precision of 139 ppb).
[3] This AGUILLARD 23 value is the combination of all 2018, 2019 and 2020 data, including the ABI 21 value. The new FNAL 2019 and 2020 data alone combined yield $(11659205.7 \pm 2.5) \times 10^{-10}$.
[4] AGUILLARD 23 combined their value with the previous independent BNL measurement of BENNETT 06.
[5] ABI 21 combined their value with the previous independent BNL measurement of BENNETT 06. ABI 21 also report that the difference of this combination with the standard model value of $(11659181.0 \pm 4.3) \times 10^{-10}$ (AOYAMA 20) has a significance of 4.2 σ.
[6] BAILEY 79 values recalculated by HUGHES 99 using the COHEN 87 μ/p magnetic moment. The improved MOHR 99 value does not change the result.

$(g_{\mu^+} - g_{\mu^-})/g_{\text{average}}$

A test of CPT invariance.

[1] This limit assumes a giant resonance excitation of the daughter Ca nucleus (mean energy and width both 20 MeV).
[2] KAULARD 98 obtained these same limits using the unified classical analysis of FELDMAN 98.
[3] This limit assumes the daughter Ca nucleus is left in the ground state. However, the probability of this is unknown.
[4] Assuming a giant-resonance-excitation model.

LIMIT ON MUONIUM → ANTIMUONIUM CONVERSION

Forbidden by lepton family number conservation.

$R_g = G_C / G_F$

The effective Lagrangian for the $\mu^+ e^- \to \mu^- e^+$ conversion is assumed to be

$$\mathcal{L} = 2^{-1/2}\, G_C\, [\overline{\psi}_\mu \gamma_\lambda\, (1-\gamma_5)\, \psi_e]\, [\overline{\psi}_\mu \gamma_\lambda\, (1-\gamma_5)\, \psi_e] + \text{h.c.}$$

The experimental result is then an upper limit on G_C/G_F, where G_F is the Fermi coupling constant.

0.782 ±0.031			KRUGER	61			
0.78 ±0.05	8354		PLANO	60	HBC	+	Whole spectrum

[1] The quoted systematic error includes a contribution of 0.00006 (added in quadrature) from uncertainties on radiative corrections and on the Michel parameter η.
[2] BALKE 88 uses $\rho = 0.752 \pm 0.003$.
[3] VOSSLER 69 has measured the asymmetry below 10 MeV. See comments about radiative corrections in VOSSLER 69.

$|(\xi$ PARAMETER$)\times(\mu$ LONGITUDINAL POLARIZATION$)|$

($V-A$) theory predicts $\xi = 1$, longitudinal polarization = 1.

0.93 ±0.06	PLANO	60	HBC	+	8.8 kG
0.97 ±0.05	BARDON	59	CNTR		Bromoform target

[1] The corresponding 90% confidence limit from IMAZATO 92 is $|\xi P_\mu| > 0.990$. This measurement is of K^+ decay, not π^+ decay, so we do not include it in an average, nor do we yet set up a separate data block for K results.
[2] Depolarization by medium not known sufficiently well.

$\xi \times (\mu$ LONGITUDINAL POLARIZATION$) \times \delta / \rho$

VALUE	CL%	DOCUMENT ID		TECN	CHG	COMMENT

>0.99682	90	[2] JODIDIO	86	SPEC	+	TRIUMF
>0.9966	90	[3] STOKER	85	SPEC	+	μ-spin rotation
>0.9959	90	CARR	83	SPEC	+	11 kG

[1] BAYES 11 obtains the limit > 0.99909 (90% CL) with the constraint that $\xi\times(\mu$ LONGITUDINAL POLARIZATION$) \times \delta/\rho \leq 1.0$.
[2] JODIDIO 86 includes data from CARR 83 and STOKER 85. The value here is from the erratum.
[3] STOKER 85 find $(\xi P_\mu \delta/\rho) > 0.9955$ and > 0.9966, where the first limit is from new μ spin-rotation data and the second is from combination with CARR 83 data. In $V-A$ theory, $(\delta/\rho) = 1.0$.

ξ' = LONGITUDINAL POLARIZATION OF e^+

($V-A$) theory predicts the longitudinal polarization = ± 1 for $e^\pm$, respectively. We have flipped the sign for e^- so our programs can average.

τ

$J = \frac{1}{2}$

τ discovery paper was PERL 75. $e^+e^- \to \tau^+\tau^-$ cross-section threshold behavior and magnitude are consistent with pointlike spin-1/2 Dirac particle. BRANDELIK 78 ruled out pointlike spin-0 or spin-1 particle. FELDMAN 78 ruled out $J = 3/2$. KIRKBY 79 also ruled out J=integer, $J = 3/2$.

[1] ADACHI 23C, AUBERT 09AK and BELOUS 07 fit τ pseudomass spectrum in $\tau \to \pi\pi^+\pi^-\nu_\tau$ decays. Result assumes $m_{\nu_\tau} = 0$.

[2] Previously also reported LEVICHEV 14. Superseedes ANASHIN 07.

[3] ABLIKIM 14D fit $\sigma(e^+e^- \to \tau^+\tau^-)$ at different energies near threshold.

[4] ABBIENDI 00A fit τ pseudomass spectrum in $\tau \to \pi^\pm \leq 2\pi^0\nu_\tau$ and $\tau \to \pi^\pm\pi^+\pi^- \leq 1\pi^0\nu_\tau$ decays. Result assumes m_{ν_τ}=0.

[5] BAI 96 fit $\sigma(e^+e^- \to \tau^+\tau^-)$ at different energies near threshold.

[6] ALBRECHT 92M fit τ pseudomass spectrum in $\tau^- \to 2\pi^-\pi^+\nu_\tau$ decays. Result assumes m_{ν_τ}=0.

[7] BACINO 78B value comes from $e^\pm X^\mp$ threshold. Published mass 1782 MeV increased by 1 MeV using the high precision $\psi(2S)$ mass measurement of ZHOLENTZ 80 to eliminate the absolute SPEAR energy calibration uncertainty.

[8] BALEST 93 fit spectra of minimum kinematically allowed τ mass in events of the type $e^+e^- \to \tau^+\tau^- \to (\pi^+ n\pi^0\nu_\tau)(\pi^- m\pi^0\nu_\tau)$ $n \leq 2$, $m \leq 2$, $1 \leq n+m \leq 3$. If $m_{\nu_\tau} \neq 0$, result increases by $(m^2_{\nu_\tau}/1100$ MeV).

[9] BAI 92 fit $\sigma(e^+e^- \to \tau^+\tau^-)$ near threshold using $e\mu$ events.

$(m_{\tau^+} - m_{\tau^-})/m_{\rm average}$

A test of CPT invariance.

[1] AAD 25BB limits are obtained by comparing the inclusive $\tau^+\tau^-$ fiducial cross-section in pp collisions as a function of visible invariant mass at large masses to the Standard Model prediction.
[2] AAD 23BM measurement is derived from $\gamma\gamma \to \tau^+\tau^-$ total cross-section TeV. Authors report both the measured value and the corresponding 95% CL limit. from 1.44 nb^{-1} LHC Pb−Pb collisions at $\sqrt{s_{NN}} = 5.02$
[3] Measurement ill-suited for a standard average because its likelihood appears to be remarkably non-Gaussian and asymmetric according to the model-dependent extraction procedure and the reported 95% CL limits.
[4] TUMASYAN 23AS measurement is derived from $\gamma\gamma \to \tau^+\tau^-$ total cross-section from 404 μb^{-1} LHC Pb-Pb collisions at $\sqrt{s_{NN}} = 5.02$ TeV.
[5] ABDALLAH 04K measurement is derived from $e^+e^- \to e^+e^-\tau^+\tau^-$ total cross-section measurements at $\sqrt{s}$ between 183 and 208 GeV. In addition to the measurement, the authors also quote 95% CL limits of > -0.052 and < 0.013.
[6] ACHARD 04G limit is derived from $e^+e^- \to e^+e^-\tau^+\tau^-$ total cross-section measurements at $\sqrt{s}$ between 189 and 206 GeV, and is on the absolute value of the magnetic moment anomaly.
[7] GONZALEZ-SPRINBERG 00 use data on tau lepton production at LEP1, SLC, and LEP2, and data from colliders and LEP2 to determine limits. Assume imaginary component is zero.
[8] ACCIARRI 98E use $Z \to \tau^+\tau^-\gamma$ events. In addition to the limits, the authors also quote a value of $0.004 \pm 0.027 \pm 0.023$.
[9] ACKERSTAFF 98N use $Z \to \tau^+\tau^-\gamma$ events. The limit applies to an average of the form factor for off-shell τ's having p^2 ranging from m_τ^2 to $(M_Z - m_\tau)^2$.
[10] ESCRIBANO 97 use preliminary experimental results.
[11] ESCRIBANO 93 limit derived from $\Gamma(Z \to \tau^+\tau^-)$, and is on the absolute value of the magnetic moment anomaly.
[12] SILVERMAN 83 limit is derived from $e^+e^- \to \tau^+\tau^-$ total cross-section measurements for q^2 up to (37 GeV)^2.

τ ELECTRIC DIPOLE MOMENT (d_τ)

A nonzero value is forbidden by both T invariance and P invariance.

The q^2 dependence is expected to be small providing no thresholds are nearby.

Lepton Family number (LF), Lepton number (L), or Baryon number (B) violating modes

L means lepton number violation (*e.g.* $\tau^- \to e^+\pi^-\pi^-$). Following common usage, LF means lepton family violation *and not* lepton number violation (*e.g.* $\tau^- \to e^-\pi^+\pi^-$). B means baryon number violation.

CONSTRAINED FIT INFORMATION

An overall fit to 85 branching ratios uses 170 measurements and one constraint to determine 46 parameters. The overall fit has a $\chi^2 = 135.0$ for 125 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

τ^- BRANCHING RATIOS

$\Gamma(\text{particle}^- \geq 0 \text{ neutrals } \geq 0K^0 \nu_\tau (\text{"1-prong"}))/\Gamma_{total}$ Γ_1/Γ

$\Gamma_1/\Gamma = (\Gamma_3+\Gamma_5+\Gamma_9+\Gamma_{10}+\Gamma_{14}+\Gamma_{16}+\Gamma_{20}+\Gamma_{23}+\Gamma_{27}+\Gamma_{28}+\Gamma_{30}+\Gamma_{36}+\Gamma_{38}+\Gamma_{41}+\Gamma_{43}+\Gamma_{45}+\Gamma_{48}+\Gamma_{49}+\Gamma_{50}+\Gamma_{52}+\Gamma_{56}+\Gamma_{57}+0.7195\Gamma_{150}+0.7195\Gamma_{152}+0.7195\Gamma_{154}+0.7195\Gamma_{156}+0.336\Gamma_{170}+0.0833\Gamma_{178}+0.0833\Gamma_{179}+0.0833\Gamma_{180})/\Gamma$

The charged particle here can be e, μ, or hadron. In many analyses, the sum of the topological branching fractions (1, 3, and 5 prongs) is constrained to be unity. Since the 5-prong fraction is very small, the measured 1-prong and 3-prong fractions are highly correlated and cannot be treated as independent quantities in our overall fit. We arbitrarily choose to use the 3-prong fraction in our fit, and leave the 1-prong fraction out. We do, however, use these 1-prong measurements in our average below.
