

# Optimizing precision of columnar methane retrievals

Ralf Sussmann, Frank Forster, Tobias Borsdorff, Markus Rettinger

## Motivation:

- investigate prior impact on column precision / response to true variability: complementary but related to TCCON
- ENVISAT/SCIAMACHY XCH<sub>4</sub> validation with Zugspitze FTIR in 2005 had quantified strong time-dependent biases due to icing problems in channel 8
- newest SCIA IMAP-DOAS (ver. 49) XCH<sub>4</sub> retrievals (channel 6) have been significantly improved
- repeat SCIA validation with an optimized set of MIR-NDACC-FTIRs (HYMN project)
- point to a riddle in the annual cycle found by MIR-FTIR versus SCIAMACHY

Optimizing precision of CH<sub>4</sub> columns

## MIR-FTIR XCH<sub>4</sub> precision: **Specific questions addressed in this talk**

---

MIR-FTIR retrieval of CH<sub>4</sub> within the EC-HYMN project:

2613.70 - 2615.40

2650.60 - 2651.30

2835.50 - 2835.80

2903.60 - 2904.03

2921.00 - 2921.60

HITRAN 2004

XCH<sub>4</sub> calculated via daily local pT-profiles (fasmus)

Optimizing precision of CH4 columns

## MIR-FTIR XCH4 precision/diurnal variation: the problem with OE regularization

---

- because of CH<sub>4</sub> spectroscopy problems OE (realistic  $\mathbf{S}_e$  and climatological  $\mathbf{S}_a$ , e.g.,  $dofs \approx 3$ ) leads to profile oscillations
- to avoid oscillations stronger regularization is required
- for this purpose, sometimes the (diagonal) variances of an OE  $\mathbf{S}_a$  are reduced empirically, but this leads to a significant forcing towards the a priori
- as a consequence, this leads to a significant under-estimation of true columns variability, e.g., for  $dofs \approx 2$  one may find  $\approx 50\%$  under-estimation of day-to-day-variability

## Optimize MIR-FTIR XCH4 precision: Tikhonov first derivative regularization $L_1$

$$\mathbf{R} = \mathbf{S}_a^{-1} = \alpha \mathbf{L}_1^T \mathbf{L}_1 = \alpha \times \begin{pmatrix} 1 & -1 & 0 & \dots & 0 \\ -1 & 2 & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 2 & -1 \\ 0 & \dots & 0 & -1 & 1 \end{pmatrix} \in \mathfrak{R}^{n \times n} \quad (1)$$

with regularization strength  $\alpha$ .

Case  $\alpha \rightarrow \infty$  is a VMR-profile scaling retrieval with  $dofs \rightarrow 1$ .

Case  $\alpha \rightarrow 0$  is a totally unconstrained profile retrieval with  $dofs \rightarrow n = \text{number of model layers}$

We derive an analytic relation between  $\alpha$  and  $dofs$  by putting eq. 1 into eq. 3.28 of Rodgers (2000):

$$dofs = \text{trace}(\mathbf{A}) = \text{trace}((\mathbf{K}_x^T \mathbf{S}_\varepsilon^{-1} \mathbf{K}_x + \alpha \mathbf{L}_1^T \mathbf{L}_1)^{-1} \mathbf{K}_x^T \mathbf{S}_\varepsilon^{-1} \mathbf{K}_x) \quad (2)$$

## MIR-FTIR XCH4 precision / diurnal variation: why optimize via Tikhonov $L_1$ ?

---

- profile scaling ( $L_1$  with  $\alpha \rightarrow \infty$ ,  $dofs \equiv 1$ ) is known to be a good starter for getting reasonable  $\text{CH}_4$  columns
- starting from that  $\alpha$  can be empirically reduced ( $dofs$  increased) to allow for some additional flexibility in the profile to account for true profile variations and/or cloud impact on the spectra  
 $\Rightarrow$  to get even more precise columns than by profile scaling
- whatever the  $dofs$  ( $\alpha$ ) is, there is *per definitionem* never any under-estimation of true profile-scaling-type variability using  $L_1$

## XCH4 retrieval: as to which quantity optimize $L_1$ regularization strength $\alpha$ ?

---

- „the colleagues use  $dofs = 3$ , therefore we tune  $\alpha$  in a way to achieve  $dofs = 3$ ”

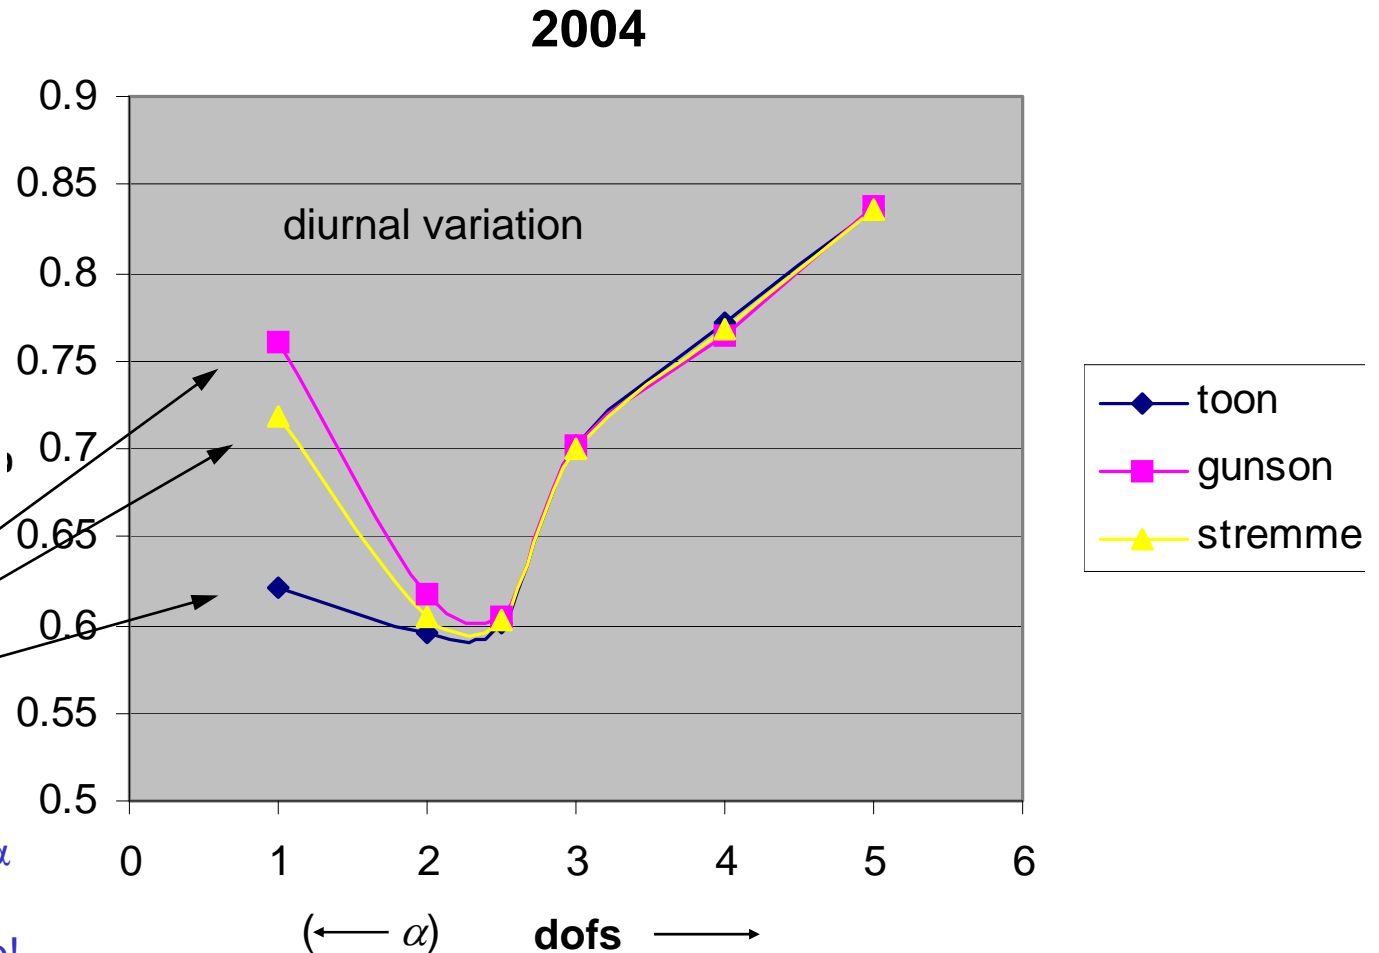

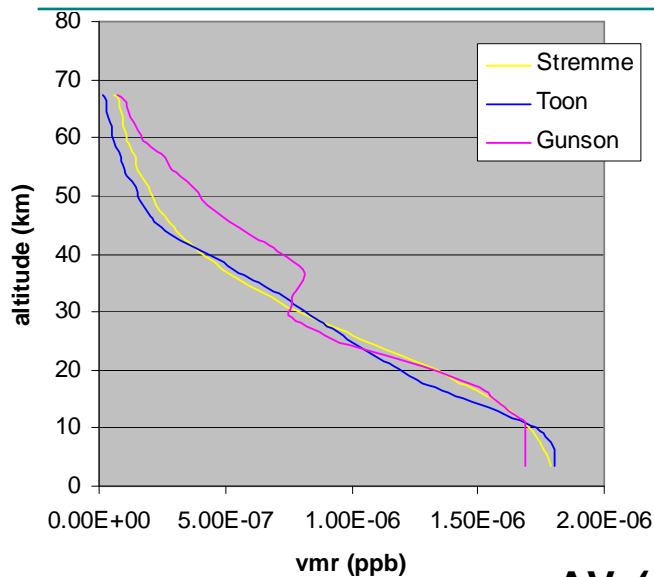

or better:

- elbow plot “residual-rms versus  $\alpha$ ”
- reduce  $\alpha$  until first profile oscillations occur
- tune  $\alpha$  for optimum trade off between smoothing errors and retrieval noise (Steck, Appl. Opt., 2002)

or (this talk):

- tune  $\alpha$  for minimum XCH4 diurnal variation
- tune  $\alpha$  for minimum XCH4 day-to-day variability

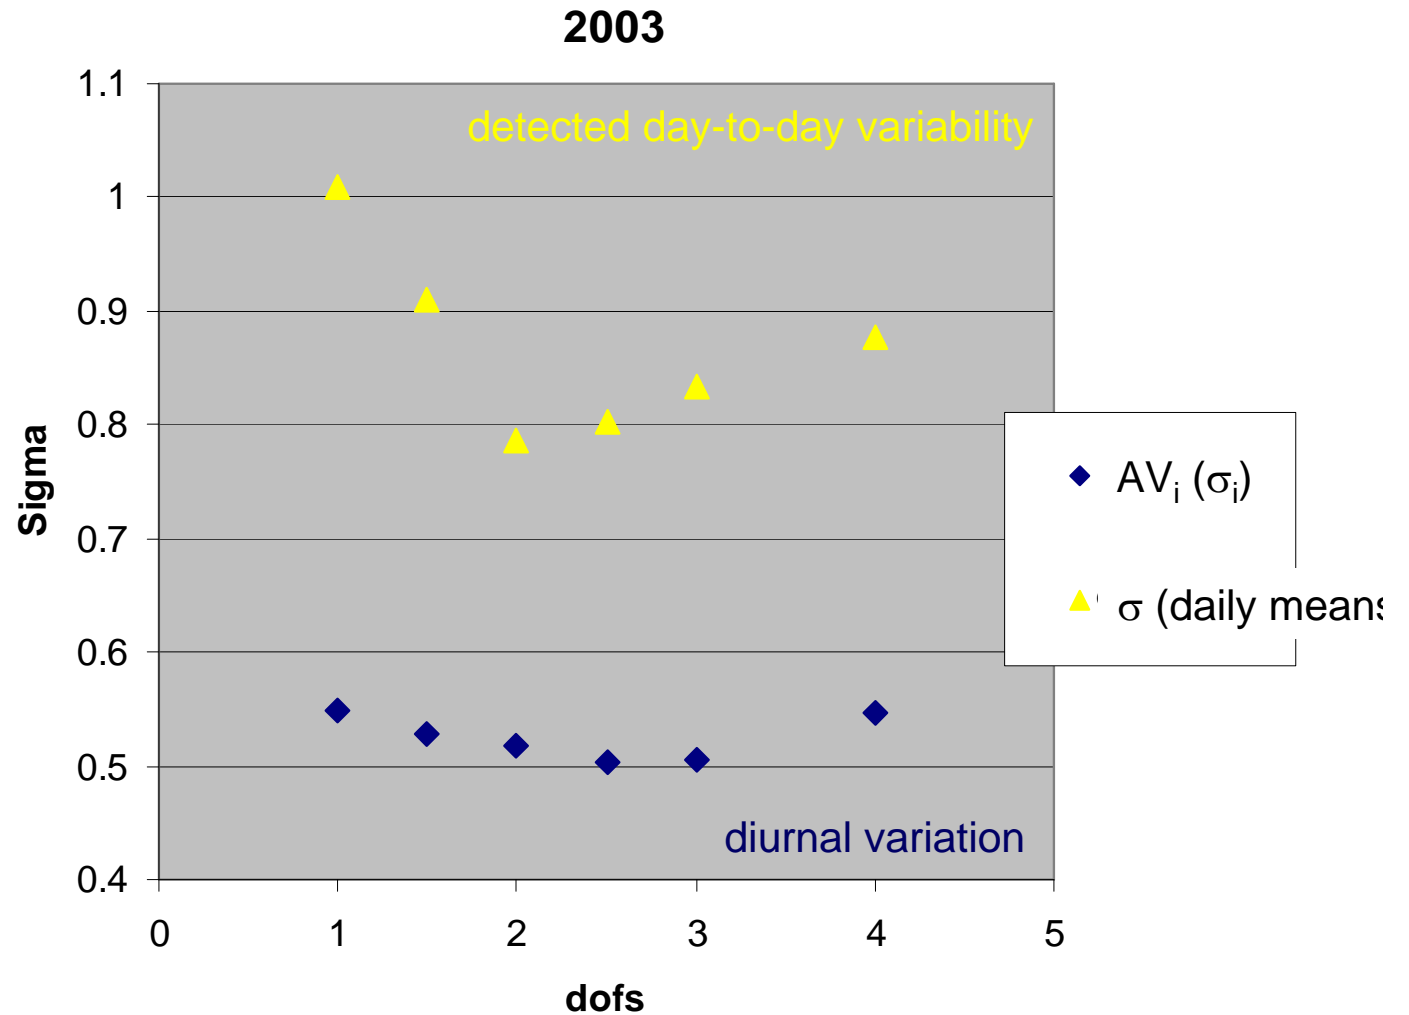

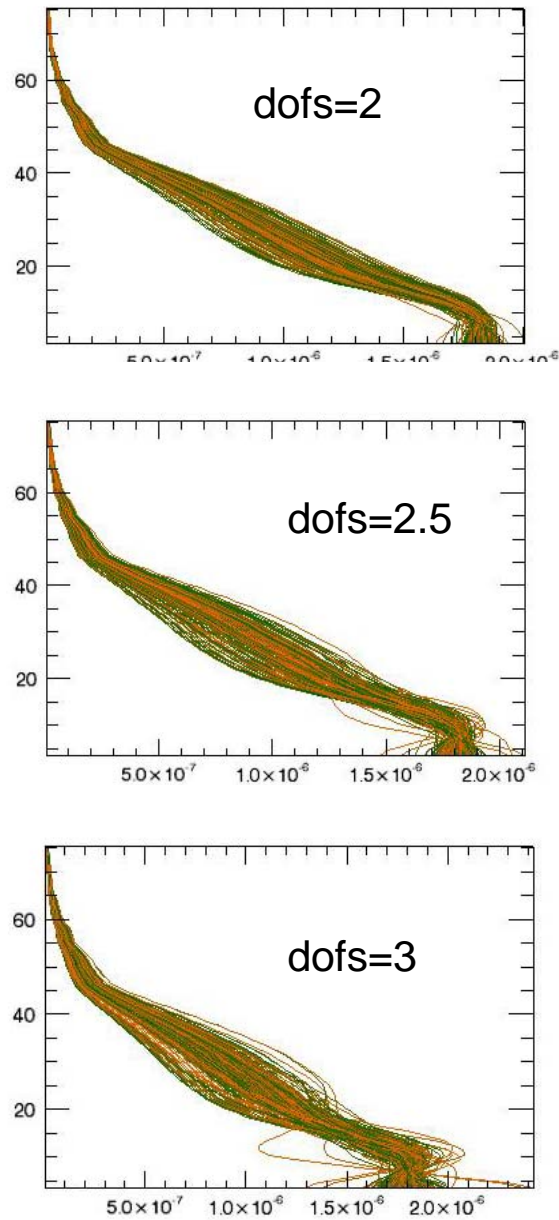

# $L_1$ as a function of $\alpha$ (dofs): minimize diurnal variation averaged over all days

note strong a priori impact for profile scaling (dofs = 1)

⇒ using  $L_1$  there is no big risk for producing nonsense  $\sigma$ 's whatever  $\alpha$  you use; but with a diagonal  $\mathbf{S}_a$  ( $L_0$ ) you could produce  $\sigma$ 's down to zero!

# Minimize: diurnal variation, detected day-to-day variability, and profile oscillations

Optimizing precision of CH<sub>4</sub> columns

## Summary and conclusions

---

- since there are problems with CH<sub>4</sub> spectroscopy, often stronger regularization is applied to avoid profile oscillations ( $\Rightarrow$  lower *dofs* than OE-derived *dofs*)
- in this case classical OE-based regularization leads to a forcing towards a priori and thereby significant under estimation of true columns variability (e.g., day-to-day variability)
- this can be avoided by using a Tikhonov  $L_1$  (or related) regularization scheme
- in tuning  $L_1$  regularization strength, there is both a minimum in diurnal variation and day-to-day variability around *dofs*  $\approx$  2-3
- this regularization setting is assumed to yield the best measure for true day-to-day variability
- there is a riddle as to the phase of the annual cycle of XCH<sub>4</sub> derived from MIR-FTIR versus ENVISAT/SCIAMACHY we are currently investigating
- the strategy of tuning Tikhonov  $L_1$  to minimum diurnal variation might be tested for NIR retrievals (TCCON) and be applied to future validation of GOSAT XCH<sub>4</sub>
