

Mixing-layer height and low-level jets

Stefan Emeis stefan.emeis@kit.edu

INSTITUTE OF METEOROLOGY AND CLIMATE RESEARCH, Atmospheric Environmental Research

Introduction

- definition of mixing layer
- definition of low-level jet
- relevance for wind energy
 - remote sensing

Mixing-layer height

101/0	raian	halaht
$H \cap V \cap$		$I \cap \omega \cap I \cap I \cap I$
IIIVC	IJIUII	height

literally: inversion in the temperature profile, increase of temperature with height, strong decrease of moisture, radiation inversions, sinking inversions, surface inversions, lifted inversions

Mixing-layer height

(mixing height, mixed-layer height)

upper boundary for vertical exchange (mixing), upper boundary of the well-mixed layer, entrainment, defined by the turbulence profile or by the vertical distribution of a tracer (aerosol, pot. temperature)

Boundary layer height

SBL: at night, height of the near-surface layer influenced

by surface friction

CBL: at day, height of convective plumes

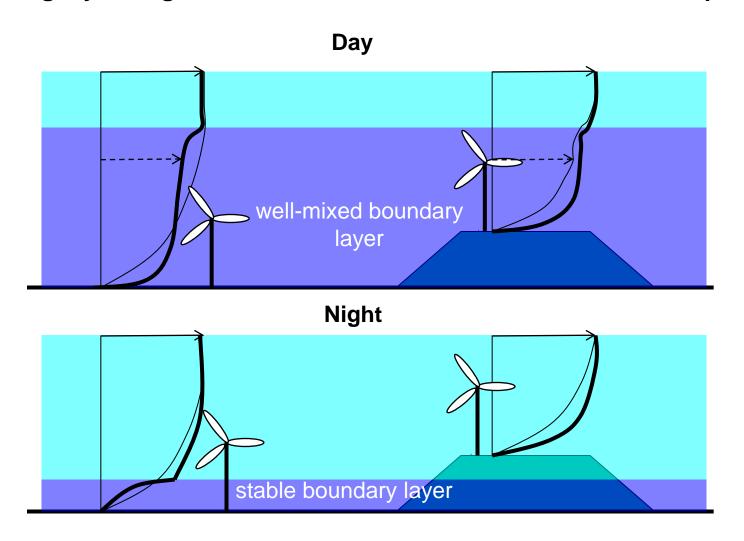

boundary layer height ≈ mixing-layer height

boundary layer height ≥ inversion height

Mixing-layer height influences diurnal variation of vertical wind profiles

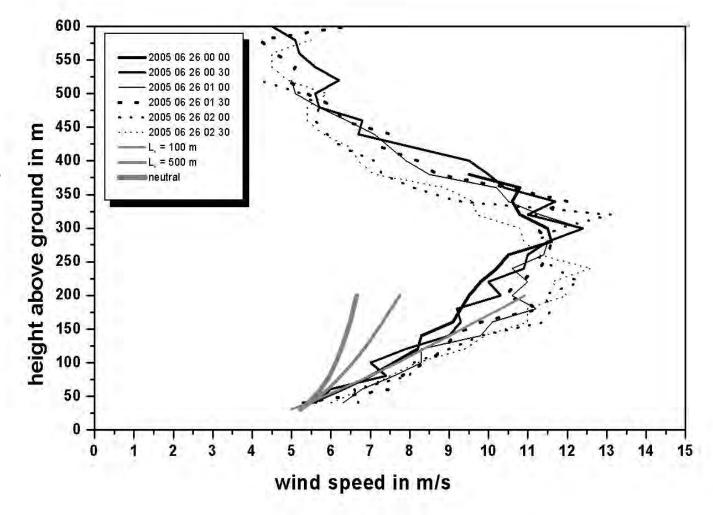

Low-level jet

vertical profiles of wind speed

26 June 2005

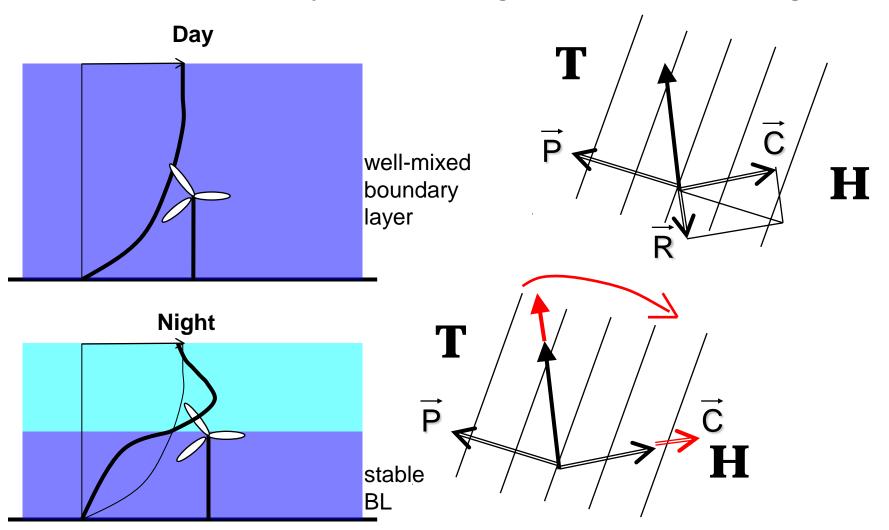

AdP Ch d G

Nocturnal low-level jet and the turning of wind direction with height

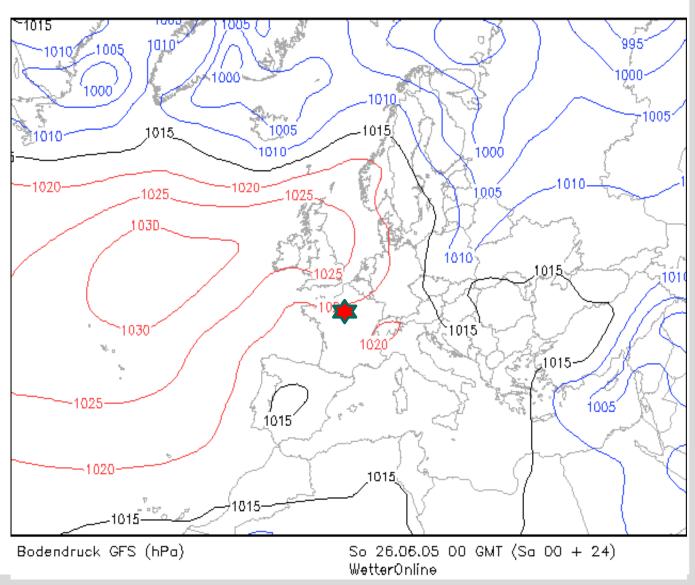

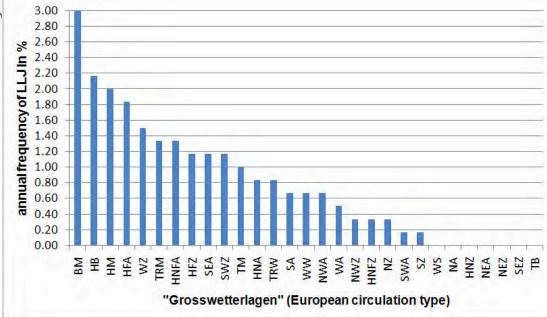

surface pressure **00 GMT**

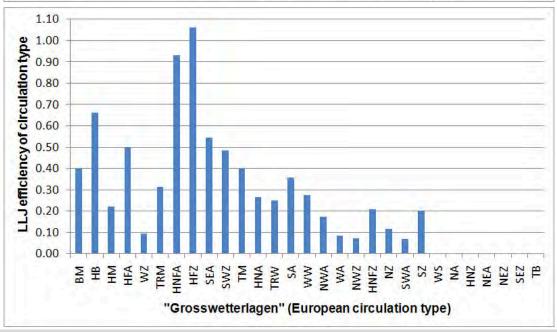

26 June 2005

asterisk denotes location where LLJ was observed

frequency of LLJ over Hanover for 20 months in the years 2001 to 2003

total is 23.17% of all nights

circulation types:

BM ridge over Central Europe high over British Isles HB HM high over Central Europe

HFZ high over Scandinavia **HNFA** high over North Atlantic

"efficiency" of a circulation type to produce a LLJ over Hanover for 20 months in the years 2001 to 2003

Relevance for wind energy

The vertical wind profile (equilibrium conditions)

logarithmic law

(with stability correction)

$$u(z) = (u_*/\kappa) (ln(z/z_0) - \psi(z/L_*))$$

power law

$$u(z) = u(z_A) (z/z_A)^n$$

New proposal (Gryning et al. 2007)

$$u(z) = \frac{u_{*0}}{\kappa} \left(\ln \left(\frac{z}{z_0} \right) + \frac{z}{L_{MBL,N}} - \frac{z}{z_i} \left(\frac{z}{2L_{MBL,N}} \right) \right)$$

needs information on the PBL or mixing-layer height

Gryning, S.-E., E. Batchvarova, B. Brümmer, H. Jørgensen, S. Larsen, 2007: On the extension of the wind profile over homogeneous terrain beyond the surface boundary layer. Bound.-Lay. Meteorol., **124**, 251–268.

Peña, A., S.-E. Gryning, C.B. Hasager, 2010: Comparing mixing-length models of the diabatic wind profile over homogeneous terrain. Theor. Appl. Climatol., **100**, 325-353.

LLJ can only be described by time-dependent equations!

subject of this lecture

Basic remote sensing techniques

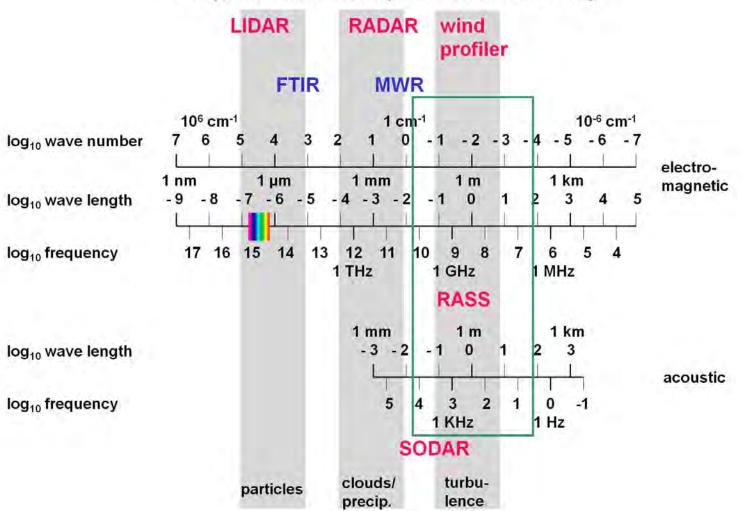

name	princple	spatial resolution	direction	type
RADAR	backscatter, electro-magnetic pulses, fixed wave length	profiling	scanning, slanted	active, monostatic
SODAR	backscatter, acoustic pulses, fixed wave length	profiling	fixed, slanted, vertical	active, usually monostatic
LIDAR ceilometer	backscatter, optical pulses, fixed wave length(s)	profiling	scanning, fixed, horizontal, slanted, vertical	active, monostatic
RASS	backscatter, acoustic, electro-magnetic, fixed wave length	profiling	fixed, vertical	active, monostatic
	absorption, infrared, spectrum	path-averaging	fixed, horizontal, slanted	active, bistatic or passive
FTIR	emission, infrared, spectrum	path-averaging	fixed, horizontal, slanted	passive
DOAS	absorption, optical, fixed wave lengths	path-averaging	fixed, horizontal	active, bistatic
radiometry	electro-magnetic, fixed wave length(s)	averaging, profiling	fixed, scanning, slanted, vertical	passive
tomography	travel time, acoustic, fixed wave length	horizontal distribution	fixed, horizontal	active, multiple emitters and receivers

Frequencies for atmospheric remote sensing

Emeis, S., 2010: Measurement Methods in Atmospheric Sciences - In situ and remote. Borntraeger, Stuttgart, 272 pp., 103 figs, 28 tables, ISBN 978-3-443-01066-9.

Surface-based Remote Sensing Systems

at IMK-IFU

SODAR (Large system), acoustic backscatter, Doppler shift analysis → wind, turbulence

Wind-LIDAR, optical backscatter, Doppler shift analysis, wave length ~ 1.5 µm → wind and

aerosol profiles

Ceilometer,
backscatter, optical
pulses, wave
length ~ 0.9 µm
→ aerosol profiles

SODAR

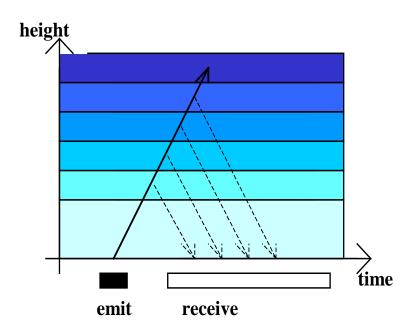

algorithms for the determination of mixing-layer height

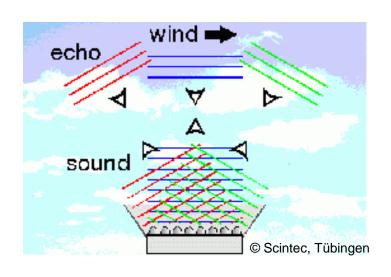

and low-level jet observations

monostatic SODAR: measuring principles

deduction:

sound travel time = he backscatter intensity = tu

Doppler-shift

= height

= turbulence

= wind speed

Emission of sound waves into three directions:

in order to measure all three components of the wind (horizontal and vertical)

The SODAR equation:

$$P_R = r^2 (c_s \tau A \varepsilon / 2) P_0 \beta_s e^{-2\sigma r} + P_{bg}$$

P_R received power,

P₀ emitted power,

ε antenna efficiency,

A effective antenna area,

σ sound absorption in air due to classical and molecular absorption due to the collision of water molecules with the oxygen and nitrogen molecules of the air,

r distance between the scattering volume and the instrument,

 τ pulse duration (typically between 20 and 100 ms),

 β_s backscattering cross-section (typically in the order of 10⁻¹¹ m⁻¹ sr⁻¹),

c_s sound speed,

P_{bg} background noise.

Emitted power: ~ 10³ W, received (backscattered) power: 10⁻¹⁵ W

The SODAR equation:

$$P_R = r^2 (c_s \tau A \varepsilon / 2) P_0 \beta_s e^{-2\sigma r} + P_{bg}$$

The ratio of the two terms on the right-hand side of the SODAR equation is called signal-to-noise ratio (usually abbreviated as SNR).

The backscattering cross-section β_s is a function of the temperature structure function C_T^2 (Tatarskii 1961).

For a monostatic SODAR we find (Reitebuch 1999) when using the wave number $k = 2\pi/\lambda$:

$$\beta_s(180^\circ) = 0.00408 \ k^{1/3} \ C_T^2 / T^2$$

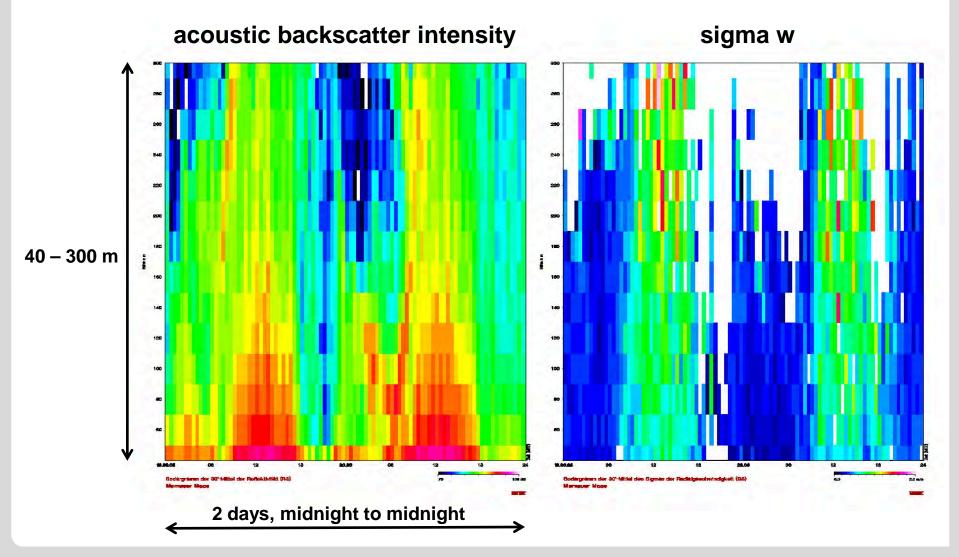

Reitebuch, O., 1999: SODAR-Signalverarbeitung von Einzelpulsen zur Bestimmung hochaufgelöster Windprofile. Schriftenreihe des Fraunhofer-Instituts für Atmosphärische Umweltforschung, Shaker Verlag GmbH Aachen, Bd. 62, 178 S.

Tatarskii, V.I., 1971: The effect of the turbulent atmosphere on wave propagation. Kefer Press, Jerusalem, 472 S.

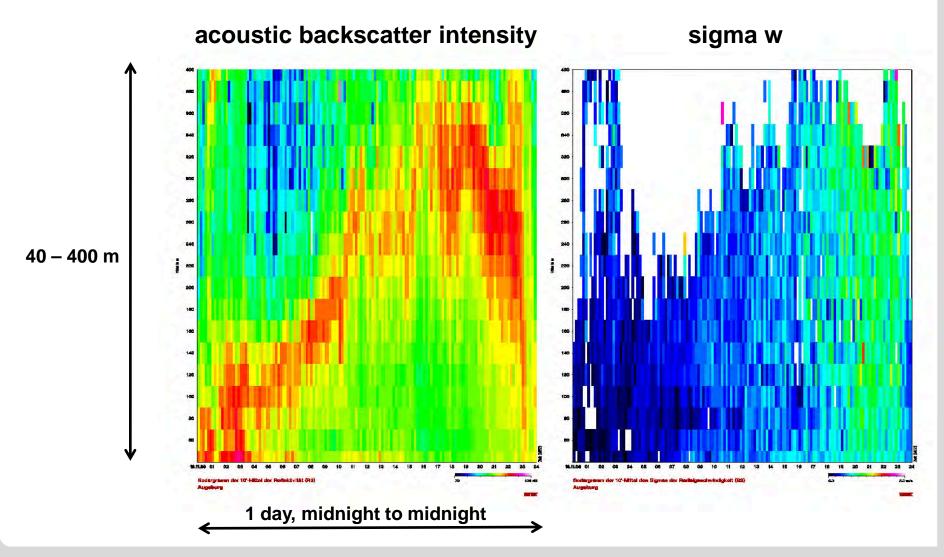

SODAR sample plot (daytime convective BL)

SODAR sample plot (lifted inversion)

Algorithms to detect MLH from SODAR data

surface

= MLH

inversion

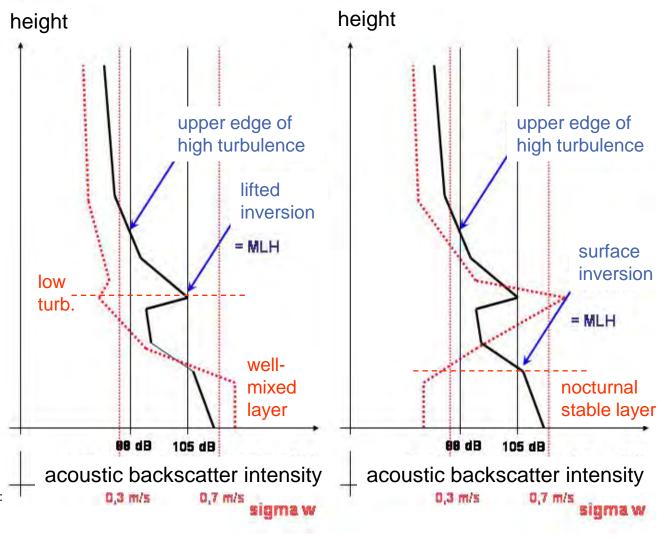

upper edge of high turbulence

criterion 2:

surface and lifted inversions

MLH = Min (C1, C2)

Emeis, S., K. Schäfer, C. Münkel, 2008: Surface-based remote sensing of the mixing-layer height – a review. Meteorol. Z., 17, 621-630.

example 1: daytime

example 2: night-time

Ceilometer

algorithms for the determination of mixing-layer height

Ceilometer/LIDAR measuring principle

detection:

travel time of signal backscatter intensity Doppler-shift

- = height
- = particle size and number distribution
- = cannot be analyzed from ceilometer data

(available only from a Wind-LIDAR: velocity component in line of sight)

The LIDAR equation:

$$P_R(\lambda,r) = r^2 (c\tau A \varepsilon/2) P_0 [\beta_m(\lambda,r) + \beta_p(\lambda,r)] e^{-2\sigma r} + P_{bg}$$

- r distance between the LIDAR and the backscattering object,
- c speed of light,
- τ pulse duration,
- A antenna area,
- ε correction term for the detector efficiency and losses due to the lenses,
- P_o emitted energy,
- β_m backscatter coefficient for molecules
- β_p backscatter coefficient for particles,
- σ absorption of light in the atmosphere,
- P_{bq} background noise.

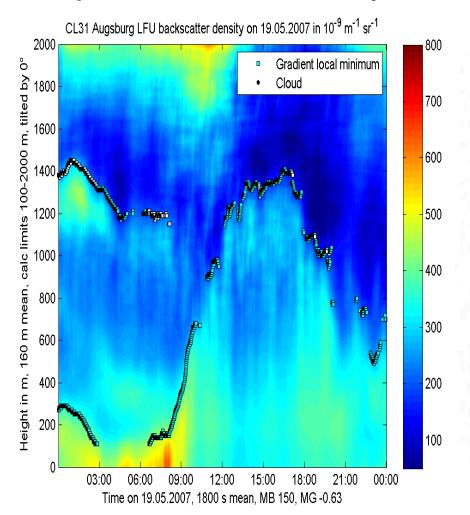

For a ceilometer β_m is negligible and only β_p is important

Summary

Clicker question: quality criteria:

Which instrument is best? data availability

A sodar vertical range

B ceilometer direct/indirect detection

C wind lidar Doppler analysis

D RASS

E don't know

○ ○ ○ ◆ RASS delivers temperature profiles, wind profiles are additionally available. MLH directly from temperature profiles. LLJ from wind profiles.

Does not work properly under high wind speeds. Restricted range.

○ ○ ○ ◆ wind lidar detects wind profiles, aerosol distribution and water droplets. It has to be assumed that the aerosol follows the thermal structure of the atmosphere and the wind.

MLH from aerosol backscatter, wind speed variance, LLJ from wind profiles. Does not work properly in extreme clear (aerosol-free) air and during precipitation events and fog.

○ ○ 🍑 🍑 Ceilometer detects aerosol distribution and water droplets. It has to be assumed that the aerosol follows the thermal structure of the atmosphere. MLH indirectly from aerosol backscatter using a MLH algorithm. Does not work properly in extreme clear (aerosol-free) air and during precipitation events and fog.

○ ♣ ♣ SODAR detects wind profiles, temperature fluctuations and gradients, but no absolute temperature.

MLH indirectly from acoustic backscatter (MLH algorithm). LLJ from wind profiles. <u>Does not work properly</u> under perfectly neutral stratification, with very high wind speeds, and during stronger precipitation events. Restricted range.
