*Work performed within the association in the field of fast reactors between the European Atomic Energy Community and Gesellschaft für Kernforschung m.b.H., Karlsruhe.
1. INTRODUCTION

The long-time behaviour of fast power reactors with plutonium recycling generally includes the overall time behaviour caused by the fuel burn-up in the reactor and the internal and external fuel management. It is useful to distinguish between two types of problems:

(a) The behaviour of the reactor between two loading events which refers to the time dependence of neutron flux, reactivity, power distribution, fuel composition etc.; usually it is the object of the conventional fuel burn-up studies.

(b) The behaviour of the reactor during many reloading cycles, which refers to the time dependence of the isotopic composition of plutonium, the uranium and plutonium content of the fuel, the breeding gain etc.

In this paper we will confine ourselves to the second class of problems only. We consider a fast power reactor in which only fissionable material is consumed which is bred in the same reactor, except for the plutonium amount to start up the reactor and for a certain period afterwards. Therefore, we have to consider a closed fuel cycle including the core and the external plants for reprocessing the irradiated fuel and refabricating the fuel elements. The blanket plutonium is introduced into the closed fuel cycle, the breeding gain is drawn off this cycle. The fuel cycle for common reprocessing of the core and blanket elements is shown in Fig. 1.

The time variations of the isotopic composition of the plutonium in the fuel cycle system are caused by the neutron irradiation in the reactor and by the internal and external fuel management*). The composition of the refabricated fuel elements is determined by that uranium-to-plutonium ratio which maintains the reactor critical, assuming the total number of the heavy isotopes in the fuel elements to be constant.

*) Internal fuel management is always done to improve the burn-up behaviour of the reactor; external fuel management refers to reprocessing and refabrication.
The problems which we are going to investigate were studied first in [1] on the basis of an idealized zero-dimensional model without taking into account the internal and external fuel management. Loading and unloading the core and blanket elements were regarded as continuous processes. In this paper we will investigate the long-time behaviour of the plutonium composition in the fuel and the physical aspects of the fuel cycle economy under more realistic conditions. Especially loading and unloading the core and blanket elements will be treated as discontinuous processes; the external fuel management and the times for reprocessing and refabrication will be taken into account.

As we will not look at the first type of problems of long-time behaviour, we can make some simplifications which refer essentially to the secondary time variations of neutron flux and spectrum caused by the fuel burn-up. By these simplifications we are able to solve the long-time problems with sufficient accuracy by tolerable numerical efforts. The formalism developed below is applied to a sodium cooled 1 000 MW(e) power reactor [2]. The main numerical results are given in the last section of this paper.

2. THE MATHEMATICAL FORMALISM FOR CALCULATING THE LONG-TIME BEHAVIOUR

2.1. Conditions for Reactor Operation

We consider a cylindrical reactor with few core zones, an axial and a radial blanket (Fig. 2). Exchanging the core and blanket elements takes place at each of the discrete time values

\[ t_s = s \cdot \Delta t_C, \quad s = 1, 2, 3, \ldots \]

\( \Delta t_C \) is a given constant correlated to the thermal reactor power \( Q \) and the given maximum burn-up of the fuel elements as shown in equation (6).

The core elements are loaded and unloaded according to the cyclic burn-up scheme described in [3]. The core is subdivided into radial regions; the elements of the same radial region are combined into groups of \( n \) elements (e.g. \( n=3 \)). At each point of time \( t_s \) only one element of each group
is exchanged for a fresh fuel element. During a period of time \( n \Delta t_C \) each element of a group is exchanged once and only once. The lifetime of the core elements is \( \delta = n \Delta t_C \), i.e. the total irradiation time of a fuel element in the core. At each time \( t_s \) only the \( n \)-th part of the core elements is exchanged for fresh elements. If \( V_C \) is the total fuel element volume of the core, the exchanged fuel element volume at \( t_s \) is

\[
\Delta V_C = \frac{1}{n} V_C.
\]

The operation of the axial and radial blankets must be in agreement with the rhythm given by (1); i.e. loading and unloading the blanket elements must succeed in intervals \( m \Delta t_C \), \( m \) may be a positive integer. The elements of the axial blanket are coupled with the core elements; therefore both are managed jointly. Contrary to this the management of the radial blanket is largely independent of the core management. We assume the radial blanket to be divided into \( N_B \) radial zones, which are exchanged as a whole. The lifetime of the \( j \)-th zone of the radial blanket may be

\[
\delta_{Bj} = m_j \Delta t_C, \quad j = 1, 2, \ldots, N_B;
\]

the integer \( m_j \) is related to the maximum burn-up in the \( j \)-th zone.

The amount of uranium and plutonium discharged out of the core and the axial and radial blankets is calculated in two steps: a) the calculation of the space dependent uranium and plutonium concentrations of the discharged elements by solving the fuel burn-up equations; b) the calculation of the uranium and plutonium content of these elements by volume integration. The fuel burn-up calculations and the volume integration for the core and blanket elements are discussed in the following sections.

2.2. The Fuel Burn-up Equations

The time behaviour of the fuel composition during neutron irradiation in the reactor is determined by the well-known fuel burn-up equations. As the main components of the fuel we regard the two uranium
isotopes $^{235}\text{U}$ and $^{238}\text{U}$ and the four plutonium isotopes $^{239}\text{Pu}$, $^{240}\text{Pu}$, $^{241}\text{Pu}$, and $^{242}\text{Pu}$. Therefore, we have to solve a system of six first-order differential equations in time and flux time, respectively. The coefficients of these equations are the one group space dependent neutron flux and microscopic cross sections for neutron absorption and capture, which are defined in the multigroup picture as

$$(4) \quad \psi(r,z) = \sum_i \psi_i(r,z), \quad \sigma(r,z) = \frac{\sum_i \sigma_i \psi_i(r,z)}{\psi(r,z)}$$

$\psi_i(r,z)$ is the neutron flux in the $i$-th neutron energy group at $r,z$; the $\psi_i(r,z)$ are determined by multigroup calculations. The $\sigma_i$ are the microscopic cross sections of the heavy nuclei in the fuel for neutron absorption and capture in the $i$-th energy group.

In general, $\psi$ and also the $\sigma$ are time dependent as a consequence of the variation of the fuel composition in the reactor during neutron irradiation. But it will be possible to calculate the uranium and plutonium concentrations in the irradiated elements at the end of their life time by solving the fuel burn-up equations with sufficient accuracy, if we take into account time averaged $\psi$ and $\sigma$ instead of the exact time dependent quantities. The latter, in general, would require the simultaneous solution of the burn-up equations and the criticality equation of the reactor, e.g. multigroup-diffusion equations. In our case the time averaged one group quantities are calculated according to equation (4) with time averaged neutron spectra, which are determined by multigroup calculations for an average burn-up state of the reactor assuming a homogeneous distribution of the fuel. The one group neutron flux for the average burn-up state is normalized to the given reactor power $Q$ which is regarded as constant.

2.3. The Uranium and Plutonium Output of the Core and the Axial Blanket

We suppose that the core is divided into $N$ radial zones of different fuel compositions. The $N_{j,k}(s,o)$ may be the time dependent initial concentrations of the nuclei $k = 1,2,\ldots,6$ in the fuel elements which are

1) The indices $k = 1,2,\ldots,6$ refer to the isotopes $^{235}\text{U}$, $^{238}\text{U}$, $^{239}\text{Pu}$, respectively, which are the components of the fuel mixture.
loaded into the core zone \( j = 1, 2, \ldots, N \) at the time \( t_s \). We presume

\[
N_{j,k}(s,o) = N_{j,k}(o,o) \quad \text{for all } s < s_o \quad j = 1, 2, \ldots, N \quad k = 1, 2, \ldots, 6
\]

\( s_o \) designates the time \( t_{s_o} \) at which refabricated fuel elements are loaded into the core for the first time, i.e. for closing the fuel cycle. \( s_o \) is determined by the external fuel management as shown below. The \( N_{j,k}(o,o) \) denote the \( j \)-th initial composition of the fuel elements at \( t_o = 0 \). For all \( s > s_o \) the \( N_{j,k}(s,o) \) are to be calculated as functions of \( s \), as shown below.

Now we have to calculate the fuel output of the core at the time \( t_s \). The \( N_{j,k}(s, \tau_{\text{max}_j}) \) may be the concentrations of the heavy nuclei in the fuel elements unloaded from the \( j \)-th zone at \( t_s \). The corresponding initial concentrations may be given by \( N_{j,k}^*(s,o) \). The \( N_{j,k}^*(s, \tau_{\text{max}_j}) \) are the solutions of the fuel burn-up equations with these initial values and the space dependent flux times

\[
(5) \quad \tau_{\text{max}_j} = n \cdot \Delta t_c \cdot \phi(x,z), \quad j = 1, 2, \ldots, N
\]

\( x, z \) is any point of the core zone \( j \). \( \tau_{\text{max}_j} \) is related to the maximum fuel burn-up for the elements of the core zone \( j \) in \( \text{MWd/tonne} \). From equation (5) follows the relation between \( \Delta t_c \), the maximum burn-up for the inner core zone \( j = 1 \) expressed by the corresponding maximum flux time, and the neutron flux at the core center \( \phi(o,o) \):

\[
(6) \quad \Delta t_c = \frac{1}{n} \frac{\tau_{\text{max}1}}{\phi(o,o)}
\]

\( \phi(o,o) \) is proportional to the reactor power \( Q \).

Obviously, the following relation holds:

\[
(7) \quad N_{j,k}^*(s,o) = \begin{cases} 
N_{j,k}(o,o) & \text{for } s - n < s_o, \\
N_{j,k}(s-n,o) & \text{for } s - n \geq s_o.
\end{cases} \quad j = 1, 2, \ldots, N; \quad k = 1, 2, \ldots, 6
\]
The total number \( \Delta N_{j,k}^*(s) \) of the nucleus \( k \) which is unloaded from the core zone \( j \) at \( t_s \) follows by integrating \( N_{j,k}^*(s,t_{max,j}) \) over the volume of the unloaded fuel elements. We obtain

\[
\Delta N_{j,k}^*(s) = \frac{2\pi}{n} \int_{R_j}^{R_{j+1}} \int_{-\frac{H+D}{2}}^{\frac{H+D}{2}} N_{j,k}^*(s,t_{max,j}) r dr dz, \quad k = 1, 2, \ldots, 6
\]

where the discharged nuclei of the axial blanket are included. \( H \) denotes the height of the core, \( D \) the total thickness of the axial blanket, \( R_j \) the inner and \( R_{j+1} \) the outer radial boundary of the \( j \)-th zone. The division by \( n \) is necessary, for only the \( n \)-th part of the elements of the zone \( j \) is discharged. In the core range we have to take into account the time dependence of the initial composition of the fuel; in the axial blanket region we take the initial composition of the elements constant.

The total output of the core and the axial blanket expressed as the total number of the discharged nuclei at the time \( t_s \), denoted as \( \Delta N_{Ck}^*(s) \), is

\[
\Delta N_{Ck}^*(s) = \sum_{j=1}^{N} \Delta N_{j,k}^*(s), \quad k = 1, 2, \ldots, 6
\]

2.4. The Uranium and Plutonium Output of the Radial Blanket

The uranium and plutonium content of the radial blanket zone \( j \) at the time of discharging, which may be denoted as \( \Delta N_{Bj,k}^* \), \( j = 1, 2, \ldots, N_B \); \( k = 1, 2, \ldots, 6 \), is also calculated by a volume integral in analogy to equation (8). But in the case of the radial blanket \( n \) is equal to 1 and the initial values of the elements are time independent. The flux time distribution in the \( j \)-th zone for solving the burn-up equation is

\[
t_{max,j} = m_j^* \Delta t_{C}^* \phi(r,z), \quad j = 1, 2, \ldots, N_B,
\]

\( r, z \) is any point in the radial blanket zone \( j \).
For a given value of \( s \) only that zone \( j \) of the radial blanket is unloaded for which

\[
\frac{t}{m_j \Delta t_C} = \frac{s}{m_j} = \text{an integer.}
\]

If no value of \( j \) exists for a given \( s \), the total output \( \Delta N_{Bk}^*(s) \), \( k = 1, 2, \ldots, 6 \) of the radial blanket is zero:

\[
(11a) \quad \Delta N_{Bk}^*(s) = 0 \quad \text{for all } k.
\]

If there are \( \ell \) special values of \( j \) for a given \( s \), denoted as \( j(\ell'), \ell' = 1, 2, \ldots, \ell \), for which equation (10) is valid, all the designated zones are unloaded at \( t_s \). Thus, the uranium and plutonium output of the radial blanket at \( t_s \) is

\[
(11b) \quad \Delta N_{Bk}^*(s) = \sum_{\ell' = 1}^{\ell} \Delta N_{Bj(\ell')}^*(s)k
\]

2.5. The Composition of the Refabricated Fuel Elements and the Breeding Gain

In the case of joint reprocessing of core and blanket elements the total number of nuclei, which are unloaded from the reactor at \( t_s \) and which are to be reprocessed, is

\[
\Delta N_k^*(s) = \Delta N_{Ck}^*(s) + \Delta N_{Bk}^*(s), \quad k = 1, 2, \ldots, 6, \quad s = 1, 2, \ldots;
\]

the \( \Delta N_{Bk}^*(s) \) may vanish for certain values of \( s \) as shown before. The total numbers of uranium and plutonium nuclei are

\[
(12) \quad \Delta N_U^*(s) = \Delta N_1^*(s) + \Delta N_2^*(s), \quad \Delta N_{Pu}^*(s) = \sum_{k=3}^{6} \Delta N_k^*(s).
\]

Losses during reprocessing reduce the number of nuclei by a factor of \( P_U \) and \( P_{Pu} \), respectively. Thus, after reprocessing we have

\[
\Delta N_U^*(s) \leq P_U \cdot \Delta N_U^*(s)
\]
\[
\Delta N_{Pu}^*(s) \leq P_{Pu} \cdot \Delta N_{Pu}^*(s)
\]
using the same symbols for the reduced numbers. The enrichment of the uranium available after reprocessing is

\[
\Gamma(s) = \frac{\Delta N^*_U(s)}{\Delta N^*_U(s)}
\]

and the relative composition of the plutonium mixture available for the refabrication of the fuel elements is given by

\[
\Omega_k(s) = \frac{\Delta N^*_U(s)}{\Delta N^*_{Pu}(s)} , \quad k = 3, 4, 5, 6.
\]

The initial uranium and plutonium concentrations of the fuel elements for the \(j\)-th core zone, which are refabricated from plutonium of the \(s\)-th discharge, i.e. from \(\Delta N^*_{Pu}(s)\), may be denoted as \(n_{j_u}(s)\) and \(n_{jPu}(s)\), respectively. The \(n_{j_k}(s)\), \(k = 1, 2, \ldots, 6\) may be the initial concentrations of the uranium and plutonium isotopes in the refabricated fuel elements. Thus, the following relations hold:

\[
\begin{align*}
n_{j_u}(s) &= n_{j_1}(s) + n_{j_2}(s) \\
n_{jPu}(s) &= \sum_{k=3}^{6} n_{j_k}(s)
\end{align*}
\]

The \(n_{j_u}\), \(n_{jPu}\) and \(n_{j_k}\) are space independent.

The basis for calculating the initial compositions of the refabricated fuel elements are the \(2N\) linear algebraic equations

\[
\begin{align*}
6 \sum_{k=1}^{6} C_{j_k} \cdot n_{j_k}(s) &= K_j(o) \\
6 \sum_{k=1}^{6} n_{j_k}(s) &= Z_j(o)
\end{align*}
\]

with the abbreviations

\[
\begin{align*}
C_{j_k} &= (\nu\sigma^T)_{j_k} = \sigma_{j_k}^a , \quad k = 1, 2, \ldots, 6; \\
K_j(o) &= \sum_{k=1}^{6} C_{j_k} n_{j_k}(o), \quad n_{j_k}(o) = N_{j_k}(o, o) \\
Z_j(o) &= \sum_{k=1}^{6} n_{j_k}(o)
\end{align*}
\]
The one group quantities \( c_{j,k}^a \) and \( (\nu_0 \sigma_f)_{j,k} \) refer to any reference point in the \( j \)-th zone (e.g. \( r = R_j, z = 0 \)). As mentioned above, they are calculated for the average fuel burn-up state of the reactor assuming a homogeneous fuel distribution. The \( \nu_0 \sigma_f \) are defined by analogy to equation (4).

The equations (16) are used to calculate the \( 2N \) unknown initial concentrations \( n_{j,U} \) and \( n_{j,Pu} \) with a presupposed uranium enrichment and the isotopic composition of the plutonium given by (14). The first equations (16) are given to maintain criticality. By these equations the reactivity worth of the refabricated fuel elements is fixed approximately at a constant value for each zone by adjusting the fuel composition to a constant difference between neutrons produced and absorbed in the fresh fuel at a given point of each zone. The constant differences are defined by the fresh fuel of the initial reactor at \( t_0 = 0 \).

The second equations (16) take the total number of heavy nuclei in the fresh fuel elements for each zone to be constant. The constants are given again by the initial conditions at \( t_0 = 0 \). For simplification we assume that the enrichment of the uranium used for fuel element refabrication is constant and equal to the initial enrichment \( \gamma \) at \( t_0 = 0 \). Thus, we have the relations

\[
(17) \quad n_{j,U}(s) = \gamma \cdot n_{j,U}(s), \quad n_{j,Pu}(s) = (1-\gamma) \cdot n_{j,U}(s).
\]

If only the plutonium mixture from the \( s \)-th discharge of the reactor is used for refabricating, i.e., in the case of positive breeding gain, the concentrations of the plutonium isotopes are

\[
(18) \quad n_{j,k}(s) = Q_k(s) \cdot n_{j,Pu}, \quad k = 3_4^{4}, 5_6^{5}.6.
\]

With the relations (17) and (18) the equations (16) are rearranged to

\[
(19) \quad n_{j,U}(s) \cdot C_{j,U} + n_{j,Pu}(s) \cdot C_{j,Pu}(s) = K_j(0) \quad n_{j,U}(s) + n_{j,Pu}(s) = Z_j(0)
\]
with

(19a) \[ C_{j \cdot U} = C_{j \cdot 1} \gamma + C_{j \cdot 2} (1-\gamma), \quad C_{j \cdot Pu}(s) = \sum_{k=3}^{6} C_{j \cdot k} Q_k(s) \]

If \( C_{j \cdot Pu}(s) \neq C_{j \cdot U} \) the equations are solved by

\[
\begin{align*}
n_{j \cdot U}(s) &= \frac{Z_j(o)C_{j \cdot Pu}(s) - K_j(o)}{C_{j \cdot Pu}(s) - C_{j \cdot U}}, \\
n_{j \cdot Pu}(s) &= \frac{-Z_j(o)C_{j \cdot U} + K_j(o)}{C_{j \cdot Pu}(s) - C_{j \cdot U}},
\end{align*}
\]

(20)

For physical reasons \( n_{j \cdot U}(s) \) and \( n_{j \cdot Pu}(s) \) must be positive. If

(21) \[ C_{j \cdot U} \leq 0, \]

i.e. \( \gamma \leq 1 / (1-C_{j \cdot 1}/C_{j \cdot 2}) \), \( n_{j \cdot Pu}(s) \) is positive. If (21) is true, the numerator of the first equation (20) must be positive, i.e.

(22) \[ C_{j \cdot Pu}(s) \geq \frac{K_j(o)}{Z_j(o)}, \quad j = 1,2,\ldots,N. \]

In the most interesting cases of fast power breeders with natural or depleted uranium as the fertile material the two conditions (21) and (22) are always true and the solutions (20) are positive \(^2\). In the following we will restrict ourselves to these cases. But the initial compositions for the refabricated fuel elements are only determined by equation (20), if the number \( \Delta N_{Pu}(s) \) of the available plutonium nuclei is enough for manufacturing the fuel element volume \( \Delta V_C \), i.e. in the case of positive breeding gain. The total number of plutonium nuclei from the \( s \)-th unloading of the reactor which is required for refabricating the fuel element volume \( \Delta V_C \) is given by

\(^2\) In the cases of higher enrichments of the uranium in the fuel the equations (16) continue to be true. But the time dependence of the uranium enrichment is to be taken into account which is caused by the fuel burn-up and perhaps by the fuel management. Especially in the case of starting up the reactor as a converter with \(^{235}\)U as the fissionable material we have to distinguish the time dependent enrichment of the uranium in the closed fuel cycle according to (13) and the presupposed enrichment of the uranium which is introduced into the fuel cycle from the outside to compensate for the consumed fertile material. By these facts the equations (17) and (19) are modified. But we will not discuss these more general equations and the conditions by which the solutions are positive here.
\[ N_{\text{Pu}}(s) = \frac{1}{n} \sum_{j=1}^{N} \Delta v_j n_{j,\text{Pu}}(s), \]

\( \Delta v_j \) is the total volume of the fuel elements of the core zone \( j \); thus, 
\( \Delta v_j / n \) is the exchanged fuel element volume. Losses during the fuel element fabrication reduce the number of plutonium nuclei by a factor \( q_{\text{Pu}} \), therefore, the number of the required plutonium nuclei is \( N_{\text{Pu}}(s)/q_{\text{Pu}} \), instead of \( N_{\text{Pu}}(s) \). If

\[ N_{\text{Pu}}(s) \frac{1}{q_{\text{Pu}}} \leq \Delta N_{\text{Pu}}^*(s), \]

the initial compositions of the refabricated fuel elements, are determined by the equations (20).

The breeding gain of the \( s \)-th fuel cycle is defined by

\[ N_{\text{BG}}(s) = \Delta N_{\text{Pu}}^*(s) - \frac{1}{q_{\text{Pu}}} N_{\text{Pu}}(s); \]

it is positive in accordance with (23).

2.6. The Parameter \( s_o \)

The time required for the external fuel management is \( (s_o-1)\Delta t_c \) with the above definition of \( s_o \). Thus, the plutonium unloaded from the reactor at \( t_s \) is reloaded into the core at \( t_{s+s_o-1} = (s+s_o-1)\Delta t_c \). Therefore, we have the relation

\[ N_{j,k}(s+s_o-1,0) = n_{j,k}(s) \text{ for all values of } k \text{ and } j, \]

\( s_o \) is determined by the characteristics of the reprocessing and refabricating plants. The external fuel cycle is characterized essentially by the parameters \( \delta_c, \delta_r, \) and \( \delta_f \), which are the minimum cooling time and the times for reprocessing and refabricating, respectively. These quantities define a new parameter

\[ \delta_{\text{ex}} = \delta_c + \delta_r + \delta_f; \]

furthermore, we define

\[ p = \left\lfloor \frac{\delta_{\text{ex}}}{\Delta t_c} \right\rfloor, \quad [x] \text{ is the maximum integer below } x.\]
For simplification we will assume in the following that the refabricated fuel element volume $\Delta V_C$ of any fuel cycle is loaded into the core as a whole, i.e. it should not be distributed over different loading events. Now, we will express the time for loading the fuel element volume $\Delta V_C$ of the $s$-th fuel cycle into the core in terms of $p$.

The time at which the first elements of the $s$-th fuel cycle are refabricated lies between $t_s + p\Delta t_C$ and $t_s + (p+1)\Delta t_C$ as the case may be, whether or not $\delta_{ex}/\Delta t_C$ is an integer. For economical reasons we assume that the time after which the complete volume $\Delta V_C$ is refabricated will not exceed $\Delta t_C$, i.e. the last elements of the $s$-th cycle may be refabricated not later than $t_s + (p+1)\Delta t_C$. This condition avoids unnecessary accumulations of plutonium in the external fuel cycle. In general, three values of $s_o$ are possible:

$$s_o = p + \varepsilon \quad , \quad \varepsilon = 1, 2 \text{ or } 3$$

$\varepsilon = 1$: if $\delta_{ex}/\Delta t_C = p$ and if the fuel element volume $\Delta V_C$ is managed as only one batch. $\varepsilon = 2$: (1) if $\delta_{ex}/\Delta t_C \leq p$ and if the fuel element volume $\Delta V_C$ is divided into partial batches and the last batch is refabricated not later than $t_s + (p+1)\Delta t_C$; (2) if $\delta_{ex}/\Delta t_C > p$ and if $\Delta V_C$ is managed as a whole. $\varepsilon = 3$: only if $\delta_{ex}/\Delta t_C > p$ and if $\Delta V_C$ is divided into partial batches and the last batch is refabricated later than $t_s + (p+1)\Delta t_C$

3. NUMERICAL RESULTS

The numerical results refer to the sodium cooled reactor Na1 [2]. The availability of the reactor may be 80 per cent; thus, the thermal power is assumed to be

$$Q = 2,000 \text{ MW}$$

on the average. Furthermore, we suppose

$$n = 3, \quad \Delta t_C = 200 \text{ d}$$

for the fuel burn-up cycles in the core. The corresponding maximum burn-up in $r = 0$ is 86,000 MWd/tonne averaged in the $z$-direction. The geometrical data are given in Fig. 2. The initial composition of the core and blanket elements at $t_0 = 0$ is given in TABLE I:
TABLE I  Initial composition of the core and blanket elements at \( t_0 = 0 \) in \( 10^{21} \) nuclei per cm\(^3\) reactor volume [5]

</table>

The 26-multigroup calculations are carried out for the average burn-up state of the reactor specified in TABLE II. The fuel compositions given in this Table are taken to be constant in the subzones of the reactor designated in Fig. 2. The Karlsruhe 26-group set \([4] \) is used for the multi-group calculations.

The radial blanket is divided into two radial zones, i.e. \( N_B = 2 \). The radial boundary between the two zones (Fig. 2) is \( R = 164 \) cm. The inner zone is always exchanged after the irradiation time \( 3\Delta t_C \), the outer zone always after \( 12\Delta t_C \), i.e. \( n_1 = 3 \), \( n_2 = 12 \). The maximum burn-up of the radial blanket in the plane \( z = 0 \) is \( 10,000 \) MWD/tonne in the inner and \( 9,500 \) MWD/tonne in the outer zone. The \(^{238}\text{U}\) and \(^{239}\text{Pu}\) output of the radial blanket as functions of time are given in Fig. 3. The unloaded plutonium consists of about 97 \% \(^{239}\text{Pu}\) and 4 \% \(^{240}\text{Pu}\).

The parameters for the external fuel management are \( \delta_c = 100 \) days for cooling, \( \delta_r = 30 \) days for reprocessing, \( \delta_f = 70 \) days for refabricating. Dividing the discharged fuel element volume \( \Delta V_C \) into partial batches, we get \( s_0 = 3 \). Thus, the external fuel inventory, which corresponds to the fuel element volume of \( (s_0-1)\Delta V_C = 2\Delta V_C \), amounts to \( 2,020 \) kg plutonium of the initial composition and \( 8,460 \) kg uranium.

Fig. 4 shows the time behaviour of the relative plutonium composition of the fuel elements in the core. As a consequence of the group structure of the fuel elements in the core with \( n = 3 \), there are three lines for each plutonium isotope. Each of these refers to those fuel elements which are loaded and unloaded jointly. The diagram shows the continuous behaviour of the plutonium mixture in the fuel during neutron irradiation (idealized as linear to simplify plotting) and the discontinuous behaviour at the times \( t_s \) caused by exchanging the fuel elements. The initial composition of the plutonium is plotted as \( \text{Pu}\_\text{i} \).

TABLE III shows the most important quantities of the reactor Na1 which are changed by the time variations of the plutonium composition in the fuel mixture.
The numerical results reveal the dependence of the time behaviour of the plutonium composition in the fuel elements on the fuel burn-up and the internal and external fuel management. In particular, there is a strong coupling between the radial blanket operation and the closed fuel cycle in the case of joint reprocessing of the core and blanket elements, which increases the variations of the plutonium composition by exchanging the fuel elements as well as during burn-up (Fig. 4). Furthermore, it follows from the numerical results that the fuel cycle economy of the reactor system depends on the time variations of the plutonium composition in the fuel (TABLE III).

Finally, it follows from the results of this paper what importance must be attached to the long-time behaviour of the plutonium composition in fast power reactors with plutonium recycling. It may be the purpose of further investigations of these problems to find out conditions of the internal and external fuel management by which the variations of the plutonium composition are caused essentially only by the fuel burn-up in the reactor. Thus, the time variations of the plutonium composition may be constant during the long-time operation of the reactor as far as possible, i.e. a so-called quasi-stationary behaviour of the plutonium composition. Finding out conditions of such type requires additional numerical investigations to be carried out by the method given in this paper, varying the parameters of the problem. In addition, the method may be extended to the cases of partial plutonium recycling by which plutonium is fed into the system from the outside in a given composition.
# Table III
The most important quantities of the reactor system which are changed by plutonium recycling as functions of the time parameter $s$:

- Plutonium loaded into the core at time $t_s$: $\Delta M_{Pu}(s)$
- Plutonium unloaded from the core at time $t_s$: $\Delta M_{Pu}^u(s)$
- Uranium loaded into the core at the time $t_s$: $\Delta M_U(s)$
- Net uranium introduced into the system from the outside: $M_U(s)$
- Breeding gain of the $(s-s_o+1)$-th fuel cycle: $\Delta M_BG(s-s_o+1)$, $s_o=3$

| $s$ | $\Delta M_{Pu}(s)$ | $\Delta M_{Pu}^u(s)$ | $\Delta M_U(s)$ | $M_U(s)$ | $\Delta M_BG(s-s_o+1)$ | Relative Pu composition of $\Delta M_BG(s-s_o+1)$ and $\Delta M_{Pu}(s)$ |
