Abstract

MIGRØS-2 allows the production of microscopic group constants of the ABN - type. The Karlsruhe nuclear data file KEDAK is used as the nuclear data basis. All group constants necessary for diffusion-, consistent P1 -, and S_n-calculations, taking the anisotropy into account up to P_5 , can be calculated.
A description of the code and the underlying theory is given. An input and an output description, a sample problem and the program lists are provided.

Zusammenfassung:

MIGRØS-2 erlaubt die Bereitstellung von mikroskopischen Gruppenkonstanten vom ABN-Typ. Als Datenbasis wird die Karlsruher Kerndatenbibliothek KEDAK benutzt. Es können alle Gruppenkonstanten berechnet werden, die für Diffusions-, konsistente P_1- und anisotrope S_n-Rechnungen benötigt werden.
Der Code und die zugrundeliegende Theorie werden beschrieben.
Es werden ein Eingabe - und Ausgabebeschreibung, ein Rechenbeispiel und die Programmlisten bereitgestellt.

Table of Contents:

INTRODUCTION

The code MIGROS-2 has been established to produce microscopic group constants for arbitrary isotopes. MIGROS-2 allows the production of group cross section sets of the ABN-type [1]. The Karlsruhe nuclear data file KEDAK [2] is used as the nuclear data basis. The code has been further developed from the code MIGROS [3], which has been used so far for the production of the Karlsruhe 26-group cross section sets. The microscopic group constants, which are calculated by MIGROS-2, can be used for the production of macroscopic group cross sections for diffusion, consistent P_1- and for S_n- calculations, taking the anisotropy into account up to P_5. They are :

- average group cross sections for infinite dilution (without resonance self shielding) for all types of neutron reactions, from energy dependent cross sections tabulated point by point;
- energy resonance self shielding factors and average group cross sections for infinite dilution for capture, fission, elastic scattering and total neutron reaction from resolved resonance parameters, from statistical resonance parameters and from energy dependent cross sections, tabulated point by point, in the resonance region;
- matrices of the elastic scattering up to the P_5-approximation from angular distributions;
- matrices of the zero'th moment of inelastic scattering from inelastic exitation cross sections or by an evaporation model;
- 1/v-average group values;
- fission spectra;
- cross sections for the thermal energy region (one energy group).

The code MIGROS-2 has a modular structure, which is very flexible in its need of storage.
A standard input is provided internally for the production of a 26-group cross section set with the same group structure as the ABN-set. The output of the results is given in two forms; on paper and on an external unit.
The input of MIGROS-2 is very versatile. If the user does not use the standard

input, he has to prove whether or not the input is physically meaningful and the methods in the used modules are adequate. In the following a short description of the task of MIGROS-2 is given.

The calculation of average group cross sections from pointwise data on KEDAK.

Group averages for all types of cross sections that are available on KEDAK are calculated. A trapezoidal rule for the integration is used. As integration points the energy points on KEDAK are used. Besides the average group cross-sections group values for the average cosine of the elastic scattering, for the number of secondaries per fission, for α and η are calculated.

The calculation of energy resonance self shielding factors and average group cross sections from resolved resonance parameters and from statistical parameters.

For capture, fission and elastic scattering flux weighted ($w(E) \sim \frac{1}{\sigma_t(E)+\sigma_o}$) resonance self shielding factors and for elastic scattering and the total neutron reaction current weighted ($w(E) \sim \{\frac{1}{\sigma_t(E)+\sigma_o}\}^2$) self shielding factors dependent on temperature and on the background cross section σ_o and the average group cross sections are calculated from resonance parameters. In the resolved resonance region Breit-Wigner single level parameters and Doppler-broadened line shape functions are used. Interference between potential and resonance scattering and the overlapping of resonances is taken into account exactly.
In the unresolved resonance region an analytical model, based on average resonance parameters and χ^2-distributions for the parameters, is used. Interference between potential and resonance scattering is partly taken into account. Overlapping of resonances is considered approximately.

The calculation of energy resonance self shielding factors from pointwise data.

The same types of self shielding factors that are calculated from resonance parameters can also be calculated from pointwise data by a tropezoidal rule. They can only be calculated for the temperature for which the cross sections are tabulated.

The calculation of the zero'th and higher moments of the elastic scattering transfer elements.

There exist two approaches. In the first one average transfer elements from one group into another or into the same group are calculated. The average over the outscattering group may be weighted.
In the second approach, the outscattering group is subdivided into several intervals. To describe the transfer from one group to another, for each outscattering group the average values over the intervals are calculated. In both cases an integration is done over the in-scattering groups.
Both approaches expect tabulated angular distributions. The angles must be the same for all energies, at which the distributions are tabulated.
The two approaches use different interpolation and quadrature procedures. In the first one the angular distributions are transformed from the centre of mass system to the laboratory system. The interpolations in the energy and in the angle are done by polinomials of the order four. The integration over the in-scattering group is performed as integration over the corresponding angle interval in the laboratory system by a Simpson rule, the integration over the outscattering group is performed by a trapezoidal rule.
In the second approach the interpolation for the angle in the centre of mass system is done by a linear interpolation, the interpolation in energy is performed logarithmic. The integration over the in-scattering groups is transformed to an integration over the corresponding angle intervals in the centre of mass system. Both integration, over the angle intervals and over the outscattering groups is done by a Romberg procedure.

The calculation of the inelastic scattering matrix.

For the calculation of the inelastic scattering matrix in the range of discrete levels excitation cross sections are used. The total inelastic scattering cross section and the excitation cross sections are interpolated linearly. All energy integrations are done by a trapezoidal rule.
At higher energies the Weißkopf evaporation model is used.

The calculation of the fission spectra.

Fission spectra are calculated by a Watt-formula. The fragment kinetic energy per nucleon and the Watt fragment nuclear "temperature" are used.

Thermal cross sections.

One thermal group with a Maxwellian spectrum is assumed.

1. The organization of MIGRØS-2

1.1 The logical structure of MIGRØS-2

The code MIGRØS-2 has a modular structure. It consists of a control module and of several computational modules. In the control module all the input information, except the nuclear data, is checked, the order of processing is fixed and the information for the single computational modules is prepared. A computational module is defined as a logically complete, executable computer procedure, consisting of several subroutines and functions. In a computational module a specific type of group constants is calculated. The necessary nuclear data are read from the Karlsruhe nuclear data library, KEDAK /1/, in the computational modules. Also in these the group constants are output on paper and on an external storage unit. The available computational modules are given in table I.

The control is transferred from the control module to a computational module by a CALL-statement which calls the entry subroutine of the module. It is not possible to transfer the control directly from one module to another. A computational module can be called by the control module several times.

All computational modules are written in FØRTRAN-IV. All arrays are variably dimensioned, when they are influenced by input information. The control module is written in FORTRAN-IV, except for the routine DATAMAIN, which is written in ASSEMBLER.

Since the input of nuclear data and the output of the results is performed in the computational modules, the only information that must be transferred between the control module and the computational modules is input information other than nuclear data and information necessary for the control of the program. The transfer of data is partly done by an unlabeled CØMMØN-array. However, most of the data transfer is accomplished by the parameter lists in the entry subroutines of the computational modules.

MIGROS-2 is organized in an overlay structure, given in table II.

1.2 The control module

The control module has three tasks:

- to read all input information exept the nuclear data,
- to provide a central data array and the unlabeled CØMMØN-array,
- to control the order of computation of the computational modules.

In the routines DATAMAIN und MAIN a central data array is provided, whose length can be defined by the user in the IBM/OS control language (see chapter 2).

In the subroutine INPUT, all input information exept the nuclear data is read and checked. The central data array is prepared and the computational modules are called.

The input information is stored and the working arrays for the computational modules are provided in the central data array. It consists of two sections. One is permanent and the same for all computational modules. The other section depends on the particular module being considered and is allocated only when the control is actually transferred to the module. All information of the central data array is transferred by parameter lists in the entry sub-routines of the computational modules. A description is given in table III.

Also there is an unlabeled CØMMØN-array, described in table IV.

1.3 The organization of the central data array XL

The ASSEMBLER-routine DATAMAIN provides a central array named XL for the subroutine MAIN. The length of XL is defined by the user in the PARM.G-parameter of the EXEC-card in the IBM/OS control language. The subroutine MAIN calls the subroutine EING, which first prints an input description of the MIGRØS-system. Then all the input for the first material is read and that necessary for the variable dimensioning of the input arrays in the XL-array is retained, e.g., the number of group boundaries, the number of points of the weighting function, the number of computational modules that shall be used etc. The input unit is "backspaced" to the beginning and the subroutine INPUT is called. The starting addresses of the input arrays in the XL-array are arguments of INPUT. The index NFR indicates the beginning of the non-permanent section of the XL-array and is also an argument of the subroutine INPUT. All input arrays are filled with the information from the input cards or the standard built-in data. The input is also checked for consistency. Then the computational modules are called in the order fixed by the input.

Before every call of a computational module the length of the non-permanent section of the XL-array is checked to determine, if it is long enough for the working arrays of the module. The length of these working arrays are dependent on the input information and in some cases, can finally be defined only in the computational module itself. In this case an iterative procedure is used to determine the proper length. As a first step, a minimum length of the working array is assumed. If it turns out to be too small, control is given back to the control module and the size of the array is increased. When the required size of the working array is so large that the XL-array is not long enough the computational module in question is passed and a message to the user is given.

After all the required computational modules for one material have been called, a RETURN-statement to the subroutine MAIN is given. If there are more materials, a new arrangement of the XL-array is made etc.

1.4 Auxiliary subroutines

1.4.1 Reading program for the Karlsruhe nuclear data library KEDAK

For reading KEDAK, the subroutine NDF is necessary. A description is given in /3/.

1.4.2 Weighting functions

In the case, that there are specified no weighting functions for the group cross sections and matrices by input, the following two functions are used:

```
FUNCTIØN PHI(E)
PHI = 1./E
RETURN
END
```

E is the energy in [eV].
This weighting function is used for all group constants except the first and higher Legendre moments for elastic scattering.

```
FUNCTIØN PHI1 (L,E)
PHI1 = 1./E ** L
RETURN
END
```

E is the energy in [eV]
L = l + 1, l = Legendre moment.

This weighting function is used for the first and higher Legendre moments in the module 6 (not in module 9).

Table III, cont.

b) The non-permanent section

Besides the permanent section a non-permanent section is defined, when a computational module is actually called. This non-permanent part exists only during the execution of a computational module. The non-permanent section starts with the index NFR, defined in the subroutine MAIN. The names of the auxiliary arrays are the same as used in the formal parameters of the entry subroutines of the computational modules. All other symbols are the same as in the input description of chapter 2.

2. Input and output of MIGRØS-2

2.1 Description of the input

In the following input description the expression "card" is used for the information that is read by one READ-statement. The input is unformatted. The following rules must be observed: The information of one "card" may actually be punched on several cards. Column one of the first physical card must not be blank, for the following physical cards belonging to the same READ-statement it must be blank. The information of two words must be separated by at least one blank. Alphanumeric information may consist of eight symbols or less. It is represented in the form 'TEXT bbbb'. The blanks and apostrophes are obligatory. For alphanumeric information consisting of five or less symbols the following representation is also allowed: αTEXTα. In this case no blanks are necessary. They are only necessary, if several words are linked: αTEX1α αTEX2α or linked αTEX1bTEX2bα.

2.1.1 Input description

Card 1

MAT		name of the material in the KEDAK-nomenclature /1/
ISTRUK	= o:	light or medium weight material, no temperature dependent resonance cross-sections
	= 1:	heavy isotopes, temperature dependent resonance cross sections

Card 2

αBLØCα	1	constant

Card 3

ISPA	= o:	non-fissile isotope
	= 1:	fissile isotope

Comment: If card 2 and card 3 are not defined, it is assumed that the isotope is fissile, if the last figure of the material name is odd.

Card 4

αBLØCα	2	constant

Card 5

NE	number of group boundaries
(ENG(I), I=1, NE)	group boundaries in (eV) ENG(I) < ENG(I + 1)

Comment: There is no limitation for the number of groups.
If "card 4" and "card 5" are not defined, as standard input the group boundaries of the 26-group ABN-set /2/ are used.
o.215, o.465, 1.o, 2.15, 4.65, 1o.o, 21.5, 46.5, 1oo, 215, 465, 1ooo, $2.15.1o^3$, $4.65.1o^3$, $1o^4$, $2.15.1o^4$, $4.65.1o^4$, $1o^5$, $2.1o^5$, $8.1o^5$, $1.4.1o^6$, $2.5.1o^6$, $4.o.1o^6$, $6.5.1o^6$, $1o^7$.

Only the group boundaries of the non-thermal groups must be specified.

Card 6

αBLØCα	3	constant

Card 7

NSPEC	number of weighting functions
NFE	number of energy points
(EF(I), I = 1, NFE)	energy points for the macroscopic weighting functions in (eV) ordered with increasing energy
((F(I,J), I = 1, NFE), J = 1, NSPEC)	Corresponding values of the macroscopic weighting functions
Comment:	The weighting functions need not be normalized. The macroscopic weighting function represents the resonance free part of the weighting, normally a collision density $\Sigma(E)$. $\phi(E)$ is expected (Σ = total cross section, $\phi(E)$ = neutron flux density) The weighting functions (F(1,J), I = 2, NSPEC) are only used in the module 6.
	The number of weighting functions should be the same as the number of moments of the elastic scattering matrix. If only one weighting function is given, it will be used for all moments of the elastic scattering matrix.
	The number of energy points is arbitrary. The weighting function

must cover the whole energy range, in which weighted group constants shall be calculated.

If card 6 and card 7 are not provided, the following standard is used:

F(I,1) is given by the FUNCTIØN PHI (E) and (F(I,L), L=2, NLE + 1) by FUNCTIØN PHI1 (L,E) (NLE is defined in card 23).

```
FUNCTIØN PHI(E)
PHI = 1./E
RETURN
END
```

```
FUNCTIØN PHI1 (L,E)
PHI1 = 1./E x x L)
RETURN
END
```

E: energy
See also card 27

Card 8

αBLØCα	4	constant

Card 9

NA	number of calls of any computational modules
((NR(I,J), I=1,3), J=1,NA)	NR(1,J) identification number of the module to be called (see table I. in chapter 1)

NR(2,J) number of the first energy group,

NR(3,J) number of the last energy group, for which the module NR(1,J) is called.

Comment: The numbers of the energy groups are fixed by the chosen group boundaries in card 4 and card 5. the groups are numerated from 1 to NE-1, starting with the group of the highest energy.

NR(2,J), NR(3,J) must be ordered with increasing energy, e.g. NR(2,J) $\geq$ NR(3,J). The module NR(1,J) is executed for all groups from NR(2,J) to NR(3,J). A module can be specified several times. There is no limitation for NA. In the case of scattering matrices, NR(2,I) and NR(3,J) are the outscattering groups. The transfer elements for all inscattering groups belonging to an outscattering group are calculated.

In the case when one of the modules 1 or 2 for the calculation of selfshielding factors is called, the following two cards are necessary:

Card 1o

αBLØCα	5	constant

Card 11

NT	number of temperatures
(TEMP(I), I=1, NT)	temperatures in ^{o}K
Comment:	If card 1o and card 11 are not specified, the following standards are used:
	$3oo^{o}K$, $9oo^{o}K$, $21oo^{o}K$ for heavy isotopes (ISTRUK = 1)
	$o^{o}K$ for light and medium weight isotopes, (ISTRUK = o).
	There is no limitations for the number of temperatures.

For the case when one of the modules 1, 2 or 3 for the calculation of self shielding factors is called, the following two cards are necessary:

Card 12

αBLØCα	6 constant

Card 13

MI	number of background cross sections σ_o
(SIGO(I), I=1, MI)	background cross sections σ_o in (barn)
Comment:	If card 12 and card 13 are not specified, the following standards are used: MI = 7, σ_o = o, 1o, $1o^2$, $1o^3$, $1o^3$, $1o^4$, $1o^5$, $1o^6$ barns
	There is no limitation for the number of σ_o-values.

If module 4 or module 10 is called, the following two cards must be specified:

Card 14

αBLØCα	7	constant

Card 15

NTYP	number of cross section types
(ITYP(I), I=1, NTYP)	names of the cross section types.
Comment:	The number of cross section types is not limited. All cross sections types available on the Karlsruhe nuclear data file KEDAK /1/ can be computed. For the names the KEDAK-nomenclautre must be used. If card 14 and card 15 are not specified, the following standards are used: MUEL, NUE, SGA, SGF, SGI, SGN, SG2N. In the case that SGA and SGF are computed, always SGC ≡ SGA - SGF is computed too. SGC can also be specified as cross section type in the input, although it is no KEDAK-type.

If module 1 is called, the following four cards are necessary:

Card 16

αBLØCα	8	constant

Card 17

NRES		number of resonances
Comment:		For the calculation of the cross sections at the energy E contribution from NRES resonances above E and NRES resonances below E are taken into account. If card 16 and 17 are not specified, a standard, NRES = 1o, is used.

Card 18

αBLØCα	9	constant

Card 19

ERRØR		allowed integration error
Comment:		ERRØR corresponds to ε in chapter 4, formulas (4.18), 4.19). If card 18 and card 19 is not specified, a standard, ERRØR = o.o5, is used.

If the module 5 is called, the following two cards are necessary:

Card 2o

αBLØCα	1o	constant

Card 21

XNUE		parameter for the Weisskopf evaporation model
Comment:		XNUE corresponds to the parameter ν in chapter 6. If card 2o and card 21 are not specified the standard XNUE = o.16 is used.

If the module 6 is called, the following eight cards are necessary:

Card 22

αBLØCα	11	constant

Card 23

ISEL	parameter, which defines the averaging procedure for the transferelements. ISEL = 2: The transferelements are the group averaged transfer cross sections normalized to the group averaged total elastic cross section. ISEL = 1: The transferelements are the group averaged, to the total elastic cross sections normalized elastic transfer cross sections.
NLA	lowest Legendre moment
NLE	highest Legendre moment
Comment:	NLA ist always set to zero by the program. NLE must be smaller or equal to five. If NLE < 1, NLE is set to one by the program. If card 22 and card 23 are not specified, the following standards are used:

ISEL = 2 for ISTRUK = o
ISEL = 1 for ISTRUK = 1
NLA = o
NLE = 5

Card 24

αBLØCα	12	constant

Card 25

NMAT	number of materials in a composition
(NAME(I), TZ(I), I=1, NMAT)	
NAME:	names of the materials
TZ:	atomic densities x $1o^{-24}$
Comment:	card 24 and card 25 are only necessary if the fine structure of the weighting function for a defined composition is to be taken into account (see chapter 7)

Card 26

αBLØCα	13	constant

Card 27

MAZ(1)	= o:	all Legendre moments are weighted with the macroscopic weighting function of the zero'th moment (see weighting function in card 7, F(I,1)).
	= 1:	each Legendre moment is weighted with it's own macroscopic weighting function (see card 7, F(I,J)).
MAZ(2)	= o:	all Legendre moments are weighted with the microscopic weighting function of the zero'th moment ∿ 1/Σ(E), Σ(E)!

macroscopic total neutron cross section for a composition.

= 1: the microscopic weighting function for the l^{-th} Legendre moment is $\sim \{ 1/\Sigma \}^{l+1}$

Comment: If card 26 and card 27 are not specified, the following standards are used:
MAZ(1) = o, MAZ(2) = o

Card 28

αBLØCα 14 constant

Card 29

NS maximum number of groups in one "macro" group.

NK number of basic energypoints used in that energy range in a group, for which scattering into neighbouring groups is possible.

NR Number of basic energy points used in that energy range in a group, for which no out-scattering into neighbouring groups is possible.

Comment: If card 28 and card 29 are not specified, the following standards are used:
NS = 4, NK = 7o, NR = 16

If module 9 is called, the following five cards are necessary:

Card 3o

αBLØCα	15	constant

Card 31

ERR	allowed integration error.
NJM	$2^{NJM} + 1$ is the number angles for the integration.
NUJM	$2^{NUJM} + 1$ is the maximum number of energy points for the integration.
Comment:	If card 3o and card 31 are not specified, the following standards are used: ERR = o,o5 NJM = 6 NUJM= 1o ERR, NJM, NUJM correspond to ε, NJM, NUJM in appendix IV

Card 32

αBLØCα	16	constant

Card 33

ISELR	= 1:	The transferelements from subintervals of the out-scattering group into other groups are interval averaged transfer cross sections, normalized to the interval averaged total elastic cross section.

ISELR	= o:	The transfer cross sections are first normalized to the total elastic cross sections. The average of the outscattering interval is performed afterwards.
NLRA		lowest Legendre moment
NLRE		highest Legendre moment
NCALL	= o:	The way of subdiving the groups, given by card 5, shall be the same for all groups. It is assumed, that the groups are subdivided into 14 fine groups and the fine groups are subdivided into five intervals. The subdivision is always performed equidistant in lethargy. The result of this procedure are 7o intervals per group.
NCALL > o	:	If the intervals shall be constructed in a different way as for NCALL = o, NCALL is the number of calls of module 9. This number must be the same as specified in card 9.

If NCALL > o, the next card must be specified NCALL-times.

Card 34

NGRE	number of subdividing procedures in one call of module 9.

(N1(I),N2(I),NFG(I),NFI(I),I=1,NGRE)

N1(I)	number of the first energy group subdivided by the I-th procedure
N2(I)	number of the last energy group subdivided by the I-th procedure
NFG(I)	number of fine groups per group in the I-th procedure
NFI(I)	number of intervals per fine group in the I-th procedure.
Comment:	If card 32 and card 33 are not specified, the following standards are used: ISELR = 1 for ISTRUK = o ISELR = o for ISTRUK = 1 NLRA = o NLRE = 5 NCALL = o NFG = 14 NFI = 5 In this case, card 34 must be omitted. In the case that card 32, card 33 and card 34 are specified, ist must be noted, that N1(I) $\geq$ N2(I) and N1(I) > N1(I+1), N2(I) > N2(I+1). (See also comment to card 9).

Card 35

αENDEα	17	constant
Comment:		This is the last card of the input for one material. It must not be omitted.

The cards 1 to 35 must be repeated for each material. The last card of the input must be

αENDEα	18	constant

2.1.2 Description of the necessary external units and memory capacity

MIGRØS-2 needs the following external units:

unit number

8	for the input with FREEFØ.
1	Karlsruhe nuclear data library KEDAK.
3	unit for the unformatted output of the results.
1o	is only necessary in the module 6 as working unit.

The necessary memory capacity must be specified by the user by the PARM.G-parameter in the EXEC-card of the IBM-job control language. The length of the PARM.G-array depends on the input information. The memory capacity, necessary for the single modules, is given in the following:
(The symbols of the input description are used).

Control module

$$2 \times NTYP + 3 \times NMAT + NFE \times (NSPEC + 1) + NT + MI + 1 + 3 \times NE + 4 \times NA \times (1 + NE)$$

words. In the case, that one of these values are not specified by the input, the standard must be used: NTYP = 6, NFE = 1, NSPEC = 1, NT = 3, MI = 7, NMAT = 1.
The memory demand of that called computational module with the largest memory demand must be added to the memory demand of the control module.

Number of the module	Memory demand of the module
1	7 x MI + 3 x NE + 7 x max (3oo, number of resonances on KEDAK) + 5 x max (4oo, maximum number of energy points, necessary for the integration over one energy group)-words. Comment: The number of integration points can not be estimated at the beginning of a calculation. If the assumed 4oo words are not sufficient, the dimension of the corresponding array is enlarged automatically by the control module, provided that the PARM.G-array is large enough. If the PARM.G-array is not large enough, the module is passed. In thise case it is recommended to duplicate the number of words for the integration array in the PARM.G-array.
2	35 x MI - words
3	6 x NE + 16 x MI x NE + 2 x max (15oo, number of MUEL-values on KEDAK in the wanted energy range) + 6 x max (15oo, number of SGA-values, number of SGN-values, number of SGF-values in KEDAK in the wanted energy range)-words.

4 6 x NE + 2 x max (1500, number of SGN-values, number of SGF-values on KEDAK in the wanted energy range)-words

5 12 x NE + 3 x (NE + 1) + 3 x max (700, number of SGI-values on KEDAK above the threshold for inelastic scattering) + 3 x max (25, number of inelastic exitation levels) + max (25 x 400, number of inelastic exitation levels times the number of the energy points for the exitation cross section belonging to the first level) + max (400, number of SGI-values above the threshold for inelastic scattering)-words.

6 5 x max (400, ISM) + 7 x max (1000, ISD) + 4 x (NE + 1) + 4 x NE + max (400 x 21, ISM x ICØS) + max (400 x 2, ISM x NECU) + 6 x max (2, NECU) x NE + 2 x ICØS + 2 x max (4000, NTT)-words

ISM: 300 + maximum number of energy points for the SGNC on KEDAK within four neighbouring energy groups.

ISD: ISM + maximum number of SGN- or MUEL-values on KEDAK within one energy group.

ICØS: number of angle points for the SGNC on KEDAK.

NECU: maximum energy loss by elastic scattering measured in energy groups (= 2 for scattering into the neighbouring group).

NTT: number of SGT-values for a given composition in four neighbouring energy groups.

7 NE-words

8 3 x NE + 2 x max (1o x NE, NFE)-words

9 39 + NM1 x IMAX + (3 + NUJM) + ICØS x (2 + NIV) + NIV + IMAX + 2 x NJM + 3 x NDAT + NE + NFIN x IZV + BUF - words.

NM1: NLRE +1

NFIN: number of energy points in one energy group

NDAT: maximum number of SGT- or SGN-values on KEDAK in one energy group.

NIV: number of energy points for the SGNC on KEDAK

BUF: max (NDAT, 2 + IMAX x NFIN)

IZV: max (4, IMAX x NM1)

IMAX: maximum energy loss by elastic scattering measured in energy groups (identical with NECU in module 6).

ICØS: identical to module 6

1o -

The REGIØN-parameter on the JOB-card is given by the length of the PARM.G-array in K-bytes + 17o K-bytes for the MIGRØS-programs and the buffer.

2.2 Description of the output

2.2.1 Printed output

Each computational module has an output of the results on paper. In table V an explanation of the symbols is given.

2.2.2 Unformatted output

Besides the printed output an unformatted output on unit 3 is provided. The arrangement of this output is described in table VI.

2.2.3 Output of error messages

In table VII a list of error messages and warnings is given. In this list only those messages are given which are not self explaining.

Table V

Module 1

Symbol	content	defined by formula	required KEDAK-types
SIGMA G	average group cross section for infinite dilution, radiative capture	(4.6)	RES
SIGMA N	average group cross section for infinite dilution, elastic scattering	(4.6)	RES
SIGMA F	average group cross section for infinite dilution, fission	(4.6)	RES
SIGMAN1	identical with SIGMA N	-	RES
SIGMAT1	SIGM G + SIGMA N + SIGMA F	-	RES
SIGMA o	background cross section σ_o	(4.1)	RES
FG	flux weighted resonance self shielding factors: radiative capture	(4.1)	RES
FN	flux weighted resonance self shielding factors: elastic scattering	(4.1)	RES
FF	flux weighted resonance self shielding factors: fission	(4.1)	RES
FN1	current weighted resonance self shielding factors: elastic scattering	(4.3)	RES
FT1	current weighted resonance self shielding factors: total	(4.3)	RES

Temperatures are given in ^{o}K, the group boundaries in eV, cross sections in barns.

Module 2

Symbol	content		defined by formula	required KEDAK-types
SIGMA G	average group cross sections for infinite dilution	radiative capture	(5.37)	
SIGMA N		elastic scattering	(5.38)	
SIGMA F		fission	(5.37)	
SIGMAN1	identical with SIGMA N		-	ISØT1
SIGMAT1	SIGMA G + SIGMA N + SIGMA F		-	ISØT2
SIGMA o	background cross section σ_o		(5.1)	ST
FG	flux weighted resonance self shielding factors	radiative capture	(5.1)	STGF
FN		elastic scattering		
FF		fission		
FN1	current weighted resonance self shielding factors	elastic scattering	(5.8)	
FT1		total		
Temperatures are given in ^{o}K, group boundaries in eV, cross sections in barns				

Module 3

Symbol	content		defined by formula	required KEDAK-types
SIGMA A	average group cross sections for infinite dilution,	absorption	(9.1o)	SGA
SIGMA C		capture		
SIGMA N		elastic scattering		SGN
SIGMA F		fission		SGF
SIGMA No1		$\sigma_e \cdot \bar{\mu}_e$	(9.11)	
SIGMA N1	identical to SIGMA No1		-	SGT
SIGMA T1	SIGMA C + SIGMA N + SIGMA F		-	MUEL
FA	flux weighted resonance self shielding factors,	absorption	(9.1)	
FC		capture		
FN		elastic scattering		
FF		fission		
FNo1	flux weighted resonance self shielding factor for	$\sigma_e \cdot \bar{\mu}_e$	(9.3)	
FN1	current weighted resonance self shielding factor for $\sigma_e \cdot \bar{\mu}_e$		(9.8)	
FT1	current weighted total resonance self shielding factor		(9.5)	
SIGO	background cross section σ_o			

Group boundaries are given in eV, cross sections in barns

Module 4

Symbol	content		defined by formula	required KEDAK-types
SGN	average group cross section for	elastic scattering	(3.1)	SGN
SGA		absorption		SGA
SGF		fission		SGF
SGI		inelastic scattering		SGI
SGC		capture = SGA - SGF		SGA, SGF
SG2N		(n, 2n) reaction		SG2N
MUEL	average cosine of elastic scattering		(3.2)	SGN, MUEL
NUE	average number of secondaries per fission		(3.3)	SGF, NUE
ALPHA	average α-value		(3.4)	SGG, SGF
ETA	average η-value		(3.5)	NUE,SGG,SGF

If group averages of other types of cross sections available on KEDAK are calculated, averages in the sense of formula (3.1) are calculated. The names are the same as the names of the underlying KEDAK-types. Cross sections are given in barns.
If SGN for the material HbbbbbØ1 is calculated, also a type STR is calculated, which corresponds to formula (3.6).

Module 5

Symbol	content	defined by formula	underlying KEDAK-type
PRØBSGI	inelastic scattering probabilities, in the discrete region	(6.6), (6.7)	SGI, ISØT2
	inelastic scattering probabilities, in the continuous range	(6.15)	SGI,SGIZ,ISOT2
In the first column the numbers of the outscattering groups are printed. The numbers above the values of PRØBSGI are the inscattering groups.			

Module 6

Symbol	content	defined by formula	underlying KEDAK-type
SGNC0	zero'th moment of elastic scattering matrix, normalized to the total elastic cross section		SGN,
SGNC1	1^{st} moment		SGNC,
SGNC2	2^{nd} moment		MUEL,
SGNC3	3^{th} moment		SGT
SGNC4	4^{th} moment		
SGNC5	5^{th} moment		

Module 7

Symbol	content	defined by formula	required KEDAK-types
CHI	fission spectrum	(12.2),(12.1)	CHICR

Module 8

Symbol	content	defined by formula	required KEDAK-types
1/V	1/v-group averages in [sec/cm]	(11.1)	-

Module 9

Symbol	content	defined by formula	required KEDAK-types
SGT	average total cross section	(8.1)	SGT
SGN	average elastic scattering cross section	(8.1)	SGN
MUEL	average cosine of elastic scattering	(8.2)	MUEL
FLUX	average flux (weighting function)	-	-
SGNCn	the n-th legendre moment for elastic scattering	(8.3)	SGN, SGNC
Cross sections are given in barns, the legendre moments are normalized to the total elastic cross section. The interval averages within one group are arranged with increasing energy.			

Module 1o

In this module the group constants for the thermal group are calculated. The same types as in module 4 are possible. The group constants are defined by the formulas (1o.1) to (1o.5).

Table VI (The symbols of table V are used)

Module 1

1. record: o , 'MIGR----'
2. record: n , material name, temperature in [°K], number of the energy group, lower group boundary in [eV], upper group boundary in [eV]
3. record: n , SIGMA G, SIGMA N, SIGMA F, SIGMA N1, SIGMAT1
4. record: n , SIGMA 0, FG, FN, FF, FN1, FT1

. . .

. for all SIGMA 0-values

n is an Integer I x 4 and gives the number of 4-bytes words in the record. The material names are 8-bytes alphanumerical words. All other words are R x 4. The 8-bytes alphanumeric words are counted as two words in n. These conventions are the same for all ohter modules. Exceptions are mentioned. "-" in the label names must be interpreted as blank.

Module 2

1. record: o , 'FSTAT---'
2. record: n , material name, temperature in [°K], number of the energy group, lower group boundary in [eV], upper group boundary in [eV].
3. record: n , SIGMA G, SIGMA N, SIGMA F, SIGMAN1, SIGMAT1
4. record: n , SIGMA 0, FG, FN, FF, FN1, FT1

. .

. for all SIGMA 0-values

Module 3

1. record: o , 'FSTRK---'
2. record: n , material name, number of the energy group, lower group boundary in [eV], upper group boundary in [eV]
3. record: n , SIGMA A, SIGMA N, SIGMA NO1, SIGMA N1, SIGMA T1
   for non heavy isotopes (ISTRUK = o)
   n , SIGMA C, SIGMA N, SIGMA F, SIGMA NO1, SIGMA N1, SIGMA T1
   for heavy isotopes (ISTRUK = 1)
4. record: n , SIGO, FA, FN, FNO1, FN1, FT1
   . for non heavy isotopes (ISTRUK = o)
   . n , SIGO, FC, FN, FF, FNo1, FN1, FT1
   . for heavy isotopes (ISTRUK = 1)
   repeated for all SIGO-values

Module 4

1. record: o , 'SGKE----'
2. record: n , highest energy group (lowest number), lowest energy group
3. record: n , material name, name of reaction type (8-byte, alphanumeric)
4. record: n , group constant of the type defined by the 3^{rd} word in the $3.^{rd}$ record, for all energy groups, specified by the 2^{nd} record. The values are ordered with increasing energy and decreasing group numbers.

The records 2 to 4 are repeated for all reaction types, specified by the input.

Module 5

1. record: o , 'SMTØT---'
2. record: n , material name, total number of outscattering groups
3. record: n , number of the outscattering group, elements of
. the matrix PRØBSGI in the sense that the first
. element describes scattering within the group,
. then scattering into the neighbouring group etc.

repeated for all outscattering groups.

Module 6

1. record: o , 'FLUM----'
2. record: n , material name, number of outscattering groups, number of Legendre moments.
3. record: n , number of the outscattering groups, group averaged total elastic cross section, group averaged cosine for elastic scattering.

repeated for all outscattering groups.

4. record: n , number of the Legendre moment, number of the outscattering group, matrix elements SGNCi (i = number of the moment) arranged in the sense that the first word describes scattering within the group, the next one scattering into the neighbouring group etc.

repeated for all outscattering groups (for a certain Legendre moment)
repeated for all Legendre moments.

Module 7

1. record: o , 'SPALT---'
2. record: n , material name, energy of the fission inducing neutron in [eV], number of the lowest energy group, number of the highest energy group.
3. record: n , CHI for all groups specified in the 2nd record, arranged with increasing energy.

Module 8

1. record: o , 'S1/V----'
2. record: n , 1/V-values for all energy groups defined by the group boundaries in the input, arranged with increasing energy and decreasing group numbers.

Module 9

1. record: o , 'REMØ----'
2. record: n , material name, total number of outscattering groups, total number of Legendre moments.
3. record: n , number of the outscattering group, number of subgroups in the outscattering group, number of intervals in one subgroup (the same for all subgroups in one outscattering group), SGT for all intervals in one group (product of the number of subgroups and the number of intervals in one subgroup) arranged with increasing energy, SGN for all intervals in one group, MUEL for all intervals in one group, FLUX for all intervals in one group.

   repeated for all outscattering groups.
4. record: n , number of the Legendre moment, number of the outscattering group, SGNCi (i = Legendre moment) for all intervals in one group arranged in the sense

that first the elements describing scattering within the group, then the elements describing scattering into the neighbouring group etc. are stored.

repeated for all outscattering groups (for a fixed Legendre moment)
repeated for all Legendre moments.

Module 1o

1. record: o , 'THERM---'
2. record: n , material name, name of the reaction type, number of the thermal group.
3. record: n , value of the group constant specified in the 2nd record

Table VII Error messages and warnings

*** WARNING 2.04

Comment: To get a correct overlapping correction, Γ/Δ should be much smaller than one. Normally it is assumed, that $\Gamma/\Delta < 0.5$ is small enough. See chapter 5, formula (5.24).

*** WARNING 2.05

Comment: For the calculation of the current weighted resonance self shielding factors an approximation is used, which in some cases is not valid for small σ_o-values. In this cases, the self shielding factors are not calculated and negative figures are printed. See chapter 5, and Appendix III, formula (25).

*** WARNING 2.06

Comment: The reason for this warning might be the same as in *** WARNING 2.04. If not, the formalisme for approximating the overlapping correction is insufficient.
The warning is given, when the denominator in formula (5.14) becomes negative. If the resulting $s_{\sigma_{r,g}}$ in (5.14) is small against the contribution of all other resonance series, this warning may be ignored.

3. The calculation of average group cross sections from tabulated neutron cross sections. Module 4.

3.1 The average group cross sections are defined by

$$ {}^{k}\tilde{\sigma}_{x,g} = \frac{\int_{(g)} {}^{k}\sigma_{x}(E)\,\phi(E)\,dE}{\int_{(g)} \phi(E)\,dE} \qquad (3.1) $$

k = isotope

x = neutron reaction (n,x)

g = energy group

$\phi(E)$ is the neutron flux density. In the resonance region, normaly a slowly varying collision density is used, so that formula (3.1) defines the average group cross section for infinite dilution. The average group cross sections for all types of neutron reactions are calculated by formula (3.1), except:

- the average cosine of the elastic scattering

$$ {}^{k}\bar{\mu}_{e,g} = \frac{\int_{(g)} {}^{k}\bar{\mu}_{e}(E)\,{}^{k}\sigma_{e}(E)\,\phi(E)\,dE}{\int_{(g)} {}^{k}\sigma_{e}(E)\,\phi(E)\,dE} \qquad (3.2) $$

- the average number of secondaries per fission

$$ {}^{k}\nu_{g} = \frac{\int_{(g)} {}^{k}\nu(E)\,{}^{k}\sigma_{f}(E)\,\phi(E)\,dE}{\int_{(g)} {}^{k}\sigma_{f}(E)\,\phi(E)\,dE} \qquad (3.3) $$

f = fission

- the average α-value

$$\alpha_g = \frac{\int_{(g)} {}^k\sigma_\gamma(E)\ \phi(E)\,dE}{\int_{(g)} {}^k\sigma_f(E)\ \phi(E)\,dE} \tag{3.4}$$

γ = radiative capture

- the average η-value

$$\eta_g = \frac{\nu_g}{1+\alpha_g} \tag{3.5}$$

For which type of neutron reaction an average cross-section shall be calculated can be choosen by input. There must be information available on KEDAK-library.

Besides that, the following group average

$$\sigma_{beH} = \frac{\int_{(g)} \frac{\sigma_e(E)}{E}\ F(E)\,dE}{\int_{(g)} F(E)\,dE} \tag{3.6}$$

is calculated for hydrogen. This group average can be used for the production of the elastic scattering matrix.

3.2 The integration in the averages (3.1) to (3.4) are done by a trapezoidal rule. As integration points the energy points at which the nuclear data on the KEDAK-library are tabulated and the group boundaries are used. The values of the cross sections at the boundaries are calculated by linear interpolation or extrapolation from the tables on KEDAK. The weighting function is either interpolated linearly from tables or is given by a function.

3.3 The following subroutines is necessary:

```
SUBROUTINE SUND (MM, ENG, NFE, REFE, EFE, ITYP, ITNAM, SGC, DUE,
                 XINTE, ZINT, XNEN, STREU, LDIM, LDIMP, SE, FSE)
```

The following parameters are defined by the control program :

MM : Number of energy group boundaries.

ENG : one-dimensional field containing the energy group boundaries in [eV].

NFE : number of points of the neutron flux density.
= o, if the function PHI(E) is used.

REFE : one-dimensional field containing the energy points of the neutron flux density in [eV].

EFE : one-dimensional field containing the neutron flux density.

ITYP : number of cross section types.

ITNAM : one-dimensional field containing the names of these reaction types for which the average group cross sections shall be calculated.

LDIM : dimension of the following fields SE and FSE which is max (1500, number of σ_e(E)-values on KEDAK, number of σ_f(E)-values on KEDAK in all regarded energy groups).

The following parameters are work fields used by the subroutine SUND :

SGC, DUE, XINTE, ZINT, SNEN, STREU	one-dimensional fields of the length MM
SE, FSE	one-dimensional fields of the length LDIM .

The following parameter is calculated in the subroutine

LDIMP: o , if the length of the working fields dimensioned with LDIM is sufficient.

: n , number, by which LDIM should be increased.

4. The calculation of average group cross sections for infinite dilution and of energy resonance self shielding factors from resolved resonance parameters. Module 1.

4.1 Flux-weighted energy resonance self shielding factors are calculated for capture, fission and elastic scattering. They are defined as

$$ {}^{k}f_{x,g}(\sigma_o, T) = \frac{{}^{k}\tilde{\sigma}_{x,g}(\sigma_o, T)}{{}^{k}\tilde{\sigma}_{x,g}(\sigma_o \to \infty, T)} \qquad (4.1) $$

k = isotope

x = neutron reaction (n,x)

g = energy group

T = temperature in ^{o}K

σ_o = background cross section in barns

where

$$ {}^{k}\tilde{\sigma}_{x,g}(\sigma_o, T) = \frac{\left\langle \frac{{}^{k}\sigma_x(T,E)\,F(E)}{{}^{k}\sigma_t(T,E) + \sigma_o} \right\rangle}{\left\langle \frac{F(E)}{{}^{k}\sigma_t(T,E) + \sigma_o} \right\rangle} \qquad (4.2) $$

is the microscopic effective cross section.

The weighting function F(E) is the collision density and is assumed to have no resonance structure in the NR-approximation.

The average is defined as

$$\langle y(E) \rangle = \frac{1}{\Delta E_g} \int_{\Delta E_g} y(E)\, dE$$

where ΔEg is the group width of group g .

The current-weighted resonance self shielding factors are calculated for elastic scattering and for the total neutron reaction

$$ {}^{k}_{1}f_{x,g}(\sigma_o, T) = \frac{{}^{k}_{1}\tilde{\sigma}_{x,g}(\sigma_o, T)}{{}^{k}_{1}\tilde{\sigma}_{x,g}(\sigma_o \to \infty, T)} \qquad (4.3)$$

where

$$ {}^{k}_{1}\tilde{\sigma}_{x,g}(\sigma_o, T) = \frac{\left\langle \frac{{}^{k}\sigma_x(T,E)\, F(E)}{\{{}^{k}\sigma_t(T,E) + \sigma_o\}^2} \right\rangle}{\left\langle \frac{F(E)}{\{{}^{k}\sigma_t(T,E) + \sigma_o\}^2} \right\rangle} \qquad (4.4)$$

is the current weighted microscopic effective cross section. For infinite dilution

$$ \lim_{\sigma_o \to \infty} {}^{k}_{1}\tilde{\sigma}_{x,g}(\sigma_o, T) = \lim_{\sigma_o \to \infty} {}^{k}\tilde{\sigma}_{x,g}(\sigma_o, T) = {}^{k}\tilde{\sigma}^{\infty}_{x,g} \qquad (4.5)$$

and

$$ {}^{k}\tilde{\sigma}^{\infty}_{x,g}(T) = \frac{\left\langle {}^{k}\tilde{\sigma}_{x}(E,T)\, F(E) \right\rangle}{\left\langle F(E) \right\rangle} \qquad (4.6) $$

Therefore the denominators of (4.1) and (4.3) may be replaced by (4.6).

Normally ${}^{k}\sigma^{\infty}_{x,g}$ is independent of temperature, but in cases when only few resonances are within an energy group, and the group boundary cuts the wings of an important resonance, ${}^{k}\sigma^{\infty}_{x,g}$ may be temperature dependent.

The averages of (4.3), (4.4) and (4.6) are calculated by numerical integration. The microscopic cross sections $\sigma_x(E)$* are calculated from resonance parameters by a Breit-Wigner single level formula.

$$ \tilde{\sigma}_{x}(E,T) = \sum_{r=1}^{R} \tilde{\sigma}_{x}(E, E_r, T) \qquad (4.7) $$

r = resonance
R = number of resonances taken into account
E_r = resonance energy

$$ \tilde{\sigma}_{x}(E, E_r, T) = {}_{r}\tilde{\sigma}_{ox} \cdot \Psi_{r}(\theta, x) \qquad (4.8a) $$

for capture and fission ,

---

* (the index for the isotope will be neglected)

$$\sigma_t(E,E_r,T) = \sigma_p + {}_r\sigma_{oc} \cdot \{ \psi_r \cdot \cos 2\delta_l + \chi_r \cdot \sin 2\delta_l \} \qquad (4.8b)$$

and for elastic scattering

$$\sigma_e(E,E_r,T) = \sigma_t(E,E_r,T) - \sum_x \sigma_x(E,E_r,T) \qquad (4.8c)$$

x = capture, fission, where

$${}_r\sigma_{ox} = 4\pi \lambda^2(E_r)\, g \cdot \frac{\Gamma_n(E_r)\,\Gamma_x(E_r)}{\Gamma^2(E_r)} \cdot \left(\frac{E}{E_r}\right)^{l-1/2} \qquad (4.9)$$

$${}_r\sigma_{oc} = 4\pi \lambda^2(E_r) \cdot g \cdot \frac{\Gamma_n(E_r)}{\Gamma(E_r)} \cdot \left(\frac{E}{E_r}\right)^{l-1/2} \qquad (4.10)$$

$$\psi(\theta,x) = \frac{\theta}{2\sqrt{\pi}} \int_{-\infty}^{+\infty} \frac{\exp\{-\frac{\theta^2}{4}\cdot(x-y)^2\}}{1+y^2} \qquad (4.11)$$

$$\chi(\theta,x)=\frac{\theta}{2\sqrt{\pi}}\int_{-\infty}^{+\infty}\frac{y\cdot\exp\left\{-\frac{\theta^2}{4}\cdot(x-y)^2\right\}}{1+y^2} \qquad (4.12)$$

$$\theta=\frac{\Gamma}{\Delta}\quad,\quad x=\frac{2(E-E_r)}{\Gamma},\quad y=\frac{2(E'-E_r)}{\Gamma} \qquad (4.13)$$

$\Delta = \frac{4kTE_r}{A}$ = Doppler width

Γ = total width

$g = \frac{2I+1}{2(2i+1)}$, I = total spin, i = spin of the nucleus

$\delta_l = \frac{R'}{\lambda\!\!\!^{-}} - \text{arctg}\ \frac{R'}{\lambda\!\!\!^{-}} \cdot l$ for l = o,1

R' = effective radius of the nucleus

$\lambda\!\!\!^{-}$ = reduced neutron length

Γ_n = neutron width

Γ_x = fission or capture width

σ_p = potential cross section

For T → 0, that means Θ → ∞, and

$$\Psi(\theta\to\infty,\ x)=\frac{1}{1+x^2} \qquad (4.14)$$

$$\chi(\theta \to \infty, x) = \frac{x}{1+x^2} \tag{4.15}$$

For resonances at negative resonance energies the formulas (4.9) and (4.1o) are modified to

$$_r\sigma_{ox} = 4\pi\lambda_o^2 \cdot g \cdot \frac{\Gamma_n(E_r)\,\Gamma_x(E_r)}{\Gamma^2(E_r)} \cdot E^{l-1/2} \tag{4.16}$$

$$_r\sigma_{oc} = 4\pi\lambda_o^2 \cdot g \cdot \frac{\Gamma_n(E_r)}{\Gamma(E_r)} \cdot E^{l-1/2} \tag{4.17}$$

where $\lambda_o = \lambda\!\!\!^{-}\ (1\ \mathrm{eV})$.

4.2 The method of integration for the averages in (4.2), (4.4) and (4.6).

The expressions (4.2), (4.4) and (4.6) are calculated by numerical integration. A trapezoidal rule is used. To keep the number of integration points as small as possible, which is necessary, because the calculation of the function values is very time consuming, the integration points are not taken equidistant. To be sure that the resonances are not lost during the integration,

the resonance energies are chosen as integration points. Let X_i be the integration points and Y_i the corresponding function values. Then the integration algorithm can be described in the following way:

First step: $X^o = (X_1^o, X_2^o, \ldots X_n^o) = (E_{g+1}, E_{r,i}\ (i=1, n-2), E_g)$

$Y^o = (Y_1^o, Y_2^o, \ldots Y_n^o)$

E_{g+1} lower group limit

E_g upper group limit

$E_{r,i}$ resonance energy of the i-th resonance in energy group g.

Second step: $X^1 = (X_1^o, \frac{X_1^o+X_2^o}{2}, X_2^o, \ldots X_n^o) = (X_1^1, X_2^1, \ldots X_{n+1}^1)$

$Y^1 = (Y_1^1, \ldots Y_{n+1}^1)$

$a = \frac{1}{2}(X_2^1 - X_1^1) \cdot (Y_1^1 + Y_2^1)$

$b = \frac{1}{2}(X_2^1 - X_1^1) \cdot (Y_1^1 + \tilde{Y}_2^1)$

$\tilde{Y}_2^1 = \frac{1}{2}(Y_1^1 + Y_3^1)$

The condition

$$\frac{b-a}{a} < \varepsilon \qquad (4.18)$$

where ε is a given error limit, must be satisfied.

If condition (4.18) is not fulfilled, the second step is repeated until condition (4.18) is fulfilled, let's say, after repeating the second step (l-1) times.

$$X^1 = (X_1^{1-1}, \frac{X_1^{1-1}+X_2^{1-1}}{2}, X_2^{1-1}, \ldots X_{n+1-1}^{1-1}) = (X_1^1, \ldots X_{n+1}^1)$$

$$Y^1 = (Y_1^1, \ldots Y_{n+1}^1)$$

Third step: $a = \frac{1}{2}(X_3^1 - X_2^1) \cdot (Y_2^1 + Y_3^1)$

$$b = \frac{1}{2}(X_3^1 - X_2^1) \cdot (\tilde{Y}_2^1 + Y_3^1)$$

$$\tilde{Y}_2^1 = \frac{1}{2}(Y_1^1 + Y_3^1)$$

The condition

$$\frac{b-a}{a} < \varepsilon \qquad \text{must be satisfied .} \qquad (4.19)$$

If the condition is fulfilled, the integral over the interval $\left[X_1^1, X_3^1\right]$ is given as

$$I_1 = \frac{1}{2}(X_3^1 - X_1^1) \cdot (Y_1^1 + Y_3^1)$$

and the algorithm is repeated in the interval $\left[X_3^1, X_{n+1}^1\right]$ starting with the integration points

$$X^o = (X_3^1, \ldots X_{n+1}^1) = (X_1^o, X_2^o, \ldots X_{n+1-2}^o) .$$

If condition (4.19) is not fulfilled, the integral in the interval $\left[X_1^1, X_2^1\right]$ is calculated as

$$I_1 = \frac{1}{2}(X_2^1 - X_1^1) \cdot (Y_1^1 + Y_2^1)$$

and the algorithm is repeated in the interval $\left[X_2^1, X_{n+1}^1\right]$ starting with the integration points

$$X^{o} = (X_2^1, \ldots X_{n+1}^1) = (X_1^o, X_2^o, \ldots X_{n+1-1}^o)$$

The algorithm is repeated until the integration over the total energy width is performed. The integral over the energy group is given by the sum.

$I = \sum_{i=1}^{N+1} I_i$, where N is the number of repetitions of the algorithm.

4.3 For the calculation of energy resonance self shielding factors and average group constants from resolved resonance parameters the following subroutine are used:

FGEM (NS, SIGO, NE, ENG, NEF, ES, F, NT, TEMP, PR, NMR, NFST, SUM, SUO, IRE, IREP, ER, L, GJ, GAT, GAN, GAG, GAF, ISTE, ISTEP, STE)

In this subroutine the input of the nuclear data from the Karlsruhe nuclear data library KEDAK and the output of the f-factors and the average cross sections is organized. Also the integration algorithm is performed in this subroutine. The following parameters must be defined:

NS	: number of σ_o-values.
SIGO(NS)	: one-dimensional field containing the σ_o-values [barn].
NE	: number of the group boundaries.
ENG(NE)	: one-dimensional field containing the group boundaries [eV].
NEF	: number of energy points of the weighting spectrum.
ES(NEF)	: one-dimensional field containing the energy points of the weighting spectrum [eV].
F(NEF)	: one-dimensional field containing the weighting function at the energy points of field ES.

NT : number of temperatures.

TEMP(NT) : one-dimensional field containing the temperatures [°K].

PR : error limit ε, as defined in (4.18).

NMR : R/2 as defined in (4.7).

IRE : length of working fields, should be longer than the number of resonances for one isotope.

ISTE : length of a working field for integration, should be longer than the number of integration points necessary for the integration of effective group cross sections within one group.

Working fields:

SUM(NS,7), SUO (NE,3), ER (IRE), GJ (IRE), GAT (IRE), GAN (IRE), GAG (IRE), GAF (IRE), STE (5, ISTE).

The following parameters are calculated in the subroutine:

NFST : number of the first energy group, for which f-factors can be calculated only from statistical resonance parameters. This parameter is important only, if the f-factors are calculated for an energy range, covering both, the range of resolved and the range of unresolved resonances.

IREP : 0, if the length of the working fields dimensioned with IRE is sufficient.

: n number, by which IRE should be increased.

ISTEP : 0, if the length of the working field dimensioned with ISTE is sufficient.

: n number, by which ISTE should be increased.

Information is also transferred by the unlabeled COMMON. It is described in chapter 1.

A description of the output is given in chapter 1.

WIRQ (INR, E, SF, SG, ST, IRE, ER, GJ, GAN, GAT, GAF, L, GAG, T, A, R, RLA)

In this subroutine the contribution of one resonance to the energy dependent cross section at a given energy is calculated by a Breit-Wigner single level formula.
The following parameters must be defined:

INR	: number of the resonance (all resonances of an isotope are numbered with increasing resonance energies).
E	: energy, [eV].
ER(IRE)	: one-dimensional field containing the resonance energies for one isotope, [eV].
IRE	: must be greater or equal to the number of resonances for one isotope.
GJ(IRE)	: one dimensional field containing the statistical parameters g_j for all resonances of one isotope.
GAN(IRE)	: one dimensional field containing the neutron half widths for all resonances of one isotope, [eV].
GAT(IRE)	: one dimensional field containing the total half widths for all resonances of one isotope, [eV].
GAF(IRE)	: one dimensional field containing the fission widths for all resonances of one isotope, [eV].
L(IRE)	: one dimensional field containing the neutron angular momentum for all resonances of one isotope.
GAG(IRE)	: one dimensional field containing the capture widths for all resonances of one isotope, [eV].
T	: temperature in ^{o}K.
A	: atomic weight.
R	: radius of the nucleus, $[\sqrt{\text{barn}}]$.
RLA	: reduced neutron wave length, $[\sqrt{\text{barn}} \cdot \sqrt{\text{eV}}]$

The following parameters are calculated in the subroutine:

SF : contribution to the fission cross section at the energy E from the resonance with number INR, [barn].

SG : contribution to the capture cross sections at the energy E from the resonance with number INR [barn].

ST : contribution to the total resonance cross section at the energy E from the resonance with number INR, [barn].

WIRQU (NR1, E, SIFG, SIGG, SIGT, NR, IRE, ER, GJ, GAN, GAT, GAF, L, GAG, T, A, R, RLA, NMIN)

In this subroutine the sum of the contribution to the cross section at the energy E from all resonances, that are taken into account, is performed.
The following parameters must be defined:

NR1 : the number of the resonance belonging to the first resonance energy that is greater than the higher energy limit of the actual energy group.
All resonances of an isotope are numbered with increasing resonance energies).

E : energy [eV].

NR : maximum number of resonances for one isotope.

IRE : must be greater or equal to NR.

ER(IRE) : one-dimensional field containing the resonance energies for one isotope.

GJ(IRE) : one-dimensional field containing the statistical parameters g_j for all resonance of one isotope.

GAN(IRE) : one-dimensional field containing the neutron half widths for all resonance of one isotope [eV].

GAT(IRE) : one-dimensional field containing the total half widths for all resonances of one isotope. [eV].

GAF(IRE) : one-dimensional field containing the fission half widths for all resonances of one isotope. [eV].

L(IRE) : one-dimensional field containing the neutron angular momentum for resonances of one isotope.

GAG(IRE) : one dimensional field containing the capture widths for all resonances of one isotope. [eV].

T : temperature in ^{o}K.

A : atomic weight.

R : radius of the nucleus in $[\sqrt{barn}]$

RLA : reduced neutron wave length, $[\sqrt{barn} \cdot \sqrt{eV}]$.

NMIN : the number of resonances at higher and at lower resonance energies than the energy E, that are taken into account for the calculation of the cross sections at the energy E.

The following parameters are calculated in the subroutine:

SIFG : fission cross section at the energy E, [barn].

SIGG : capture cross section at the energy E, [barn].

SIGT : total cross section at the energy E, [barn].

STOSS (E1, E2, E3, F1, F2, F3, NFE, ES, F)

In this subroutine the macroscopic weighting function (collision density) at the energies E1, E2, E3 is calculated either from an energy point wise given weighting function by interpolation or from a function PHI(E). As standard PHI(E) = 1/E is used.

The following parameters must be defined:

E1, E2, E3 : energies in [eV].

NFE : number of energy points of the weighting spectrum. If NFE = o,1, the standard PHI(E) = 1/E is used.

ES(NFE) : one-dimensional field containing the energy points of the weighting spectrum [eV].

F(NFE) : one-dimensional field containing the weighting spectrum.

The following paramters are calculated in this subroutine:

F1, F2, F3 : weighting spectrum at the energies E1, E2, E3.

PSIXI (X, T, U, V) /1/, /2/.

In this subroutine the functions (4.11) and (4.12) are calculated.

The following parameters must be defined:

X : defined as (4.13)
T : is defined as $\left\{\frac{1}{\theta}\right\}^2$, where θ is given in (4.13).

The following parameters are calculated in the subroutine:

U : defined by (4.11)
V : defined by (4.12)

5. The calculation of average group cross sections for infinite dilution and of energy resonance self shielding factors from statistical resonance parameters. Module 2.

5.1 The flux weighted resonance self shielding factors are calculated for capture, fission and elastic scattering. They are defined as

$$ {}^{k}f_{x,g}(\sigma_o, T) = \frac{{}^{k}\tilde{\sigma}_{x,g}(\sigma_o, T)}{{}^{k}\tilde{\sigma}_{x,g}(\sigma_o \to \infty, T)} \qquad (5.1) $$

${}^{k}\sigma_{x,g}$ = microscopic effective group cross section

k = isotope

x = neutron reaction (n,x)

g = energy group

T = temperatur in ^{o}K

σ_o = background cross section in barns.

The following approximation is used:

$$ {}^{k}\tilde{\sigma}_{x,g}(\sigma_o \to \infty, T) \cong {}^{k}\tilde{\sigma}_{x,g}(\sigma_{o,max}, T) \qquad (5.2) $$

with

$$ \sigma_{o,max} = max(10^6, \text{highest } \sigma_o \text{ value given by the input}) \qquad (5.3) $$

The microscopic effective group cross section may be represented by

$$\tilde{\sigma}_{x,g}(\sigma_o,T)=\frac{\sum_j \phi_j \cdot \tilde{\sigma}_{x,g}(\sigma_o,T,E_j)\cdot\Delta E_j}{\sum_j \phi_j \cdot \Delta E_j} \qquad (5.4)$$

ϕ_j = is a slowly varying, resonance free flux density at the energy E_j, normally approximated by a collision density

ΔE_j = energy interval around E_j

$\sigma_{x,g}(E_j)$ = is the effective cross section in the energy interval ΔE_j around E_j for the temperature T and the background cross section σ_o.

The $\sigma_{x,g}(E_j)$ are slowly varying with energy when calculated from statistical resonance parameters. The group average of (5.4) is therefore performed in the following approximate way

$$\tilde{\sigma}_{x,g}(\sigma_o,T)\simeq\frac{\sum_j \phi_j \cdot \tilde{\sigma}_{x,g}(E_j)}{\sum_j \phi_j} \qquad (5.5)$$

where for the E_j are choosen the upper and the lower group boundary of group g, E_g and E_{g+1}, and $(E_g + E_{g+1})/2$.

$\sigma_{x,g}(E_j)$ is composed of the contributions of all resonance series s.

$$\tilde{\sigma}_{x,g}(E_j) = \sum_s {}^s\tilde{\sigma}_{x,g}(E_j) \tag{5.6}$$

for capture and fission, and

$$\tilde{\sigma}_{e,g}(E_j) = \sum_s \left\{ {}^s\tilde{\sigma}_{f,g}(E_j) - {}^s\tilde{\sigma}_{c,g}(E_j) - {}^s\tilde{\sigma}_{f,g}(E_j) + \tilde{\sigma}_p \right. \tag{5.7}$$

${}^s\sigma_{r,g}(E_j)$ is the total resonance cross section, (c = capture, f = fission).

The current weighted resonance self shielding factors are calculated for the total neutron reaction and for elastic scattering. They are defined as :

$$ {}^k_1 f_x(\sigma_o, T) = \frac{{}^k_1\tilde{\sigma}_{x,g}(\sigma_o, T)}{{}^k_1\tilde{\sigma}_{x,g}(\sigma_o \to \infty, T)} \tag{5.8}$$

where

$$ {}^k_1\tilde{\sigma}_{x,g}(\sigma_o \to \infty, T) \cong {}^k_1\tilde{\sigma}_{x,g}(\sigma_{o,max}, T) \tag{5.9}$$

$\sigma_{o,max}$ is given by (5.3).
The microscopic effective cross section for the neutron reaction (n,x) in the energy group g may be written as :

$$ {}_1\sigma_{x,g} = \frac{\sum_j {}_1\phi_j \cdot {}_1\sigma_{x,g}(E_j) \cdot \Delta E_j}{\sum_j {}_1\phi_j \cdot \Delta E_j} \qquad (5.1o) $$

${}_1\phi_j$ is a slowly varying, resonance free current density, normaly approximated by a collision density.

For (5.1o) the same approximation for averaging as for (5.4) is used.

${}_1\sigma_{x,g}(E_j)$ is composed of the contributions of the single resonance series s.

$$ {}_1\sigma_{e,g}(E) = \sum_s \left\{ {}^s_1\sigma_{r,g}(E_j) - {}^s_1\sigma_{c,g}(E_j) - {}^s_1\sigma_{f,g}(E_j) + \sigma_p \right\} \qquad (5.11) $$

$$ {}_1\sigma_{t,g}(E) = \sum_s {}^s_1\sigma_{r,g} + \sigma_p \qquad (5.12) $$

The effective resonance cross section at the energy E_j and the series s is calculated by a modified theory*, first developed by R. Froelich /1/, /2/.

$$ {}^s\sigma_{x,g}(E) = {}^s\sigma_{p,\mathrm{eff}} \frac{\left[1+\frac{\langle {}^s\sigma_r\rangle}{\langle \sigma_t\rangle}\right] \cdot \frac{\overline{{}^s\Gamma_x \cdot J({}^s\beta, {}^s\theta)}}{{}^sD \cdot \cos 2\delta_l} - \frac{{}^s\overline{D}\,\langle {}^s\sigma_x\rangle \langle {}^s\sigma_r\rangle}{\Delta\sqrt{2\pi}\cdot\langle\sigma_t\rangle^2} \cdot \varepsilon}{1 - \left[1+\frac{\langle {}^s\sigma_r\rangle}{\langle \sigma_t\rangle}\right] \cdot \frac{\overline{{}^s\Gamma_r \cdot J({}^s\beta, {}^s\theta)}}{{}^sD} + \frac{{}^s\overline{D}\,\langle {}^s\sigma_r\rangle^2}{\Delta\sqrt{2\pi}\langle\sigma_t\rangle^2} \cdot \varepsilon} \qquad (5.13) $$

for fission and capture

* see appendix I

and

$$ {}^{s}\tilde{\sigma}_{r,g}(E) = {}^{s}\tilde{\sigma}_{p,\mathrm{eff}} \frac{\left[1+\frac{\langle {}^{s}\tilde{\sigma}_r\rangle}{\langle \tilde{\sigma}_t\rangle}\right]\frac{\overline{{}^{s}\Gamma . J({}^{s}\beta,{}^{s}\theta)}}{\overline{{}^{s}D}} - \frac{\overline{{}^{s}D}\,\langle {}^{s}\tilde{\sigma}_r\rangle^2}{\Delta\sqrt{2\pi}\,\langle \tilde{\sigma}_t\rangle^2}\cdot\mathcal{E}}{1-\left[1+\frac{\langle {}^{s}\tilde{\sigma}_r\rangle}{\langle \tilde{\sigma}_t\rangle}\right]\frac{\overline{{}^{s}\Gamma . J({}^{s}\beta,{}^{s}\theta)}}{\overline{{}^{s}D}} + \frac{\overline{{}^{s}D}\,\langle {}^{s}\tilde{\sigma}_r\rangle^2}{\Delta\sqrt{2\pi}\,\langle \tilde{\sigma}_t\rangle^2}\cdot\mathcal{E}} \qquad (5.14) $$

for the total resonance cross section.

${}^{s}\Gamma_x$ width for the neutron reaction (n,x) and the resonance series s

${}^{s}\Gamma$ total width for the resonance series s.

$$ J(\beta,\theta) = \int_0^\infty \frac{\psi(\theta,x)}{\psi(\theta,x)+\beta}\,dx \qquad (5.15) $$

$$ \psi(\theta,x) = \frac{\theta}{2\sqrt{\pi}} \int_{-\infty}^{+\infty} \frac{\exp\left\{-\frac{\theta^2}{4}\cdot(x-y)^2\right\}}{1+y^2}\,dy \qquad (5.16) $$

$$ \theta = \frac{\Gamma}{\Delta} \quad , \quad \Delta = \sqrt{\frac{4kTE}{A}} \qquad (5.17) $$

k = Boltzmann constant

E = energy

A = mass number

T = temperatur

$\delta_l = \frac{R}{\lambda\!\!\!^{-}} - \operatorname{arctg}\frac{R}{\lambda\!\!\!^{-}} \cdot l \quad$ for $l = o,1$

R = effective radius of the nucleus

$\lambda\!\!\!^{-}$ = reduced neutron wave length

$\overline{{}^{s}D}$ = average level distance for the resonance series s.

$$\overline{\Gamma_n \Gamma_f} = \int_0^\infty \Gamma_n \Gamma_f \, {}^{s}F_n({}^{s}\Gamma_n) \cdot {}^{s}F_f({}^{s}\Gamma_f) \, d{}^{s}\Gamma_n \, d{}^{s}\Gamma_f \qquad (5.18)$$

where ${}^{s}F_n({}^{s}\Gamma_n)$ is the distribution of the neutron width of the resonance series s and ${}^{s}F_f({}^{s}\Gamma_f)$ is the distribution of the fission width of the resonance series s.

$\langle {}^{s}\tilde{\sigma}_x \rangle$ — average cross section of the neutron reaction (n,x) for the series s

$\langle {}^{s}\tilde{\sigma}_r \rangle$ — average resonance cross section of the series s.

$$\langle \tilde{\sigma}_t \rangle = \sigma_o + \sigma_p + \sum_s \langle {}^{s}\tilde{\sigma}_r \rangle \quad , \qquad (5.19)$$

with

$$\sigma_o = \frac{1}{N}\left\{ \Sigma_t - N \cdot \left(\sigma_p + \sum_s \langle {}^{s}\tilde{\sigma}_r \rangle \right) \right\} \qquad (5.20)$$

the average background cross section.
Σ_t is the total cross section of the mixture.

$$ {}^s\sigma_{p,eff} = \langle \sigma_t \rangle - \langle {}^s\sigma_r \rangle \tag{5.21} $$

$$ {}^s\beta = \frac{\langle \sigma_t \rangle}{{}^s\sigma_{oc}} \tag{5.22} $$

$$ {}^s\sigma_{oc} = 4\pi \lambda^2 \cdot g \cdot \frac{{}^s\Gamma_n}{{}^s\Gamma} \cdot \cos 2\delta_l \tag{5.23} $$

$$ \varepsilon = 2 \cdot \int_0^\infty \exp\left\{ -\frac{D^2}{2\Delta^2} \right\} \cdot \Omega(D)\, dD \tag{5.24} $$

There must be noted that the expression (5.24) for the correction is only correct for Doppler broadened resonances, so that $\Gamma/\Delta << 1$. The formalism cannot be used for the natural line shape of the resonances.

$$ \Omega(D) = \frac{1}{D} \sum_{\mathcal{H}=1}^{\nu/2} \cos\left\{ \frac{4\pi}{\nu}\mathcal{H} + \frac{\nu \cdot D}{2\bar{D}} \sin \frac{4\pi}{\nu}\mathcal{H} \right\} \exp\left\{ \frac{\nu D}{2\bar{D}} \left(\cos \frac{4\pi}{\nu}\mathcal{H} - 1 \right) \right\} \tag{5.25} $$

with $\nu = 10$.

To calculate the current weighted effective cross sections for the resonance series s, an approximation of H. Huschke* is used. That means, that the current weighted effective cross section can be calculated by the formulas (5.13) to (5.25), when $\langle\sigma_t\rangle$ is replaced by $\langle\sigma_t\rangle/2$. This also means, that ${}^s\sigma_{p,eff}$ is replaced by $\{{}^s\sigma_{p,eff}-\langle{}^s\sigma_r\rangle\}/2$.

The average level distance $\overline{{}^sD}$ for the resonance series s at the energy E is given by

$$\overline{{}^sD}=\overline{{}^{os}D}\cdot\frac{\{{}^sE_B+E\}^2}{\{{}^sE_B\}^2}\cdot exp\left\{-\sqrt{89{,}72\,({}^sE_B-E)}+\sqrt{89{,}72\,{}^sE_B}\right\} \quad (5.26)$$

$\overline{{}^{os}D}$ average level distance of resonance series s for low energies, $E \ll E_B$.

E_B binding energy of the last neutron in the compound nucleus in MeV.

E energy in MeV.

The statistical mean values of $\overline{{}^s\Gamma_x\cdot({}^s\beta,\,{}^s\theta)}$ are normaly calculated by numerical integration. For the distribution of the neutron half widths $F_n(\Gamma_n)$ and the fission half widths $F_f(\Gamma_f)$ χ^2-distribution are used.

$$F(\Gamma)\,d\Gamma=\frac{\nu}{2\overline{\Gamma}\cdot G\left(\frac{\nu}{2}\right)}\left(\frac{\nu\cdot\Gamma}{2\overline{\Gamma}}\right)^{-1/2}\cdot exp\left\{-\frac{\nu}{2}\frac{\Gamma}{\overline{\Gamma}}\right\}d\Gamma \quad (5.27)$$

ν degree of freedom

G here is the Γ-function

---

* see appendix II

In the case, where

$$\frac{\overline{{}^{s}D}}{\sqrt{2\pi}\cdot\Delta}\cdot\frac{\langle{}^{s}\tilde{\sigma}_{r}\rangle}{{}^{s}\tilde{\sigma}_{p,eff}}\cdot{}^{s}E_{r}<0.1 \tag{5.28}$$

the following approximations are used:

$$\overline{{}^{s}\Gamma\cdot J({}^{s}\beta,{}^{s}\theta)}\simeq\frac{\overline{{}^{s}D}\cdot\langle{}^{s}\tilde{\sigma}_{r}\rangle}{{}^{s}\tilde{\sigma}_{p,eff}}\left[1-\frac{\overline{{}^{s}D}}{\sqrt{2\pi}\Delta}\cdot\frac{\langle{}^{s}\tilde{\sigma}_{r}\rangle}{{}^{s}\tilde{\sigma}_{p,eff}}\cdot{}^{s}E_{r}\right] \tag{5.29}$$

$$\overline{{}^{s}\Gamma_{x}\cdot J({}^{s}\beta,{}^{s}\theta)}\simeq\frac{\overline{{}^{s}D}\cdot\langle{}^{s}\tilde{\sigma}_{x}\rangle\cos2\delta_{l}}{{}^{s}\tilde{\sigma}_{p,eff}}\left[1-\frac{\overline{{}^{s}D}}{\sqrt{2\pi}\Delta}\cdot\frac{\langle{}^{s}\tilde{\sigma}_{r}\rangle}{{}^{s}\tilde{\sigma}_{p,eff}}\cdot{}^{s}E_{x}\right] \tag{5.30}$$

for x = capture, fission.

The ${}^{s}E_{r}$, ${}^{s}E_{x}$ are defined as

$${}^{s}E_{r}=\frac{\overline{\{{}^{s}\Gamma_{n}\}^{2}}}{\{\overline{{}^{s}\Gamma_{n}}\}^{2}}=1+\frac{2}{\nu_{n}} \tag{5.31}$$

ν_n degree of freedom of the χ^2-distribution for the neutron half width.

$$ {}^{s}E_{\chi} = \frac{\overline{\left[\frac{\{{}^{s}\Gamma_n\}^2 \cdot {}^{s}\Gamma_{\chi}}{{}^{s}\Gamma}\right]}}{{}^{s}\Gamma_n \overline{\left[\frac{{}^{s}\Gamma_n \cdot {}^{s}\Gamma_{\chi}}{{}^{s}\Gamma}\right]}} \qquad (5.32) $$

The ${}^{s}E_{x}$ are calculated by numerical integration, with the χ^2-distributions defined in (5.21).

The average cross sections of the neutron reaction (n,x) for the resonance series s are given by

$$ \langle {}^{s}\tilde{\sigma}_{\chi} \rangle = \frac{2\pi^2}{{}^{s}D} \cdot \lambda^2 \cdot g \cdot \overline{{}^{s}\Gamma_n} \cdot {}^{s}S_{\chi} \qquad (5.33) $$

with

$$ {}^{s}S_{\chi} = \frac{\overline{\left[\frac{{}^{s}\Gamma_n \cdot {}^{s}\Gamma_{\chi}}{{}^{s}\Gamma}\right]}}{\overline{{}^{s}\Gamma_n}} \qquad (5.34) $$

and

$$ \langle {}^{s}\tilde{\sigma}_{r} \rangle = \frac{2\pi^2}{{}^{s}D} \cdot \lambda^2 \cdot g \cdot \overline{{}^{s}\Gamma_n} \cdot \cos 2\delta_l \qquad (5.35) $$

The ${}^{s}S_{x}$ are calculated by numerical integration with the χ^2-distributions defined in (5.21)

The average neutron half widths are calculated from the reduced average neutron half widths

$$\overline{{}^{s}\Gamma_n} = \overline{{}^{os}\Gamma_n} \cdot \sqrt{E} \cdot \frac{R^2 + (1+l)\lambda^2}{R^2 + \lambda^2} \qquad (5.36)$$

for $l = o,1$.

The average group cross sections for infinite dilution are calculated in the following way:

$$\tilde{\sigma}^{\infty}_{x,g} = \frac{\sum_j \phi_j \left\{ \sum_s \langle {}^{s}\tilde{\sigma}_x \rangle \right\}}{\sum_j \phi_j} \qquad (5.37)$$

for capture and fission,

$$\tilde{\sigma}^{\infty}_{e,g} = \frac{\sum_j \phi_j \left\{ \sum_s \left(\langle {}^{s}\tilde{\sigma}_r \rangle - \langle {}^{s}\tilde{\sigma}_c \rangle - \langle {}^{s}\tilde{\sigma}_f \rangle \right) + \tilde{\sigma}_p \right\}}{\sum_j \phi_j} \qquad (5.38)$$

for elastic scattering, where ϕ_j is the weighting function at the group boundaries and in the middle of the group.

5.2 The numerical procedure in calculating the statistical averages.

Statistical averages of the following type have to be calculated:

$$\overline{f(\Gamma)} = \int_0^\infty f(\Gamma)\, F(\Gamma)\, d\Gamma \tag{5.39}$$

where $f(\Gamma)$ is a function, which depends on Γ, $F(\Gamma)$ is a probability distribution. $F(\Gamma)$ is a χ^2-distribution of the degree of freedom ν.

The procedure of integration is the following. The whole range of integration is divided into n intervals so that

$$\int_{\Gamma_i}^{\Gamma_{i+1}} F(\Gamma)\, d\Gamma = \frac{1}{n} \qquad \text{for all intervals } i=1,n \tag{5.40}$$

In the interval i the average $\overline{\Gamma}_i$ is calculated

$$\overline{\Gamma}_i = \frac{\int_{\Gamma_i}^{\Gamma_{i+1}} \Gamma\, F(\Gamma)\, d\Gamma}{\int_{\Gamma_i}^{\Gamma_{i+1}} F(\Gamma)\, d\Gamma} = n \cdot \int_{\Gamma_i}^{\Gamma_{i+1}} \Gamma\, F(\Gamma)\, d\Gamma \tag{5.41}$$

For χ^2-distributions for several degrees of freedom

$$\chi_i = \frac{\overline{\Gamma}_i}{\overline{\Gamma}} \quad ; \quad i = 1, n \tag{5.42}$$

are tabulated.

$$\overline{\Gamma} \equiv \int_0^\infty \Gamma \cdot F(\Gamma)\, d\Gamma \tag{5.43}$$

The integral (5.39) then is approximated by

$$\overline{f(\Gamma)} = \sum_{i=1}^{n} f(\overline{\Gamma}\cdot\chi_i) \cdot \int_{\Gamma_i}^{\Gamma_{i+1}} F(\Gamma)\, d\Gamma = \frac{1}{n} \sum_{i=1}^{n} f(\overline{\Gamma}\cdot\chi_i) \tag{5.44}$$

This approximation reproduces $\overline{\Gamma}$ exactly

$$\overline{\Gamma} = \frac{1}{n} \sum_{i=1}^{n} \overline{\Gamma}\cdot\chi_i = \frac{1}{n} \sum_{i=1}^{n} \overline{\Gamma_i}$$

Using equation (5.41) one gets

$$\overline{\Gamma} = \sum_{i=1}^{n} \int_{\Gamma_i}^{\Gamma_{i+1}} \Gamma \cdot F(\Gamma)\, d\Gamma = \int_0^\infty \Gamma \cdot F(\Gamma)\, d\Gamma .$$

In the same way the statistical averages of the type

$$\overline{f(\Gamma_1,\Gamma_2)} = \int_0^\infty d\Gamma_1 \int_0^\infty d\Gamma_2\, f(\Gamma_1,\Gamma_2)\cdot F_1(\Gamma_1)\cdot F_2(\Gamma_2) \tag{5.45}$$

are approximated by

$$\overline{f(\Gamma_1,\Gamma_2)} = \frac{1}{n_1\cdot n_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} f(\overline{\Gamma_1}\cdot\chi_{1,i}\,,\,\overline{\Gamma_2}\cdot\chi_{2,j}) \tag{5.46}$$

with

$$\chi_{1,i} = \frac{\overline{\Gamma_{1,i}}}{\overline{\Gamma_1}} \quad , \quad \chi_{2,j} = \frac{\overline{\Gamma_{2,j}}}{\overline{\Gamma_2}} \quad . \tag{5.47}$$

5.3 For the calculation of energy resonance self shielding factors and average group constants from statistical resonance parameters the following subroutines are used:

FSTAT (MI, SIGO, J, ENG, NFE, REFE, EFE, MT, TEMP, SE, SM, XEUGZ)

In this subroutine the average group cross sections and the energy resonance self shielding factors are calculated from statistical parameters residing on the KEDAK-file. After the subroutine QUER has calculated the microscopic average cross sections and the effective microscopic cross sections at three energy points E numerical integration is performed and the average group cross sections and the self shielding factors are printed on paper and are stored on an external unit.

MI	: number of values of the background cross section σ_o.
SIGO(MI)	: one-dimensional field containing the background cross sections [barns].
J	: number of energy group limits.
ENG(J)	: one-dimensional field containing the energy group limits in [eV].
NFE	: number of points of the collision density, 0 or 1, if the function PHI(E) = 1/E is used.
REFE(NFE)	: one-dimensional field containing the energy points of the collision density in [eV].
EFE(NFE)	: one-dimensional field containing the flux density for all energy points in REFE.
MT	: number of temperatures.

TEMP(MT) : one-dimensional field containing the temperatures in [°K].

SE(3,5,MI) : three-dimensional field which is calculated in the subroutine QUER .

SM(3,5,MI) : three-dimensional field which is calculated in the subroutine QUER .

XEUG(5,MI) : two-dimensional field containing the resonance self shielding factors for all σ_o-values . The first index indicates the reaction type

1: capture, flux-weighted
2: elastic scattering, flux-weighted
3: fission, flux-weighted
4: elastic scattering, current-weighted
5: total, current-weighted

A description of the CØMMØN and of the output is given in chapters 1 and 2.

QUER (E, TT, N, SE, SM, XNYN, FXNY, DEL, RQU, CHI, DN, EBI, XA, XL, GN, GG, NEY, EY, GFA, GI, IT, MI, SIGO)

In this subroutine the effective microscopic cross sections for the resonance series s at the energy E as defined by equation (5.13) and (5.14) are calculated. Also the effective microscopic cross sections at the energy E including the contributions of all resonance series s as defined by the equations (5.6), (5.11) and (5.12) are calculated in this subroutine. The following parameters must be defined:

E : energy in [eV], at which the effective cross section should be calculated .

TT : temperature in [°K].

N : n-th energy point within an energy group at which the microscopic effective cross sections are calculated for the evaluation of the effective group cross sections.

XNYN(1o) : one-dimensional field containing the ν_n, the degree of freedom of the χ^2-distributions for the neutron width, for all resonance series s ($s \leq 1o$).

FXNY(1o) : one-dimensional field containing the ν_f, the degree of freedom of the χ^2-distribution for the fission width, for all resonance series.

DEL : $(4k/A) \cdot 1o^6$, k = Boltzmann constant in [eV/°K], A = mass number.

RQU : R^2 [barn], R = radius of the nucleus.

CHI(25,4) : 2-dimensional field, containing the χ_i as defined in equation (5.42) for second degrees of freedom for the χ^2-distribution (n = 25, ν = 1, 2, 3, 4).

DN(1o) : one-dimensional field containing the average level distance at low energies $\overline{{}^{os}D}$ for all resonance series s ($s \leq 1o$) [meV].

EBI : binding energy of the last neutron in the compound nucleus [eV].

XA : $\lambda_o^2 = E \cdot \lambda^2$ [eV barn].

XL(1o) : one-dimensional field containing the quantum numbers l for the angular momentum in all resonance series.

GN(1o) : one-dimensional field containing the average reduced neutron widths $\overline{\Gamma}_n^o \cdot 1o^3$ for all resonance series. $\overline{\Gamma}_n^o$ in [eV $^{1/2}$].

GG(1o) : one-dimensional field containing the average capture widths for all resonance series in [meV].

NEY : number of energy points, for which the fission widths are tabulated on the KEDAK-library.

EY(1oo) : one-dimensional field containing the energy points, for which the fission widths are read from the nuclear data library [eV]; maximum number of points is 100.

GFA(1o, 1oo) : two dimensional field containing the average fission widths at the energies EY for all resonance series in [meV],
first parameter for the series,
second parameter for the energy points.

GI(1o) : one-dimensional field containing the statistical parameter $\frac{2J+1}{2(2I+1)}$ for all resonance series.

IT : number of resonance series.

MI : number of values of the background cross section σ_o.

SIGO(MI) : one-dimensional field containing the values of the background cross sections.

The following parameters are calculated in the subroutine

SE(3,5,MI) : three-dimensional field containing the microscopic effective cross section in [barn],
first index for energy,
second index for the reaction type.

1: capture, see formula (5.6)
2: elastic scattering, see formula (5.7)
3: fission, see formula (5.6)
4: elastic scattering, see formula (5.11)
5: total, see formula (5.12)

third index for the background cross section σ_o.

SM(3,5,MI) : three-dimensional field containing the microscopic average cross sections in [barn],
first index for energy,
second index for the reaction type as for SE,
third index for the background cross section σ_o,
(not significant, because the average cross section does not depend on σ_o).

EZZ (E, NS, EZG, EZC, EZF, DRSG, DRFS, CHI, XNYN, FXNYN, GN, RQU, XL, XA, GG, NEY, EY, GF)

In this subroutine the statistical mean values, defined by equation (5.32) and (5.34), are calculated.
The following parameters must be defined:

E : energy [eV].

NS : number of the resonance series to be calculated.

CHI(25,4) : two-dimensional field containing the χ_i as defined in equation (5.42) for several degrees of freedom for the χ^2-distribution (n = 25, ν = 1, 2, 3, 4).

XNYN(1o) : one-dimensional field containing the ν_n, the degree of freedom of the χ^2-distribution for the neutron half width, for all resonance series s ($s \leq 1o$).

FXNYN(1o) : one-dimensional field containing the ν_f, the degree of freedom of the χ^2-distribution for the fission width, for all resonances.

GN(1o) : one-dimensional field containing the average reduced neutron widths $\overline{\Gamma}^{o}_{n} \cdot 1o^3$ for all resonance series. $\overline{\Gamma}^{o}_{n}$ in [$\sqrt{eV}$].

RQU : R^2 [barn], R = radius of the nucleus.

XL(1o) : one-dimensional field containing the quantum numbers ℓ for the angular momentum for all resonance series.

XA : $\Lambda_o^2 = E \cdot \lambda\!\!\!^{-2}$ [eV barn].

GG(1o) : one-dimensional field containing the average capture widths for all resonance series [meV].

EY(1oo) : one-dimensional field containing the energy points, for which the fission widths are read from the nuclear data library [eV]; maximum number of points is 100.

GF(1o, 1oo) : two-dimensional field containing the average fission widths at the energies EY for all resonance series in [meV],
first index for the series,
second index for the energy points.

The following parameters are calculated in the subroutine:

EZG : defined by equation (5.32), for capture.

EZC : defined by equation (5.31).

EZF : defined by equation (5.32), for fission.

DRSG : defined by equation (5.34), for capture.

DRFS : defined by equation (5.34), for fission.

TAB(XT, XK, LG, DSJ, XABCJ, DJK)

In this subroutine the $J(\beta,\theta)$-function and the derivatives $\frac{\partial J}{\partial \beta}$ and $\frac{\partial J}{\partial \theta}$ are calculated.

The following parameters must be defined:

XT : $\theta = \frac{\Gamma}{\Delta}$, Γ and Δ in [eV], (5.17).

XK : k, where k is defined by $\beta = 2^k \cdot 10^{-5}$, β is defined by (5.22).

LG : 1, if XABCJ is calculated
2, if DJK is calculated
0, if DSJ is calculated
negative, if XABCJ, DJK and DSJ are calculated

The following parameters are calculated by the subroutine:

XABCJ : $J(\beta,\theta)$-function as defined by (5.15).

DSJ : $\frac{\partial J(\beta,\theta)}{\partial \theta}$

DJK : $\frac{\partial J(\beta,\theta)}{\partial k}$, with $\beta = 2^k \cdot 10^{-5}$.

SUCH (E, NSU, EY)

This is an auxiliary subroutine

Besides the subroutines the following functions are necessary:

DMIT (E, NS, DN, EBI)

In this function the average level distance at the energy E is calculated by formula (5.26).

E	: energy in [eV].
NS	: number of the resonance series.
DN(1o)	: one-dimensional-field containing the $\overline{{}^{os}D}$ for all resonance series s [meV].
EBI	: binding energy E_B of the last neutron in the compound nucleus [eV].
DMIT	: $\overline{{}^{s}D}$ at the energy E for the resonance series NS in [meV].

GAMN (E, NS, GN, RQU, XL, XA)

In this function the average neutron width at the energy E is calculated by the formula (5.36).

E	: energy in [eV].
NS	: number of the resonance series.
GN(1o)	: one-dimensional field containing the reduced average neutron half widths $\overline{{}^{o}\Gamma_n}$ for all resonance series in [meV].
RQU	: R^2 in [barn], R = radius of the nucleus
XL(1o)	: one-dimensional field containing the quantum numbers for the angular momentum for all resonance series.
XA	: $\lambda^2 \cdot E$ in [barn], λ is the neutron wave length.
GAMN	: $\overline{\Gamma_n}$, the average neutron half width at the energy E for the resonance series NS [meV].

GAMG (E, NS, GG)

In this subroutine the average capture half width at the energy E is provided.

E	: energy in [eV].
NS	: number of the resonance series.
GG(1o)	: one-dimensional field containing the average capture half widths for all resonance series in [meV].
GAMG	: average capture half widths at the energy E for the resonance series NS in [meV].

GAFM (E, NS, NEY, EY, GF)

In this subroutine the average fission half width at the energy E is interpolated from the tabulated values.

E	: energy [eV].
NS	: number of the resonance series.
EY(1oo)	: one-dimensional field, containing the energies, at which the average fission widths are tabulated [eV].
GF(1o, 1oo)	: one-dimensional field, containing the tabulated average fission widths in [meV].
GAFM	: average fission width at the energy E for the resonance series NS in [meV]

POL (X, X1, FX1)

Auxiliary function for a linear interpolation .

X	: argument, for which an arbitrary function should be interpolated .
X1(2)	: one-dimensional field, containing two arguments of the function .
FX1(2)	: one-dimensional field, containing the values of the function at the arguments X1.
POL	: value of the function at X.

EPSI (E, T, NS, DN, EBI, DEL)

In this function the overlapping correction ε, defined by formula (5.24) is calculated.

E	: energy in [eV].
T	: temperature in [^{o}K].
NS	: number of resonance series.
DN(1o)	: one-dimensional field containing the $\overline{^{os}D}$ for all resonance series s [meV].
EBI	: binding energy E_B of the last neutron in the compound nucleus [eV].
DEL	: $(4k/A)\cdot 1o^6$, k = Boltzmann constant in [eV/^{o}K], A = mass number.

DELTA (E, T, NS, DEL)

In this function the Doppler width, formula (5.17), is calculated.

E	: energy in [eV].
T	: temperature in [^{o}K],
NS	: number of resonance series.
DEL	: $\frac{4k}{A} \cdot 1o^6$; k = Boltzmann constant in [eV/^{o}K], A = mass number.

PHASE (E, NS, XA, RQU, XL)

In this function cos $2\delta_l$ is calculated, where $\delta_l = R/\lambda\!\!\!^{-} - \text{arctg}\,\frac{R}{\lambda\!\!\!^{-}} \cdot l$. R is the effective radius of the nucleus, $\lambda\!\!\!^{-}$ is the reduced neutron wave length.

E	: energy in [eV].
NS	: number of resonance series.

XA : $\Lambda_o^2 = E \cdot \lambda^2$ [eV·barn].

XL(1o) : one-dimensional field containing the quantum numbers l for the angular momentum in all resonance series.

SIGC(E, NS, XA, GI, DN, EBI, GN, RQU, XL)

In this function the average capture cross section at the energy E for a single resonance series is calculated

E : energy in [eV].

NS : number of resonance series.

XA : $\Lambda_o^2 = E \cdot \lambda^2$ [eV·barn].

GI(1o) : one-dimensional field containing the statistical parameter $\frac{2J+1}{2(2I+1)}$ for all resonance series.

DN(1o) : one-dimensional field containing the average level distance at low energies $\overline{^{os}D}$ for all resonance series in [meV].

EBI : binding energy of the last neutron in the compound nucleus in [eV]

GN(1o) : one-dimensional field containing the average reduced neutron widths $\overline{\Gamma}_n^o \cdot 1o^3$ for all resonance series, $\overline{\Gamma}_n^o$ in [$eV^{1/2}$].

RQU : R^2 in [barn], R = effective radius of the nucleus.

XL(1o) : one-dimensional field containing the quantum number l of the angular momentum for all resonance series.

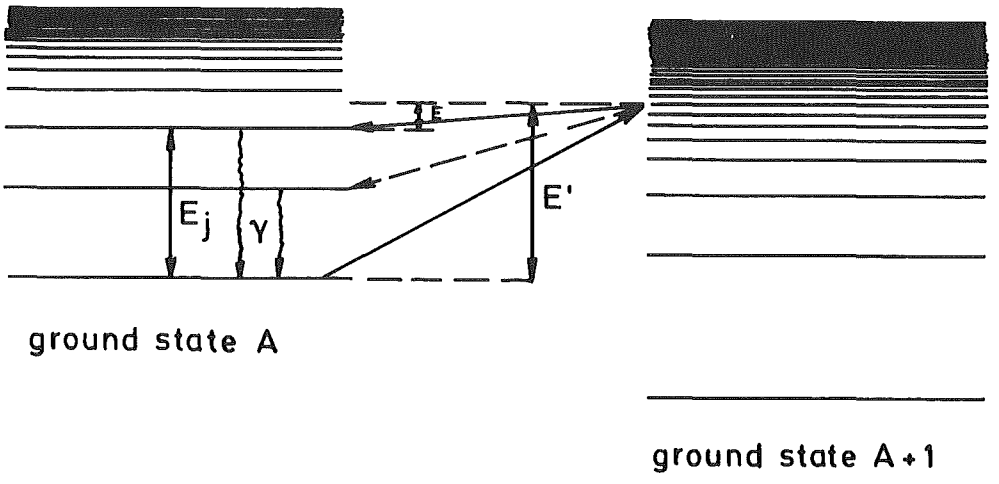
6. The calculation of the matrices of the average zeroth moments of inelastic scattering. Module 5.

6.1 Description of the inelastic scattering process

Capture of a neutron with incident energy E' by a nucleus of atomic mass A leads to the formation of a compound nucleus A + 1 with excitation energy $AE = E_B + E'$ where E_B is the binding energy of the neutron in the compound nucleus. The compound nucleus decays then by emission of a neutron to an excited level of the residual nucleus, and the transition to the ground state occurs by γ-emission.



The excitation levels of the residual nucleus are either discrete ones or are belonging to the so-called continuum. The levels in the continuum cannot be resolved experimentally and concerning their position one can make statements only from statistical theory. In the discrete region the energies of the excitation levels are well-known from experiment.

The general expression for the probability of inelastic scattering out of any energy group g to any group h for an isotope k is given by Yiftah, Okrent, Moldauer /3/ in the following form:

$$ {}^{k}\sigma^{\infty}_{i,g\to h} = \frac{\int_{E_{h+1}}^{E_h} dE \int_{E_{g+1}}^{E_g} dE' \, {}^{k}\sigma_i(E')\,\varphi(E')\,P(E'\to E)}{\int_{E_{g+1}}^{E_g} \varphi(E')\,dE'} \qquad (6.1) $$

Here is E' the incident neutron energy and E the energy of the scattered neutron. $\phi(E')$ represents the energy dependent neutron flux. P (E' → E) indicates the transition probability of the inelastically scattered neutrons. For its determination one has to distinguish between the range of resolved excitation levels of the residual nucleus and the so-called continuum range in which the levels of the residual nucleus are undistinguishable.

6.1.1 Energy groups with discrete excitation levels for inelastic scattering

For given incident neutron energies E' in group g and outgoing neutron energies E in group h inelastic scattering can occur only to those excitation levels for which $E = E' - E_j$ where E_j is the energy of the jth level.
The transition probability therefore is a δ-function which has the value one, if the above condition is fulfilled and zero, if not. Thus we have

$$ {}^{k}\sigma_i(E')\,P(E'\to E) = \sum_{j=1}^{N} {}^{E_j}\sigma_i(E')\,P_j(E'\to E) $$

$$ = \sum_{j=1}^{N} {}^{E_j}\sigma_i(E')\,\delta(E'-E-E_j) \qquad (6.2) $$

where N is the number of excitation levels of the isotope considered,

P_j the probability of the transition to the jth level of the residual nucleus and σ_i^{Ej} the inelastic excitation cross section of the jth level. With this special form of the transition - probability the double integration in equation (6.1) can be reduced to a single one over the energy group h to which the scattering occurs.

$$ {}^k\sigma^{\infty}_{i,g\to h} = \frac{\sum_j \int_{(h)} dE\, {}^k\sigma_i^{E_j}(E+E_j)\,\varphi(E+E_j)}{\int_{(g)} \varphi(E')\,dE'} \qquad (6.3) $$

With the transformation $E + E_j \to E'$ it follows:

$$ {}^k\sigma^{\infty}_{i,g\to h} = \frac{\sum_j \int_{E_{h+1}+E_j}^{E_h+E_j} dE'\, {}^k\sigma_i^{E_j}(E')\,\varphi(E')\,\chi(E_{g+1} \le E' \le E_g)}{\int_{E_{g+1}}^{E_g} \varphi(E')\,dE'} \qquad (6.4) $$

By the distribution function χ it was taken into account that the incident neutron energy E' should be contained in a 26-group g. On the other hand it must be of course

$$E_{h+1} + E_j \le E' \le E_h + E_j$$

because of the integration over this range. The integration therefore has to be extended only over the interval $[E_u, E_o]$ with the following definition

$$E_u = \begin{cases} E_{g+1}, & \text{if } E_{h+1} + E_j < E_{g+1} \\ E_{h+1} + E_j, & \text{if } E_{h+1} + E_j \geq E_{g+1} \end{cases}$$

$$E_o = \begin{cases} E_g, & \text{if } E_h + E_j > E_g \\ E_h + E_j, & \text{if } E_h + E_j \leq E_g \end{cases} \qquad (6.5)$$

Instead of the neutron flux the collision density $F(E') = \Sigma_t(E')\,\phi(E')$ was taken as weighting spectrum since outside the resonance region $\Sigma_t(E')$ can be considered as constant and then $F(E') \sim \phi(E')$ (see also /5/). The formula (6.4) then becomes the form:

$$k\sigma^{\infty}_{i,g\to h} = \frac{\sum_j \int_{E_{h+1}+E_j}^{E_h+E_j} dE'\, {}^k\sigma_i^{E_j}(E')\, F(E')\, \chi(E_{g+1} \leq E' \leq E_g)}{\int_{E_{g+1}}^{E_g} F(E')\, dE'} \qquad (6.6)$$

The matrix elements $\sigma_{i,g\to h}$ are normalized in the computer program SCAT (described under section 6.2.1) to the total inelastic scattering cross section value over group g

i.e.

$$k\sigma^{\infty}_{i,g} = \frac{\int_{(g)} \sigma_i(E')\, F(E')\, dE'}{\int_{(g)} F(E')\, dE'} \qquad (6.7)$$

The total inelastic scattering cross sections and the inelastic excitation cross sections are taken from the Karlsruhe Neutron Nuclear Data File KEDAK /6/.

6.1.2 Energy groups with unresolved excitation levels for inelastic scattering

If the incident neutron energy is high enough, to excite energy levels in the "continuum region" of the residual nucleus A, the level densities are calculated using the formula of Weisskopf.

Let U be the excitation energy of the nucleus of mass A and C and ν free parameters, then according to Weisskopf the level density $\omega(U)$ is

$$w(U) = C \exp(2\sqrt{\nu A U}) \tag{6.8}$$

The probability of inelastic scattering of a neutron from incident energy E' to final energy E is given by the statistical model as

$$P_i(E' \rightarrow E) = NE \exp(-E/\Theta(E')) \tag{6.9}$$

where N is a normalization constant and Θ is the "nuclear temperature", which is related to the level density of the nucleus by

$$\frac{1}{\Theta(E')} = \frac{d}{dU} \ln w(U) \Big|_{U=E'} \tag{6.10}$$

For our special formula (6.8) this results in

$$\Theta(E') = \sqrt{\frac{E'}{\nu A}} \quad [\text{MeV}] \quad \begin{cases} E' \text{ in MeV} \\ \nu \text{ in MeV}^{-1} \end{cases} \tag{6.11}$$

The free parameter ν is an input quantity for the program. Szwarcbaum et al. /2/ recommend $\nu = 0.16\ \text{MeV}^{-1}$ for all nuclei, whereas in the YOM-cross-section-set /3/ $\nu = 0.0961\ \text{MeV}^{-1}$ had been used. The figure 1 shows the influence of the parameter ν on the spectrum of the inelastically scattered neutrons. As an example the inelastic scattering of neutrons with an incident energy $E' = 8.5$ MeV on U 238 was taken, using $\nu = 0.16$, $\nu = 0.0961$ and $\nu = 0.06$. Figure 2 shows the spectra for neutrons inelastically scattered by U 238 using $\nu = 0.16$ and for $E' = 10.5$ MeV, $E' = 8.5$ MeV and $E' = 6.5$ MeV. With (6.8) and (6.11) inserted into (6.1) the cross section for inelastic scattering of a neutron on material k from group g to group h is given by

$$\begin{aligned} {}^{k}\sigma_{i,g\to h}^{\infty} &= \frac{\int_{(g)} dE'\, {}^{k}\sigma_i(E')\, F(E')\, N\, \Theta(E')^2 \exp\left(-\frac{E_{h+1}}{\Theta(E')}\right)\left(\frac{E_{h+1}}{\Theta(E')}+1\right)}{\int_{(g)} F(E')\, dE'} \\ &= \frac{\int_{(g)} dE'\, {}^{k}\sigma_i(E')\, F(E')\, N\, \Theta(E')^2 \exp\left(-\frac{E_{h}}{\Theta(E')}\right)\left(\frac{E_{h}}{\Theta(E')}+1\right)}{\int_{(g)} F(E')\, dE'} \end{aligned} \tag{6.12}$$

In (6.12) the integration over the final energy group, which can be done analytically, has already been carried out.

The integration over E' can be carried out numerically only. As the original program was written for the IBM 7074 computer and we had only a limited region of computer storage for the inelastic scattering routine, the following approximation, the same as in /2/ and /3/ was used. For the nuclear temperature $\Theta(E')$ the value averaged by $F(E')$ over the energy-group g is taken. With this the integration over E' in (6.12) can be carried out easily with the result

$$
\begin{aligned}
{}^{k}\sigma^{\infty}_{i,g\to h} = {}^{k}\sigma^{\infty}_{i,g} \cdot N \Bigg[& \Theta_g^2 \exp\left(-\frac{E_{h+1}}{\Theta_g}\right)\left(\frac{E_{h+1}}{\Theta_g}+1\right) \\
& - \Theta_g^2 \exp\left(-\frac{E_h}{\Theta_g}\right)\left(\frac{E_h}{\Theta_g}+1\right)\Bigg] \qquad (6.13) \\
= {}^{k}\sigma^{\infty}_{i,g} \; {}^{k}\tilde{P}_{i,g\to h} \cdot N &
\end{aligned}
$$

the normalization constant N is obtained by the relation.

$$
\sum_{h\geq g} {}^{k}\sigma^{\infty}_{i,g\to h} = {}^{k}\sigma^{\infty}_{i,g} \quad \text{, that means} \qquad (6.14)
$$

$$
N = \frac{1}{\sum\limits_{h\geq g} {}^{k}\tilde{P}_{i,g\to h}}
$$

so that finally the probability for inelastic scattering of a neutron by material k from group g to group h is

$$ {}^{k}P_{i,g\to h} = \frac{{}^{k}\tilde{P}_{i,g\to h}}{\sum\limits_{h\geq g} {}^{k}\tilde{P}_{i,g\to h}} \qquad (6.15) $$

Different from Szwarcbaum et al. /2/ and from the ABN-set /4/ we calculate the transition probabilities ${}^{k}P_{i,g\to h}$ for all groups h, which can be reached from group g until down to thermal energies. For groups of small energy however, the quantities E_{h+1}/Θ_g and E_h/Θ_g are very small compared to one (Θ_g is around o.5 MeV for U 238 and neutron incident energy E' = 8.5 MeV). When calculating the expression (6.13) on the computer two almost equal quantities have to be substracted, which results in numerical inaccuracies. As a consequence i.e. the values of ${}^{k}P_{i,g\to h}$ were not monotonically descending for h $\geq$ 2o in the energy-structure of the 26-group-ABN-set /4/ and sometimes even became negative. As a direct double precision calculation on the IBM 36o/65 did not completely eliminate the inaccuracies, we programmed a double precision function, that calculates

$$ \sum_{n=1}^{\infty} \frac{x^n}{n!} = \exp(x) - 1 = \tilde{F}(x) $$

By use of this function and **using** the following abbreviations

$$ x_h = \frac{E_h}{\Theta_g} \qquad x_{h+1} = \frac{E_{h+1}}{\Theta_g} \qquad \Delta x_h = x_h - x_{h+1} $$

the expression, which has to be calculated to obtain ${}^{k}P_{i,g\to h}$ (6.13) is

$$ \Theta_g^2 \exp(-x_{h+1}) \left[-\Delta x_h - \tilde{F}(-\Delta x_h) - x_{h+1}\tilde{F}(-\Delta x_h) - \Delta x_h \tilde{F}(-\Delta x_h) \right] \qquad (6.16) $$

With this numerical procedure values for ${}^{k}P_{i,g\to h}$ are calculated, that are monotonically descending for $h \geq 2o$.

6.1.3 Energy groups, where the excitation levels of the residual nucleus are partly resolved and partly unresolved.

For nearly all materials the last neutron incident energy, which can be treated with the discrete level method, lies within a 26 group, so that two different methods for calculation of the $P_{i,g\to h}$ have to be used in the same group. The results for the lower and upper part of the group are linked together as follows. Let ΔE_g^d be the energy range of group g, where the discrete level method is used, and ΔE_g^c the energy range, where the statistical model is used. Then for group g the transition probability for inelastic scattering is calculated according to the formula

$$ {}^{k}P^{(d+c)}_{i,g\to h} = d_g\,{}^{k}P^{d}_{i,g\to h} + c_g\,{}^{k}P^{c}_{i,g\to h} \qquad (6.17) $$

In (6.17) $d_g\,{}^{k}P^{d}_{i,g\to h}$ is the transition probability to group h of neutrons, whose incident energies lie in the range of resolved excitation levels of the residual nucleus within group g, that means

$$ d_g\,{}^{k}P^{d}_{i,g\to h} = \frac{\int_{\Delta E_g^d} dE' \int_{(h)} dE\; {}^{k}\sigma_i(E'\to E)\,F(E')}{\int_{(g)} dE'\; {}^{k}\sigma_i(E')\,F(E')} $$

and correspondingly (6.18)

$$ c_g\,{}^{k}P^{c}_{i,g\to h} = \frac{\int_{\Delta E_g^c} dE' \int_{(h)} dE\; {}^{k}\sigma_i(E'\to E)\,F(E')}{\int_{(g)} dE'\; {}^{k}\sigma_i(E')\,F(E')} $$

In the program ${}^{k}P^{d}_{i,g\to h}$ and ${}^{k}P^{c}_{i,g\to h}$ are both normalized in the following manner

$$\sum_{h\geq g} {}^{k}P^{d}_{i,g\to h} = 1 \quad \text{and} \quad \sum_{h\geq g} {}^{k}P^{c}_{i,g\to h} = 1 \tag{6.19}$$

so that

$$d_g = \frac{\int dE' \, {}^{k}\sigma_i(E') F(E')}{\Delta E^{d}_{g}} \Big/ \int_{(g)} dE' \, {}^{k}\sigma_i(E') F(E'), \qquad c_g = \frac{\int dE' \, {}^{k}\sigma_i(E') F(E')}{\Delta E^{c}_{g}} \Big/ \int_{(g)} dE' \, {}^{k}\sigma_i(E') F(E') \tag{6.2o}$$

A special subroutine for the calculation of (n, 2n) transition probabilities is being developped. So far the inelastic scattering transition probabilities are used for (n, 2n) reactions too.

6.2 Description of the computer program

The computer program for the calculation of the inelastic scattering matrices called SCAT is a subroutine of the managing program. It consists of the following subprograms:

A K E D, T R A, X K O N

Furthermore it uses the computer programs for retrieval of KEDAK-data NDFOPN, NDFLOC, NDFNXT. The function of the above computer-programs is outlined below.

6.2.1 S C A T

SCAT (NX, EG, XNUE, NFE, EF, FI, NE 27, WAHR, PROB, VW, QUER, E, NET, ET, NAE, AE, SU, QUOT, LBA, WEIN, AG, NETP, SGIT, NAEP, KMAX, ISG, ISGP, SGIP, IWE, IWP, WERT).

The parameters which have to be defined before calling SCAT are:

NX	:	number of energy group boundaries
NE 27	:	NX + 1
EG(NX)	:	energy group boundaries in eV
NFE	:	= o in the case the weighting spectrum is given by a function
		= constant equal to the number of points at which the weighting spectrum is given in this case
EF(NFE)	:	energy points of the weighting spectrum
FI(NFE)	:	values of the weighting spectrum
NET	:	dimension corresponding to the number of points of the inelastic scattering cross section on KEDAK for energies up to E (NAB + 1)
NAE	:	dimension corresponding to the number of inelastic excitation levels
ISG	:	dimension corresponding to the maximum of the number of KEDAK energy points for the different inelastic excitation levels
IWE	:	dimension corresponding to the number of KEDAK energy points in the "discrete" region (up to E (NAB + 1)

Only working fields are the following quantities:

NETP, NAEP, ISGP, IWP, SGIT (NET), LBA(NX), VW(NX), QUER(NX), PROB(NX), AG(NX), E(NX) and a group of parameters delivered by the subroutine AKED:

ET(NET), SGIP (NAE, ISG), JMAT, KMAX (NAE), AE (NAE), SU (NX), QUOT (NX), WERT (IWE)

Quantities calculated in SCAT are

WAHR(NX) = WEIN(NX) : normalized probabilities for inelastic scattering out of an energy group g into a group h.

The functions of the program SCAT are:

Calculation of the scattering matrices and organisation of the output for one material. This is done by the following successive steps:

1. Determination of the integration limits E_u, E_o for a given j, g, h.
2. linear interpolation of ${}^k\sigma_i^{E_j}(E')$ and F(E') at E_u, E_o
3. calculation of the integral over E_u, E_o by trapezoidal rule
4. return to 1. and next j by keeping the g and h; summation over all j excitation levels for a given g, h, and division by $\int_{(g)} F(E')\,dE'$ (calculated in AKED)
5. return to 1. and next h by keeping g; calculation of $\sum_{h=1}^{g} {}^k\sigma_{ig\to h}^{\infty}$ and normalization of the probabilities

$$ {}^kP_{i,g\to h} = \frac{{}^k\sigma_{i,g\to h}^{\infty}}{\sum_{h=1}^{g} {}^k\sigma_{i,g\to h}^{\infty}} $$

6. return to 1. and next g and so on until g becomes the energy group, where the excitation levels are partly resolved and partly unresolved. Then instead of 6. the subroutine XKON is called and 5. is calculated only for the part of group g in which the excitation levels are resolved (see section 6.1.3).

6.2.2 AKED

The subroutine AKED is called in SCAT with the following arguments AKED (E, ET, SGIP, JMAT, KMAX, LMAX, SU, QUOT, WERT, AE, EMAX, EMIN, IA, NAB, NFE, EF, FI, NE, NX, NET, NETF, NETP, SGIT, NAE, NAEF, NAEP, ISG, ISGF, ISGP, IWE, IWF, IWP).

Parameters which have to be defined before calling AKED are:

NX	:	number of boundaries of the energy groups not necessarily including the thermal energy group
NE	:	number of energy group boundaries including the thermal energy group
	=	NX + 1 in the case the energy groups defined externally do not contain a thermal energy group (o.oo1 eV - o.o25 eV); NX in the case they do contain the thermal energy group
E(NE)	:	energy group boundaries
NFE	:	= o in the case the weighting spectrum is given by a function
	=	constant equal to the number of points at which the weighting spectrum is given in this case
EF(NFE)	:	energy points of the weighting spectrum
FI(NFE)	:	values of the weighting spectrum
NET	:	dimension corresponding to the number of points of the inelastic scattering cross section on KEDAK for energies up to E (NAB + 1)
NAE	:	dimension corresponding to the number of inelastic excitation levels
ISG	:	dimension corresponding to the maximum of the number of KEDAK energy points for the different inelastic excitation levels
IWE	:	dimension corresponding to the number of KEDAK energy points in the "discrete" region (up to E (NAB + 1))

working fields in AKED are the following:

SGIT (NET), FELD (6), KFEL (6), NFEL (6), NEFT, NETP, NAEF, NAEP, ISGF, ISGP, IWP, IWF.

Parameters which are determined in AKED and are transferred to SCAT are:

ET(NET) : KEDAK energies

SGIP(NAE,ISG) : two dimensional field filled by the inelastic excitation cross sections for a level NAE

JMAT : number of inelastic excitation levels for the material considered

KMAX(NAE) : number of energy points for the inelastic excitation cross sections of the different levels.

SU(NX) : one dimensional field giving the integral of the collision density $\int_{(g)} F(E)\,dE$ about a particular energy group g

QUOT(NX) : one dimensional field giving the value of the integral $\dfrac{\int_{(g)} {}^{k}\sigma_i(E')F(E')dE'}{SU}$

WERT(IWE) : one dimensional field giving the value of the weighting function at the KEDAK energies

AE(NAE) : one dimensional field indicating the energies of the excitation levels

EMAX : upper energy limit of the "discrete" region

EMIN = ET(1) : last KEDAK energy at which ${}^{k}\sigma_i$ is still equal to zero

IA : number of the energy group in which EMIN is lying, i.e. lowest energy group out of which inelastic scattering is possible

NAB : number of the energy group in which EMAX is lying, i.e. where the excitation levels are to be considered to be partly resolved and partly unresolved.

AKED has the following functions:

1. reading of $\sigma_i(E')$ and the corresponding energy values E'
   reading of $\sigma_i^{E_j}(E')$ and the corresponding energy values E' above the treshold of the (n, n') process

2. linear interpolation of F(E') at the KEDAK energy points

3. linear interpolation of F(E') (by calling TRA) and $\sigma_i(E')$ at the energy boundaries of a given group structure

4. Integration of $\int_{(g)} F(E')\,dE'$ and $\int_{(g)} F(E')\,\sigma_i(E')\,dE'$ by using the trapezoidal rule

5. calculation of $\int_{(g)} F(E')\,\sigma_i(E')\,dE' / \int_{(g)} F(E')\,dE'$ and return to 3, and next g until the last g is reached i.e. the energy group NAB where the excitation levels are partly resolved and partly unresolved.

6.2.3 TRA

This subroutine has the following arguments:

TRA (EFI, FIS, NFE, EF, FI). The parameters which have to be defined before the subroutine call are:

NFE : = o in the case the weighting spectrum is given by a function
= constant equal to the number of points at which the weighting spectrum is given in this case.

EF(NFE) : energy points of the weighting spectrum

FI(NFE) : values of the weighting spectrum

The two other parameters are determined in TRA.

EFI : energy at which the weighting function is calculated

FIS : value of the weighting function at EFI.

The weighting spectrum is either given by a function (NFE = o) and is then available over CALL FUNCTION PHI(E) or is given pointwise.

6.2.4 The subroutine XKON

XKON (NZG, NUGR, DI, EMAX, W, A, NE, ENG, NF, E, F, XNUE, NX)

Arguments submitted by the calling program:

NZG : group number of that energy group, in which inelastic scattering occurs partially on unresolved excitation levels of the residual nucleus

NUGR : number of energy group g, from which the neutron starts before the process of inelastic scattering.

DI : normalization factor, that corresponds to c_g^k in formula (6.19).
DI is different from o. only for NUGR = NZG.

EMAX : highest energy of incident neutron, for which inelastic scattering occurs on resolved levels of the residual nucleus.

A : mass number of the residual nucleus.

ENG(NE) : one dimensional array, which contains the limits of the energy groups. (NE - 1) = number energy groups.

NF : If NF is equal to 1, the weighting function for the averaging of the nuclear temperature is submitted by a function subprogram. Otherwise NF means the number of energy points, E(NF), at which the value of the weighting function, F(NF), is submitted by input.

E(NF), F(NF) : energies and corresponding values of the weighting function, submitted by input. If NF is equal to 1, E and F are not used by XKON.

NX : dimension of the vector field for the transition probabilities for inelastic scattering.

quantities, calculated by XKON

W(NX) : double precision vector field, which by XKON is filled with Pi, g→h (see formula (6.15)) for a

group g corresponding to NUGR and all down-scattering groups h with equal or lower energy than g.

For

the numerical methods, using the function EXD(X) are applied as described above. The function EXD(X) called in XKON performs a double precision calculation of $\sum_{n=1}^{\infty} \frac{X^n}{n!} = \exp(X) - 1$. The function DNFAK(N) called in EXD(X) supplies the double precision values of N!

6.2.5 Output for one material

The program SCAT has an output on tape in the framework of the MIGROS - output and an output on listing. The output on listing has the following form:

1. line: SUBROUTINE SCAT

2. line:

2 Materialname Number of energy groups out of which inelastic scattering occurs

3. and eventually further lines

The scattering probabilities P_i, g→h in the form:

g	g + 1	g + 2	g + 3	.....
Pi, g→h	Pi, g→h + 1	Pi, g→h + 2	Pi, g→h + 3

7. Microscopic Multigroup Scattering Matrices for Elastic Neutron Scattering in a P_l-Approximation, $l \leq 5$ *. Module 6.

7.1 Definition of the quantities calculated in this module

Given the KEDAK data

$\sigma(E)$ = microscopic cross section for elastic neutron scattering at energy E (KEDAK type SGN),

$\bar{w}(E, \bar{\mu}_o)$ = angular distribution in the c.m.-system for elastic neutron scattering with

$$2\pi \int_{-1}^{+1} d\bar{\mu}_o \, \bar{w}(E, \bar{\mu}_o) = 1$$

E = energy of the incoming neutron,

$\bar{\mu}_o$ = scattering cosine in the c.m.-system, (KEDAK type SGNC),

$\bar{\mu}(E)$ = mean scattering cosine for elastic neutron scattering at energy E in the laboratory system (KEDAK type MUEL),

$\sigma_t(E)$ = total microscopic neutron reaction cross section at energy E (KEDAK type SGT),

and given a prescription for the approximation of the weighting functions $\Psi_l(E)$, $l = o, 1, .., 5$, this module calculates as final results three sets of quantities: the elastic cross section in the g-th group

$-\int_g$ means $\int_{Eg}^{Eg-1}$ with the group boundaries $E_1 > E_2 > .. > E_G$ -

$$\sigma^g = \int_g dE\, \sigma(E)\, \Phi_o(E) \Big/ \int_g dE\, \Phi_o(E) \,, \quad g = 1, 2, 3, \ldots, G \qquad (7.1)$$

---

* A detailed report (ref.1) of the code FLUMMI which is an extended version of this MIGRØS 2 module will be published as a KFK-report (in German). Further references will be found there.

the normalized matrixelements for scattering from group h into group g

$$s_\ell^{h\to g} = \frac{1}{\sigma^h}\int_h dE\,\sigma(E)\,w_\ell(E\to g)\,\Phi_\ell(E)\Big/\int_h dE\,\Phi_\ell(E) \qquad (7.2)$$

$$\ell = 0,1,2,3,4,5, \quad g,h = 1,2,\ldots,G, \quad g \geq h$$

and the mean scattering cosine in the g-th group

$$\bar{\mu}^g = \sum_{h\geq g} s_1^{g\to h}, \qquad g = 1,2,3,\ldots,G \qquad (7.3)$$

In (7.2) the quantity $w_1(E\to g)$ is defined as

$$w_\ell(E\to g) = \int_g dE'\,w_\ell(E,E'), \qquad (7.4)$$

where

$$w_\ell(E,E') = \begin{cases} \frac{d}{dE'}\int_{-1}^{\mu_o(E,E')} d\mu_o\, 2\pi\, w(E,\mu_o)\,P_\ell(\mu_o) & \text{if } E'\leq E\leq E'/\alpha \\ 0 & \text{otherwise} \end{cases} \qquad (7.5)$$

Here $\mu_o(E,E')$ is the scattering cosine for scattering from energy E to energy E' in the laboratory system:

$$\mu_o(E,E') = \frac{A+1}{2}\sqrt{\frac{E'}{E}} - \frac{A-1}{2}\sqrt{\frac{E}{E'}} \quad , \tag{7.6}$$

A = atomic weight of the scattering nucleus in neutron mass units, $P_l(\mu_o)$ is the l-th Legendre polynomial, $\alpha = \left(\frac{A-1}{A+1}\right)^2$

Further $w(E,\mu_o)$ is the angular distribution for elastic neutron scattering in the laboratory system, related to $\bar{w}(E,\bar{\mu}_o)$ through

$$w(E,\mu_o) = \bar{w}\left(E,\bar{\mu}_o(\mu_o)\right)\frac{d\bar{\mu}_o(\mu_o)}{d\mu_o} \quad , \tag{7.7}$$

where

$$\bar{\mu}_o(\mu_o) = \frac{1}{A}\left(\mu_o^2 - 1 + \mu_o\sqrt{\mu_o^2 - 1 + A^2}\right)$$

and therefore

$$\frac{d\bar{\mu}_o(\mu_o)}{d\mu_o} = \frac{1}{A}\,\frac{\left(\mu_o + \sqrt{\mu_o^2 - 1 + A^2}\right)^2}{\sqrt{\mu_o^2 - 1 + A^2}}$$

For computation the righthand side of the defining equation (7.4), which involves a double integration as it stands, can easily be simplified.

In the case of isotropy in the c.m.-system we have

$$W_l(E,E') = \begin{cases} \dfrac{d}{dE'}\,\dfrac{1}{2A}\displaystyle\int_{-1}^{\mu_o(E,E')} d\mu_o\,\frac{\left(\mu_o + \sqrt{\mu_o^2 - 1 + A^2}\right)^2}{\sqrt{\mu_o^2 - 1 + A^2}}\,P_l(\mu_o) & \text{if } E' \leq E \leq E'/\alpha \\ 0 & \text{otherwise} \end{cases}$$

hence

$$w_\ell(E \to g) = \frac{1}{2A} \int_{\hat{\mu}_0(E,E_g)}^{\hat{\mu}_0(E,E_{g-1})} d\mu_0 \, \frac{\left(\mu_0 + \sqrt{\mu_0^2 - 1 + A^2}\right)^2}{\sqrt{\mu_0^2 - 1 + A^2}} \, P_\ell(\mu_0) \qquad (7.8)$$

where

$$\hat{\mu}_0(E,E_g) = \begin{cases} -1 & \text{if } E \gg E_g/\alpha \text{ and } E_g > \hat{E} \\ +1 & \text{if } E \lesssim E_g \text{ and } E_g > \hat{E} \\ \mu_0(E,E_g) & \text{if } E_g < E < E_g/\alpha \text{ and } E_g > \hat{E} \\ -1 & \text{if } E_g = \hat{E} \end{cases} \qquad (7.9)$$

Here $\hat{E}$ is the lower limit of the considered energy region (In LECAL $\hat{E}$ = ABN (IM + 1)). With (7.4) scattering to energies below $\hat{E}$ is avoided, in particular: there is not scattering out of the lowest group.

In the case of anisotropy in the c.m.-system we have

$$w_\ell(E \to g) = 2\pi \int_{\hat{\mu}_0(E,E_g)}^{\hat{\mu}_0(E,E_{g-1})} d\mu_0 \, w(E,\mu_0) \, P_\ell(\mu_0) \qquad (7.10)$$

7.2 Integration, energy- and cosine-mesh, interpolation, and weighting

The multigroup constants to be determined according to (7.1) and (7.2) are integrals over weighting functions and cross sections given at discrete energies with a varying density of these energy points. In the energy integrals we have as weighting functions the Legendre moments $\Phi_l(E)$ of the angle- and energy-dependent flux density $\Psi(E,\mu)$, approximated by the product of a slowly varying macro-spectrum and a possibly rapidly varying micro-spectrum. In angular integrations the Legendre polynomials $P_l(\mu)$ appear as weighting functions.

The numerical technique applied for integration is a follows:

- integrals are approximated by finite sums;
  angular integration is performed with Simpson's rule since the cosine mesh can easily be spaced uniformly;
- energy integration is performed with the trapezoidal rule because of the varying density of the discrete cross section energies and the need for a fine mesh in the outgroup scattering region (defined below);
- the number of discrete points is chosen so that the program calculates cases which can be treated analytically with a maximum absolute error of $4 \cdot 10^{-4}$ in the normalized scattering matrix elements.

Interpolation of the SGN, MUEL, and SGT is linear; energy and angle interpolation of the SGNC is performed using polynomials of degree four.

The angular integrals are those in equ. (7.8) and (7.10). Since the Legendre polynomial $P_l(\mu_o)$ has l zeros in $[-1, +1]$, the integrals change sign , and there is partial cancellation.

The effect of cancellation increases with l, but this can be overcome by a cosine mesh with a number of meshpoints increasing with l.

For the computation of the integral in (7.1o) - unisotropy in the c.m.-system - the following table gives the number NST(L) of the cosine meshpoints in $[-1, +1]$ for the L-th moment:

L	o	1	2	3	4	5
NST(L)	81	81	161	161	321	321

The integration according to (7.1o) is performed by LEGANS. The integral in (7.8) is analytically given and does not depend on energy. The integrals

$$B_\ell(\omega) = \frac{1}{2} \int_{-1}^{\omega} d\mu_o \frac{d\bar{\mu}_o}{d\mu_o} P_\ell(\mu_o) \qquad (7.11)$$

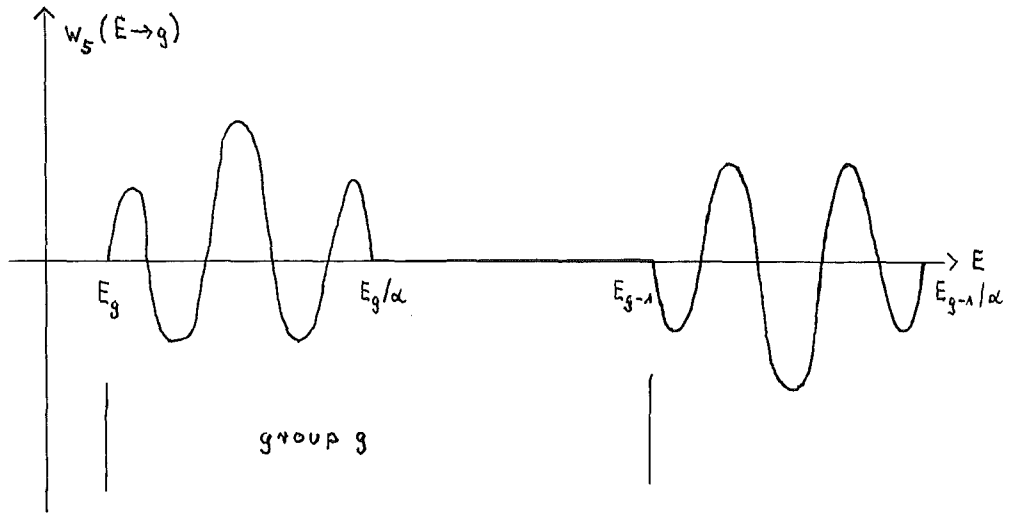
with $\bar{\mu}_o(\mu_o)$ according to (7.7) need be calculated only once for all groups in the region of isotropic scattering in the c.m.-system. So we can afford to determine $B_1(\omega)$ at NST(5) = 321 ω-points in $[-1, +1]$. The integration is done analytically, using different forms and approximations of the above integral for A = 1, $1 < A \leq 3o$, A > 9o, A = atomic weight of the scattering nucleus (see ref. 1).

The calculation of the $w_1(E \to g)$ according to (7.8) is performed by LEGIST, by interpolating in the table of the $B_1(w)$ determined by LEGINT.

The energy integral that requires the finest energy mesh is

$$\int_h dE\, \sigma(E)\, w_\ell(E \to g)\, \Phi_\ell(E) \qquad (7.12)$$

The $w_l(E \to g)$ are of a form qualitatively shown in the following figure for l = 5:



The intervall $[\, E_g,\ E_g/\alpha \,]$ from which scattering to energies $E < E_g$ is possible is called outgroup scattering region; if $E_g/\alpha < E_{g-1}$, the intervall $[\, E_g/\alpha,\ E_{g-1} \,]$, from which scattering occurs only to energies $E \geq E_g$, is called **ingroup scattering** region.

In the outgroup scattering region, $w_l(E \to g)$ may change its sign several times. To describe this behavior properly we need a sufficiently fine energy mesh (independent of α). In the ingroup scattering region there is only a weak dependence on energy so that a coarse mesh will do.

Comparisons with analytical cases show that for $\ln \frac{E_{g-1}}{E_g} = \Delta u_g \lesssim 0.7$

NK = number of discrete energies in the outgroup scattering region, uniformly spaced in lethargy
= 70,

NR = number of discrete energies in the ingroup scattering region, uniformly spaced in lethargy
= 16

is an appropriate choice; other values can be specified by input.

NR should be large enough to quarantee a sufficiently accurate pointwise representation of the makro-weighting spectrum if there are only a few discrete SGN-energies.
The whole group is an outgroup scattering region if $E_g/\alpha \geq E_{g-1}$; in this case NK discrete energies are assigned to the group.
These NK + NR discrete energies per group are called basic points; they are determined in PUNK. Together with the discrete SGNC-energies found on KEDAK they form the coarse mesh corresponding to which the $w_l(E \to g)$ are calculated in LECAL.

In GRUPIN the coarse mesh and the discrete SGN-energies are joined by means of PUSUM to form the fine mesh. Linear interpolation of the $w_l(E \to g)$ and the $\sigma(E)$ to the discrete energy points of the fine mesh yields a pointwise representation of the $\sigma_l(E \to g) = \sigma(E) \cdot w_l(E \to g)$ which contains on one hand the information available from KEDAK (without smoothing by interpolation), and on the other hand the oszillatory behavior of the $\sigma_l(E \to g)$ in the outgroup scattering region.

The weighting function $\Phi_l(E)$ is approximated by the product of a macro- and a micro-spectrum. In the following table the twelve possible forms of approximation of $\Phi_l(E)$ are listed.

Macro-spectrum	Micro-spectrum	MAZ(1)	MAZ(2)	NSPEC
$1/E$	1	o	o	o
$1/E$	$1/\Sigma_t(E)$	o	o	o
$1/E$	$1/(\Sigma_t(E))^{l+1}$	o	1	o
$1/E^{l+1}$	1	1	o	o
$1/E^{l+1}$	$1/\Sigma_t(E)$	1	o	o
$1/E^{l+1}$	$1/(\Sigma_t(E))^{l+1}$	1	1	o
$F_o(E)$	1	o	o	1
$F_o(E)$	$1/\Sigma_t(E)$	o	o	1
$F_o(E)$	$1/(\Sigma_t(E))^{l+1}$	o	1	1
$F_l(E)$	1	1	o	l+1
$F_l(E)$	$1/\Sigma_t(E)$	1	o	l+1
$F_l(E)$	$1/(\Sigma_t(E))^{l+1}$	1	1	l+1

MAZ(1), MAZ(2) and NSPEC are input parameters controlling the weighting of the higher moments. The fine-structure mixture from which Σ_t is determined, and macro-pointspectra are input quantities.

Now the integral (7.12) is determined in the following way:
Let $E_1 < E_2 < \ldots < E_{IKK}$ be the discrete energies of the fine mesh in group h, where E_1, E_{IKK} are the lower and upper boundary of group h. We put

$$f(E) = \sigma(E) \cdot w_\ell(E \to g) \cdot m(E)$$

- m(E) denotes the macro-spectrum; then (7.12) reads

$$\int_h dE\, f(E) \cdot g(E)$$

where g(E) denotes the micro-spectrum. After determination of $m(E_i)$, i = 1,2,...,IKK, by interpolation or with FUNCTIØN PHI or FUNCTIØN PHIL, we have

$$\int_h dE\, f(E)\, g(E) = \sum_{i=1}^{IKK-1} \int_{E_i}^{E_{i+1}} dE\, f(E)\, g(E)$$

$$\approx \sum_{i=1}^{IKK-1} \overline{f}_i \cdot \Delta_i^g E \qquad (7.13)$$

where $\overline{f_i} = 0.5\,(F(E_i) + f(E_{i+1}))$ and $\Delta_i^g E = \int_{E_i}^{E_{i+1}} dE\, g(E)$. The $\Delta_i^g E$ are called weighted intervall lengths (see GRUPIN, SPRAL, TRAPEZ). If fine-structure weighting is not taken into account, $\Delta_i^g E$ reduces to $\Delta E = E_{i+1} - E_i$ and (7.13) is the usual trapezoid sum. In the case of fine-structure weighting $\int dE\, g(E)$ is evaluated with the trapezoidal rule.

7.3 The routines of this module: purpose and a description of the argument lists and the commons

Subroutine :	Purpose :
FLUMMI	main control program
SUM	summation
IPØLA	interpolation with polynomials of degree 4
PUSUM	joining of point sets
MAKRØ	construction of a macro-group structure
MIXSGT, ADD	calculation of the total macroscopic cross section for fine-structure weighting
TRAFØ	transformation of angular distributions
INFØRM	printing of additional information: groups, macro-groups, distributions of SGNC and SGN, group lethargy widths, group integrals of the zeroth moment of the weighting spectrum, number of discrete SGN- and SGT-energies per macro-group, number of fine-mesh energy points per macro-group
PUNK	generation of a basic energy mesh
(NDF)	reading of KEDAK
LØØKO	reading of ISØT1 (atomic weight) using NDF
LØØK1	reading of SGN, MUEL, SGT using NDF
LØØK2	reading of SGNC using NDF
LØØK3	reading of SGNC-energies using NDF
LECAL	control of the calculation of the $w_1(E \to g)$ according to (7.8) and (7.1o)
LEGPØL	calculation of pointwise Legendre polynomials
LEGINT	calculation of Legendre integrale according to (7.11)
G(FUNCTIØN)	$G(N, X, Y) = (X^N - Y^N)/(X - Y)$
LEGIST	calculation of partial Legendre coefficients according to (7.8)
LEGANS	calculation of partial Legendre coefficients according to (7.1o)
GRUPIN	weighted energy integration according to (7.2)

IPØLIN	linear interpolation
SPRAL	presentation of the moment-dependent total weighting spectrum as described in chapter 7.2
PHI(FUNCTIØN)	PHI(E) = 1/E
PHIL(FUNCTIØN)	PHIL(L,E) = $1/E^L$
MUKØN	final determination of group constants according to (7.1), (7.2), (7.3)
PRINT	printing and reserving of final results

In the following a description of the argument lists and the commons of the subroutines is given. Under the heading "Arguments" those quantities are found which must be defined before computation will start. Under the heading "Results" those quantities are listed which are calculated by the routine. For a detailed description of the routines themselves see ref. 1.

SUBRØUTINE FLUMMI (A, B, EA, EB, E, EN, SGN, ECØ, SCØ, V, W, F, AR,
FU, ABN, INT, GR, FEKØE, EG, R, RSP, ESP, SPEK,
SGNC, FEKØ, ELSIG, ELTØT, ET, ST, MAT, DAT, NLA,
NLE, ISEL, NMAX, NX, NE27, NSPEK, LSPEK, MAZ,
NTK, KT, NTTT, NTTP, ICØS, ICØSP, NECU, NECUP,
ISM, ISMP, ISØ, ISØP, ISCØ, ISCØP, ISEC, ISECP,
KIM, NS, NK, NR)

CØMMØN STØFF, ISTRUK, ISPA, NØUT, KPR, IM, IL, KL

Purpose:

- Construction of macro-groups by means of MAKRØ;
- calculation of unnormalized scattering matrices for each macro-group by means of LECAL and GRUPIN,
- calculation of normalized scattering matrices etc. by means of MUKØN,
- printing and reserving of results with PRINT

Arguments:

NX = number of energy group boundaries (input or standard)

(EG(I), I=1, NX) = energy group boundaries (increasing) (input or standard)

NE27 = NX + 1

Comment: the group boundaries will be modified and rearranged in the following manner:

ABN(I) = EG(NX - I+1), I = 1,2,...,NX,

if ABN(NX) $\begin{cases} > 1o^{-3} & : \text{NEGR} = \text{NE27}, \text{ABN(NEGR)}=1o^{-3} \\ = 1o^{-3} & : \text{NEGR} = \text{NX} \\ < 1o^{-3} & : \text{ERRØR 6.8} \end{cases}$

NGR = NEGR-1

Now we have for further use in this module

NGR = number of energy groups

NEGR = number of group boundaries

(ABN(I),I=1,NEGR) = group boundaries (decreasing)

IL,IM = indices of the first and last energy group for which scattering matrices etc. shall be calculated (input)

NMAX = highest Legendre order which can be treated (NMAX = 5 in this version)

NLA = first Legendre moment to be calculated (input or standard, but finally NLA = o always)

NLE = last Legendre moment to be calculated (input or standard)

NSPEK = macro-weighting spectrum control parameter (NSPEK = 1: spectrum from FUNCTIØN PHIL; we have KSPE = KSPEK = o in GRUPIN; NSPEK > 1: NSPEK = number of discrete energies of the macro-weighting spectrum; we have KSPE = 1 and KSPEK = NSPEK in GRUPIN)

LSPEK = number of values of the macro-weighting spectrum if NSPEK > 1, LSPEK = 1 otherwise

(ESP(I),I=1,NSPEK) = discrete energies of the macro-weighting spectrum if NSPEC > 1, no meaning otherwise (input)

(SPEK(I),I=1,LSPEK) = values of the macro-weighting spectrum (the first NSPEK values for the o. moment, the second NSPEK values for the 1. moment etc. if MAZ(1) = 1, the first NSPEK values - there will be no more in this case - for all moments if MAZ(1) = o) (input)

NTK = micro-weighting spectrum pointer (NTK = 1: the fine-structure mixture from which the micro-weighting spectrum is to be calculated is given in the arrays MAT and DAT; NTK = o: no fine-structure weighting)

KT = number of different nuclei in the fine-structure mixture (input)

(MAT(I),I=1,KT) = nuclei in KEDAK notation in the fine-structure mixture (input)

(DAT(I),I=1,KT) = densities in particles per ccm times $1o^{-24}$ of the nuclei in the fine-structure mixture (input)

NTTT = estimated number of discrete energies of the micro-spectrum

(MAZ(I),I=1,2) = control parameters concerning the weighting of the higher moments (input)

ISM = estimated number of energy meshpoints of the coarse mesh per macro-group

ISD = estimated number of energy meshpoints of the fine mesh per macro-group

ICØS = number of angular meshpoints of the angular distributions (SGNC) on KEDAK

NECU = scattering width

ISCØ = Max (NECU·ISD, ISM·ICØS)

ISEC = Max (ISD, ISM·NECU)

NS = maximum number of energy groups per macro-group (input or standard)

NK = number of basic points in the out-group scattering region per group (input or standard)

NR = number of basic points in the ingroup scattering region per group (input or standard)

STØFF = nucleus in KEDAK notation for which scattering matrices etc. shall be calculated

NØUT = printed-output unit (usually NØUT=6)

KPR = unit on which the final results are stored

ISEL = pointer for additional output (input or standard)

KL = MIGRØS counting index

Auxiliary arrays: A(ISM), B(ISM), EA(ISM), EB(ISM), E(ISM), EN(ISD), SGN(ISD), ECØ(ISD), SCØ(ISD), V(ISD), W(ISD), F(ISD), AR(ICØS), FU(ICØS), ABN(NE27), INT(NE27), GR(NE27), FEKØE(NE27), R(NX), RSP(NX), SGNC(ICØS, ISM), FEKØ(ISM, NECU), ELSIG(6, NECU, NX), ELTØT(2, NX), ET(NTTT), ST(NTTT)

Results:

NTTP = increment of NTTT if NTTT is found to be for small during execution

ICØSP = increment of ICØS if ICØS is found to be too small during execution

NECUP, ISMP, ISDP, ISCØP, ISECP } analogous

KIM = downward extension in groups of the energy region to be calculated in order to treat outscattering in the low energy groups correctly

SUBRØUTINE SUM(M, A, S)

Purpose: Summation of real numbers different in sign and magnitude with minimization of rounding errors

Arguments: M = number of summands
(A(I),I=1,M) = summands

Results: $S = \sum_{I=1}^{M} A(I)$

SUBRØUTINE IPØLA (M, A, B, N, X, Y, T)

Purpose: Continuous and diffentiable interpolation with polynomials of degree four (for details see ref. 1)

Arguments: M = number of given points
(A(I),I=1,M) = given abszissae
(B(I),I=1,M) = given ordinates
N = number of the given new abszissae
(X(I),I=1,N) = given new abszissae
with X(1) = A(1), X(N) = A(M), X(I-1) < X(I),
I = 2, N

Auxiliary array: T(M)

Results: (Y(I),I=1,N) = new ordinates corresponding with the given new abszissae

SUBRØUTINE PUSUM (KA, A, KE, E, B)

Purpose: Joining of point sets

Arguments: KA = number of elements in the array A
(A(I),I=1,KA) = first point set (increasing)
KE = number of elements in the array E
(E(I),I=1,KE) = second point set (increasing)

Auxiliary array: B(KE)

Results: KE = number of different points in A and E
(E(I),I=1,KE) = different points in A and the given E (increasing)

SUBRØUTINE MAKRØ (ALFA, ISØ, IL, IM, NGR, ABN, ISD, ISM, ISDP, NS, NK, NECU, NUEB, V, W, LST, INTT, INT, NEGR, ISEL)

CØMMØN STØFF, ISTRUK, ISPA, NØUT

Purpose: A macro-group is defined as an energy region consisting of one group or several groups adjoining in pairs. MAKRØ subdivides the given energy region (ABN(IM +1), ABN(IL)) into macro-groups meeting the following conditions:
each macro-group contains
a) as many groups as possible
b) NS groups at most
c) ISD - ISM SGN-meshpoints at most
d) either groups with only isotropic outscattering in the c.m.-system or groups with only anisotropic outscattering in the c.m.-system

Arguments: ALFA=$((A-1)/(A+1))^2$ where A is the atomic weight of the scattering nucleus in neutron mass units
IL, IM = indices of the first and last group for which scattering matrices shall be calculated
ISØ = index of the first group with only isotropic outscattering in the c.m.-system
NUEB = scattering width
NS = maximum number of groups per macro-group
NK = number of basic points in the out-group scattering region per group

NGR = number of energy groups
NEGR = number of energy group boundaries
(ABN(I),I=1,NEGR) = energy group boundaries
NECU = maximum scattering width
ISM = maximum number of basic points plus discrete SGNC-energies per macro-group
ISD = ISM plus maximum number of discrete SGN-energies per macro-group
STØFF = nucleus in KEDAK notation for which scattering matrices etc. shall be calculated
NØUT = printed-output unit
ISEL = pointer for additional output

Auxilary arrays: V(ISD), W(ISD), LST(2, NGR)

Results: INTT = number of macro-group boundaries
(INT(I),I=1,INTT) = macro-group boundaries given by group indices
ISDP = increment of ISD if ISD is found to be too small during execution
comment: the determined macro-groups are as follows:

1. macro-group: [ABN(INT(2)+1), ABN(IN(1))]
I-th macro-group: [ABN(INT(I+1)+1), ABN(INT(I)+1]
I = 2,3,....,INTT-1

SUBRØUTINE MIXSGT (KT, MAT, DAT, NTT, NTP, NT, ET, ST, EA, EE)

CØMMØN STØFF, ISTRUK, ISPA, NØUT

Purpose: Calculation of the total macroscopic cross section of a given mixture according to

$$\Sigma_t(E) = \sum_{I=1}^{KT} d_I \cdot \sigma_{t,I}(E)$$

where d_I = density in nuclei per ccm times 10^{-24} of the I-th nucleus in the mixture and $\sigma_{t,I}$ = total microscopic cross section of the I-th

nucleus in the mixture; KT see below. E stands for the joint set of discrete energies for which for at least one nucleus in the mixture a σ_t is found on KEDAK.

Arguments:

KT = number of different nuclei in the mixture

(MAT(I),I=1,KT) = nuclei in the mixture

(DAT(I),I=1,KT) = densities (DAT(I) = d_I)

EA, EE = lower and upper boundary of the energy intervall in which Σ_t shall be calculated

NTT = estimated number of discrete energies of the mixture in the intervall $\lceil$ EA, EE $\rfloor$.

NØUT = printed-output unit

Results:

NT = number of discrete energies of the mixture in the intervall $\lceil$ EA, EE $\rfloor$

(ET(I),I=1,NT) = discrete energies in $\lceil$ EA, EE $\rfloor$

(ST(I),I=1,NT) = total macroscopic cross sections of the mixture corresponding to the ET(I)

NTP = increment of NTT if NTTT is found to be too small during execution

SUBRØUTINE ADD (K, NTT, NTP, NT, ET, ST, NU, D, E, S, EV, SV, EW, SW, EA, EE)

Purpose:

Determination of $P_{K,NU+1}(F|ET, ST)$ from $P_{K,NU}(F|ET, ST)$ (definition of $P_{I,J}(F|ET, ST)$ see below)

Arguments:

K = index of the nucleus which shall be added to the hitherto calculated mixture of the first K-1 nuclei

EA, EA, NTT see MIXSGT

NT = number of the hitherto determined discrete energies of the mixture
= number of ET(J) in $P_{K,NU}$ (E/ET, ST)

(ET(I),I=1,NT) = hitherto determined discrete energies

(ST(I),I=1,NT) = hitherto determined total cross sections

NU = index of the highest energy up to which the K-th nucleus has been taken into account

D = density of the K-th nucleus

E, EV = energy points of the polynomial to be added

S, SV = microscopic total cross sections at E and EV

EW = ET(NU) before the last modification

SW = ST(NU) before the last modification

Results:

NT = number of discrete energies of the mixture up to E

(ET(I),I=1,NT) = discrete energies up to E

(ST(I),I=1,NT) = total macroscopic cross sections up to E

NU = index of the highest energy up to which the K-th nucleus has been taken into account

NTP see MIXSGT

Definition of $P(E|ET, ST)$ and $P_{I,J}(E|ET, ST)$:

Be

$$P(E|ET,ST) = P(E|ET(1), ET(2),\ldots,ET(NT); ST(1), ST(2),\ldots,ST(NT))$$

$$= \begin{cases} 0 & \text{if } E < ET(1) \text{ or } E > ET(NT) \\ ST(J) & \text{if } E = ET(J) \\ ST(J-1) + \dfrac{ST(J) - ST(J-1)}{ET(J) - ET(J-1)} (E-ET(J-1)) & \\ & \text{if } ET(J-1) < E < ET(J) \end{cases}$$

provided ET(1) < ET(2) < ... < ET(NT).
Be now

$$P_{I,J}(E|ET,ST) = \sum_{K=1}^{I-1} P_{K,NT_K}(E|ET,ST)$$

$$+ P(E|ET_I(1), ET_I(2), \ldots, ET_I(J);$$
$$ST_I(1), ST_I(2), \ldots, ST_I(J))$$

where the $ET_I(K)$ are the discrete σ_t-energies of the I-th nucleus and the $ST_I(K)$ are the corresponding macroscopic cross sections.

SUBRØUTINE TRAFØ (IC, NE, ISM, S, XM, AL, A)

Purpose: Transformation of angular distributions for elastic neutron scattering from the c.m.-system into the laboratory system according to equ. (7.7)

Arguments:
- IC = number of uniformly spaced cosine meshpoints of the angular distributions in the c.m.-system
- NE = number of angular distributions undergoing transformation
- ISM = maximum number of angular distributions
- ((S(I,J),I=1,IC),J=1,NE) = angular distributions in the c.m.-system
- (A(I),I=1,IC) = uniformly spaced cosine meshpoints of the angular distributions in the c.m.-system with A(1) = -1, A(IC) = 1
- AL = ALFA (see MAKRØ)

Results:
- (A(I),I=1,IC) = cosine meshpoints in the laboratory system
- ((S(I,J),I=1,IC),J=1,NE) = angular distributions in the laboratory system

SUBRØUTINE INFØRM (ALFA, NEGR, ABN, R, RSP, IL, IM, INTT, INT, NST, NSTIS, IR, ISTT, K, NTK, NTT, NØUT)

Purpose: Printing of additional information if ISEL < o

Arguments:
ALFA, NEGR, ABN, IL, IM, INTT, INT, NØUT see MAKRØ
(R(I),I=1,NEGR-1) = group lethargy widths
(RSP(I),I=1,NEGR-1) = group integrals over the total weighting spectrum of zeroth order
(NST(I),I=1,6), NSTIS see LECAL
IR = macro-group index
ISTT = number of energy meshpoints in the fine-mesh in the IR-th macro-group
K = number of discrete SGN-energies in the IR-th macro-group.
NTK = pointer for micro-weighting
NTT = number of discrete energies of the micro-weighting spectrum in the IR-th macro-group if NTK ≠ o

SUBRØUTINE PUNK (NGR, NEGR, ABN, NA, NE, NEN, ALFA, NK, NR, ISM, ISMP, ISN, E)

Purpose: Generation of a basic energy mesh uniformly spaced in lethargy

Arguments:
NGR = number of energy groups
NEGR = number of energy group boundaries
(ABN(I),I=1,NEGR) = group boundaries
NA, NE = first and last group in the considered macro-group
NEN = number of angular distributions in the considered macro-group
ALFA = $\left(\frac{A-1}{A+1}\right)^2$, A = atomic weight of the scattering nucleus in neutron mass units

NK = number of basic points in outgroup scattering region

NR = maximum number of basic points in ingroup scattering region

ISM = maximum number of basic points plus discrete SGNC-energies per macro-group

Results:

ISN = calculated number of basic points in the macro-group defined through NA, NE

(E(I),I=1,ISN) = calculated basic points in this macro-group

ISMP = increment of ISM if ISM is too small

SUBRØUTINE LØØKO (XMAT, MASSE, CØM, *)

CØMMØN STØFF, ISTRUK, ISPA, NØUT

Purpose: Reading the atomic weight from KEDAK and relating it to the neutron mass as mass unit, calculation of the mass number and of the mean scattering cosine in the laboratory system for isotropic scattering in the c.m.-system

Arguments: STØFF = nucleus in KEDAK notation

Results:

XMAT = atomic weight of the nucleus in STØFF in neutron mass units

MASSE = mass number

CØM = $\frac{2}{3 \cdot XMAT}$

Remark: LØØKO calls the Entry NDFLØC of the KEDAK routine NDF

SUBRØUTINE LØØK1 (ISD, K, E, SGN, EØ, EE, NT)

CØMMØN STØFF, ISTRUK, ISPA, NØUT

Purpose: Reading of SGN, MUEL and SGT from KEDAK

Arguments:
- STØFF = nucleus in KEDAK notation for which data shall be read from KEDAK
- ISD = maximum number of data which may be read with a single call
- EØ, EE = lower and upper boundary of the energy region for which data shall be read
- NT = data-type pointer (NT = 1: SGN are read; NT = 2: MUEL are read; NT = 3: SGT are read)
- NØUT = printed-output unit

Results:
- K = number of data (SGN, MUEL or SGT) in [EØ, EE].
- (E(I),I=1,K) = discrete energies at which data a given
- (SGN(I),I=1,K) = data read from KEDAK (SGN, MUEL or SGT)

Remarks: The conditions E(1) = EØ and E(K) = EE are met by linear interpolation or constant extrapolation. LØØK1 calls the Entries NDFLØC and NDFNXT of the KEDAK routine NDF.

SUBRØUTINE LØØK2 (NEN, EA, ICØS, ICØSP, ISM, AR, SGNC)

CØMMØN STØFF, ISTRUK, ISPA, NØUT

Purpose: Reading of SGNC from KEDAK

Arguments:
- STØFF = nucleus in KEDAK notation
- NEN = number of discrete energies at which SGNC are given

(EA(I),I=1,NEN) = discrete energies for which SGNC shall be read (they have been read before with LØØK3)
ICØS = maximum number of SGNC cosine meshpoints
ISM = maximum number of discrete SGNC-energies
NØUT = printed-output unit

Results:
ICØSP = 1 if ICØS is too small
= o otherwise
(AR(I),I=1,ICØS) = SGNC cosine meshpoints from KEDAK
((SGNC(I,J),I=1,ICØS),J=1,NEN) = SGNC from KEDAK corresponding to the cosine mesh AR and the energy mesh EA

Remarks:
The cosine mesh must be the same for all energies.
LØØK2 calls the Entries NDFLØC and NDFNXT of the KEDAK routine NDF.

SUBRØUTINE LØØK3 (NE, EA, ISØ, NGR, ABN, ISM, ISMP, LST, NEGR, ISEL)

CØMMØN STØFF, ISTRUK, ISPA, NØUT

Purpose:
Reading from KEDAK the entire SGNC-energy-mesh for one nucleus

Arguments:
STØFF, ISM, NØUT see LØØK2
NGR, NEGR, ABN see MAKRØ

Results:
ISEL = pointer for additional output
ISMP = estimated increment of ISM if there are more than ISM angular distributions on KEDAK for the considered nucleus
NE = number of angular distributions on KEDAK for the nucleus in question
(EA(I),I=1,NE) = SGNC-energy mesh on KEDAK for the considered nucleus
(LST(I),I=1,NGR) where LST(I) = number of energies EA(N) with ABN(I+1)

$\leq$ EA(N) < ABN(I)

ISØ see MAKRØ

Remark: LØØK3 calls the Entry NDFLØC of the KEDAK routine NDF

SUBRØUTINE LECAL (MASSE, XMAT, ALFA, ISØT, LEG, NLE, NANF, NEND, NUEB, IL, IM, NEGR, ABN, ICØS, AR, ISN, E, SGNC, NST, NSTIS, ISM, ISD, NECU, ITA, NF, GR, FEKØE, FU, EW, A, H, V, W, F, FEKØ)

Purpose: Control of the calculation of the $w_1(E \to g)$ according to equations (7.8) and (7.1o)

Arguments:

MASSE = atomic mass number of the scattering nucleus

XMAT = atomic weight of the scattering nucleus in neutron mass units

ALFA = $((XMAT-1)/(XMAT+1))^2$

ISØT = anisotropy pointer (ISØT=1: the considered macro-group is within the energy region of anisotropic scattering in the c.m.-system, ISØT = o otherwise)

(LEG(I),I=1,6) = sequence of calculated moments

NLE = upper Legendre index (input)

NANF, MEND = indices of the first and the last group in the macro-group for which scattering matrices etc. shall be calculated

NUEB = scattering width

IL, IM = indices of the first and the last group for which scattering matrices etc. shall be calculated

NEGR = number of energy group boundaries

(ABN(I),I=1,NEGR) = energy group boundaries

ICØS = number of cosine meshpoints of the SGNC on KEDAK

(AR(I),I=1,ICØS) = cosine meshpoints of the SGNC on KEDAK

ISM = number of basic points plus discrete SGNC-energies in the macro-group to be calculated

(E(I),I=1,ISN) = basic points plus discrete SGNC-energies in the macro-group to be calculated (coarse mesh)

((SGNC(I,J),I=1,ICØS),J=1,ISN) = angular distributions in the laboratory system

(NST(I),I=1,6) = moment-dependent number of uniformly spaced cosine meshpoints for μ_o-integration when ISØT = 1

NSTIS = moment-independent number of uniformly spaced cosine meshpoints for μ_o-integration when ISØT = o

ISM = maximum number of basic points and discrete SGNC-energies per macro-group

ISD = ISM plus maximum number of discrete SGN-energies per macro-group

NECU = maximum scattering width

ITA = pointer for the calculation of Legendre integrals by means of LEGINT
(ITA = o: Legendre integrals are calculated,
ITA = 1: Legendre integrals have already been calculated)

NF = unit on which the $w_l(E \to g)$ are stored temporarily

Auxiliary arrays: GR(NEGR), FEKØE(NEGR), FU(ICØS), EW(ISM), A(ISD), H(ISD), V(ISD), W(ISD), F(ISD), FEKØ(ISM, NECU)

Results: $w_l(E \to g)$ on unit NF

SUBRØUTINE LEGPØL (NST, A, N, NSTIS)

CØMMØN /INTEG/ X, F, D

Purpose: Calculation of pointwise Legendre polynomials

Arguments:
- NST = number of uniformly spaced cosine meshpoints
- N = order up to which Legendre polynomials shall be calculated
- NSTIS = number of uniformly spaced cosine meshpoints if ISØT = o (here: maximum length of A)

Results:
- (A(I),I=1,NST) = uniformly spaced cosine meshpoints
- (X(I),I=1,NST) = uniformly spaced cosine meshpoints
- (F(L,I),I=1,NST),L=1,N+1) = Legendre polynomials pointwise
  F(L,I) = $P_{L-1}(A(I))$
- D = spacing of the A(I):
  D = A(I) - A(I-1), I = 2, NST

SUBRØUTINE LEGINT (N, NAK, XMAT, ITA)

CØMMØN /INTEG/ H, GRAL, D

Purpose: Calculation of Legendre integrals

$$B_n(\omega) = \frac{1}{2A} \int_{-1}^{\omega} d\mu_o \frac{\left(\mu_o + \sqrt{\mu_o^2 - 1 + A^2}\right)^2}{\sqrt{\mu_o^2 - 1 + A^2}} P_n(\mu_o)$$

$$n = 0, 1, \ldots, 5$$

Arguments:
- N = upper Legendre index (is ignored; the $B_n(w)$ are always determined for n = o, 1, 2, 3, 4, 5
- NAK = number of cosine meshpoints
- XMAT = atomic weight in neutron mass units

Results: (H(I),I=1,NAK) = uniformly spaced cosine mesh-points, H(1) = -1, H(NAK) = 1

D = spacing of the H(I)

(GRAL(L,I),L=1,6),I=1,NAK) where GRAL(L,I) $= 2 \cdot B_{L-1}(H(I))$

ITA = pointer (ITA = 1 after calculation)

Remarks: For A = 1, 1 < A ≤ 3o, A > 3o the above integral is treated numerically in different ways. For details see ref. 1.

FUNCTIØN G(N, X, Y)

$$G(N, X, Y) = \frac{X^N - Y^N}{X - Y}$$

is determined according to

$$\frac{X^N - Y^N}{X - Y} = D^{N-1} + \binom{N}{1} D^{N-2} Y + \binom{N}{2} D^{N-3} Y^2 + \ldots + \binom{N}{N-1} Y^{N-1}$$

where

$$D = X - Y$$

SUBRØUTINE LEGIST (L, NST, IA, IB, NEGR, GR, E)

CØMMØN /INTEG/ X, GRAL, D

Purpose: Calculation of partial Legendre coefficients when scattering is isotropic in the c.m.-system according to equ. (7.8)-multiplication with 2π is performed in LECAL:

$$E(I) = \frac{1}{4\pi} \int_{GR(I+1)}^{GR(I)} d\mu_o \frac{d\bar{\mu}_o}{d\mu_o} P_{L-1}(\mu_o)$$

using the previously in LEGINT determined integrals

$$GRAL(L,I) = 2 \int_{-1}^{X(I)} d\mu_o \frac{d\bar{\mu}_o}{d\mu_o} P_{L-1}(\mu_o)$$

Arguments:

L = Legendre degree plus 1

NST = number of uniformly spaced cosine mesh-points

(X(I),I=1,NST) = cosine mesh from LEGINT

D = spacing of the X(I)

((GRAL(L,I),L=1,6),I=1,NST) see above

NEGR = length of array E

IA, IB = boundary indices within which the E(I) shall be determined

(GR(I),I=IA,IB) = cosine integration boundaries

Results:

(E(I),I=IA,IB-1) = partial Legendre coefficients (see above)

E(NEGR) = total Legendre coefficient

$$= \sum_{I=IA}^{IB-1} E(I)$$

SUBRØUTINE LEGANS (L, NST, F, IA, IB, NEGR, GR, E, PØLY, A)

CØMMØN /INTEG/ X, PØL, D

Purpose:

Calculation of partial Legendre coefficients when scattering is anisotropic in the c.m.-system according to equ. (7.1o)-multiplication with 2π is performed in LECAL:

$$E(I) = \int_{GR(I+1)}^{GR(I)} d\mu_0 \, w(E,\mu_0) \, P_{L-1}(\mu_0)$$

Arguments:

L, NST, D, NEGR, IA, IB, GR see LEGIST

(X(I),I=1,NST) = cosine mesh from LEGPØL

(F(I),I=1,NST) = pointwise angular distribution corresponding with the X(I)

((PØL(L,I),L=1,6),I=1,NST) = Legendre polynomials pointwise from LEGPØL corresponding with the X(I)

Auxiliary arrays: PØLY(NST), A(NST)

Results: (E(I),I=IA,IB-1) = partial Legendre coefficients (s. above)

E(NEGR) = total Legendre coefficient

$$= \sum_{I=IA}^{IB-1} E(I)$$

SUBRØUTINE GRUPIN (MASSE, XMAT, ALFA, CØM, ISØT, PM, LEG, NLE, NANF, NEND, NUEB, IL, IM, NGR, NEGR, ABN, ISN, EH, K, H, F, M, G, EN, NTT, ET, ST, MAZ, KSPE, KSPEK, ESP, SPEK, NSPEK, LSPEK, ISM, ISD, NECU, ISCØ, ISEC, NF, E, EW, GR, WA, U, V, W, ISTT, RSP, ELSIG)

Purpose: Weighted energy integration according to (7.2)

Arguments: MASSE, XMAT, ALFA, ISØT, LEG, NLE, NANF, NEND, NUEB, IL, IM, NEGR, ABN, ISN, ISM, ISD, NECU, NF see LECAL

CØM = mean scattering cosine when scattering is isotropic in the c.m.-system = 2/(3·XMAT)

PM = fraction of MUEL in the corrected first moment

NGR = number of energy groups

(EH(I),I=1,ISN) = basic points plus discrete SGNC-energies in the macro-group to be calculated

K = number of SGN

(H(I),I=1,K) = discrete SGN-energies

(F(I),I=1,K) = SGN corresponding with the H(I)

M = number of MUEL

(G(I),I=1,M) = discrete MUEL-energies

(EN(I),I=1,M) = MUEL corresponding with the G(I)

NTT = micro-weighting spectrum control parameter (NTT = 1: no micro-weighting; NTT > 1: micro-weighting with NTT = number of energy points of the micro-weighting spectrum)

(ET(I),ST(I),I=1,NTT) = micro-weighting spectrum if NTT > 1

(MAZ(I),I=1,2) = control parameters for the weighting of higher moments (input)

KSPE = pointer for macro-weighting (KSPE = o: weighting with FUNCTIØN PHI if MAZ(1) = o, with FUNCTIØN PHI and FUNCTIØN PHIL if MAZ(1) = 1; KSPE = 1: weighting with point-spectrum in ESP and SPEK according to MAZ(1)

KSPEK = number of discrete energies of the macro-weighting spectrum if KSPE = 1, = o otherwise

NSPEK = Max (1, KSPEK)

LSPEK = number of values of the macro-weighting spectrum if KSPE = 1 = 1 otherwise

(ESP(I),I=1,KSPEK) = macro-spectrum discrete energies if KSPE = 1; no meaning otherwise

(SPEK(I),I=1,LSPEK) = macro-spectrum values if KSPE = 1; no meaning otherwise

ISCØ = dimension of WA (see below and FLUMMI)

ISEC = dimension of U (see below and FLUMMI)

Auxiliary arrays: E(ISD), EW(ISM), GR(NEGR), WA(ISCØ), U(ISEC), V(ISD), W(ISD)

Results: ISTT = number of energy meshpoints in the fine-mesh consisting of the basic points (from PUNK), the discrete SGNC-energies, the discrete SGN- and MUEL-energies

(RSP(I),I=1,NGR) = energy group integrals of
the zeroth order weighting spectrum
(ELSIG(L,I,NN),NN=IL,IM),I=1,NUEB),L=1,NLE+1)
where with II = NN + I-1

$$ELSIG(L,I,NN) = \sigma_{L-1}^{NN \to II}$$

$$= \frac{\int_{NN} dE\, \sigma(E)\, w_{L-1}(E \to II)\, \Phi_{L-1}(E)}{\int_{NN} dE\, \Phi_{L-1}(E)}$$

SUBRØUTINE IPØLIN (M, A, B, N, X, Y, HR)

Purpose: Linear interpolation

Arguments:
M = number of given points
(A(I),B(I),I=1,M) = given points
N = number of given new abszissae
(X(I),I=1,N) = given new abszissae
where X(1) = A(1), X(N) = A(M)

Auxiliary array: HR(M)

Results: (Y(I),I=1,N) = new ordinates corresponding
with the X(I)

SUBRØUTINE TRAPEZ (M, E, F, G, W, H, L)

Purpose: Trapezoidal integration according to

$$W = \frac{1}{2} \sum_{I=2}^{M} (F(I)+F(I-1))\cdot E(I-1) \quad \text{if } L = o$$

$$W = \frac{1}{2} \sum_{I=2}^{M} (F(I)\cdot G(I)+F(I-1)\cdot G(I-1))\cdot E(I-1) \quad \text{if } L = 1$$

(see chapter 7.2)

Arguments: M = number of meshpoints
(E(I),I=1,M-1) = weighted intervall lengths
(F(I),I=1,M) = function to be integrated
(G(I),I=1,M) = weighting function
L = pointer for weighting (L = o: constant weighting function; L =1: weighting function not constant in G)

Auxiliary array: H(M)

Results: W(see above)

FUNCTIØN PHI(E) = 1/E
FUNCTIØN PHIL(L,E) = $1/E^L$

SUBRØUTINE MUKØN (ELSIG, ELTØT, NLE, NECU, NUEB, IL, IM, NGR)

Purpose: Determination of σ^{NN}, $S_L^{NN\to II}$ and $\bar{\mu}^{NN}$ from $\sigma_L^{NN\to II}$ according to (7.1), (7.2) and (7.3):

$$\sigma^{NN} = \sum_{II \geq NN} \sigma_o^{NN\to II},$$

$$S_L^{NN\to II} = \sigma_L^{NN\to II}/\sigma^{NN}, \quad L = o,1,\ldots,NLE,$$

$$\bar{\mu}^{NN} = \sum_{II \geq NN} S_1^{NN\to II}$$

Arguments: NLE = Legendre degree up to which scattering matrices are calculated
NUEB = scattering width
IL, IM = first and last calculated energy group
(((ELSIG(L,I,NN),NN=IL,IM),I=1,NUEB),L=1,NLE+1) where (see GRUPIN) ELSIG(L,I,NN) = $\sigma_{L-1}^{NN\to NN+I-1}$
NGR = number of energy groups (for dimensioning)
NECU = maximum scattering width (for dimensioning)

Results: (((ELSIG(L,I,NN),NN=IL,IM),I=1,NUEB),L=1,NLE+1)

where

ELSIG(L,I,NN) = $S_{L-1}^{NN\to NN+I-1}$ (see above)

((ELTØT(I,NN),NN=IL,IM),I=1,2) where

ELTØT(1,NN) = σ^{NN}

ELTØT(2,NN) = $\bar{\mu}^{NN}$ (see above)

Remark: Comparisons with cases which can be treated analytically (see ref. 1: FLUMMI tests) show that the matrixelements $S_{L-1}^{NN\to NN+I-1}$ are calculated here with a maximum absolute error

$$\Delta S \approx 4 \cdot 10^{-4}$$

Thus quantities smaller than 10^{-5} in absolut value are ignored and set equal to zero.

SUBRØUTINE PRINT (ELSIG, ELTØT, NLA, NLE, NECU, NUEB, ISEL, NGR, KSPEK, MAZ, NTK, KIM)

CØMMØN STØFF, ISTRUK, ISPA, NØUT, KPR, NEND, NANF

Purpose: Printing and reserving of final results

Arguments:

ELSIG, ELTØT see MUKØN results

NLE, NECU, NUEB, NGR see MUKØN

NLA = first Legendre moment to be calculated (NLA = o always)

NANF, NEND = indices of the first and last group for which scattering matrices have been calculated

STØFF = nucleus for which scattering matrices have been calculated

MAZ, NTK, KIM see FLUMMI

KSPEK corresponds to KSPE in GRUPIN

ISEL = pointer for additional output

NØUT = printed-output unit

KPR = unit on which all MIGRØS-results are stored

8. Calculation of the fine interval elastic scattering transfer matrices up to P_5 approximation and other quantities required for the REMO-correction. Module 9.

8.1 Basic formulae and notations

a) The fine interval system

The I-th group of the basic broad group system is divided into NFG(I) fine-groups, equidistant in lethargy. Any of these fine groups is divided into NFI(I) fine intervals, equidistant in lethargy. The fine interval width is denoted by ΔE_ℓ.

b) The fine-interval averaged cross-sections are defined by:

$$\langle \sigma \rangle = \frac{\int_{\Delta E} dE\, \sigma(E) F(E)}{\int_{\Delta E} dE\, F(E)} \tag{8.1}$$

The REMO correction procedure requires the total σ_t and the elastic scattering cross-sections σ_e and the averaged cosine which is defined by

$$\langle \mu_e \rangle = \frac{\int_{\Delta E} dE\, \mu_e(E)\, \sigma_e(E)\, F(E)}{\int_{\Delta E} dE\, \sigma_e(E)\, F(E)} \tag{8.2}$$

c) The elastic scattering transfer probability matrices are defined by

$$\langle {}^{\ell}P(E\to h) \rangle = \frac{\int_{\Delta E} dE\, \sigma_e(E)\, \pi_\ell(E\to h)\, F(E)}{\sum_h \int_{\Delta E} dE\, \sigma_e(E)\, \pi_o(E\to h)\, F(E)} \tag{8.3}$$

where

$$\pi_l(E \to h) = \frac{(A+1)^2}{4A} \cdot \frac{1}{E} \cdot \int_{\max(\alpha E,\, E_{h+1})}^{E_h} dE'\, \varphi(\mu_c)\, P_l(t) \qquad (8.4)$$

where $P_l(t)$ are the Legendre polynomials.

A is the mass of the scatterer, and

$$\alpha = \left(\frac{A-1}{A+1}\right)^2 .$$

The scattering angle in the center-of-mass system

$$\mu_c = 1 - \frac{(A+1)^2}{2A} \cdot \left(1 - \frac{E'}{E}\right),$$

and that in the labor system,

$$t = \frac{A+1}{2}\sqrt{\frac{E'}{E}} - \frac{A-1}{2}\sqrt{\frac{E}{E'}} .$$

$\varphi(\mu_c)$ = the angular distribution of the elastic scattering in the center of mass system. It should be normalized i.e.

$$\frac{1}{2}\int_{-1}^{+1} d\mu_c\, \varphi(\mu_c) = 1$$

($\varphi(\mu_c) \equiv 1$, for isotropic case)

It is practical to transform the integral (8.4) into

$$\pi_l(E \to h) = \frac{1}{2}\int_{\mu_{h+1}}^{\mu_h} d\mu_c\, \varphi(\mu_c)\, P_l(t(\mu_c)), \qquad (8.5)$$

where

$$t(\mu_c)=0.5\sqrt{1-(1-\mu_c)\frac{2A}{(A+1)^2}}\left\{A+1-\frac{A-1}{1-(1-\mu_c)\frac{2A}{(A+1)^2}}\right\} \quad (8.6)$$

Let the energy E fall into the group g. The neutron transfer may occur into the groups g, g+1, ... g+k, where $E_k > \alpha E > E_{k+1}$. As there is an unambigous relation between the scattering angle μ_c and energy loss, a division of the angle interval $-1 \leq \mu_c \leq 1$ corresponds to the acceptor groups, i.e.

$$-1 \equiv \mu_{k+1} < \mu_k \ldots < \mu_1 < 1$$

Thus the neutrons scattered with angle $1 \geq \mu > \mu_1$ remain in the group g, and those with the angle $\mu_j \geq \mu \geq \mu_{j+1}$ will fall into the group g+j.

According to our experience, the calculation and the physical interpretation are the simplest when the integration is performed over the center-of-mass scattering angle.

8.2 Method of calculation

According to the formulae (8.1), (8.2), (8.3) and (8.5) the main task is to perform numerical integrations.

For (8.1) and (8.2) a simple trapezoidal rule is used with the mesh points given by the nuclear data file KEDAK. At the end of the integration interval the cross-sections are interpolated.

For the integral (8.3) and (8.5) the Romberg integration method (see app.III) is used. The alternating sign of the Legendre poly-

nomial P_1 and the "ill-behaviour" of the $f(\mu_c)$ at some energy values require special consideration which are described in app. IV.

Before the integral (8.3) is performed, the fine interval ΔE is to be divided into subintervals with the following mesh-points:

i All energy points for which elastic scattering cross-section are given in the nuclear data file should be a mesh point.

ii If an energy value E_k/α falls into the fine interval, this also should be a mesh point. The Romberg integration procedure is performed for each subinterval.

8.3 The removal of the inconsistency between the average cosine calculated from the angular distribution and the average cosine available on KEDAK.

There are two types of the above inconsistency:

a) The angular distribution of the scattered neutrons for the energy range in question are not given, but the retrieved average cosine $\overline{\mu_{ret}}$ is different from 2/3A. In this case a linear anisotropy is assumed i.e. the following center of mass angular distribution is used

$$f(\mu_c) = 1 + \left(\overline{\mu_{ret}} - \frac{2}{3A}\right) \cdot \frac{3}{1 - \frac{3}{5A^2}} \cdot \mu_c \qquad (8.7)$$

b) The nuclear data file gives center of mass angular distributions for the energy range in question, but the calculated average cosine differs from the retrieved one. This difference can be attributed to the uncertainties in the evaluated angular distribution as well as to the uncertainties in their interpolation. Consequently there exist only ad hoc methods for the removal of this inconsistency. We have applied the following simple treatment.

Let the Legendre expansion of the scattering probability in the labor system be.

$$W_s(\mu) = \sum_{l=0}^{\infty} \frac{2l+1}{2} \cdot b_{s,l} \cdot P_l(\mu), \quad b_{s,0} = 1, \; b_{s,1} = \bar{\mu}_{ang} \tag{8.8}$$

$\bar{\mu}_{ang}$ is the labor average cosine calculated from the given mass angular distribution. The above scattering probability is corrected with the retrieved average cosine i.e.

$$\overline{W_s}(\mu) = W_s(\mu) + \frac{3}{2}\left(\bar{\mu}_{ret} - \bar{\mu}_{ang}\right) P_1(\mu) \tag{8.8'}$$

and the correction to a transfer matrix element is

$$\Delta \pi_l(E \to h) = \frac{3}{2}\left(\bar{\mu}_{ret} - \bar{\mu}_{ang}\right) \int_{\mu_{h+1}}^{\mu_h} d\mu \, P_l(\mu) P_1(\mu) \tag{8.9}$$

where (μ_h, μ_{h+1}) is the angle interval in the labor atory system belonging to the scattering from E into the group H.

8.4 Strategy of the extrapolation

It is often the case that for a cross-section or angular distribution the energy interval given in the KEDAK file does not cover the energy range of the group system. In this case an extrapolation is necessary. As the difference between the last energy point and the end of the group energy range is generally not too large, additional energy point coinciding with the end of the group

is taken, with the cross-section value (or angular distribution) equal with the next one. (i.e. the extrapolation is horizontal)

8.5 The description of the program REMO and of the related subroutines

The subroutine REMO is called by the statement

```
CALL REMO (NG, ENG, NSP, F, E, ERR, NLA, NLE, NGRE, NFG, NFI, NJM, NUJM,
          ISEL, IWORK, WORK, L)
```

NG	The number of energy boundaries
ENG(I),I=1, NG	The energy group boundaries /eV/
NSP	The number of energy points for the neutron spectrum
F(I),I=1, NSP	The neutron spectrum
E(I),I=1, NSP	Energy points for the neutron spectrum
ERR	The error limit for the Romberg integration
NLA, NLE	The first and the last moment to be calculated
NGRE	The number of groups to be calculated
NFG(I),I=1, NGRE	The number of finegroups
NFI(I),I=1, NGRE	The number of fine-intervals per fine-group.
NJM	The maximum number of mesh points for angle integration is 2**NJM+1
NUJM	The maximum number of mesh points for energy integration is 2**NUJM+1
ISEL	= 1: the formula (8.3) will be computed 0: the formula to be obtained from (8.3), when $\sigma_s(E) = 1$, will be computed.
IWORK(I),WORK(I),I=1,L	Work-field
L	The length of the work-field.

In the subroutine system related to REMO the dynamical programming method is used, i.e. any dimensioned variable, the dimension of which depends on the task option is dimensioned with variable length. All of such variables are placed in the work field (WORK and IWORK) respectively) to be passed by the main control program. This field is generally transfered from one subroutine to the other and it contains a great deal of information to be passed. The first 34 words of WORK contain mainly the control information. (see Table VIII)

The function of the main subroutine REMO is the following:
To settle the control information contained in the Table VIII, and to determine the length of WORK.
To call the subroutine KEDLEC (see below) in order to retrieve the angular distributions in the energy region to be calculated.
REMO calls the subroutine

REMP (ENG, NFG, NFI, F, E, WORK, IWORK, IS) +

IS is the lowest energy group for which angular distributions are given.

The function of REMP: to organize the calculation by group.
It calls the following subroutines: KEDDAT, SINT, ISOFAL, ZWIN, NORM

The subroutine underlying the retrieval of KEDAK data has four entries.

α) KEDDAT (NAMIZ, NAMTYP, NW, NW1, FNW, NDAT, FA, FF, EP, EM, *, *, *)

NAMIZ /8-bytes/ name of the material
NAMTYP /8-bytes/ data type name

NW	if there is a further name the sequential number of the required namecombination, otherwise without meaning.
NW1	if there is a further name then the number of retrieved name combination, otherwise without meaning.
FNW	if there is a further name then its value, otherwise without meaning.
NDAT	the number of retrieved data pairs.
FA(I),I=L,NDAT	argument values.
FF(I),I=1,NDAT	function values.
EP,EM	upper and lower energy boundary /eV/, for which the cross-section values are to be retrieved.

If the material and the type are not found then follow RETURN1 and RETURN2 respectively.

+ If the parameters of the subroutines are not described by the same symbols as in the program lists, symbols described before or in the input description are used.

b) DATNUM (NAMIZ, NAMTYP, NDAT, NW, EP, EM, *, *, *)

This entry is used when only NDAT is to be determined

c) KEDLEC (NAMIZ, NAMTYP, NW1, EA, IAE, EPW, EMW, FA, FF, FAW, FFW, EP, EM, *, *, *)

This entry is used to retrieve angular distributions in the energy interval /EPW, EMW/ /eV/
In this case EP, EM are not energy but cosine of the scattering angle.
EA(I),I=1,NW1 the number of energy points.
IEA(I),I=1,NW1 the number of angle points per angular distribution.
FAW(I),I=1,NW1xNDAT the angle points of angular distributions.
FFW(I),I=1,NW1xNDAT the angular distributions (in one field, one by one)

d) NIVNUM (NAMIZ, NAMTYP, NW1, EPW, EMW, EFR, *, *, *)

EFR is the energy for the first angular distribution. This entry is used for the determination of NW1, and EFR.

SUBROUTINE SINT (ENG(I), NFG(I), NFI(I), F, E, WORK, N, M)

SINT calculates the group averaged total and elastic scattering cross sections and average cosine in the group I.
M = IWORK(7)
For N = IWORK(5) SINT calculates $\langle\sigma_t\rangle$
For N = -IWORK(5) SINT calculates $\langle\sigma_s\rangle$ and $\langle\mu_s\rangle$
Called by REMP.

SUBROUTINE NORM (J2, J1, SGNC, WORK)

NORM normalizes the angular distribution from the J2-th up to the J1-th one.
Called by REMP.

SUBROUTINE ISOFAL (ENG(I), NFG(I), NFI(I), F, E, WORK)

ISOFAL divides the group I into fine intervals and organises the calculation of elastic transfer probabilities for the group I.
Called by REMP.

SUBROUTINE WAHRS (EP, EM, IMAX, WORK(N), ENG(I), NM1, NUJM, F, E, TE, WORK, PER)

N = IWORK (22)

NM1 = NLE+1

EP, EM are the higher and the lower boundary of the energy interval to be calculated [eV].

WAHRS divides the interval [EP, EM] further according to the principles given in 8.2.

Called by ISOFAL

SUBROUTINE LMI (EP, EM, E_1, E2, SG1, SG2, AMU1, AMU2, IMAX1, ENG(I), TE, NM1, NUJ, NUJM, F, E, WORK, PER (IMAX+2), IMAX,PL)

SG1, SG2, AMU1, AMU2, E1, E2 elastic scattering cross sections, retrieved average cosine and the related energy points [eV]

IMAX1 The maximum group change by a scattering in the interval [EP, EM]

Called by WAHRS.

FUNCTION ANINT (BU, BL, K, SG, XL, AZ, ICOS, WORK, T, NJM)

ANINT calculates the integral (8.5) and the correspondence of notations is the following

K = n

BU = μ_k

BL = μ_{k+1}

XL → μ_c

SG → $\int(\mu_c)$

ICOS number of mesh points

AZ = $(\overline{\mu}_{ret} - \frac{2}{3A})$

Called by NORM, LMI.

SUBROUTINE AMESH(BU, BL, Z, L2, NX, K)

AMESH prepares the division of angle interval [BU, BL] according to the roots of Legendre polynomial of order K.(see appendix IV)

Z L2,...Z NX-1 The roots of the K-th Legendre polynomials in the interval BU, BL

Called by ANINT.

SUBROUTINE HIDR (BU, BL, K, A, *)

In the case of hydrogen the integral (8.5) can analytically be calculated.
This is done by HIDR.
A = result of the calculation
Called by ANINT.

FUNCTION WINK (XL, SG, KJ, ICOS, AZ, XA)

WINK determines $\mathcal{G}'(\mu)\sigma_s$ by means of linear interpolation from the point-wise angular distribution /XA → μ/
Called by ANINT.

FUNCTION FXINT (EP, EM, SGN, ES, F, E, NSP, NDAT)

FXINT calculates the integral $\int_{EM}^{EP} dE\ \sigma(F)\ F(E)$ by means of trapezoidal rule.

SGN(I) cross-section
ES(I) energy mesh-points [eV]
Called by SINT.

FUNCTION BCM (EI, EO, WORK)

BCM gives the cosine of scattering angle in the center of mass system.
EI the energy of neutrons before scattering.
EO the energy of neutron after scattering.
Called by LMI.

FUNCTION ICSOP (E, ENG)

ICSOP gives the group number for energy E.
Called by REMO, LMI, FXINT, MASSIN.

FUNCTION (ANG, XA, A, XM)

ANG gives the cosine of scattering angle in labor system.
XA cosine of scattering angle in center of mass system.
A atomic mass.
XM= $(A+1)^2/2A$.
Called by ANINT.

FUNCTION PTL (N, X)

PTL gives the value $P_N(X)$
Called by ANINT.

SUBROUTINE ZWIN (K, EP, EM, ES, J2, J1)

ES(I),I=1,k energy mesh-points in [eV].
ZWIN gives the values J2, J1. These have the meaning: ES(J2),..
ES(J1) cover the energy interval EP, EM.
Called by REMP, LMI, FXINT, WAHRS.

SUBROUTINE MASSIN (WORK, ENG)

MASSIN calculates the mass dependent quantities and places them in the corresponding words of WORK /see Table 1./
Called by REMO.

SUBROUTINE INTEN (E, SG, SGNC, EA, ICOS)

INTEN interpolates the angular distribution in energy.
E is the energy for which the angular distribution is to be interpolated.
Called by LMI.

SUBROUTINE SMORN (PI, N, M1, IMAX, WORK)

SMORN normalizes the calculated elastic transfer matrixes in order to get the transfer probabilities (8.3.)
PI(NM1, IMAX) the elastic transfer matrix.
Called by ISOFAL.

SUBROUTINE SEARCH (NFG, NFI, WORK, IWORK, I)

SEARCH organizes the output of $\langle\sigma_t\rangle$, $\langle\sigma_s\rangle$, $\langle\mu_s\rangle$ for the group.
Called by REMO.

SUBROUTINE SUCHM (NFG, NFI, IWORK, WORK, MOM, I, ENG)

SUCHM organizes the output of $\langle\sigma\ (E_i \rightarrow h)\rangle$ for the group I.
Called by REMO

FUNCTION IWO (N, IWORK)

IWO gives the value IWORK(N).

SUBROUTINE IWIN (L, N, IWORK)

IWIN performs the statement IWORK(L) = N.
In the future program is intended to generalize to the inelastic case. The subroutines INRE, IMPE, EGRENZ serve for this purpose. For elastic scattering calculation these have no any influence.

SUBROUTINE AKOR (BU, BL, L, A)

It calculates the integral in (8.9) for average cosine correction. BU and BL are the c. of mass scattering angles corresponding to μ_2 and μ_1 respectively. L is the order of the moment, A is the mass of the scatterer.
Called by LMI.

9. The calculation of average group cross sections for infinite dilution and of energy resonance self shielding factors from energy point wise data in the resonance region. Module 3.

9.1 The flux weighted energy resonance self shielding factors are calculated for capture, fission, elastic scattering

$$ {}^{k}f_{x,g}(\sigma_o) = \frac{{}^{k}\tilde{\sigma}_{x,g}(\sigma_o)}{{}^{k}\tilde{\sigma}_{x,g}(\sigma_o \to \infty)} \qquad (9.1) $$

k = isotope
x = neutron reaction (n,x)
(n,e)= elastic scattering, (n,f)=fission,
(n,c)= total absorption - fission.
g = energy group
σ_o = back ground cross section in barns.

$$ {}^{k}\tilde{\sigma}_{x,g}(\sigma_o) = \frac{\left\langle \frac{{}^{k}\sigma_x(E)\cdot F(E)}{{}^{k}\sigma_t(E)+\sigma_o} \right\rangle}{\left\langle \frac{F(E)}{{}^{k}\sigma_t(E)+\sigma_o} \right\rangle}^{*} \qquad (9.2) $$

is the microscopic effective cross section.
F(E) collision density
$\sigma_t(E)$ is the microscopic total cross section.
Besides that, a flux weighted self shielding factor of the following type is calculated:

$$ {}^{*}\left\langle y(E)\right\rangle = \frac{1}{\Delta E_g}\int_{\Delta E_g} y(E)\,dE $$

$$ {}_{1,0}f_{e,g}(\sigma_0) = \frac{\left\{ {}^{k}\sigma_e \cdot {}^{k}\bar{\mu}_e \right\}_g (\sigma_0)}{\left\{ {}^{k}\sigma_e \cdot {}^{k}\bar{\mu}_e \right\}_g (\sigma_0 \to \infty)} \tag{9.3} $$

with

$$ \left\{ {}^{k}\sigma_e \cdot {}^{k}\bar{\mu}_e \right\}_g (\sigma_0) = \frac{\left\langle \frac{{}^{k}\sigma_e(E) \cdot {}^{k}\bar{\mu}_e(E) \cdot F(E)}{{}^{k}\sigma_t(E) + \sigma_0} \right\rangle}{\left\langle \frac{F(E)}{{}^{k}\sigma_t(E) + \sigma_0} \right\rangle} \tag{9.4} $$

$\bar{\mu}_e(E)$ = average cosine for elastic scattering

The current weighted resonance self shielding factors are calculated for elastic scattering and for the total neutron cross section.

$$ {}^{k}_{1}f_{t,g}(\sigma_0) = \frac{{}^{k}_{1}\sigma_{t,g}(\sigma_0)}{{}^{k}_{1}\sigma_{t,g}(\sigma_0 \to \infty)} \tag{9.5} $$

$$ {}^{k}_{1}f_{e,g}(\sigma_0) = \frac{{}_{1}\left\{ {}^{k}\sigma_e \cdot {}^{k}\bar{\mu}_e \right\}_g (\sigma_0)}{{}_{1}\left\{ {}^{k}\sigma_e \cdot {}^{k}\bar{\mu}_e \right\}_g (\sigma_0 \to \infty)} \tag{9.6} $$

with

$$ {}^{k}_{1}\tilde{\sigma}_{t,g}(\sigma_o) = \frac{\left\langle \frac{{}^{k}\tilde{\sigma}_t(E)\cdot F(E)}{\{{}^{k}\tilde{\sigma}_t(E)+\sigma_o\}^2} \right\rangle}{\left\langle \frac{F(E)}{\{{}^{k}\tilde{\sigma}_t(E)+\sigma_o\}^2} \right\rangle} \qquad (9.7) $$

$$ \left\{ {}^{k}_{1}\tilde{\sigma}_e \cdot {}^{k}\bar{\mu}_e \right\}_g (\sigma_o) = \frac{\left\langle \frac{{}^{k}\tilde{\sigma}_e(E)\,{}^{k}\bar{\mu}_e(E)\,F(E)}{\{{}^{k}\tilde{\sigma}_t(E)+\sigma_o\}^2} \right\rangle}{\left\langle \frac{F(E)}{\{{}^{k}\tilde{\sigma}_t(E)+\sigma_o\}^2} \right\rangle} \quad , \qquad (9.8) $$

The average group cross sections for infinite dilution are defined:

$$ {}^{k}\tilde{\sigma}^{\infty}_{x,g} = \lim_{\sigma_o\to\infty} {}^{k}\tilde{\sigma}_{x,g}(\sigma_o) = \lim_{\sigma_o\to\infty} {}^{k}_{1}\tilde{\sigma}_{x,g}(\sigma_o) \qquad (9.9) $$

or

$$ {}^{k}\tilde{\sigma}^{\infty}_{x,g} = \frac{\langle {}^{k}\tilde{\sigma}_x(E)\cdot F(E)\rangle}{\langle F(E)\rangle} \qquad (9.10) $$

for capture, fission, elastic scattering and the total neutron reaction, and

$$\left\{ {}^{k}\tilde{\sigma}_e \, {}^{k}\bar{\mu}_e \right\}_g^{\infty} = \frac{\left\langle {}^{k}\tilde{\sigma}_e(E) \cdot {}^{k}\bar{\mu}_e(E) \cdot F(E) \right\rangle}{\left\langle F(E) \right\rangle} \qquad (9.11)$$

F(E) is a slowly varying weighting-function, normaly a collision density.

9.2 The microscopic cross sections are taken from energy point wise data on the KEDAK-library. The integrations are done by a trapezoidal rule. As integration points the energy points of the KEDAK-tables for $\sigma_t(E)$ and the group boundaries are used. In the averages (9.8) and (9.11) the energy points of the tables for $\sigma_e(E)$ and $\bar{\mu}_e(E)$ are used. If they are tabulated at different energies, they are linearly interpolated.
The weighting function is either interpolated from tables or calculated by a function.

9.3 The calculations are performed in the subroutine

FSTRUK (MI, SIGO, NE, ENG, NFE, REFE, EFE, XINTE, ZA, XN, SE, XII,
ZB, XI, MDIM, MDIMP, EMU, XMU, NER, NERP, SN, EN)

The following parameters must be defined:

MI	: number of σ_o-values.
SIGO	: one-dimensional field containing the σ_o-values [barn].
NE	: number of group boundaries.
ENG	: one-dimensional field containing the group boundaries [eV].
NFE	: number of energy points of the weighting spectrum.
REFE	: one-dimensional field containing the energy points of the weighting spectrum [eV].

EFE : one-dimensional field containing the weighting function at the energy points of field REFE.

MDIM : length of working fields, should be larger than the number of $\bar{\mu}_e$-values on KEDAK within one energy group.

NER : length of working fields, should be larger than the maximum number of values for σ_a, σ_e, σ_f on KEDAK within one energy group.

Working fields:

XINTE (NE,4), ZA (MI, NE, 5), XN (NI, NE, 4), SE (MI, NE, 6), XII (NE), ZB (MI, NE), XI (NE), EMU (MDIM), XMU (MDIM), SN (NER, 3), EN (NER, 3).

The following parameters are calculated in the subroutine:

MDIMP : o, if MDIM is large enough .
n, number, by which MDIM should be increased.

NERP : o, if NER is large enough .
n, number, by which NER should be increased.

1o. The calculation of group constants in the thermal group. Module 1o.

1o.1 There is assumed, that the thermal energy range is covered by one energy group. For the cross sections except the elastic scattering cross section a 1/v-law, and for the weighting function a Maxwell - distribution is assumed. So the thermal group cross sections are defined as

$$ {}^{k}\bar{\sigma}_{x,th} = \frac{\sqrt{\pi}}{2} \cdot {}^{k}\sigma_{x}\,(0{,}0253\ eV) \qquad (1o.1.) $$

k = isotope
x = neutron reaction (n,x) except (n,n) process
th = thermal

The thermal group cross sections are calculated by formula (1o.1.) for all types x of neutron reactions. Furthermore the following group constants are calculated :

- the average elastic scattering cross section

$$ {}^{k}\bar{\sigma}_{n,th} = {}^{k}\sigma_{n}\,(0{,}0253\ eV) \qquad (1o.2.) $$

- the average cosine of the elastic scattering

$$ {}^{k}\bar{\mu}_{e,th} = {}^{k}\mu_{e}\,(0{,}0253\ eV) \qquad (1o.3.) $$

- the average number of secondary neutrons per fission

$$ {}^{k}\bar{\nu}_{th} = {}^{k}\nu\,(0{,}0253\ eV) \qquad (1o.4.) $$

- the average α - value

$$ {}^{k}\bar{\alpha}_{th} = \frac{{}^{k}\sigma_{\gamma,th}}{{}^{k}\sigma_{f,th}} \qquad (1o.5.) $$

γ = radiative capture
f = fission

- the average η - value

$$\overline{{}^{k}\eta_{th}} = \frac{{}^{k}\nu_{th}}{1 + {}^{k}\alpha_{th}} \qquad (1o.6.)$$

1o.2. The following subroutine is necessary :

THERM (NE, NTY, TYP)

The following parameters are defined by the control program.

NE : number of energy group limits.

NTY : number of cross section types.

TYP (NTY) : one-dimensional field containing the cross section types.

11. The calculation of the average 1/v values. Module8 .

11.1 The average 1/v values are defined as

$$\left(\frac{1}{v}\right)_g = \frac{\int_{(g)} \frac{1}{v} \cdot F(E)\, dE}{\int_{(g)} F(E) dE} \qquad (11.1)$$

11.2 The numerical integration is performed by the following formula:

$$\left(\frac{1}{v}\right)_g = C \cdot \frac{\sum_{i=1}^{n} \left\{ \frac{F_i}{\sqrt{E_i}} + \frac{F_{i+1}}{\sqrt{E_{i+1}}} \right\} \cdot \left\{ E_{i+1} - E_i \right\}}{\sum_{i=1}^{n} \left\{ F_i + F_{i+1} \right\} \cdot \left\{ E_{i+1} - E_i \right\}} \qquad (11.2)$$

i : index for the integration points
E_i : energy in [eV]
F_i : weighting function
n : number of integration points in group g.
c : constant = $7{,}229286 \cdot 10^{-7}$

If the weighting function is given pointwise, as integration points the energy points of the weighting function are used. Therefore the user must take care of the number of energy points.
If the weighting function is given in an analytic form, ten integration points per groups, equidistant in energy, are used.

In the thermal group the 1/v value at o,o253 is taken.

11.3 The following subroutine is used:

EDV (MM,A, NEF, XS, G, E, V, Y, NES, ES, F)

The following parameters must be defined:

MM : number of group boundaries
A(MM) : group boundaries in [eV].
NEF : number of energy points of the weighting function.
XS(NEF): energy points of the weighting function in [eV]
G(NEF) : weighting function at the energy points XS (NEF)
NES : max (1o x number of groups boundaries, number of energy points of the weighting function)

E (MM), V(MM), Y(MM), ES(NES), F(NES)
one-dimensional working fields.

12. The calculation of the fission spectrum. Module 7.

12.1 For the calculation of fission spectra the Watt formula is used.

$$\chi(E) = \frac{\exp\left\{-\frac{E_f}{T}\right\}}{\sqrt{\pi \cdot E_f \cdot T}} \cdot \exp\left\{-\frac{E}{T}\right\} \cdot \sinh\left\{\frac{2}{T}\sqrt{E \cdot E_f}\right\} \qquad (12.1)$$

E energy in MeV.

E_f fragment kinetic energy per nucleon in MeV.

T Watt fragment nuclear "temperature" in MeV.

The fission spectrum in energy group g is defined as

$$\chi_g = \int_{(g)} \chi(E)\, dE \qquad (12.2)$$

E_g upper group limit in MeV.

E_{g+1} lower group limit in MeV.

Using formula (12.1) one gets

$$\chi_g = \frac{1}{2\sqrt{\pi}} \sqrt{\frac{T}{E_f}} \left\{ \exp(-x_{g+1}^2) - \exp(-x_g^2) - \exp(-y_{g+1}^2) + \exp(-y_g^2) \right\} - \frac{1}{2} \left\{ \operatorname{erf}(x_{g+1}) - \operatorname{erf}(x_g) + \operatorname{erf}(y_{g+1}) - \operatorname{erf}(y_g) \right\} \qquad (12.3)$$

$$x_g = \sqrt{\frac{E_g}{T}} - \sqrt{\frac{E_f}{T}} \; ; \quad x_{g+1} = \sqrt{\frac{E_{g+1}}{T}} - \sqrt{\frac{E_f}{T}}$$

$$y_g = \sqrt{\frac{E_g}{T}} + \sqrt{\frac{E_f}{T}} \; ; \quad y_{g+1} = \sqrt{\frac{E_{g+1}}{T}} + \sqrt{\frac{E_f}{T}}$$

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

12.2 The following subroutine is necessary:

SUBROUTINE SPALT (NE, ENG, X)

The following parameters are defined by the control program.

NE number of energy group limits.

ENG(NE) one-dimensional field containing the energy group limits in[e V].

The following parameter is defined by the subroutine SPALT.

X(NE) one-dimensional field containing the fission spectrum.

Appendix I

A modified version of the formalism of Froelich /1/, /2/, for the calculation of energy resonance self shielding factors in the range of "statistical resonances".*

To take into account overlapping of resonances of the same series, Froelich makes the following assumption /2/, (formula 2.41a):

$$ {}^{s}\tilde{\sigma}_{p,eff} + {}^{s}_{r}\tilde{\sigma}_{oc} \cdot {}^{s}_{r}\psi \gg \sum_{r' \neq r} {}^{s}_{r'}\tilde{\sigma}_{oc} \cdot {}^{s}_{r'}\psi \qquad (1) $$

This condition is not fulfilled in the case of strong overlapping, if the resonances are higher than the background cross section ${}^{s}\sigma_{p.eff}$. Therefore a weaker condition will be used, namely

$$ {}^{s}\tilde{\sigma}_{p,eff} + \langle {}^{s}\tilde{\sigma}_{c} \rangle + {}^{s}_{r}\tilde{\sigma}_{oc} \cdot {}^{s}_{r}\psi \gg \left| \sum_{r' \neq r} {}^{s}_{r'}\tilde{\sigma}_{oc} \cdot {}^{s}_{r'}\psi - \langle {}^{s}\tilde{\sigma}_{c} \rangle \right| \qquad (2) $$

Expression 2.40 in /2/ can be modified to

$$ \sum_{r} \left\langle \frac{{}^{s}_{r}\tilde{\sigma}_{ox} \cdot {}^{s}_{r}\psi}{\left[{}^{s}\tilde{\sigma}_{p,eff} + {}^{s}\tilde{\sigma}_{c} + {}^{s}_{r}\tilde{\sigma}_{oc} \cdot {}^{s}_{r}\psi \right] \left[1 - \frac{\sum_{r' \neq r} {}^{s}_{r'}\tilde{\sigma}_{oc} \cdot {}^{s}_{r'}\psi - {}^{s}\tilde{\sigma}_{c}}{{}^{s}\tilde{\sigma}_{p,eff} + {}^{s}\tilde{\sigma}_{c} + {}^{s}_{r}\tilde{\sigma}_{oc} \cdot {}^{s}_{r}\psi} \right]} \right\rangle \qquad (3) $$

Using condition (2), expanding the second term of the denominator of (3) and neglecting quadratic terms in

$$ \sum_{r' \neq r} {}^{s}_{r'}\tilde{\sigma}_{oc} \cdot {}^{s}_{r'}\psi - \langle {}^{s}\tilde{\sigma}_{c} \rangle $$

, one gets

* in this appendix the same symbols as in /2/ are used.

the following expression:

$$\sum_r \frac{{}^s_r\tilde{\sigma}_{ox}}{{}^s_r\tilde{\sigma}_{oc}} \left\langle \frac{{}^s_r\psi}{\frac{\langle\tilde{\sigma}_t\rangle}{{}^s_r\tilde{\sigma}_{oc}} + {}^s_r\psi} \right\rangle + \langle {}^s\tilde{\sigma}_c \rangle \sum_r \frac{{}^s_r\tilde{\sigma}_{ox}}{\left\{{}^s_r\tilde{\sigma}_{oc}\right\}^2} \left\langle \frac{{}^s_r\psi}{\left\{\frac{{}^s\tilde{\sigma}_c}{{}^s_r\tilde{\sigma}_{oc}} + {}^s_r\psi\right\}^2} \right\rangle$$

$$- \sum_r \sum_{r' \neq r} \frac{{}^s_r\tilde{\sigma}_{ox} \cdot {}^s_{r'}\tilde{\sigma}_{oc}}{\left\{{}^s_r\tilde{\sigma}_{oc}\right\}^2} \left\langle \frac{{}^s_{r'}\psi \cdot {}^s_{r'}\psi}{\left\{\frac{\langle\tilde{\sigma}_t\rangle}{{}^s_r\tilde{\sigma}_{oc}} + {}^s_r\psi\right\}^2} \right\rangle \qquad (4)$$

with

$$\langle\tilde{\sigma}_t\rangle = \tilde{\sigma}_{p,eff} + \langle {}^s\tilde{\sigma}_c \rangle$$

The first and the third term of (4) are the same as in expression (2.42) in /2/, when ${}^s\sigma_{p.eff}$ is replaced by $\langle\sigma_t\rangle$.

To calculate the overlapping effect, the assumption is made:

$$\langle\sigma_t\rangle \gg {}^s_r\sigma_{oc} \cdot {}^s_r\psi \qquad (5)$$

This condition corresponds to the condition (2.50) and (2.51) in /2/.

With this condition, for the third term of (4) one gets the identically same result as for the second term of (2.42) in /2/.

$$\sum_r \sum_{r' \neq r} \frac{{}^s_r\tilde{\sigma}_{ox} \cdot {}^s_{r'}\tilde{\sigma}_{oc}}{\left\{{}^s_r\tilde{\sigma}_{oc}\right\}^2} \left\langle \frac{{}^s_r\psi \cdot {}^s_{r'}\psi}{\left\{\frac{\langle\tilde{\sigma}_t\rangle}{{}^s_r\tilde{\sigma}_{oc}} + {}^s_r\psi\right\}^2} \right\rangle \simeq \frac{{}^s\overline{D} \cdot \langle {}^s\tilde{\sigma}_x \rangle \cdot \langle {}^s\tilde{\sigma}_c \rangle}{\Delta\sqrt{2\pi}\,\langle\tilde{\sigma}_t\rangle^2} \cdot \varepsilon \qquad (6)$$

From condition (5), the following approximation for the denominator of the second term of (4) can be deduced:

$$\left\{\frac{\langle\tilde{\sigma}_t\rangle}{{}^s_r\tilde{\sigma}_{oc}} + {}^s_r\psi\right\}^2 \cong \frac{\langle\tilde{\sigma}_t\rangle}{\{{}^s_r\tilde{\sigma}_{oc}\}^2} \cdot \left\{\langle\tilde{\sigma}_t\rangle + {}^s_r\tilde{\sigma}_{oc} \cdot {}^s_r\psi\right\} \tag{7}$$

Then for the second term of (4) one gets

$$\frac{\langle{}^s\tilde{\sigma}_c\rangle}{\langle\tilde{\sigma}_t\rangle} \cdot \sum_r \frac{{}^s_r\tilde{\sigma}_{ox}}{{}^s_r\tilde{\sigma}_{oc}} \left\langle \frac{{}^s_r\psi}{\frac{\langle\tilde{\sigma}_t\rangle}{{}^s_r\tilde{\sigma}_{oc}} + {}^s_r\psi} \right\rangle \tag{8}$$

Now the first and the second term of (4) can be combined to

$$\left\{1 + \frac{\langle{}^s\tilde{\sigma}_c\rangle}{\langle\tilde{\sigma}_t\rangle}\right\} \sum_r \frac{{}^s_r\tilde{\sigma}_{ox}}{{}^s_r\tilde{\sigma}_{oc}} \left\langle \frac{{}^s_r\psi}{\frac{\langle\tilde{\sigma}_t\rangle}{{}^s_r\tilde{\sigma}_{oc}} + {}^s_r\psi} \right\rangle \tag{9}$$

and for this, one gets in the same manner as for the first term of (2.42) in /4/ the following expression.

$$\left\{1 + \frac{\langle{}^s\tilde{\sigma}_c\rangle}{\langle\tilde{\sigma}_t\rangle}\right\} \frac{\overline{{}^s\Gamma_x \cdot J({}^s\beta, {}^s\theta)}}{\overline{{}^sD} \cdot \cos 2\delta_l} \tag{10}$$

where now ${}^s\beta$ is given by

$${}^s\beta = \frac{\langle\tilde{\sigma}_t\rangle}{{}^s\tilde{\sigma}_{oc}} \tag{11}$$

So for the effective microscopic cross section one gets the modified result

$$ {}^s\sigma_{x,g}(E) = {}^s\sigma_{p,eff} \frac{\left[1+\frac{\langle {}^s\sigma_c\rangle}{\langle \sigma_t\rangle}\right]\overline{{}^s\Gamma_x \cdot J({}^s\beta, {}^s\theta)} - \overline{{}^sD}\cdot\langle {}^s\sigma_x\rangle\cdot\langle {}^s\sigma_c\rangle \cdot \varepsilon}{\overline{{}^sD}\cdot\cos 2\delta_l \qquad \Delta\sqrt{2\pi}\cdot\langle\sigma_t\rangle^2} \qquad (12) $$

$$ 1-\left[1+\frac{\langle {}^s\sigma_c\rangle}{\langle \sigma_t\rangle}\right]\frac{\overline{{}^s\Gamma\cdot J({}^s\beta, {}^s\theta)}}{\overline{{}^sD}} + \frac{\overline{{}^sD}\cdot\langle {}^s\sigma_c\rangle^2}{\Delta\sqrt{2\pi}\,\langle\sigma_t\rangle^2}\cdot\varepsilon $$

for capture and fission, and

$$ {}^s\sigma_{c,g}(E) = {}^s\sigma_{p,eff} \frac{\left[1+\frac{\langle {}^s\sigma_c\rangle}{\langle \sigma_t\rangle}\right]\frac{\overline{{}^s\Gamma\cdot J({}^s\beta, {}^s\theta)}}{\overline{{}^sD}} - \frac{\overline{{}^sD}\cdot\langle {}^s\sigma_c\rangle^2}{\Delta\cdot\sqrt{2\pi}\,\langle\sigma_t\rangle^2}\cdot\varepsilon}{1-\left[1+\frac{\langle {}^s\sigma_c\rangle}{\langle \sigma_t\rangle}\right]\frac{{}^s\Gamma\cdot J({}^s\beta, {}^s\theta)}{\overline{{}^sD}} + \frac{\overline{{}^sD}\cdot\langle {}^s\sigma_c\rangle^2}{\Delta\cdot\sqrt{2\pi}\cdot\langle\sigma_t\rangle^2}\cdot\varepsilon} \qquad (13) $$

for the total resonance cross section.

All symbols have the same meaning as in /2/, formula (2.68), except

$$ {}^s\beta = \frac{\langle\sigma_t\rangle}{{}^s\sigma_{oc}} \quad \text{instead of} \quad \frac{{}^s\sigma_{p,eff}}{{}^s\sigma_{oc}} . $$

An approximate calculation of current weighted resonance self shielding factors from statistical resonance parameters.

1. Introduction

For the calculation of resonance self shielding factors from statistical resonance parameters a formalism /3/, first developed by R. Froelich in his paper on Doppler theory /2/, was used in the first version of MIGROS, which did not allow the calculation of current weighted self shielding factors. An approximation is proposed, which allows to use the modified formalism for flux weighted self shielding factors of Froelich, given in Appendix I, also for current weighted self shielding factors.

The flux weighted f-factor for the neutrons reaction (n,x) in the energy group g for a resonance isotope may be written as

$$f_{x,g} = \frac{\sum_j \phi_j \cdot \sigma_{x,g}(E_j) \cdot \Delta E_j}{\sum_j \phi_j \cdot \sigma^{\infty}_{x,g}(E_j) \cdot \Delta E_j} \qquad (1)$$

The ΔE_j are energy intervals in the group g, ϕ_j is a weighting function, constant over ΔE_j.

$$\sigma_{x,g}(E) = \frac{\left\langle \frac{\sigma_x(E)}{\sigma_t(E)+\sigma_0} \right\rangle}{\left\langle \frac{1}{\sigma_t(E)+\sigma_0} \right\rangle} \qquad (2)$$

1)

is the effective cross section in the energy interval ΔE around E for the neutron reaction (n,x) for the resonance isotope.

1) $$\langle y(E) \rangle = \frac{1}{\Delta E} \int_{\Delta E} y(E)\, dE$$

$\tilde{\sigma}_x(E)$ microscopic cross section of the resonance isotope for the neutron reaction (n,x)

$\tilde{\sigma}_t(E)$ microscopic total cross section of the resonance isotope.

σ_o total back ground cross section per resonance atom.

$$\tilde{\sigma}^{\infty}_{x,g}(E) = \left\langle \tilde{\sigma}_x(E) \right\rangle \tag{3}$$

is the average cross section in ΔE around E. The relation

$$\tilde{\sigma}^{\infty}_{x,g}(E) = \lim_{\sigma_o \to \infty} \tilde{\sigma}_{x,g}(E) \tag{4}$$

means that for infinite dilution of the resonance isotope the effective cross section is the same as the average cross section. The interval ΔE is assumed to be so large that many resonances are in it. There is no problem in calculating the average cross section from statistical resonance parameters | 2 |, | 3 |, | 4 |. However, it is not so easy to calculate the effective cross section because of the overlapping of the resonances. The effective cross section is composed of the contributions of the single resonances series s

$$\begin{aligned} \tilde{\sigma}_{x,g}(E) &= \sum_s {}^s\tilde{\sigma}_{x,g}(E) && \text{for capture and fission} \\ \tilde{\sigma}_{t,g}(E) &= \sum_s {}^s\tilde{\sigma}_{c,g}(E) + \sigma_p && \text{for the total cross section} \end{aligned} \tag{5}$$

${}^s\tilde{\sigma}_{c,g}(E)$ is the total resonance cross section of series s (c = compound, not capture)

$$ {}^s\tilde{\sigma}_{x,g}(E) = \frac{\left\langle \dfrac{{}^s\tilde{\sigma}_x(E)}{{}^s\tilde{\sigma}_c(E) + \sum_{s' \neq s} {}^{s'}\tilde{\sigma}_c(E) + \sigma_p + \sigma_o} \right\rangle}{\left\langle \dfrac{1}{{}^s\tilde{\sigma}_c(E) + \sum_{s' \neq s} {}^{s'}\tilde{\sigma}_c(E) + \sigma_p + \sigma_o} \right\rangle} \tag{6}$$

${}^s\tilde{\sigma}_c(E)$ is the resonance part of the total cross section of series s.

$\tilde{\sigma}_p$ potential cross section

R. Froelich showed that under the assumption that

$$\frac{\sum_{s' \neq s} \left[{}^{s'}\tilde{\sigma}_c(E) - \langle {}^{s'}\tilde{\sigma}_c(E) \rangle \right]}{\tilde{\sigma}_p + \tilde{\sigma}_o + {}^s\tilde{\sigma}_c(E) + \sum_{s' \neq s}^{s'} \tilde{\sigma}_c(E)} \ll 1 \qquad (7)$$

at the resonances of series s, the effective cross section of series s can be approximated by

$${}^s\tilde{\sigma}_{x,g}(E) = \frac{\left\langle \frac{{}^s\tilde{\sigma}_x(E)}{{}^s\tilde{\sigma}_c(E) + \sum_{s' \neq s} \langle {}^{s'}\tilde{\sigma}_c(E) \rangle + \tilde{\sigma}_p + \tilde{\sigma}_o} \right\rangle}{\left\langle \frac{1}{{}^s\tilde{\sigma}_c(E) + \sum_{s' \neq s} \langle {}^{s'}\tilde{\sigma}_c(E) \rangle + \tilde{\sigma}_p + \tilde{\sigma}_o} \right\rangle} . \qquad (8)$$

This approximation is correct up to quadratic terms of expression (7).

Introducing

$${}^s\tilde{\sigma}_{p,\mathrm{eff}} = \tilde{\sigma}_o + \tilde{\sigma}_p + \sum_{s' \neq s} \langle {}^{s'}\tilde{\sigma}_c(E) \rangle \qquad (9)$$

one gets

$${}^s\tilde{\sigma}_{x,g}(E) = \frac{\left\langle \frac{{}^s\tilde{\sigma}_x(E)}{{}^s\tilde{\sigma}_c(E) + {}^s\tilde{\sigma}_{p,\mathrm{eff}}} \right\rangle}{\left\langle \frac{1}{{}^s\tilde{\sigma}_c(E) + {}^s\tilde{\sigma}_{p,\mathrm{eff}}} \right\rangle} . \qquad (10)$$

or in a slightly different form

$$ {}^s\tilde{\sigma}_{x,g}(E) = {}^s\tilde{\sigma}_{p,eff} \cdot \frac{\left\langle \dfrac{{}^s\tilde{\sigma}_x(E)}{{}^s\tilde{\sigma}_c(E) + {}^s\tilde{\sigma}_{p,eff}} \right\rangle}{1 - \left\langle \dfrac{{}^s\tilde{\sigma}_c(E)}{{}^s\tilde{\sigma}_c(E) + {}^s\tilde{\sigma}_{p,eff}} \right\rangle} \qquad (11) $$

This microscopic cross section of the series s is composed of the contributions of all resonances r of this series in the interval ΔE (if ΔE contains enough resonances, contributions from outside may be neglected).

$$ {}^s\tilde{\sigma}_{x,g}(E) = {}^s\tilde{\sigma}_{p,eff} \cdot \frac{\sum_r \left\langle \dfrac{{}^s\tilde{\sigma}_x^r(E)}{{}^s\tilde{\sigma}_c^r(E) + \sum_{r' \neq r} {}^s\tilde{\sigma}_c^{r'}(E) + {}^s\tilde{\sigma}_{p,eff}} \right\rangle}{1 - \sum_r \left\langle \dfrac{{}^s\tilde{\sigma}_c^r(E)}{{}^s\tilde{\sigma}_c^r(E) + \sum_{r' \neq r} {}^s\tilde{\sigma}_c^{r'}(E) + {}^s\tilde{\sigma}_{p,eff}} \right\rangle} \qquad (12) $$

Replacing the sum of all resonances by the statistical average times the average number of resonances in the interval ΔE, the modified formalism of Froelich, given in appendix I, approximates expression (11) by

$$ {}^s\tilde{\sigma}_{x,g}(E) = {}^s\tilde{\sigma}_{p,eff} \frac{\left[1 + \dfrac{\langle {}^s\tilde{\sigma}_c \rangle}{\langle \tilde{\sigma}_t \rangle}\right] \dfrac{\overline{{}^s\Gamma_x \cdot J({}^s\beta, {}^s\theta)}}{\overline{{}^sD \cdot \cos 2\delta_l}} - \dfrac{\overline{{}^sD} \cdot \langle {}^s\tilde{\sigma}_x \rangle \cdot \langle {}^s\tilde{\sigma}_c \rangle}{\Delta \sqrt{2\pi} \cdot \langle \tilde{\sigma}_t \rangle^2} \cdot \varepsilon}{1 - \left[1 + \dfrac{\langle {}^s\tilde{\sigma}_c \rangle}{\langle \tilde{\sigma}_t \rangle}\right] \dfrac{\overline{{}^s\Gamma \cdot J({}^s\beta, {}^s\theta)}}{\overline{{}^sD}} + \dfrac{\overline{{}^sD} \cdot \langle {}^s\tilde{\sigma}_c \rangle^2}{\Delta \sqrt{2\pi} \cdot \langle \tilde{\sigma}_t \rangle^2} \cdot \varepsilon} \qquad (13) $$

for x = fission, capture

$$ {}^{s}\tilde{\sigma}_{c,g}(E) = {}^{s}\tilde{\sigma}_{p,eff} \frac{\left[1+\frac{\langle {}^{s}\tilde{\sigma}_c\rangle}{\langle \tilde{\sigma}_t\rangle}\right]\frac{\overline{{}^{s}\Gamma\cdot J({}^{s}\beta,{}^{s}\theta)}}{\overline{{}^{s}D}} - \frac{{}^{s}D\cdot\langle {}^{s}\tilde{\sigma}_c\rangle^2}{\Delta\sqrt{2\pi}\,\langle \tilde{\sigma}_t\rangle^2}\cdot\varepsilon}{1-\left[1+\frac{\langle {}^{s}\tilde{\sigma}_c\rangle}{\langle \tilde{\sigma}_t\rangle}\right]\frac{\overline{{}^{s}\Gamma\cdot J({}^{s}\beta,{}^{s}\theta)}}{\overline{{}^{s}D}} + \frac{{}^{s}D\cdot\langle {}^{s}\tilde{\sigma}_c\rangle^2}{\Delta\sqrt{2\pi}\cdot\langle \tilde{\sigma}_t\rangle^2}\cdot\varepsilon} \qquad (14) $$

for the total resonance cross section.

$$\langle {}^s\sigma_c \rangle = \frac{2\pi}{{}^sD} \cdot \lambda^2 \cdot g \cdot \overline{{}^s\Gamma_n} \cdot \cos 2\delta_l$$

$$\langle \sigma_t \rangle = {}^s\sigma_{p,eff} + \langle {}^s\sigma_c \rangle$$

λ neutron wave length

g statistical parameter

The second term in the numerator and the third term in the denominator in (13), (14) are correction terms for overlapping of the resonances. They vanish for separated resonances.

The approximation of R. Froelich for the expression (12) is only valid, if the condition

$$ {}^s\sigma_{p,eff} + \langle {}^s\sigma_c \rangle + {}^s\sigma_c^r(E) \rangle \rangle \left| \sum_{r' \neq r} {}^s\sigma_c^{r'} - \langle {}^s\sigma_c \rangle \right| \qquad (15)$$

is fulfilled in the range of the resonance r.

2. The extension of the formalism of Froelich to current weighted resonance self shielding factors.

The current weighted total f-factor may be written as

$$ {}_1f_{t,g} = \frac{\sum_j \phi_j \cdot {}_1\tilde{\sigma}_{t,g}(E_j) \cdot \Delta E_j}{\sum_j \phi_j \cdot \tilde{\sigma}^{\infty}_{t,g}(E_j) \cdot \Delta E_j} \qquad (16) $$

$$ {}_1\tilde{\sigma}_{t,g}(E) = \frac{\left\langle \frac{\sigma_t(E)}{\{\sigma_t(E)+\sigma_o\}^2} \right\rangle}{\left\langle \frac{1}{\{\sigma_t(E)+\sigma_o\}^2} \right\rangle} \qquad (17) $$

is the effective current weighted cross section in the energy interval ΔE around E for the total neutron reaction of the resonance isotope.

The effective total cross section may be composed of several resonance series s

$$ {}_1\tilde{\sigma}_{t,g}(E) = \sum_s {}^s{}_1\tilde{\sigma}_{c,g}(E) + \sigma_p \qquad (18) $$

width

$$ {}^{s}_{1}\tilde{\sigma}_{c,g}(E) = \frac{\left\langle \dfrac{{}^{s}\tilde{\sigma}_c(E)}{\left\{ {}^{s}\tilde{\sigma}_c(E) + \sum_{s' \neq s} {}^{s'}\tilde{\sigma}_c(E) + \tilde{\sigma}_p + \tilde{\sigma}_o \right\}^2} \right\rangle}{\left\langle \dfrac{1}{\left\{ {}^{s}\tilde{\sigma}_c(E) + \sum_{s' \neq s} {}^{s'}\tilde{\sigma}_c(E) + \tilde{\sigma}_p + \tilde{\sigma}_o \right\}^2} \right\rangle} \qquad (19) $$

The numerator of (19) can also be written as

$$ \left\langle \frac{{}^{s}\tilde{\sigma}_c(E)}{\left\{ {}^{s}\tilde{\sigma}_c(E) + \sum_{s' \neq s} \left\langle {}^{s'}\tilde{\sigma}_c(E) \right\rangle + \tilde{\sigma}_p + \tilde{\sigma}_o \right\}^2 \cdot \left\{ 1 + \dfrac{\sum_{s' \neq s} \left[{}^{s'}\tilde{\sigma}_c(E) - \left\langle {}^{s'}\tilde{\sigma}_c(E) \right\rangle \right]}{\tilde{\sigma}_p + \tilde{\sigma}_o + {}^{s}\tilde{\sigma}_c(E) + \sum_{s' \neq s} \left\langle {}^{s'}\tilde{\sigma}_c(E) \right\rangle} \right\}^2} \right\rangle $$

Neglecting quadratic terms of

$$ \sum_{s' \neq s} \left\{ {}^{s'}\tilde{\sigma}_c(E) - \left\langle {}^{s'}\tilde{\sigma}_c(E) \right\rangle \right\} $$

in the second bracket, using condition (7) and expression (9), one gets

$$ \left\langle \frac{{}^{s}\tilde{\sigma}_c(E)}{\left\{ {}^{s}\tilde{\sigma}_c(E) + {}^{s}\tilde{\sigma}_{p,\,eff} \right\}^2} \right\rangle - 2 \cdot \left\langle \frac{{}^{s}\tilde{\sigma}_c(E) \cdot \sum_{s' \neq s} \left\{ {}^{s'}\tilde{\sigma}_c(E) - \left\langle {}^{s'}\tilde{\sigma}_c(E) \right\rangle \right\}}{\left\{ {}^{s}\tilde{\sigma}_c(E) + {}^{s}\tilde{\sigma}_{p,\,eff} \right\}^3} \right\rangle $$

Because the resonances, which belong to different series, are not correlated, the second term may be written as

$$ 2 \cdot \left\langle \frac{{}^{s}\tilde{\sigma}_c(E)}{\left\{ {}^{s}\tilde{\sigma}_c(E) + {}^{s}\tilde{\sigma}_{p,\,eff} \right\}^3} \right\rangle \cdot \left\langle \frac{\sum_{s' \neq s} \left\{ {}^{s'}\tilde{\sigma}_c(E) - \left\langle {}^{s'}\tilde{\sigma}_c(E) \right\rangle \right\}}{\left\{ {}^{s}\tilde{\sigma}_c(E) + {}^{s}\tilde{\sigma}_{p,\,eff} \right\}^3} \right\rangle $$

The second term is identically zero.

The same can be done for the denominator of (19), so that one gets

$$ {}^{s}_{1}\tilde{\sigma}_{c,g}(E) = \frac{\left\langle \dfrac{{}^{s}\tilde{\sigma}_{c}(E)}{\left\{ {}^{s}\tilde{\sigma}_{c}(E) + {}^{s}\tilde{\sigma}_{p,eff} \right\}^{2}} \right\rangle}{\left\langle \dfrac{1}{\left\{ {}^{s}\tilde{\sigma}_{c}(E) + {}^{s}\tilde{\sigma}_{p,eff} \right\}^{2}} \right\rangle} \qquad (20) $$

To calculate the current weighted effective cross section (20), one can use the formalism of Froelich described in chapter I, if the following condition is fulfilled:

$$ \left| {}^{s}\tilde{\sigma}_{c}(E) - \left\langle {}^{s}\tilde{\sigma}_{c}(E) \right\rangle \right| \ll \sum_{s'} \left\langle {}^{s'}\tilde{\sigma}_{c}(E) \right\rangle + \tilde{\sigma}_{p} + \tilde{\sigma}_{o} \qquad (21) $$

The numerator of (20) may be written as

$$ \left\langle \frac{{}^{s}\tilde{\sigma}_{c}(E)}{\left\{ \left[{}^{s}\tilde{\sigma}_{c}(E) - \left\langle {}^{s}\tilde{\sigma}_{c}(E) \right\rangle \right] + \left[{}^{s}\tilde{\sigma}_{p,eff} + \left\langle {}^{s}\tilde{\sigma}_{c}(E) \right\rangle \right] \right\}^{2}} \right\rangle $$

Using condition (21) and neglecting quadratic terms in

$$ \left| {}^{s}\tilde{\sigma}_{c}(E) - \left\langle {}^{s}\tilde{\sigma}_{c}(E) \right\rangle \right| $$

one gets

$$ \frac{1}{2 \cdot \left\{ {}^{s}\tilde{\sigma}_{p,eff} + \left\langle {}^{s}\tilde{\sigma}_{c}(E) \right\rangle \right\}} \cdot \left\langle \frac{{}^{s}\tilde{\sigma}_{c}(E)}{{}^{s}\tilde{\sigma}_{c}(E) + 0.5 \left\{ {}^{s}\tilde{\sigma}_{p,eff} - \left\langle {}^{s}\tilde{\sigma}_{c}(E) \right\rangle \right\}} \right\rangle $$

For the denominator of (20), one gets

$$\frac{1}{2\cdot\left\{{}^{s}\tilde{\sigma}_{p,eff}+\left\langle{}^{s}\tilde{\sigma}_{c}(E)\right\rangle\right\}}\left\langle\frac{1}{{}^{s}\tilde{\sigma}_{c}(E)+0.5\left\{{}^{s}\tilde{\sigma}_{p,eff}-\left\langle{}^{s}\tilde{\sigma}_{c}(E)\right\rangle\right\}}\right\rangle$$

Therefore, under condition (21) the current weighted effective cross section can be approximated by a flux weighted effective cross section of the form (11)

$${}^{s}_{1}\tilde{\sigma}_{c,g}(E)={}^{s}\tilde{\sigma}^{*}_{p,eff}\cdot\frac{\left\langle\frac{{}^{s}\tilde{\sigma}_{c}(E)}{{}^{s}\tilde{\sigma}_{c}(E)+{}^{s}\tilde{\sigma}^{*}_{p,eff}}\right\rangle}{1-\left\langle\frac{{}^{s}\tilde{\sigma}_{c}(E)}{{}^{s}\tilde{\sigma}_{c}(E)+{}^{s}\tilde{\sigma}^{*}_{p,eff}}\right\rangle}\qquad(22a)$$

and

$${}^{s}\tilde{\sigma}^{*}_{p,eff}=0.5\left\{{}^{s}\tilde{\sigma}_{p,eff}-\left\langle{}^{s}\tilde{\sigma}_{c}(E)\right\rangle\right\}\qquad(22b)$$

Now the formalism of Froelich can be used yielding the result (14), where ${}^{s}\tilde{\sigma}_{p,eff}$ is replaced by ${}^{s}\tilde{\sigma}^{*}_{p,eff}$.

3. Limits of the approximation

The limits of this approximation are given by condition (21) and the modified condition (15), when ${}^s\tilde{\sigma}_{p,eff}$ is replaced by ${}^s\tilde{\sigma}^*_{p,eff}$. Condition (15) then takes the form

$$\frac{{}^s\tilde{\sigma}_{p,eff} + \langle {}^s\tilde{\sigma}_c(E)\rangle}{2} + {}^s\tilde{\sigma}_c^{\,r}(E)\rangle\rangle \left| \sum_{r' \neq r} {}^s\tilde{\sigma}_c^{\,r'}(E) - \langle {}^s\tilde{\sigma}_c\rangle \right| \qquad (23)$$

Equation (23) is certainly fulfilled for separated resonances, as long as

$${}^s\tilde{\sigma}_{p,eff} > \langle {}^s\tilde{\sigma}_c(E)\rangle \qquad (24)$$

Equation (24) can also be written as

$${}^s\tilde{\sigma}^*_{p,eff} > 0. \qquad (25)$$

This condition is necessary, because (22a) is not defined for negative ${}^s\tilde{\sigma}^*_{p,eff}$. For strong overlapping, condition (23) is more sensible than condition (15).

In the energy range of "statistical resonances" condition (21) cannot be proved. To get some information on the influence of condition (21) on the approximation (22), some calculations in the region of resolved resonance parameters can be done. The flux weighted and the current weighted effective cross sections (10) and (20) may be calculated for a certain energy interval

exactly. In the resolved resonance region it is not necessary to distinguish the single resonance series. Then one gets for the total resonance cross section in the energy group g

$$\sigma_{c,g}(\sigma_o^*) = \frac{\left\langle \dfrac{\sigma_c(E)}{\sigma_c(E) + \sigma^*_{p,eff}} \right\rangle}{\left\langle \dfrac{1}{\sigma_c(E) + \sigma^*_{p,eff}} \right\rangle} \tag{26a}$$

$$_1\sigma_{c,g}(\sigma_o) = \frac{\left\langle \dfrac{\sigma_c(E)}{\{\sigma_c(E) + \sigma_{p,eff}\}^2} \right\rangle}{\left\langle \dfrac{1}{\{\sigma_c(E) + \sigma_{p,eff}\}^2} \right\rangle} \tag{26b}$$

$$\sigma_{p,eff} = \sigma_p + \sigma_o \tag{26c}$$

$$\sigma^*_{p,eff} = 0.5 \cdot \{\sigma_{p,eff} - \langle \sigma_c(E) \rangle\} \tag{26d}$$

$$\sigma_o^* = \sigma^*_{p,eff} - \sigma_p = 0.5\{\sigma_o - (\sigma_p + \langle \sigma_c(E) \rangle)\} \tag{26e}$$

The averages $\langle\ \rangle$ are performed over the energy group g.
For the corresponding resonance self shielding factors one gets

$$f_{t,g}(\sigma_o^*) = \frac{\sigma_{c,g}(\sigma_o^*) + \sigma_p}{\sigma^\infty_{c,g} + \sigma_p} \tag{27a}$$

and

$$ {}_1f_{t,g}(\sigma_o) = \frac{{}_1\sigma_{c,g}(\sigma_o) + \sigma_p}{\sigma_{c,g}^{\infty} + \sigma_p} \qquad (27b) $$

neglecting the macroscopic weighting.

In fig. 1 and fig. 2 the relative errors of the approximated effective resonance cross section and the approximated total resonance self shielding factor for U 235 in the energy range from 50 eV to 100 eV for several temperatures are plotted. As can be seen from these figures, the errors of the total resonance self shielding factors are smaller than those of the effective resonance cross sections because of the contribution of the potential cross section. The lowest σ_o-value, for which the approximation can be used is given by condition (24). The average resonance cross section for this example is $\langle \sigma_c(E) \rangle$ = 49,9 barns; the potential cross section is σ_p = 10,3 barns. So the lowest possible background cross section is = 39,6 barns. This restriction of the approximation to σ_o-values greater than 50 barns is unimportant, because the σ_o-values that correspond to the concentration of U 235 in reactors are in the range of several hundred barns. From fig. 1 one can see that for σ_o-values greater than 500 barns the approximation is better than 1 % for all three temperatures. Since with increasing energy the resonances become smaller and the overlapping becomes more important, one can expect, that in the range of the unresolved resonances, condition (21) is fulfilled better than in the resolved resonance region. Therefore the errors of the approximation should be smaller than in fig. 1.
In fig. 3 and fig. 4 the same results for U 238 in the energy range form 2 keV to 3,3, keV are plotted. In contrast to U 235 the errors of the approximation for the effective resonance cross section (fig. 3) of U 238 are much larger, because of the

higher resonances. On the other hand, the effective resonance cross section U 238 is smaller than the potential cross section, so that the errors in the total resonance self shielding factors are much smaller. In fig. 4 one can see that the errors are smaller than 2 - 3 % in the whole range of $\tilde{\sigma}_o$. The average resonance cross section for this example is $\langle \sigma_c(E) \rangle = 5{,}9$ barns, the potential cross section is $\tilde{\sigma}_p = 10{,}7$ barns, so that condition (24) can be fulfilled for all $\tilde{\sigma}_o$-values.

4. Conclusions

From calculations in the resolved resonance region one can draw the conclusion that the proposed approximation for the current weighted total resonance self shielding factors yields results with relative errors of a few percent. This is sufficient for reactor calculations.

Appendix III Method of integration /Romberg procedure/

The Romberg method which has been used for numerical integration is briefly the following.

Let us have a function f (x) and the integral

$$I = \int_a^b dx\, f(x) \tag{1}$$

is to be calculated.

First an equidistant mesh with 2^n+1 mesh points / including the end points of the interval | a,b |/ are taken and the sum

$$I_{on} = \{0.5\,[f(a)+f(b)] + \sum_{k=1}^{2^n-1} f(X_k^n)\}\,\Delta X_n \tag{2}$$

is calculated, where

$$\Delta X_n = \frac{b-a}{2^n} \quad ; \quad X_k^n = a + k\cdot\Delta X_n \quad (k=1,\ldots 2^n-1)$$

Evidently

$$I_{o,n+1} = 0.5\cdot I_{on} + \Delta X_{n+1} \sum_{k=1,3,\ldots}^{2^{n+1}-1} f(X_k^{n+1}) \tag{3}$$

where

$$\Delta X_{n+1} = 0.5\,\Delta X_n\,, \quad X_k^{n+1} = a + k\,\Delta X_{n+1} \quad (k=1,3,5\ldots)$$

The second summation is taken over the new mesh points of the higher order mesh.

Let us take the expression

$$I_{mn} = \frac{2^{2m}\cdot I_{m-1,n} - I_{m-1,n-1}}{2^{2m}-1} \tag{4}$$

It is easy to prove that the deviation of I_{mn} from I is of the order $(\Delta X_n)^m$ i.e. I_{nn} is the best approximation for the given n.

The I_{mn} form a triangular matrix.

I_{oo}

$I_{o1}\ I_{11}$

.
.
.

$I_{on-1}\ I_{1n-1} \cdots\cdots\ I_{n-1n-1}$

$I_{on}\ \ I_{1n}\ \cdots\cdots\ I_{n-1n}\ \ I_{nn}$

The programming of the method is quite straightforward. A row of the above matrix is always to be stored and by means of the formula (3), (4) the next row can be determined. The process is finished if the quantity

$$\left| \frac{I_{nn} - I_{n-1,n-1}}{I_{nn}} \right| < \varepsilon$$

where ε is the required accuracy.

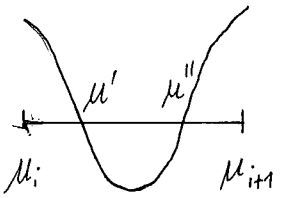
The following should be noted.

1. Only one ε /ERR/ is given. This used for the energy integration. For the angular integration ε/10 is prescribed.
2. Some of the higher moments are very small as far as heavier elements are concerned. In order to avoid a "bad" convergence, the energy integration process for the moment in question is finished when $|I_{nn}| < 10^{-10}$
3. In order to avoid a vaste of computing time the integration will be finished if n reaches a maximal value / for energy integration NUJM, for angle integration NJM /. Reaching these values in the course integration an error message will be generated and the calculation is continued. From the error message the user can decide whether the results are acceptable.

Appendix IV The subintervals in the angular integration

The integrand of (8.5) is a product of two functions. In order to save computing time the actual behaciour of these functions. in the integration interval $[\mu_i, \mu_{i+1}]$ should be taken into account.

a) The polynomial $P_n(t(\mu))$ has n zeros.E.g. let us assume that two zeros are in the interval $|\mu_i, \mu_{i+1}|$ and then the integration interval is divided into three subinterval: $[\mu_i, \mu']$, $[\mu', \mu'']$, $[\mu'', \mu_{i+1}]$. However sometimes it occurs that the intervals (μ_i, μ') or (μ'', μ_{i+1}) are too small. This can give rise to difficulties in the Romberg integration method. Therefore the width of the extreme intervals are investigated and if one of them is less than a given limit (now this limit is $|\mu'' - \mu'|/10$) then it will be joined with the next one.



b) The function $\gamma(\mu)$ has often shown a "nasty" character. This "nasty" character can already be detected at the normalization of angular distribution: N passes beyond NJM. If in a energy group a "nasty" charakter is detected then the integration interval is divided into subintervals defined by the angle point of the angular distribution given in the nuclear data file.

Appendix V. Sample problem

*'DATAMAIN' STELLT FUER EINE FORTRAN-SUBROUTINE 'MAIN' SPEICHERFELDER,
*DEREN LAENGEN IM EXEC-PARM-FELD ANGEGEBEN SIND,BEREIT UND GIBT SIE
*ALS ARGUMENTE AN 'MAIN' NACH FOLGENDEM SCHEMA WEITER.
* // EXEC FHG,PARM.G=(X,Y),REGION.G=RK X,Y SIND 2 FELDLAENGEN
*AUSFUEHRUNG VON 'DATAMAIN' LIEFERT ANFANGSADRESSEN DER ZWEI FELDER IN
*DER TASK-REGION.
* N > 0  GIBT ANZAHL DER FELDER AN (NORMALFALL)
*DURCH 'SUBROUTINE MAIN(N,X,JX,Y,JY)'KOENNEN DIE 2 FELDER IN'MAIN'SO-
*WOHL ALS FESTKOMMA-ALS AUCH ALS GLEITKOMMA-FELDER BENUTZT WERDEN.
*UNTER X(1)=JX(1) BZW. Y(1)=JY(1) KOENNEN DIE LAENGEN XX,YY IN 'MAIN'
*ABGEHOLT WERDEN.
* N = 0  IST FEHLERFALL.HINWEIS AUF FEHLERART UNTER JX(1)-JX(35).
*MAXIMALLAENGE DES PARM-FELDES IST 40 EBCDIC-ZEICHEN.
