Abstract

Traditional data flow analysis methods are designed for sequential programs. Hence they may fail when applied to control flow parallel imperative programs that share memory and are based on the MIMD computer model. Current approaches mostly use a copy-in,copy-out semantics, when entering/exiting a process, to model shared memory.

To avoid this restriction, this paper extends the notion of program execution paths. Selecting some specific paths out of the set of all possible paths, allows to give simple data flow equations which are proved to be equal to the meet over all path solution. Since these data flow equations are extensions of the sequential ones, they fit very well to the traditional optimization methods.

An example shows that the code generator of a compiler as well as a reordering assembler needs this kind of data flow analysis to avoid unnecessary memory barrier instructions and to produce correct instruction reorderings, respectively.

Another paper is currently under work (actually it’s already present, but only in german) which extends this theory so that it can be used with the control flow graph representation of a source program.

1 Introduction

To exploit the power of today's processors, optimizations like common subexpression elimination, constant folding, dead code elimination etc. must be performed for parallel programs as well as for sequential ones. Optimizing a program requires analyzing it, and this is often done by applying data flow equations to the program. Traditional data flow analysis methods are designed for sequential programs. Hence they may fail when applied to control flow parallel programs. [Midkiff et al 90] presents some examples, where traditional analyzing and optimizing techniques fail when applied to parallel programs.

Current approaches in analyzing the data flow of parallel programs have either a restricted model of shared memory, or even disallow it. [Reif 84] investigates the data flow of communicating processes, but these do not share memory. Processes communicate solely through synchronous channels. [Srinivasan et al 91a] describes an efficient method of computing the Static Single Assignment form [Cytron et al 89] for explicitly parallel programs with wait clauses. The parallel sections must be data independent, except where explicit synchronization is used. [Srinivasan et al 91b, Wolfe et al 91] introduce the Parallel Control Flow Graph and the Parallel Precedence Graph which may form the basis of concrete optimizing algorithms. [Chow et al 92] use abstract interpretation as framework to obtain program properties, like side effects, data dependencies, object lifetimes and concurrent expressions. [Grunwald et al 93] present a solution for the reaching definition problem, both with and without synchronization. But they restrict themselves to PCF FORTRAN (defined by the Parallel Computing Forum) standard conforming programs, which means access to shared variables is done only at synchronization points. For process start and process end they assume a copy in/copy out semantics.

Our investigation is based on an imperative language with explicit control flow parallelism, dynamic process creation, and shared memory. As computing model we assume a MIMD (multiple instruction, multiple data) system, where each process is executed on a separate processor. Each processor runs independently of each other and has its own set of registers, which are invisible for other processors. All processors access a shared memory, without the above mentioned restrictions. The main result of this paper is an extension of the well known sequential data flow equations covering forward/backward and may/must data flow problems:

1. Theorem 1 shows which data flow information reaches a statement (in the parallel context), and
2. theorems 2 and 3 give the information which reaches the end of the in parallel executed statements.

Section 2 defines the language we base our investigation on, section 3 presents the idea which leads to the main result, and sections 4 and 5 shows the theorems.

1.1 The classical data flow problems

The four "classical" data flow problems are classified into may and must problems and the direction of information propagation (forward / backward) (cf. table 1). If the information which reaches a program point comes from the preceding statements, the problem is called a forward problem; if it comes from the following statements, it is called a backward problem. If the information has to be available in all predecessors (successors) the problem is called a must problem, if it has to be available in at least one, it is a may problem [Hecht 77].

Usually, the data flow information is computed over a control flow graph. Another possibility is to use the structure tree of the program [Babich et al 78, Aho et al 80]. We chose this approach, since it allows easier formulation.

In this paper we consider only forward problems, for backward problems the results may be stated in a similar way.
The equations are always stated using the sets \( \text{gen}[S], \text{kill}[S], \text{in}[S], \text{out}[S] \). \text{gen} is the set of the informations generated by statement \( S \) and reaching its end. \text{kill} is the set of informations invalidated by \( S \) and still invalid at the end of \( S \). \text{in} represents the informations reaching \( S \), and \text{out} the set of informations reaching the end of \( S \). \text{gen} and \text{kill} are defined in terms of the underlying data flow problem, e.g., the set of generated definitions of a variable or set of computed expressions. For example in the reaching definition problem, the assign statement \( \text{id} := \text{expr} \) generates this definition of variable \( \text{id} \) and invalidates all other definitions of this variable.

The most important equations are the ones for propagating the information from one statement to the next in sequential execution: \( S_1 ; S_2 \). For these there is no distinction between \textit{must} and \textit{may} problems and the information is propagated as shown in table 2. The equations for the other sequential statements are given in appendix A.

\[
\begin{align*}
\text{gen}[S] &= \text{gen}[S_2] \cup \text{gen}[S_1] - \text{kill}[S_2] \quad (1) \\
\text{kill}[S] &= \text{kill}[S_2] \cup \text{kill}[S_1] - \text{gen}[S_2] \\
\text{in}[S_1] &= \text{in}[S] \\
\text{in}[S_2] &= \text{out}[S_1] \\
\text{out}[S] &= \text{out}[S_2]
\end{align*}
\]

Table 2: Data flow equation for \( S := S_1 ; S_2 \).

The following equation holds for the sequential statements [Aho et al 86]:

\[
\text{out}[S] = \text{gen}[S] \cup \text{in}[S] - \text{kill}[S] 
\]

### 1.2 What could go wrong?

This section shows the potential problems, when applying sequential data flow analysis to an explicit parallel program. The small program\(^2\) executes the processes \( P_1 \) and \( P_2 \) in parallel. It is intuitively clear that \textit{critical}_1 and \textit{critical}_2 are never executed at the same time.

A simple-minded optimizer could perform the following "optimizations" (which would be correct in sequential contexts):

- Propagate \( a = 0 \) and \( b = 0 \) to \textbf{IF} \( a = 0 \) and \textbf{IF} \( b = 0 \) respectively.
- Then the expressions could be statically evaluated to \textbf{TRUE}.
- Dead code elimination removes the \textbf{IF} and \textbf{ELSE} parts.

\[ \Rightarrow \text{Both, critical}_1 \text{ and critical}_2 \text{ are executed!} \]

But even without traditional optimizations performed by the compiler, things could go wrong when using an assembler which does instruction scheduling (reordering), to better use the processor's internal parallelism (i.e., the pipelined processing of instructions).

---

1. If \( a \) and \( b \) are sets, then \( a - b \) is the set difference and is defined as \( a - b := a \cap \overline{b} \).

2. Lamport 79 presents this problem concerning the design of parallel computers.
Table 3: Simple parallel program.

The non-optimized code of process body $P_1$ on a typical RISC processor is given in table 4. The instruction scheduler could now decide to reorder the instructions, e.g. to insert another instruction between a register load and an immediately following register use instruction (e.g. ldc 1,r0; st r0,a) which results in the code for $P_1$ shown in table 5a. In this case, it can happen that critical$_1$ and critical$_2$ are executed both, as shown in table 5b!

Table 4: Non-optimized code for Process $P_1$

Table 5: Code and execution of reordered code

Even worse, some processors (like the Dec Alpha Chip [DEC 92]) are able to reorder the memory accesses to different addresses to some degree. Hence, even the unchanged code could give the
The idea

A single run of a program may be seen as an execution of sequence of assign statements, \(\langle s_1; \ldots; s_n \rangle\), starting with \(s_1\) and ending with \(s_n\). The \(s_i\) in the sequence are selected by some
“magic”, i.e. by the conditionals, loops, and par’s\(^3\). If the program terminates, the sequence is finite. To compute the data flow information, reaching a statement in this sequence is straightforward: Use the equations for \( S := S_1; S_2 \) of table 2.

But now the meaning of data flow information is to state facts about any program run, not a specific one. Hence all possible sequences, or paths, must be considered. The following formulas show how all program paths are computed\(^4\). If \( path \) is defined as the set of all assignment sequences, \( path := \{(s_1; \ldots; s_n) | s_i \text{ is an assignment}\} \), then \( p^n \in path \) is defined as the \( n \)-fold concatenation of path \( p \), and \( p^+ = \bigcup_{k=1}^{n} p^k \), with some \( n \). The set \( paths[S] \) is now defined as the set of all paths, produced by statement \( S \). For example, \( paths[\text{Prog}] \) is the set of all possible paths of a program.

\[
\begin{align*}
paths[S] &= \left\{ \begin{array}{ll}
\text{concat}(paths[S'], paths[S'']) : S := S' ; S'' \\
paths[S'] \cup paths[S''] : S := \text{IF E THEN } S' \text{ ELSE } S'' \text{ END} \\
paths^+[S] : S := \text{REPEAT } S' \text{ UNTIL } E \\
\text{merge}(paths[S'], paths[S'']) : S := \text{PAR } S' \mid S'' \text{ END}
\end{array} \right.
\end{align*}
\]

Where \( \text{merge} \) returns all paths which may be generated by a PAR statement:

\[
\text{merge}((s_{1';} \ldots; s_{n';}), (s_{1''}; \ldots; s_{n''})) := \left\{ \begin{array}{l}
\forall i < j \in \{1, \ldots, n'\} \exists k \in \{1, \ldots, n' + n''\} : s_k = s'_i, s_l = s''_j \Rightarrow k < l \text{ or } \\\n\forall i < j \in \{1, \ldots, n''\} \exists k \in \{1, \ldots, n' + n''\} : s_k = s'_i, s_l = s''_j \Rightarrow k < l 
\end{array} \right.
\]

\( \text{merge} \) mixes the paths of the branches of a PAR statement such that the order of the statements in one branch is obeyed in the merged path, but between two statements \( s'_i, s'_{i+1} \) in a path of one branch the merged path may contain statements of the other branch; e.g. \( s'_i, s'_j, s''_{j+1} \). \( \text{merge} \) may be extended to take as arguments set of paths: \( \text{merge} : 2^{path} \times 2^{path} \rightarrow 2^{path} : \text{merge}(P', P'') := \bigcup_{p' \in P', p'' \in P''} \text{merge}(p', p'') \).

It is clear, several runs of a sequential program execute with the same input always the same path. But for a parallel program there are several paths possible.

Depending on the may/must property of the data flow problem, the data flow information is the union (may) or intersection (must) of the information computed for all paths, reaching a statement \( S \):

\[
\begin{align*}
info[S] &= \bigwedge_{p \in \text{prefix}(paths[\text{Prog}], S)} info[p] \quad (4) \\
info[S] &= \bigwedge_{p \in paths[S]} info[p] \quad (5)
\end{align*}
\]

\( \bigwedge \) and \( \bigwedge \) stands, depending on the problem, for either set union or set intersection. \( \text{prefix}(paths[\text{Prog}], S) \) is the set of paths, reaching statement \( S \). Equation (4) is used when the information depends on the preceding statements (like in), (5) is used if this not the case, like for \( \text{gen} \) and \( \text{kill} \). For \( \text{out} \) (5) can be used too, since it depends on \( \text{in} \), for which the other equation is used. These equations correspond to the so called \( \text{meet over all paths} \) solution of the data flow problem [Kildall 73].

Since for a single path it is known how to compute the data flow information, the algorithm to get the data flow information reaching a statement \( S \) is now clear. However, it has a big

---

\( ^3 \)This is possible due to the interleaving semantics of the language.

\( ^4 \)For the sake of simplicity, they are given only for PAR statements with two branches and no replicators. The generalization is straightforward.
drawback: the number of paths may be exponential in the number of conditionals or even infinite if the program contains loops.

A better solution would be: find a simple formula \( F_{info}[S] \) computing the data flow information \( info[S] \) based only on the structure tree of the program, and proof that this formula returns the same as this meet over all path solution.

The next sections show the main result of this paper:

1. it is shown which information reaches a statement (in the parallel context), and
2. which information reaches the end of a PAR statement.

For the first result, two sets \((in, \widetilde{in})\) are used to represent the data flow information reaching a statement, instead of only one in the sequential case.

The second result is based on the fact that it is sufficient to consider some specific paths instead of all possible paths. For these specific paths, a simple formula \( F_{info}[S] \) can be given and it returns the same results as the belonging meet over all path solution.

For the PAR \( S_1 \mid S_2 \) \( \text{END} \) statement with the two branches \( S_1 \) and \( S_2 \), these specific paths are: \( concat(paths[S_1], paths[S_2]) \) and \( concat(paths[S_2], paths[S_1]) \), i.e. the paths resulting from the concatenated execution of \( S_1; S_2 \) and \( S_2; S_1 \).

For example: Analysing the PAR \( s_1; s_2 \mid s_3 \text{ END} \) statement, for which the \( s_i \) are simple statements, only the two paths \( \langle s_1; s_2; s_3 \rangle \) and \( \langle s_3; s_1; s_2 \rangle \) are needed for the analysis. The third possible path \( \langle s_1; s_2; s_2 \rangle \) need not to be considered.

For PAR statements with \( n \) branches the paths from the \( n! \) concatenated statements \( S_{i_1}; \ldots; S_{i_n} \), where \( i=(i_1, \ldots, i_n) \in \text{perm}(1,n) \) is a permutation of the numbers \( 1, \ldots, n \), are used.

If the sample language would have a process synchronisation statement, the number of paths could be reduced, since some path never occur in any program run. Hence not considering this kind of statement, produces a “worst case” data flow information which is still correct.

Including a goto statements doesn’t change the ideas, it complicates only the description. This is due to the fact that we are using the structure tree and not a control flow graph for representing a program in our presentation of the ideas.

4 Which information reaches a statement (in the parallel context)

In the sequential case only one set is defined to represent the information reaching a statement. In the parallel case two sets are needed:

- \( \text{in}[S] \) The information propagated along the edges of the structure tree, i.e. without considering the effect of the statements executed parallel to \( S \). That is the information which comes from the statements executed always before \( S \).
- \( \text{\widetilde{in}}[S] \) The set of informations reaching \( S \), which stems from sequentially before \( S \) executed statements and from statements executed in parallel to \( S \).

It is obvious, that \( \text{\widetilde{in}}[S] = \bigwedge_{p \in \text{\textit{for}}(paths[Prog],S)} \text{out}[p] \). The same distinction can be made for the set of information reaching the end of a statement, but \( \text{\widetilde{out}}[S] \) is not of interest, hence only \( \text{out}[S] \) is used.

The set \( \text{sib}[S] \) (sibling) contains all assign statements which may be executed in parallel to \( S \).

**Theorem 1 (Information reaching a statement)** For an arbitrary statement \( S \) holds:

\[ \text{in}[S] = \bigwedge_{a \in \text{PROCESS}[Prog]} \text{out}[a] - \bigwedge_{a \in \text{GO TO}[Prog]} \text{out}[a]. \]

For the sake of simplicity, the following precedence rules are used: \( a \land b - c = a \land (b - c) \) and \( \bigwedge_i a_i - \bigwedge_i b_i = (\bigwedge_i a_i) - (\bigwedge_i b_i). \)
Proof (Theorem 1a) The proof is done in two steps “⊆” and “⊇”:

“⊆” It has to be shown: \( \bigcup_{p \in \text{prefix}(\text{paths}[\text{Prog}], S)} \text{out}[p] \subseteq \text{in}[S] \cup \bigcup_{s \in \text{sibl}[S]} \text{gen}[s] \)

Let \( x \in \bigcup_{p \in \text{prefix}(\text{paths}[\text{Prog}], S)} \text{out}[p] \), then there is a path \( p \in \text{prefix}(\text{paths}[\text{Prog}], S) \) a statement \( s_p \) which generates \( x \) and \( x \) is not invalidated later in \( p \). The assignment statements in \( p \) stem either from program statements, which are executed sequentially before \( S \), or from statements which may be executed in parallel to \( S^k \) (see the definition of \( \text{paths}[S] \)). If \( s_p \) is a statement which is always executed before \( S \) then \( x \in \text{in}[S] \) holds. If \( s_p \) a statement which may be executed in parallel to \( S \), then \( x \in \bigcup_{s \in \text{sibl}[S]} \text{gen}[s] \).

“⊇” It has to be shown: \( \text{in}[S] \cup \bigcup_{s \in \text{sibl}[S]} \text{gen}[s] \subseteq \bigcup_{p \in \text{prefix}(\text{paths}[\text{Prog}], S)} \text{out}[p] \)

Let \( x \in \text{in}[S] \) and \( x \notin \bigcup_{s \in \text{sibl}[S]} \text{gen}[s] \), then the claim holds obviously.

Let \( x \in \bigcup_{s \in \text{sibl}[S]} \text{gen}[s] \) be generated by a statement \( s \in \text{sibl}[S] \). Since there is for every \( s \in \text{sibl}[S] \) a path \( p_s \) which executes \( s \) as its last statement before executing \( S \), and \( p_s \in \text{prefix}(\text{paths}[\text{Prog}], S) \), the claim holds.

Proof (Theorem 1b) Lemma: Let \( x \in \bigcap_{p \in \text{prefix}(\text{paths}[\text{Prog}], S)} \text{out}[p] \), then \( x \in \text{in}[S] \) holds. That is, if \( x \) reaches \( S \), then \( x \) is generated by a statement which is executed always before \( S \). Otherwise there would be a statement \( s \in \text{sibl}[S] \) which generates \( x \) and since \( x \in \bigcap_{p \in \text{prefix}(\text{paths}[\text{Prog}], S)} \text{out}[p] \), \( s \) must be executed in all paths before \( S \), which contradicts \( s \in \text{sibl}[S] \).

“⊆” It has to be shown: \( \bigcap_{p \in \text{prefix}(\text{paths}[\text{Prog}], S)} \text{out}[p] \subseteq \text{in}[S] \cup \bigcup_{s \in \text{sibl}[S]} \text{kill}[s] \)

Let \( x \in \bigcap_{p \in \text{prefix}(\text{paths}[\text{Prog}], S)} \text{out}[p] \), hence \( x \in \text{in}[S] \). Now it has to be shown that \( x \notin \bigcup_{s \in \text{sibl}[S]} \text{kill}[s] \): Assume: there is a statement \( s \in \text{sibl}[S] \) which kills \( x \). Then we can construct a path \( p_s \), where \( s \) is the last statement before \( S \), and hence \( x \) is not part of \( \text{out}[p_s] \). Since \( p_s \in \text{prefix}(\text{paths}[\text{Prog}], S) \), \( x \) is not part of \( \bigcap_{p \in \text{prefix}(\text{paths}[\text{Prog}], S)} \text{out}[p] \) which contradicts our initial assumption. Hence if \( x \in \bigcap_{p \in \text{prefix}(\text{paths}[\text{Prog}], S)} \text{out}[p] \) it cannot be killed by a statement executed in parallel to \( S \).

“⊇” It has to be shown: \( \text{in}[S] \cup \bigcup_{s \in \text{sibl}[S]} \text{kill}[s] \subseteq \bigcap_{p \in \text{prefix}(\text{paths}[\text{Prog}], S)} \text{out}[p] \)

Because \( x \in \text{in}[S] \cup \bigcup_{s \in \text{sibl}[S]} \text{kill}[s] \) on all paths\(^6\) \( p' := p/\{\text{statements executed sequentially before } S \} \) with \( p \in \text{prefix}(\text{paths}[\text{Prog}], S) \), \( x \) is generated by a statement \( s_p \), and and

---

\(^6\)When speaking in the context of paths from statements which are executed in parallel to others, we mean that these statements are contained in a PAR statement in different branches, or if the branch is replicated, the same branch too.

\(^7\)For a path \( p \) and a set of statements \( S \), \( p/S \) is defined to be the restricted path containing only statements of the set \( S \).
\[ x \in \text{out}[p]. \] Since for all \( x \notin \bigcup_{s \in S} \text{kill}[s], x \) is not killed by statements which may be executed in parallel to \( S \). Hence \( x \) is generated on path \( p \) by \( s_p \) and it is not killed in \( p \) after executing \( s_p \), since \( p \) contains compared to \( p' \) only additional statements which may be executed in parallel to \( S \). Hence \( x \in \bigcap_{p \in \text{prefix}(\text{path}_0), S} \text{out}[p]. \]

\section{Which information reaches the end of the PAR statement}

\textbf{Theorem 2} Data flow equations for the PAR statement with \( n \) branches

For the \( S := \text{PAR } S_1 \quad \ldots \quad S_n \text{ END} \) statement, and no process body is replicated, it holds:

\[
\begin{align*}
\text{if out is a may-problem} \\
gen[S] &= \bigcup_{j=1}^{n} \text{gen}[S_j] \\
\text{kill}[S] &= \bigcup_{j=1}^{n} \text{kill}[S_j] - \bigcup_{k=1}^{n} \text{gen}[S_k] \\
\text{out}[S] &= \text{gen}[S] \cup \left( \text{in}[S] - \bigcup_{j=1}^{n} \text{kill}[S_j] \right)
\end{align*}
\]

\[
\begin{align*}
\text{if out is a must-problem} \\
gen[S] &= \bigcup_{j=1}^{n} \text{gen}[S_j] - \bigcup_{k=1}^{n} \text{kill}[S_k] \\
\text{kill}[S] &= \bigcup_{j=1}^{n} \text{kill}[S_j] \\
\text{out}[S] &= \text{gen}[S] \cup \left( \text{in}[S] - \bigcup_{j=1}^{n} \text{kill}[S_j] \right)
\end{align*}
\]

All proofs follow the same road: Compute the data flow information for the “special paths”, resulting from the \( n! \) statement sequences \( S_i \ldots S_n : \bigwedge_{\pi \in \text{perm}(1,n)} \text{info}[S_i; \ldots ; S_n] \) and show that this is equal to the meet over all paths solution \( \bigwedge_{p \in \text{path}[S]} \text{info}[p] \), which is defined to be \( \text{info}[S] \).

First we give the data flow equations for the “special paths”:

\[
\bigcup_{\pi \in \text{perm}(1,n)} \text{gen}[S_i; \ldots ; S_n] = \bigcup_{j=1}^{n} \text{gen}[S_j] \tag{6}
\]

\[
\bigcap_{\pi \in \text{perm}(1,n)} \text{gen}[S_i; \ldots ; S_n] = \bigcup_{j=1}^{n} \text{gen}[S_j] - \bigcup_{k=1}^{n} \text{kill}[S_k] \tag{7}
\]

\[
\bigcup_{\pi \in \text{perm}(1,n)} \text{kill}[S_i; \ldots ; S_n] = \bigcup_{j=1}^{n} \text{kill}[S_j] \tag{8}
\]
\[
\bigcup_{i \in \text{perm}(1, n)} \text{out}[S_i, \ldots; S_n] = \bigcup_{j=1}^n \text{gen}[S_j] \cup \left( \text{in}[S] - \bigcup_{k=1}^n \text{kill}[S_k] \right) - \bigcup_{i=1}^n \text{kill}[S_i]
\]

(10)

\[
\bigcap_{i \in \text{perm}(1, n)} \text{out}[S_i, \ldots; S_n] = \left( \bigcap_{j=1}^n \text{gen}[S_j] - \bigcup_{k=1}^n \text{kill}[S_k] \right) \cup \left( \text{in}[S] - \bigcup_{l=1}^n \text{kill}[S_l] \right)
\]

(11)

**Proof (Equations 6, 8)** Since:

\[
\text{gen}[S_1; \ldots; S_n] \overset{1}{=} \text{gen}[S_n] \cup (\text{gen}[S_{n-1}] \cup \text{gen}[S_{n-2}] \cup \ldots \cup \text{gen}[S_n]) - \text{kill}[S_{n-1}] \subseteq \bigcup_{j=1}^n \text{gen}[S_j]
\]

and

\[
\text{gen}[S_1; \ldots; S_n] \overset{1}{=} \text{gen}[S_n] \cup (\text{gen}[S_{n-1}] \cup \text{gen}[S_{n-2}] \cup \ldots \cup \text{gen}[S_n]) - \text{kill}[S_{n-1}] \subseteq \bigcup_{j=1}^n \text{gen}[S_j]
\]

then

\[
\bigcup_{i \in \text{perm}(1, n)} \text{gen}[S_i] \subseteq \bigcup_{i \in \text{perm}(1, n)} \text{gen}[S_i] \cup (\bigcup_{j=1}^n \text{gen}[S_j]) \subseteq \bigcup_{i \in \text{perm}(1, n)} \text{gen}[S_i] \cup \bigcup_{j=1}^n \text{gen}[S_j]
\]

and hence

\[
\bigcup_{i=1}^n \text{gen}[S_i] \subseteq \bigcup_{i=1}^n \text{gen}[S_i] \cup \bigcup_{j=1}^n \text{gen}[S_j] \subseteq \bigcup_{i=1}^n \text{gen}[S_i]
\]

which is the desired result.

The same is done for \(\text{kill}[S]\).

**Proof (Equations 7, 9)** The proof is given for \(\text{gen}\), equation (9) is proved similarly. The proof shows the two set inclusions: "\(\subseteq\)" and "\(\supseteq\)"

"\(\subseteq\)" To be shown: \(\bigcap_{i \in \text{perm}(1, n)} \text{gen}[S_i; \ldots; S_n] \subseteq \bigcup_{j=1}^n \text{gen}[S_j] - \bigcup_{k=1}^n \text{kill}[S_k] \cdot 9\).

\[
\bigcap_{i \in \text{perm}(1, n)} \text{gen}[S_i; \ldots; S_n] \subseteq \bigcup_{j=1}^n \text{gen}[S_j] - \bigcup_{k=1}^n \text{kill}[S_k]
\]

Let \(x \in \bigcap_{i \in \text{perm}(1, n)} \text{gen}[S_i; \ldots; S_n]\) then \(x\) can not be killed by any statement \(S_k, 1 \leq k \leq n\). Otherwise, assume \(x\) is killed by a statement \(S_k\), there is a permutation \(i\), where \(i_0 = k\), i.e. \(S_k\) is the last statement. Hence \(x \notin \text{gen}[S_i; \ldots; S_n]\), which contradicts the assumption, that \(x\) is generated by all permuted statement sequences.

Hence \(x \in \bigcup_{j=1}^n \text{gen}[S_j] - \bigcup_{k=1}^n \text{kill}[S_k]\).

"\(\supseteq\)" To be shown: \(\bigcup_{j=1}^n \text{gen}[S_j] - \bigcup_{k=1}^n \text{kill}[S_k] \subseteq \bigcap_{i \in \text{perm}(1, n)} \text{gen}[S_i; \ldots; S_n] \cdot 9\).

Let \(x \in \bigcup_{j=1}^n \text{gen}[S_j] - \bigcup_{k=1}^n \text{kill}[S_k]\) then \(x\) is not invalidated by any statement \(S_k, 1 \leq k \leq n\), but generated by some \(S_j, 1 \leq j \leq n\). Hence \(x \in \bigcap_{i \in \text{perm}(1, n)} \text{gen}[S_i; \ldots; S_n]\).

**Proof (Equation 10)**

\[
\bigcup_{i \in \text{perm}(1, n)} \text{out}[S_i; \ldots; S_n]
\]

\[
\overset{3}{=} \bigcup_{i \in \text{perm}(1, n)} (\text{gen}[S_i; \ldots; S_n] \cup \text{in}[S_i; \ldots; S_n] - \text{kill}[S_i; \ldots; S_n])
\]

since \(\forall i \in \text{perm}(1, n): \text{in}[S_i; \ldots; S_n] = \text{in}[S]\) and (6), (26), (20), (9)

\[
= \bigcup_{j=1}^n \text{gen}[S_j] \cup (\text{in}[S] - \bigcup_{k=1}^n \text{kill}[S_k]) \cup (\text{in}[S] \cap \bigcup_{l=1}^n \text{gen}[S_l])
\]

\[
= \bigcup_{j=1}^n \text{gen}[S_j] \cup (\text{in}[S] - \bigcup_{k=1}^n \text{kill}[S_k])
\]

**Proof (Equation 11)** The proof shows the two set inclusions: "\(\subseteq\)" and "\(\supseteq\)"

"\(\subseteq\)" To be shown:

\[
\bigcap_{i \in \text{perm}(1, n)} \text{out}[S_i; \ldots; S_n] \subseteq (\bigcup_{j=1}^n \text{gen}[S_j] - \bigcup_{k=1}^n \text{kill}[S_k]) \cup (\text{in}[S] - \bigcup_{l=1}^n \text{kill}[S_l])
\]
\[ \bigcap_{\pi \in \text{perm}(1,n)} \text{out}[S_i; \ldots; S_n] \quad (3) \]
\[ \bigcap_{\pi \in \text{perm}(1,n)} \left( \text{gen}[S_i; \ldots; S_n] \cup \text{in}[S_i; \ldots; S_n] - \text{kill}[S_i; \ldots; S_n] \right) \subseteq \left( \bigcap_{\pi \in \text{perm}(1,n)} \text{gen}[S_i; \ldots; S_n] \right) \cup \left( \bigcap_{\pi \in \text{perm}(1,n)} \left( \text{in}[S_i; \ldots; S_n] - \text{kill}[S_i; \ldots; S_n] \right) \right) \]

Since \( \forall \pi \in \text{perm}(1,n) \): \( \text{in}[S_i; \ldots; S_n] = \text{in}[S] \) and (19), (7), (8)

\[ = \left( \bigcup_{i=1}^{n} \text{gen}[S_i] - \bigcup_{k=1}^{n} \text{kill}[S_k] \right) \cup \left( \text{in}[S] - \bigcup_{i=1}^{n} \text{kill}[S_i] \right) \]

“\( \supseteq \)” To be shown:

\[ \left( \bigcup_{i=1}^{n} \text{gen}[S_i] \right) - \bigcup_{k=1}^{n} \text{kill}[S_k] \cup \left( \text{in}[S] - \bigcup_{i=1}^{n} \text{kill}[S_i] \right) \subseteq \bigcap_{\pi \in \text{perm}(1,n)} \text{out}[S_i; \ldots; S_n]. \]

Let \( x \in \left( \bigcup_{i=1}^{n} \text{gen}[S_i] \right) - \bigcup_{k=1}^{n} \text{kill}[S_k] \cup \left( \text{in}[S] - \bigcup_{i=1}^{n} \text{kill}[S_i] \right) \) then

1. \( x \in \bigcup_{i=1}^{n} \text{gen}[S_i] - \bigcup_{k=1}^{n} \text{kill}[S_k] \) or
2. \( x \in \text{in}[S] - \bigcup_{i=1}^{n} \text{kill}[S_i] \).

In both cases \( x \) is never killed by a statement \( S_i, 1 \leq i \leq n \). In the first case \( x \) is generated by some statement \( S_i \) and since not killed, it is contained in \( \text{out}[S_i; \ldots; S_n] \). In the second case it it reaches the start of the statement sequence \( S_i; \ldots; S_n \) and since not killed by it, \( x \in \text{out}[S_i; \ldots; S_n] \).

Now the correctness of the formula is proved, i.e. that they return the same result as the meet over all paths solutions.

\[ \bigcup_{\pi \in \text{perm}(1,n)} \text{gen}[S_i; \ldots; S_n] = \bigcup_{p \in \text{paths}[S]} \text{gen}[p] \quad \text{if gen is a may-problem} \quad (12) \]
\[ \bigcap_{\pi \in \text{perm}(1,n)} \text{gen}[S_i; \ldots; S_n] = \bigcap_{p \in \text{paths}[S]} \text{gen}[p] \quad \text{if gen is a must-problem} \quad (13) \]
\[ \bigcup_{\pi \in \text{perm}(1,n)} \text{kill}[S_i; \ldots; S_n] = \bigcup_{p \in \text{paths}[S]} \text{kill}[p] \quad \text{if kill is a may-problem} \quad (14) \]
\[ \bigcap_{\pi \in \text{perm}(1,n)} \text{kill}[S_i; \ldots; S_n] = \bigcap_{p \in \text{paths}[S]} \text{kill}[p] \quad \text{if kill is a must-problem} \quad (15) \]
\[ \bigcup_{\pi \in \text{perm}(1,n)} \text{out}[S_i; \ldots; S_n] = \bigcup_{p \in \text{paths}[S]} \text{out}[p] \quad \text{if out is a may-problem} \quad (16) \]
\[ \bigcap_{\pi \in \text{perm}(1,n)} \text{out}[S_i; \ldots; S_n] = \bigcap_{p \in \text{paths}[S]} \text{out}[p] \quad \text{if out is a must-problem} \quad (17) \]

**Proof** (Equations 12, 14) The proof is given for gen, equation (14) is proved similarly. The proof shows the two set inclusions: “\( \subseteq \)” and “\( \supseteq \)”

“\( \subseteq \)” To be shown: \( \bigcup_{\pi \in \text{perm}(1,n)} \text{gen}[S_i; \ldots; S_n] \subseteq \bigcup_{p \in \text{paths}[S]} \text{gen}[p] \).

\[ \bigcup_{\pi \in \text{perm}(1,n)} \text{gen}[S_i; \ldots; S_n] \subseteq \bigcup_{\pi \in \text{perm}(1,n)} \left( \bigcup_{p \in \text{paths}[S_i; \ldots; S_n]} \text{gen}[p] \right) \]

Since a path \( p \in \text{paths}[S_i; \ldots; S_n] \) is a path of the set \( \text{paths}[S] \), the inclusion holds.
“$\subseteq$” To be shown: $\bigcup_{i \in \text{perm}(1,n)} \text{gen}[S_i; \ldots; S_{i_n}] \supseteq \bigcup_{p \in \text{paths}[S]} \text{kill}[p]$. Let $x \in \bigcup_{p \in \text{paths}[S]} \text{gen}[p]$ then there is a path $p \in \text{paths}[S]$ with $x \in \text{gen}[p]$. In $p$ there is a statement $s_p$ with $x \in \text{gen}[s_p]$ and $s_p$ cannot be followed by a statement in $p$, which kills $x$. Now $p$ has the form $p = (X; s_p; Y)$, then in the subpath $Y$ there is no statement which invalidates $x$. Let $s_p$ be a statement from $S_j$, $1 \leq j \leq n$; then it must be shown that $x \in \text{gen}[S_j]$. If $p$ is restricted to the statements of $S_j$, then $Y / S_j$ contains only statements of $S_j$. Since $Y$ contains no statements which kill $x$, this is true for $Y / S_j$. Hence $p / S_j \in \text{paths}[S_j]$ implies $x \in \text{gen}[S_j]$.

\[\text{Proof (Equations 15, 13)}\] The proof is given for $\text{kill}$, equation (13) is proved similarly. The proof shows the two set inclusions: “$\subseteq$” and “$\supseteq$”

“$\subseteq$” To be shown: $\bigcap_{i \in \text{perm}(1,n)} \text{kill}[S_i; \ldots; S_{i_n}] \subseteq \bigcap_{p \in \text{paths}[S]} \text{kill}[p]$.

Let $x \in \bigcap_{i \in \text{perm}(1,n)} \text{kill}[S_i; \ldots; S_{i_n}] \supseteq \bigcup_{j=1}^n \text{kill}[S_j] - \bigcup_{k=1}^n \text{gen}[S_k]$ then there is $j, 1 \leq j \leq n$ with $x \in \text{kill}[S_j] - \text{gen}[S_k]$, i.e. $x$ is killed by $S_j$, and $x$ is not generated by any other branch of the PAR statement.

Let $p$ an arbitrary path of the set $\text{paths}[S]$. Since $p_j = p / S_j$ is a path from the set $\text{paths}[S_j]$, $x \in \text{kill}[p_j]$ holds, and $s_j$ is the statement killing $x$ on $p_j$, and after that statement $x$ is not generated on $p_j$. $p$ has now the form $(X; s_j; Y)$. In $Y$ there are no statements from $S_j$, which generate $x$ (otherwise $x \notin \text{kill}[S_j]$) and $p$ cannot contain statements from $S_k, 1 \leq k \leq n, j \neq k$ which generate $x$ (otherwise $x \notin \bigcup_{k=1,j \neq k} \text{gen}[S_j]$), and hence there is no statement in $Y$ generating $x$. Now we have for any path $p$: $x \in \text{kill}[p]$ and hence $x \in \bigcap_{p \in \text{paths}[S]} \text{kill}[p]$.

“$\supseteq$” To be shown: $\bigcap_{i \in \text{perm}(1,n)} \text{kill}[S_i; \ldots; S_{i_n}] \supseteq \bigcap_{p \in \text{paths}[S]} \text{kill}[p]

\bigcap_{i \in \text{perm}(1,n)} \text{kill}[S_i; \ldots; S_{i_n}] = \bigcap_{i \in \text{perm}(1,n)} \left( \bigcap_{p \in \text{paths}[S_i; \ldots; S_{i_n}]} \text{kill}[p] \right)$

Since a path $p \in \text{path}[S_i; \ldots; S_{i_n}]$ is a path of the set $\text{paths}[S]$ the inclusion holds.

\[\text{Proof (Equations 16, 17)}\] If out a may(must)-problem, then obviously gen is a may(must)- and kill a must(may)-problem. Using the previous results, when calculating $\bigcup_{i \in \text{perm}(1,n)} \text{out}[S_i; \ldots; S_{i_n}]$ and $\bigcap_{i \in \text{perm}(1,n)} \text{out}[S_i; \ldots; S_{i_n}]$, and the fact that for all permutations $i \in \text{perm}(1,n)$, in $[S_i; \ldots; S_{i_n}] = \text{in}[S]$ holds, demonstrates the goals (see appendix B).

\[\text{Theorem 3 Data flow equations for the PAR statement with replicators}\]

For the $S := \text{PAR} S_1 | \ldots | S_i | \ldots | S_n$ End statement with possibly replicated branches it holds:

(a) if $\text{upd}_i - \text{lowd}_i + 1 > 0$ the equations of theorem 1 and theorem 2 are valid.
(b) if $\text{upd}_i - \text{lowd}_i + 1 \geq 0$ the following equations hold\(^b\):

\(^a\text{Sim}[S]_i\) of the replicated statement $S_i$ now contains also its own statements.

\(^b\text{n.r.: not replicated}\)
Conclusions

If out is a may-problem (upb_k - lwk + 1 ≥ 0):

\[ \tilde{\text{in}}[S] = \text{in}[S] \cup \bigcup_{s \in \text{sub}[S]} \text{gen}[s] \]

\[ \text{gen}[S] = \bigcup_{j=1}^{n} \text{gen}[S_j] \]

\[ \text{kill}[S] = \bigcup_{j=1,S_j \text{ n.r.}}^{n} \text{kill}[S_j] - \bigcup_{k=1}^{n} \text{gen}[S_k] \]

\[ \text{out}[S] = \text{gen}[S] \cup \left( \text{in}[S] - \bigcup_{j=1,S_j \text{ n.r.}}^{n} \text{kill}[S] \right) \]

If out is a must-problem (upb_k - lwk + 1 ≥ 0):

\[ \tilde{\text{in}}[S] = \text{in}[S] - \bigcup_{s \in \text{sub}[S], s \text{ n.r.}} \text{kill}[s] \]

\[ \text{gen}[S] = \bigcup_{j=1,S_j \text{ n.r.}}^{n} \text{gen}[S_j] - \bigcup_{k=1}^{n} \text{kill}[S_k] \]

\[ \text{kill}[S] = \bigcup_{j=1}^{n} \text{kill}[S_j] \]

\[ \text{out}[S] = \text{gen}[S] \cup \left( \text{in}[S] - \bigcup_{j=1}^{n} \text{kill}[S_j] \right) \]

Proof (Theorem 3a) We have to show that, if \( S_j \) is replicated then \( \text{info[PAR } S_1 | \ldots | S_j | S_{j+1} | \ldots | S_n \text{ END]} = \text{info[PAR } S_1 | \ldots | S_j | S_j | S_{j+1} | \ldots | S_n \text{ END]} \) holds. Working out the equations for may- and must-problems using theorem 2 shows this. The proof of equation 1 is still valid (see appendix B).

Proof (Theorem 3b) The proofs are performed by calculating \( \text{info[PAR } \ldots | S_j | \ldots \text{ END]} \land \text{info[PAR } \ldots | S_k | \ldots \text{ END]} \), where in the \( S_j \) the replicators are assumed to generate more than one process and in \( S_k \) they are omitted, i.e. generate no process.■

6 Conclusions

Without doubt, control flow parallel programs have to be analyzed and optimized as well as sequential ones. Since the traditional data flow analysis methods are designed in the context of sequential programs, they have to be adapted to fit into the parallel programming paradigm.

But instead of restricting either the shared memory model in the language, or force the user to instruct the compiler not to modify certain regions of code (by e.g. specifying a variable to be volatile or using pragmas) the equations presented in this paper may be used. Since they are an extension of the sequential ones, they may be easily integrated into an existing optimizer.

Solutions to other data flow problems than those which have been presented, can be derived by the method shown in the proofs: Concatenate the process bodies, permute them, calculate a formula for the union/intersection of these n! statement sequences and proof the equality with the meet over all paths solution, using the proof techniques given in the previous sections.
References

Appendix

A Data flow equations for the IF and REPEAT statement

For the $S ::= \text{IF } E \text{ THEN } S_1 \text{ ELSE } S_2 \text{ END}$ statement the equations look like:

\[
\begin{align*}
in[S_1] &= in[S] \\
in[S_2] &= in[S] \\
gen[S] &= gen[S_1] \cup gen[S_2] \\
kill[S] &= kill[S_1] \cap kill[S_2] \\
out[S] &= out[S_1] \cup out[S_2] \\
\text{If out is a May-problem} & \quad in[S_1] = in[S] \\
\text{If out is a Must-problem} & \quad in[S_2] = in[S] \\
\text{If out is a May-problem} & \quad gen[S] = gen[S_1] \cap gen[S_2] \\
\text{If out is a Must-problem} & \quad gen[S] = gen[S_1] \\
\text{If out is a May-problem} & \quad kill[S] = kill[S_1] \cap kill[S_2] \\
\text{If out is a Must-problem} & \quad kill[S] = kill[S_1] \\
\text{If out is a May-problem} & \quad out[S] = out[S_1] \cap out[S_2]
\end{align*}
\]

For the statement $S ::= \text{REPEAT } S_1 \text{ UNTIL } E$ holds:

\[
\begin{align*}
in[S_1] &= in[S] \cup gen[S_1] \\
gen[S] &= gen[S_1] \\
kill[S] &= kill[S_1] \\
out[S] &= out[S_1] \\
\text{If out is a May-problem} & \quad in[S_1] = in[S] - kill[S_1] \\
\text{If out is a Must-problem} & \quad gen[S] = gen[S_1] \\
\text{If out is a May-problem} & \quad kill[S] = kill[S_1] \\
\text{If out is a Must-problem} & \quad out[S] = out[S_1]
\end{align*}
\]

It's important to see that no iteration is needed to compute these sets as needed if the equations are formulated over the control flow graph [Aho et al. 86].

Proof (Equation 16)

\[ \bigcup_{\mathcal{E} \in \text{perm}(1,n)} \text{out}[S_1; \ldots; S_n] \overset{[3]}{=} \bigcup_{\mathcal{E} \in \text{perm}(1,n)} \text{gen}[S_1; \ldots; S_n] \bigcup_{\mathcal{E} \in \text{perm}(1,n)} (\text{in}[S_1; \ldots; S_n] - \text{kill}[S_1; \ldots; S_n]) \]

since \( \forall \mathcal{E} \in \text{perm}(1,n) : \text{in}[S_1; \ldots; S_n] = \text{in}[S] \)

\[ = \bigcup_{\mathcal{E} \in \text{perm}(1,n)} \text{gen}[S_1; \ldots; S_n] \bigcup_{\mathcal{E} \in \text{perm}(1,n)} (\text{in}[S] - \text{kill}[S_1; \ldots; S_n]) \overset{[20]}{=} \]

\[ \bigcup_{\mathcal{E} \in \text{perm}(1,n)} \text{gen}[S_1; \ldots; S_n] \bigcup_{\mathcal{E} \in \text{perm}(1,n)} (\text{in}[S] - \text{kill}[S_1; \ldots; S_n]) \]

\[ \overset{[12],[15]}{=} \bigcup_{\mathcal{E} \in \text{path}[S]} \text{gen}[p] \bigcup_{\text{in}[S]} \neg \bigcap_{\mathcal{E} \in \text{path}[S]} \text{kill}[p] \]

\[ \overset{[13]}{=} \bigcup_{\mathcal{E} \in \text{path}[S]} \text{gen}[p] \bigcup_{\mathcal{E} \in \text{path}[S]} (\text{in}[S] - \text{kill}[p]) \]

since \( \forall \mathcal{E} \in \text{path}[S] : \text{in}[p] = \text{in}[S] \)

\[ = \bigcup_{\mathcal{E} \in \text{path}[S]} \text{gen}[p] \bigcup_{\text{in}[p]} \neg \text{kill}[p] \overset{[3]}{=} \bigcup_{\mathcal{E} \in \text{path}[S]} \text{out}[p] \]

Proof (Equation 17)

\[ \bigcap_{\mathcal{E} \in \text{perm}(1,n)} \text{out}[S_1; \ldots; S_n] \overset{[11]}{=} \bigcap_{j=1}^{n} \text{gen}[S_j] - \bigcap_{k=1}^{n} \text{kill}[S_k] \bigcup \text{in}[S] - \bigcap_{k=1}^{n} \text{kill}[S_k] \]

\[ \overset{[7],[13],[8],[14]}{=} \text{gen}[S] \bigcup \text{in}[S] - \text{kill}[S] \overset{[3]}{=} \text{out}[S] \]

by definition \( \bigcap_{\mathcal{E} \in \text{path}[S]} \text{out}[p] \)

Proof (Theorem 3b) Obviously: \( (a) : \bigcup_{j=1}^{n} \text{gen}[S_j] \subseteq \bigcup_{k=1}^{n} \text{gen}[S_k] \)

\( (b) : \bigcup_{j=1}^{n} \text{kill}[S_j] \subseteq \bigcup_{k=1}^{n} \text{kill}[S_k] \)

and \( (c) : \bigcup_{j=1}^{n} \text{kill}[S_j] \subseteq \bigcup_{k=1}^{n} \text{kill}[S_k] \).

\( \triangleright \) Must Sometimes, \( (a) \).

\( \triangleright \) Must Since \( (b) \) together with \( (22) \).

gen/kill May Obviously since, \( (a) \) and \( (b) \), respectively.

\( \triangleright \) gen/kill May It is only shown for \( \text{gen} \), \( \text{kill} \) is proved similarly.

\[ \bigcup_{j=1}^{n} \text{gen}[S_j] - \bigcup_{k=1}^{n} \text{kill}[S_k] \bigcap \bigcup_{j=1}^{n} \text{gen}[S_j] - \bigcup_{k=1}^{n} \text{gen}[S_j] \bigcup \bigcup_{j=1}^{n} \text{kill}[S_k] - \bigcup_{k=1}^{n} \text{kill}[S_k] \overset{[18]}{=} \]

since \( \mathcal{E} \), \( (a) \), \( (c) \).

out\( \) May:

\[ \bigcup_{j=1}^{n} \text{gen}[S_j] \bigcup \text{in}[S] - \bigcup_{k=1}^{n} \text{kill}[S_k] \bigcup \bigcup_{j=1}^{n} \text{gen}[S_j] \bigcup \text{in}[S] - \bigcup_{k=1}^{n} \text{kill}[S_k] = \bigcup_{j=1}^{n} \text{gen}[S_j] \bigcup \text{in}[S] - \bigcup_{k=1}^{n} \text{kill}[S_k] \bigcup \bigcup_{j=1}^{n} \text{gen}[S_j] \bigcup \text{in}[S] - \bigcup_{k=1}^{n} \text{kill}[S_k] \overset{[18]}{=} \]

since \( \mathcal{E} \), \( (c) \) and \( (22) \).

out\( \) Must:

\[ \bigcup_{j=1}^{n} \text{gen}[S_j] - \bigcup_{k=1}^{n} \text{kill}[S_k] \bigcup \text{in}[S] - \bigcup_{j=1}^{n} \text{kill}[S_j] \bigcap \bigcup_{j=1}^{n} \text{gen}[S_j] - \bigcup_{k=1}^{n} \text{gen}[S_j] \bigcup \bigcup_{j=1}^{n} \text{kill}[S_k] - \bigcup_{k=1}^{n} \text{kill}[S_k] = \bigcup_{j=1}^{n} \text{gen}[S_j] - \bigcup_{k=1}^{n} \text{kill}[S_k] \bigcup \text{in}[S] - \bigcup_{l=1}^{n} \text{kill}[S_l], \text{ see gen - Must and (b), (c) and (22).} \]

C Frequently used formulas

The following equations for set differences hold, \( a,b,c,b_1,b_2 \) are sets:

\[ a - b = a \cap \overline{b} \]

\[ a - (b \cup c) = (a - b) \cap (a - c) \]

\[ a - (b \cap c) = (a - b) \cup (a - c) \]

\[ (a \cup b) - c = (a - c) \cup (b - c) \]

\[ b_1 \subseteq b_2 \Rightarrow (a - b_2) \subseteq (a - b_1) \]

\[ a - (b \cup c) = a - b \text{ if } a \cap c = \emptyset \]
