# Outline

Marine Boundary Layers

Motivation

Review

Humidity effects at the North Sea - FINO 1

Consequences for stability

# Key features of the Marine Boundary Layer

Compared with land, marine conditions feature:

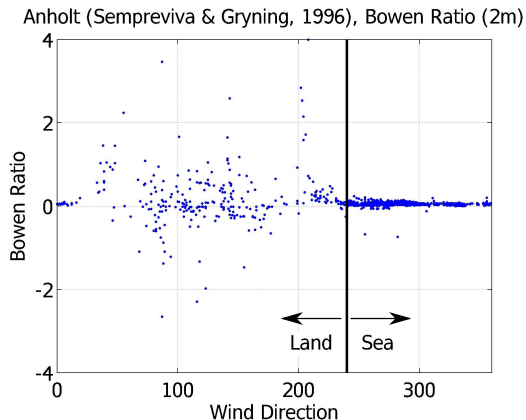

- ▶ Highly irregular, dynamic surface
- ▶ Less surface friction
- ▶ Little diurnal variation of boundary layer
- ▶ Effect of moisture on stability may not be neglected...

## Motivation - Importance of humidity for stability

- ▶ Monin-Obukhov stability parameter:  $\frac{z}{L} = \frac{zkg\langle wT_v \rangle}{T_v u_*^3}$
- ▶ Virtual potential heat flux can be estimated from:  
 $\langle wT_v \rangle = \langle wT \rangle + 0.61T \langle wq \rangle$
- ▶ An ultrasonic anemometer measures:  
 $\langle wT_s \rangle = \langle wT \rangle + 0.51T \langle wq \rangle$
- ▶ In dry and/or cold conditions,  $\langle wq \rangle =$  humidity flux can be neglected, hence  $\langle wT_v \rangle \approx \langle wT_s \rangle$
- ▶ Relative importance of heat to humidity fluxes:  
Bowen Ratio =  $\frac{c_p \langle wT \rangle}{L_v \langle wq \rangle}$ .
- ▶ For example, Andreas et al. (2006) - Evaluations of the von Karman constant in the atmospheric surface layer, assume  $\langle wT_v \rangle = \langle wT_s \rangle$  in arctic conditions (Bowen Ratio =  $\infty$ ).
- ▶ How valid is this assumption in marine conditions?

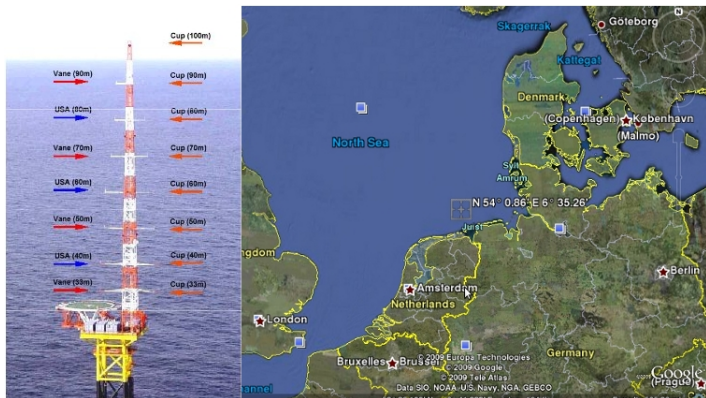

## Review

*Sempreviva & Gryning (1996) - Humidity Fluctuations in the Marine Boundary Layer measured at a coastal site...*

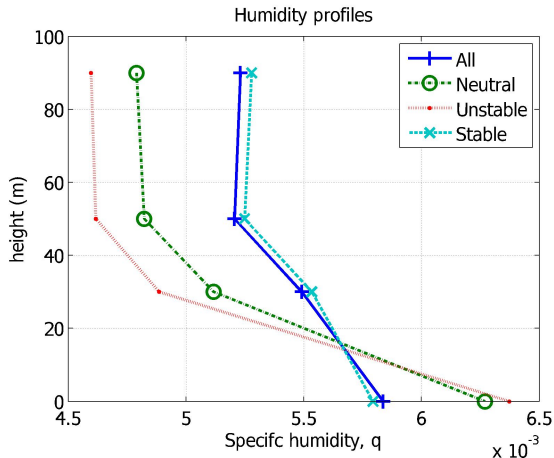

- ▶ Marine Conditions: (Bowen Ratio  $\approx 0.1$ );

# FINO 1 - Measurement platform in the North Sea

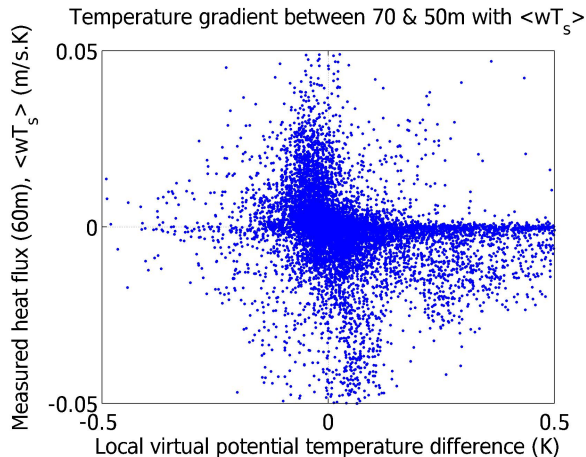

- ▶ In operation since 2003, approx. 45km North of Borkum Island.
- ▶ Cup anemometers, wind vanes, temperature sensors, ultrasonic anemometers, hygrometers at multiple levels.
- ▶ Data here presented for the period 01/01/05-15/05/05.

# Humidity at FINO1?

- ▶ Above 50m – Negative humidity flux for stable conditions, positive humidity flux for neutral & unstable.
- ▶ Are fluxes driven by local gradients above 50m, or by non-local gradients, i.e. sea surface relative humidity = 100%?

# Heat Flux - Profile Relationship

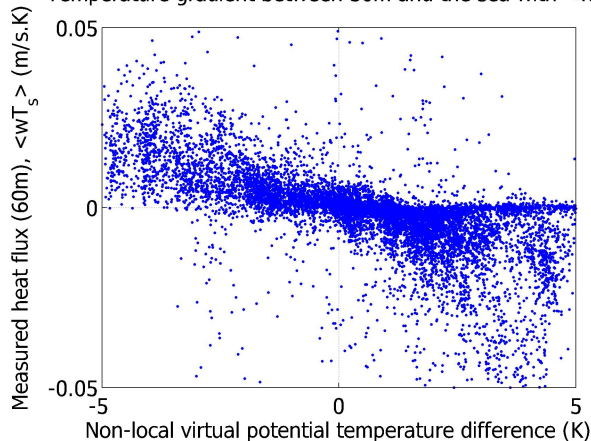

- ▶ Local heat fluxes are poorly correlated with local temperature gradients. (Correlation coefficient: -0.06)

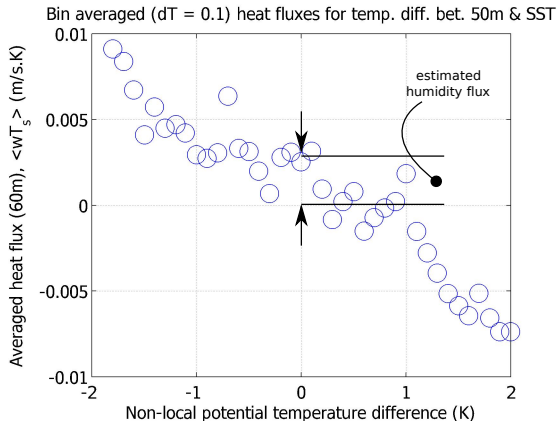

# Heat Flux - Profile Relationship

Temperature gradient between 50m and the sea with  $\langle wT_s \rangle$

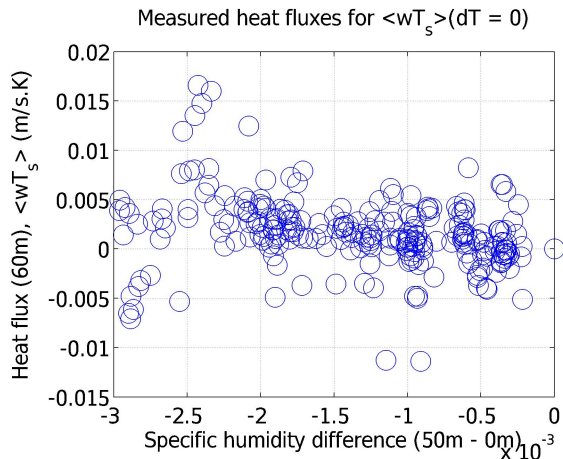

- ▶ Heat fluxes are driven by non-local temperature gradients. (Correlation coefficient: -0.47)
- ▶ Non-locally driven fluxes make it difficult to derive fluxes from profiles.

# Estimation of temperature and humidity fluxes:

- ▶ If humidity flux were zero, averaged heat flux would pass through the origin when plotted against the potential temperature.
- ▶ Therefore, since  $\langle wT_s \rangle = \langle wT \rangle + 0.51T \langle wq \rangle$ , then  $\langle wT_s \rangle (\Delta\theta = 0) = 0.51T \langle wq \rangle$ .

# Estimated humidity fluxes

- ▶ Estimated humidity fluxes poorly correlated with both fine humidity gradients and (shown here) bulk differences.
- ▶ Humidity flux a function of larger atmospheric scales?

# Estimated humidity fluxes

Measured heat fluxes for  $\langle wT_s \rangle (dT = 0)$

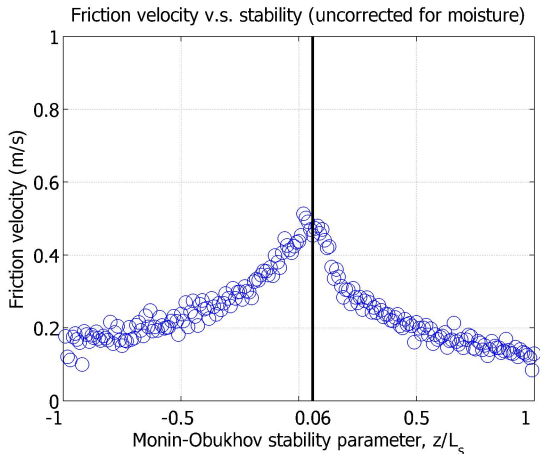

- ▶ Mean humidity flux,  $\langle wq \rangle = \frac{\langle wT_s \rangle (\Delta\theta=0)}{0.51T} = 1 \times 10^{-5}$ .
- ▶ Assuming value representative of all stabilities (poor humidity flux correlation with temperature gradient):
  - ▶ Average Bowen ratio over all stabilities = 0.31 (Sempreviva & Gryning, 1996: Bowen ratio over all stabilities  $\approx 0.1$ )

## Effect on buoyancy

- ▶ Total Buoyant flux:  $\frac{g}{T} \langle wT \rangle + 0.61g \langle wq \rangle$
- ▶ Ratio of these two terms, Buoyancy ratio:  $\frac{0.61T \langle wq \rangle}{\langle wT \rangle}$
- ▶ Converting Bowen ratio ( $\approx 0.3$ ) to the Buoyancy ratio gives  $\frac{0.61T \langle wq \rangle}{\langle wT \rangle} \approx 0.2$
- ▶ Lower than that reported in literature (Possibly because of the lower temperatures at FINO 1 early in the year):
  - ▶ Sempreviva & Gryning: Buoyancy ratio  $\approx 0.4$ .
  - ▶ Edson et al. (2004) “the moisture flux component...provided more than half of the total buoyancy flux...and this component kept the surface layer slightly unstable”.

## Consequences for stability: $u_*$ v.s. $z/L_s$

- ▶ Stability is over predicted since the peak friction velocity is detected on the slightly stable side if the stability parameter is not corrected for humidity effects (Here,  $\frac{z}{L_s} = \frac{zkg\langle wT_s \rangle}{T_v u_*^3}$ ).

# Conclusions

- ▶ Precise calculation of stability of the marine boundary layer requires direct measurement of the humidity flux since it is not governed by local gradients.
- ▶ Currently, there is no way of directly measuring humidity fluxes at FINO1 or in the recently completed FINO3 platform, also in the North Sea.
- ▶ Neglect of humidity underestimates buoyancy by approximately 20% during the analysed measurement period. This could be corrected by estimating the bulk contribution of humidity to the buoyancy.

# Acknowledgements

- ▶ We acknowledge the reception of valuable data and advice from Dr. Anna-Maria Sempreviva which has aided this work greatly.
- ▶ The work was done in the project VERITAS (work package 5 of OWEA) which is funded by the German Ministry of the Environment (BMU) via the PTJ (FKZ 0325060).
