# New Results on Gap-Treating Techniques in Extended Interval Newton Gauss-Seidel Steps for Global Optimization 

DIETMAR RATZ<br>dietmar.ratz@math.uni-karlsruhe.de<br>Institut für Angewandte Mathematik, Universität Karlsruhe, D-76128 Karlsruhe, Germany

#### Abstract

Interval-branch-and-bound methods for global optimization very often incorporate interval Newton Gauss-Seidel steps to reduce the widths of the boxes resulting from the basic branch-and-bound method. These steps try to determine the roots of the gradient of the objective function, whereas various other techniques eliminate the regions containing roots which do not correspond to global optimizers.

The interval Newton Gauss-Seidel step uses so-called extended interval arithmetic which allows the division by intervals containing zero. The latter may produce gaps in the resulting coordinate intervals, which can be used to split the resulting box of the interval Gauss-Seidel step.

We investigate the impact of gap-treating and box-splitting techniques which make use of branching rules, i.e. rules for selecting the subdivision direction in the underlying branch-andbound method. Supplementing earlier studies ([3], [12]), the investigated model algorithm (similar to that in [5]) now uses the enclosure of the Hessian matrix to incorporate a second-order branching rule. We propose a strategy, a sorted interval Gauss-Seidel step, which improves the overall efficiency of the interval Newton Gauss-Seidel step and therefore of our global optimization method. We present results of computational experiments with standard global optimization problems.

Keywords: Globaloptimization, intervalarithmetic, branch-and-bound, interval Newton GaussSeidel step

## 1. Introduction

Let $f: D \rightarrow \mathbb{R}$ be a twice continuously differentiable functionTand let $D \supseteq[x] \in I \mathbb{R}^{n}$. We address the problem of finding all points $x^{*}$ in the interval vector $[x]$ such that

$$
f\left(x^{*}\right)=\min _{x \in[x]} f(x) .
$$

We are interested in both the global minimizers $x^{*}$ and the minimum value $f^{*}=$ $f\left(x^{*}\right)$.
We use the branch-and-bound approach described in [5] and [11] with several modifications. Our method starts from an initial box $[x] \in I \mathbb{R}^{n} \Gamma$ subdivides $[x] \Gamma$ stores the subboxes in a list $L$ Гand discards subintervals which are guaranteed not to contain a global minimizerTuntil the desired accuracy (width) of the interval vectors in the list is achieved. The tests we use to discard or to prune pending subboxes are cut-off test $\Gamma$ monotonicity test $\Gamma$ concavity test $\Gamma$ and interval Newton Gauss-Seidel step. For details on these tests and on the method itselfTsee [5].

The global minimum value of $f$ on $[x]$ is denoted by $f^{*} \Gamma$ and the set of global minimizer points of $f$ on $[x]$ by $X^{*}$. That is $\Gamma$

$$
f^{*}=\min _{x \in[x]} f(x) \quad \text { and } \quad X^{*}=\left\{x^{*} \mid f\left(x^{*}\right)=f^{*}\right\}
$$

We denote real numbers by $x, y, \ldots$ and real bounded and closed interval vectors by $[x]=[\underline{x}, \bar{x}],[y]=[\underline{y}, \bar{y}], \ldots$ where $\min [x]=\underline{x} \Gamma \max [x]=\bar{x} \Gamma \min [y]=\underline{y} \Gamma \max [y]=\bar{y} \Gamma$ etc.
The set of compact intervals is denoted by $I \mathbb{R}:=\{[\underline{a}, \bar{a}] \mid \underline{a} \leq \bar{a}, \underline{a}, \bar{a} \in \mathbb{R}\}$ and the set of $n$-dimensional interval vectors (also called boxes) by $I \mathbb{R}^{n}$. For real vectors and interval vectors the notations

$$
x=\left(x_{i}\right), \quad x_{i} \in \mathbb{R}, \quad \text { and } \quad[x]=\left([x]_{i}\right), \quad[x]_{i} \in I \mathbb{R}
$$

are used.
The diameter (or width) of the interval $[x]$ is defined by $d([x])=\bar{x} \Leftrightarrow \underline{x}$ if $[x] \in I \mathbb{R}$. The midpoint of the interval $[x]$ is defined by $m([x])=(\underline{x}+\bar{x}) / 2$ if $[x] \in I \mathbb{R} \Gamma$ and $m([x])=\left(m\left([x]_{i}\right)\right)$ Гif $[x] \in I \mathbb{R}^{n}$.
We call a function $F: I \mathbb{R}^{n} \rightarrow I \mathbb{R}$ an inclusion function of $f: \mathbb{R}^{n} \rightarrow \mathbb{R}$ in $[x] \in I \mathbb{R}^{n} \Gamma$ if $x \in[x]$ implies $f(x) \in F([x])$. In other words $\Gamma f_{\mathrm{rg}}([x]) \subseteq F([x]) \Gamma$ where $f_{\mathrm{rg}}([x])$ is the range of the function $f$ on $[x]$. The inclusion function of the gradient of $f$ and the Hessian of $f$ are denoted by $\nabla F$ and $\nabla^{2} F$. It is assumed in the following that the inclusion functions have the isotonicity propertyГi.e. $[x] \subseteq[y]$ implies $F([x]) \subseteq F([y])$.

Moreover $\Gamma$ we use the following notations for $[a] \in I \mathbb{R}$ and $[x] \in I \mathbb{R}^{n}$ :

$$
\begin{aligned}
& {\left[\begin{array}{c}
0 \\
{[a]}
\end{array}:=\{a \in[a] \mid \underline{a}<a<\bar{a}\} \quad \text { (Interior of }[a]\right. \text { ), }} \\
& {\left[\begin{array}{c}
0 \\
x
\end{array}\right] \quad:=\left\{x \in[x] \mid \underline{x_{i}}<x_{i}<\overline{x_{i}} \text { for all } i\right\} \quad \text { (Interior of }[x] \text { ), }} \\
& \partial([a]):=\{\underline{a}, \bar{a}\} \quad \text { (Boundary of }[a] \text { ), } \\
& \left.\partial([x]) \quad:=\left\{x \in[x] \mid x_{i} \in \partial\left([x]_{i}\right) \text { for any } i\right\} \quad \text { (Boundary of }[x]\right) \text {, } \\
& {[x] \stackrel{\circ}{\subset}[y] \Leftrightarrow[x] \subseteq[y] \quad \text { (Inner inclusion). }}
\end{aligned}
$$

Throughout the whole paper $\Gamma$ we assume that there exists a stationary point $x^{*} \in[x]$ for which $f\left(x^{*}\right)=f^{*} \Gamma$ since we do not do anything special to handle boundary points in these studies.

## 2. Main Global Optimization Algorithm

In the following $\Gamma$ we give a simplified algorithmic description and an overview of our global optimization method. We use the notations from [5].

## ALGORITHM 1. GlobalOptimize ( $\left.F,[x], \varepsilon, L_{\mathrm{res}},\left[f^{*}\right]\right)$

1. $\tilde{f}:=\bar{F}(m([x])) ; \quad[y]:=[x] ; \quad L:=\{ \} ; \quad L_{\mathrm{res}}:=\{ \} ;$
2. repeat
(A) FindComponents ([y], $k_{1}, k_{2}$ ); Branch ([y], $\left.k_{1}, k_{2},[U]_{1},[U]_{2},[U]_{3},[U]_{4}\right)$;
(B) for $i:=1$ to 4 do
i. if $\tilde{f}<\underline{F}\left([U]_{i}\right)$ then $\operatorname{next}_{i}$;
ii. if MonotonicityTest $\left(\boldsymbol{\nabla} F\left([U]_{i}\right)\right)$ then next ${ }_{i}$;
iii. if ConcavityTest $\left(\nabla^{2} F\left([U]_{i}\right)\right)$ then next ${ }_{i}$;
iv. IntervalNewtonGaussSeidelStep $\left(F,[U]_{i}, \nabla^{2} F\left([U]_{i}\right),[V], p\right)$;
v. for $j:=1$ to $p$ do if $\tilde{f} \geq \underline{F}\left([V]_{j}\right)$ then $L:=L \uplus\left([V]_{j}, \underline{F_{V}}\right) ;$
(C) while $(L \neq\{ \})$ do
i. $\left([y], \underline{F_{y}}\right):=$ PopHead $(L)$;
ii. $\tilde{f}:=\min \{\tilde{f}, \bar{F}(m([y]))\} ; \quad$ CutOffTest $(L, \tilde{f})$;
iii. if Accept $(F,[y], \varepsilon)$ then $L_{\mathrm{res}}:=L_{\mathrm{res}} \uplus\left([y], \underline{F_{y}}\right)$ else goto 2(a);
until $(L=\{ \}) ;$
3. $\left([y], \underline{F_{y}}\right):=\operatorname{Head}\left(L_{\mathrm{res}}\right) ; \quad\left[f^{*}\right]:=\left[\underline{F_{y}}, \tilde{f}\right] ; \quad$ return $L_{\mathrm{res}},\left[f^{*}\right] ;$

Algorithm 1 first computes an upper bound $\tilde{f}$ for the global minimum value and initializes the working list $L$ and the result list $L_{\text {res }}$. The main iteration (Step 2) starts with a multisection of $[y]$. Then we apply a range check $\Gamma$ the monotonicity test $\Gamma$ the concavity test $\Gamma$ and the interval Newton step to the multisected boxes $\left[U_{1}\right] \Gamma$ $\left[U_{2}\right] \Gamma\left[U_{3}\right]$ Гand $\left[U_{4}\right]$. The interval Newton step results in $p$ boxes $\Gamma$ to which we apply a range check. If the current box $[V]_{j}$ is still a candidate for a minimizerTwe store it in $L$ in Step 2(B)v. Note that the boxes are stored as pairs ( $[y], F_{y}$ ) in list $L$ sorted in nondecreasing order with respect to the lower bounds $F_{y}=\overline{F([y])}$ and in decreasing order with respect to the ages of the boxes in $L$ (cf. [11]).
In Step $2(\mathrm{C})$ Twe remove the first element from the list $L$ Ti.e. the element of $L$ with the smallest $\underline{F_{y}}$ value $\Gamma$ and we perform the cut-off test. Then $\Gamma$ if the desired accuracy is achieved for $[y]$ Twe store $[y]$ in the result list $L_{\mathrm{res}}$. Otherwise $\Gamma$ we go to the branching step. When the iteration stops because the pending list $L$ is empty we compute a final enclosure $\left[f^{*}\right]$ for the global minimum value and return $L_{\mathrm{res}}$ and [ $\left.f^{*}\right]$.
The method can be improved by incorporating an approximate local search procedure to try to decrease the value $\tilde{f}$. See [7] for the description of such local search procedures. For our studies in this paperTwe do not apply any local method. We also do not apply any boundary treating Tso we assume that all $x^{*}$ lie in the interior of $[x]$.

## 3. Use of Branching Rules

As demonstrated in [3] and [12] $\Gamma$ the determination of "optimal" components for subdividing the current box [y] in Step 2(A) of Algorithm 1 plays an important role. Moreover $\Gamma$ the corresponding rules for selecting the subdivision direction can also be helpful in connection with the interval Newton Gauss-Seidel step $\Gamma$ as we shall see later.
In Algorithm $1 \Gamma$ a multisection is used $\Gamma$ so each of these branching rules selects directions $k_{1}$ and $k_{2}$ with $D\left(k_{1}\right) \geq D\left(k_{2}\right) \geq D(i)$ for all $i=1, \ldots, n$ and $i \notin\left\{k_{1}, k_{2}\right\} \Gamma$ where $D(i)$ is fixed by the given rule. For the current studyए we investigate four rules (we leave out Rule D from [3] and [12]):
Rule A: $\quad D(i):=d\left([y]_{i}\right)$
Rule B: $\quad D(i):=d\left(g_{i}([y])\right) \cdot d\left([y]_{i}\right)$
Rule C: $\left.\quad D(i):=d\left(g_{i}([y]) \cdot\left([y]_{i} \Leftrightarrow c_{i}\right)\right)\right)$
Rule E: $\quad D(i):=d\left(\left([y]_{i} \Leftrightarrow c_{i}\right) \cdot\left(G_{i}(c)+\frac{1}{2} \sum_{j=1}^{n}\left(H_{i j}([y]) \cdot\left([y]_{i} \Leftrightarrow c_{i}\right)\right)\right)\right)$.
Here $\Gamma G=\boldsymbol{\nabla} F \Gamma H=\boldsymbol{\nabla}^{2} F$ Гand $c=m([y])$.
Similar to Rule C (cf. [10]) Гthe underlying idea of the new Rule E is to minimize

$$
\begin{aligned}
d(F([y])) & =d(F([y]) \Leftrightarrow f(c)) \\
& \approx d\left(([y] \Leftrightarrow c)^{T} \cdot\left(\nabla f(c)+\frac{1}{2} \nabla^{2} F([y]) \cdot([y] \Leftrightarrow c)\right)\right) \\
& =d \sum_{i=1}^{n}\left(\left([y]_{i} \Leftrightarrow c_{i}\right) \cdot\left(\frac{\partial F}{\partial x_{i}}([y])+\frac{1}{2} \sum_{j=1}^{n} \frac{\partial^{2} F([y])}{\partial x_{i} \partial x_{j}} \cdot\left([y]_{j} \Leftrightarrow c_{j}\right)\right)\right) .
\end{aligned}
$$

The proofs of convergence of the underlying branch-and-bound (subdivision) algorithm with Rules АГВГ and C can be found in [12] Гthe proof for Rule E (recently proposed in [13]) can be found in [2].

## 4. Interval Newton Gauss-Seidel Step (INGSS)

In Algorithm $1 \Gamma$ we apply one step of the extended interval Newton Gauss-Seidel method (cf. [1]) to the nonlinear system $\nabla f(y)=0$ with $y \in[y]$. The subbox [y] is a candidate box for enclosing a minimizer $x^{*}$ Twhich we have assumed must satisfy $\boldsymbol{\nabla} f\left(x^{*}\right)=0$. One step of the extended interval Newton Gauss-Seidel method shall improve (prune) the enclosure [ $y]$ by formally solving the system $g=[H] \cdot(c \Leftrightarrow y) \Gamma$ where $c=m([y]) \Gamma g=\nabla f(c) \Gamma$ and $[H]=\nabla^{2} F([y])$.

Usually T this method works better if we first apply a preconditioning $\Gamma$ by using a special matrix $R \in \mathbb{R}^{n \times n}$ for computing $b:=R \cdot g$ and $[A]:=R \cdot[H]$. Then
we consider the system $b=[A] \cdot(c \Leftrightarrow y) \Gamma$ and we compute the new box $N_{\mathrm{GS}}^{\prime}([y])$ according to

$$
\begin{aligned}
& {[z]:=[y],} \\
& {[z]_{i}:=\left(c_{i} \Leftrightarrow\left(b_{i}+\sum_{\substack{j=1 \\
j \neq i}}^{n}[A]_{i j} \cdot\left([z]_{j} \Leftrightarrow c_{j}\right)\right) /[A]_{i i}\right) \cap[z]_{i}, \quad i=1, \ldots, n,} \\
& \left.N_{\mathrm{GS}}^{\prime} \mathrm{S}[y]\right):=[z] .
\end{aligned}
$$

The interval Newton Gauss-Seidel step (abbreviated by INGSS) in this form (assuming that $0 \notin[A]_{i i}$ ) has the following properties (see [7] or [9] for proofs):

Theorem 3.1 Let $f: D \subseteq \mathbb{R}^{n} \rightarrow \mathbb{R}$ be a twice continuously differentiable function, and let $[x] \in I \mathbb{R}^{n}$ be an interval vector with $[x] \subseteq D$. Then $N_{G S}^{\prime}([x])$ has the following properties:

1. Every zero $x^{*} \in[x]$ of $\nabla f$ satisfies $x^{*} \in N_{\mathrm{GS}}^{\prime}([x])$.
2. If $N_{\mathrm{GS}}^{\prime}([x])=\emptyset$, then there exists no zero of $\nabla f$ in $[x]$.
3. If $\left.N_{\mathrm{GS}}^{\prime} \mathrm{S}[x]\right) \stackrel{\circ}{\subset}[x]$, then there exists a unique zero of $\nabla f$ in $[x]$.

In the one-dimensional case with $f: \mathbb{R} \rightarrow \mathbb{R}$ and $[y] \in I \mathbb{R} \Gamma$ the interval Newton Gauss-Seidel step reduces to the interval Newton step

$$
N^{\prime}([y]):=N_{\mathrm{GS}}^{\prime}([y])=\left(c \Leftrightarrow \frac{f^{\prime}(c)}{F^{\prime \prime}([y])}\right) \cap[y]
$$

Using standard interval arithmetic $\Gamma$ the interval Newton step assumes $0 \notin F^{\prime \prime}([y])$. Like in classical Newton's methodTthe interval Newton step can be geometrically interpreted as drawing two lines from the midpoint $\left(c, f^{\prime}(c)\right)$ and intersecting them with the $x$-axis. These lines have the slope $g$ (a lower bound of the slopes of $f^{\prime}$ in $[y]$ ) and $\bar{g}$ (an upper bound of the slopes of $f^{\prime}$ in $\left.[y]\right)$ Trespectively $\Gamma$ where $[g]=F^{\prime \prime}([y])$.

Figure 1. Interval Newton step with $0 \notin F^{\prime \prime}([y])$

The points of intersection with the $x$-axis $\overline{\text { i.e. }} \lambda$ and $\rho \Gamma$ form the new interval $[\lambda, \rho]$. Figure 1 demonstrates this interval Newton step resulting in

$$
N^{\prime}([y])=[\lambda, \rho] \cap[y]=[\underline{y}, \rho] .
$$

If the intersection is empty[we know that there is no root of $f^{\prime}$ in $[y]$.

## 5. Box-Splitting and Gap-Treating

Using extended interval arithmetic (see [5] or [7] for details) $\Gamma$ we are able to treat the case $0 \in F^{\prime \prime}([y])$ that occurs $\Gamma$ for example $i f$ there are several zeros of $f^{\prime \prime}$ in the interval $[y]$. In this case $\Gamma N^{\prime}([y])$ is given by one or two intervals resulting from the interval division.

In Figure 2 Twe illustrate one extended interval Newton step geometrically. Again we draw lines through the point $\left(c, f^{\prime}(c)\right)$. The first line with the smallest (negative lower bound) slope of $f^{\prime}$ in [y] intersects the $x$-axis in point $\rho$. The line with the largest (positive upper bound) slope intersects the $x$-axis in point $\lambda$. Therefore $\Gamma$ we get

$$
N^{\prime}([y])=([\Leftrightarrow \infty, \rho] \cup[\lambda, \infty]) \cap[y]=[\underline{y}, \rho] \cup[\lambda, \bar{y}],
$$

and we "punched" out a gap in the original interval [y] which is now split.
In the multi-dimensional case $\Gamma$ we must apply extended interval arithmetic if $0 \in[A]_{i i}$ for some $i$. In this case $\Gamma$ a gap can be produced in the corresponding components $[z]_{i}$ of $[z]$. Therefore $\Gamma$ the interval Gauss-Seidel step may result in the union of several boxes $[V]_{i} \in I \mathbb{R}^{n} \Gamma i=1, \ldots, p \Gamma$ and we have $N_{\mathrm{GS}}^{\prime}([y])=$ $[V]_{1} \cup \ldots \cup[V]_{p} \Gamma$ so $[V] \in I \mathbb{R}^{p \times n}$. Since it is not necessary to compute the $[y]_{i}$ in fixed order $i=1, \ldots, n$ in a practical realization of the interval Newton GaussSeidel method $\Gamma$ very often the Hansen/Greenberg realization [6] is used. That is $\Gamma$ we first perform the single component steps of the Gauss-Seidel step for all $i$ with $0 \notin[A]_{i i}$ and then for the remaining indices with $0 \in[A]_{i i}$ by using extended interval arithmetic.
Nevertheless $\Gamma$ if $0 \in[A]_{i i}$ for several components $i \Gamma$ then the extended interval divisions in the interval Newton Gauss-Seidel method possibly produce several gaps

Figure 2. Extended interval Newton step with $0 \in F^{\prime \prime}([y])$
in the current box $[y]$. So we must split the result $N_{G S}^{\prime}([y])$ into two or more boxes. In this case $\Gamma$ different splitting techniques may be applied resulting in different values for $[V]$ and $p$. We give two examplesTwhich are used in the current study:
$p \leq 2 \quad$ Compute all possible gaps in [y], and finally use only the largest gap to split [y]. This technique is known from Hansen/Greenberg [6] Tand the Newton step results in at most 2 boxes $\Gamma$ thus $N_{G S}^{\prime}([x])=[V]_{1} \cup[V]_{2}$.
$p \leq n+1 \quad$ Compute every gap, and use it immediately to split [ $y$ ] in a special way. For this special splitting technique introduced in [10] the Newton step results in at most $n+1$ boxesTthus $N_{\mathrm{GS}}^{\prime}([x])=[V]_{1} \cup \ldots \cup[V]_{n+1}$.

In our special technique with $p \leq n+1$ Twe use each gap to store one part of the current box $[y]$ by using one part of the component $[y]_{i}$ and to update $[y]$ with the other part of $[y]_{i} \Gamma$ before continuing with the next component step of the interval Gauss-Seidel method. That is $\Gamma$ we perform one component step according to the scheme:

1. Compute $[y]_{i}=[w] \cup[v]$.
2. If $[w]=[v]=\emptyset \Gamma$ then stop $\{$ no solution in $[y]\}$.
3. If $[v] \neq \emptyset \Gamma$ then set $[y]_{i}:=[v]$ and store $[y]$.
4. Set $[y]_{i}:=[w]$ and continue with next $i$.

In some bad casesTwe only get $\left(b_{i}+\sum_{\substack{j=1 \\ j \neq i}}^{n}[A]_{i j} \cdot\left([y]_{j} \Leftrightarrow c_{j}\right)\right) /[A]_{i i}=(\Leftrightarrow \infty, \infty)$ and
no gap occurs $\Gamma$ so $[y]_{i}:=[y]_{i} \cap(\Leftrightarrow \infty, \infty)$ remains unchanged. In these cases $\Gamma$ we introduce "gaps" of width zero by splitting $[y]_{i}=[w] \cup[v]$ with $[w]:=\left[\underline{y}_{i}, m\left([y]_{i}\right)\right]$ and $[v]:=\left[m\left([y]_{i}\right), \bar{y}_{i}\right]$ That is we do a bisection.

## 6. Sorted Interval Newton Gauss-Seidel Step (SINGSS)

We investigate the branching rules applied in the main Algorithm 1 in connection with the interval Gauss-Seidel step. We use these rules to compute a sorting vector $s=\left(s_{1}, s_{2}, \ldots, s_{n}\right)$ with $s_{i} \in\{1, \ldots, n\}$ and $s_{i} \neq s_{j}$ for $i \neq j \Gamma$ which satisfies $D\left(s_{i}\right) \geq D\left(s_{i+1}\right) \Gamma i=1, \ldots, n \Leftrightarrow 1$ for the corresponding direction selection rule $D(\ldots)$. ThenTwe perform the sorted interval Newton Gauss-Seidel step (SINGSS) according to

$$
\begin{aligned}
& {[z]:=[y]} \\
& {[z]_{s_{i}}:=\left(c_{s_{i}} \Leftrightarrow\left(b_{s_{i}}+\sum_{\substack{j=1 \\
j \neq s_{i}}}^{n}[A]_{s_{i} j} \cdot\left([z]_{j} \Leftrightarrow c_{j}\right)\right) /[A]_{s_{i} s_{i}}\right) \cap[z]_{s_{i}}, i=1, \ldots, n} \\
& N_{\text {SGS }}^{\prime}([y]):=[z]
\end{aligned}
$$

incorporating the Hansen/Greenberg realization and different splitting techniques. Note that $N_{\text {SGS }}^{\prime}([y])$ is the union of several boxes in the general case. This SINGSS aims at splitting the box $[y]$ in those components first $\Gamma$ which would be chosen for multisection by the specified branching rule.

We now give an algorithmic description of the SINGSS.
ALGORITHM 2. SIntervalNewtonGaussSeidelStep (F, $[y],[H],[V], p)$

1. Compute preconditioner $R$ and sorting vector $s$;
2. $c:=m([y]) ; \quad[A]:=R \cdot[H] ; \quad b:=R \cdot \nabla f(c) ; \quad p:=0$;
3. for $l:=1$ to $n$ do $\quad\left\{\right.$ Component steps for $\left.0 \notin[A]_{i i}\right\}$
(A) $i:=s_{l} ; \quad$ if $\left(0 \in[A]_{i i}\right)$ then next $;$
(B) $[y]_{i}:=\left(c_{i} \Leftrightarrow\left(b_{i}+\sum_{\substack{j=1 \\ j \neq i}}^{n}[A]_{i j} \cdot\left([y]_{j} \Leftrightarrow c_{j}\right)\right) /[A]_{i i}\right) \cap[y]_{i}$;
(C) if $[y]_{i}=\emptyset$ then return ;
4. for $l:=1$ to $n$ do $\quad\left\{\right.$ Component steps for $\left.0 \in[A]_{i i}\right\}$
(A) $i:=s_{l} ; \quad$ if $\left(0 \notin[A]_{i i}\right)$ then next m $_{l}$
(B) $[w] \cup[v]:=\left(c_{i} \Leftrightarrow\left(b_{i}+\sum_{\substack{j=1 \\ j \neq i}}^{n}[A]_{i j} \cdot\left([y]_{j} \Leftrightarrow c_{j}\right)\right) /[A]_{i i}\right) \cap[y]_{i} ;$
(C) if $([w]=[v]=\emptyset)$ then return ;
(D) if $([v] \neq \emptyset)$ then $\left\{\right.$ Store part of $[y]$ in $\left.[V]_{p}\right\}$ $[y]_{i}:=[v] ; \quad p:=p+1 ; \quad[V]_{p}:=[y] ;$
(E) $[y]_{i}:=[w]$;
5. $\quad p:=p+1 ; \quad[V]_{p}:=[y] ;$
6. return $[V], p$;
$\left\{\right.$ Result: $\left.N_{\text {SGS }}^{\prime}([y])=\bigcup_{j=1}^{p}[V]_{j}\right\}$
The following theorem summarizes the properties of our sorted interval Newton Gauss-Seidel step with special splitting.

THEOREM 4.1 Let $f: D \subseteq \mathbb{R}^{n} \rightarrow \mathbb{R}$ be a twice continuously differentiable function, and let $[x] \in I \mathbb{R}^{n}$ be an interval vector with $[x] \subseteq D$. Then $N_{S G S}^{\prime}([x])$ computed by Algorithm 2 (including sorting and special splitting technique) has the following properties:

1. Every zero $x^{*} \in[x]$ of $\nabla f$ satisfies $x^{*} \in N_{S G S}^{\prime}([x])$.
2. If $N_{\mathrm{SGS}}^{\prime}([x])=\emptyset$, then there exists no zero of $\nabla f$ in $[x]$.
3. If $N_{\mathrm{SGS}}^{\prime}([x]) \stackrel{\circ}{\subset}[x]$, then there exists a unique zero of $\boldsymbol{\nabla} f$ in $[x]$.

## Proof:

1. Let $\Gamma_{i}([y])=\left(c_{i} \Leftrightarrow\left(b_{i}+\sum_{\substack{j=1 \\ j \neq i}}^{n}[A]_{i j} \cdot\left([y]_{j} \Leftrightarrow c_{j}\right)\right) /[A]_{i i}\right) \cap[y]_{i}$ be the new value for $[y]_{i}$ computed in one component step of the SINGSS applied to $[y] \in I \mathbb{R}^{n}$ for $i \in\{1, \ldots, n\} \Gamma$ and let $[y]^{(0)}$ be the updated value of $[y]$ after the complete Step 3 of Algorithm 2. MoreoverTlet $\mathcal{S}=\left\{s_{l_{1}}, s_{l_{2}}, \ldots s_{l_{m}}\right\}$ with $m \leq n$ be the set of those components of the sorting vector $s$ for which extended interval division must be applied when computing $\Gamma_{i} \Gamma$ that is $\Gamma 0 \in\left[A_{i i}\right]$ for all $i \in \mathcal{S}$ and $\Gamma_{i}([y])=[w] \cup[v]$ with $[w],[v] \in I \mathbb{R}$. For simplicity of the proof $\overline{\text { we }}$ use $[v]=\emptyset$ if in fact no splitting occurs in $\Gamma_{i}([y])$ Гalthough denoting this a splitting.
According to Algorithm $2 \Gamma$ the result of the $k$-th extended component step of the SINGSS (i.e. Step 4) is given by

$$
{N^{\prime}}_{\mathrm{SGS}}^{(k)}\left([y]^{(k-1)}:=[V]_{k} \cup[y]^{(k)},\right.
$$

where

$$
[V]_{k i} \cup[y]_{i}^{(k)}=\Gamma_{i}\left([y]^{(k-1)}\right) \quad \text { and } \quad i=s_{l_{k}}
$$

and where $[y]^{(k)}$ is the current value of $[y]$ after the $k$-th update in Step $4(\mathrm{E})$ of Algorithm 2 Ti.e. after $k$ splittings. Then

$$
[z]^{(k)}=[V]_{1} \cup[V]_{2} \cup \ldots \cup[V]_{k} \cup[y]^{(k)}
$$

is the current enclosure of the true solution set after $k$ splittings $\Gamma$ and with $[V]_{m+1}=[y]^{(m)}$ according to Step 5 of our algorithm we have

$$
[z]^{(m)}=\bigcup_{j=1}^{m+1}[V]_{j}=N_{\mathrm{SGS}}^{\prime}([x])
$$

Now let $x^{*} \in[x]$ be a zero of $\nabla f$.
a) $x^{*} \in[y]^{(0)}=[z]^{(0)}$ according to Theorem 3.1.
b) Given an arbitrary $k \in\{0, \ldots, m \Leftrightarrow 1\}$ Twe have two cases for $x^{*} \in[z]^{(k)}$ :
i) $x^{*} \in[V]_{1} \cup \ldots \cup[V]_{k}$ : In this case $\Gamma$ it follows immediately that

$$
x^{*} \in[V]_{1} \cup \ldots \cup[V]_{k} \cup[V]_{k+1} \subseteq[z]^{(k+1)}
$$

ii) $x^{*} \in[y]^{(k)}$ : In this case $\Gamma$ with $i=s_{l_{k+1}}$ there exists an $A^{*} \in[A]$ with $A^{*}\left(c \Leftrightarrow x^{*}\right)=b$.

For $A_{i i}^{*} \neq 0$ we get

$$
\begin{aligned}
x_{i}^{*} & =c_{i} \Leftrightarrow\left(b_{i}+\sum_{\substack{j=1 \\
j \neq i}}^{n} A_{i j}^{*} \cdot\left(x_{j}^{*} \Leftrightarrow c_{j}\right)\right) / A_{i i}^{*} \\
& \in c_{i} \Leftrightarrow\left(b_{i}+\sum_{\substack{j=1 \\
j \neq i}}^{n}[A]_{i j} \cdot\left([y]_{j}^{(k)} \Leftrightarrow c_{j}\right)\right) /[A]_{i i},
\end{aligned}
$$

and $\Gamma$ since $x_{i}^{*} \in[y]_{i}^{(k)} \Gamma$

$$
\begin{aligned}
x_{i}^{*} & \in\left(c_{i} \Leftrightarrow\left(b_{i}+\sum_{\substack{j=1 \\
j \neq i}}^{n}[A]_{i j} \cdot\left([y]_{j}^{(k)} \Leftrightarrow c_{j}\right)\right) /[A]_{i i}\right) \cap[y]_{i}^{(k)} \\
& =\Gamma_{i}\left([y]^{(k)}\right) \\
& =[V]_{k+1, i} \cup[y]_{i}^{(k+1)},
\end{aligned}
$$

and thus $x^{*} \in[V]_{k+1} \cup[y]^{(k+1)}=N_{\text {SGS }}^{\prime(k+1)}\left([y]^{(k)}\right.$.
For $A_{i i}^{*}=0 \Gamma$ a necessary consequence is that

$$
\begin{aligned}
0 & =b_{i}+\sum_{\substack{j=1 \\
j \neq i}}^{n} A_{i j}^{*} \cdot\left(x_{j}^{*} \Leftrightarrow c_{j}\right) \\
& \in b_{i}+\sum_{\substack{j=1 \\
j \neq i}}^{n}[A]_{i j} \cdot\left([y]_{j}^{(k)} \Leftrightarrow c_{j}\right),
\end{aligned}
$$

and the definition of extended interval division implies that

$$
c_{i} \Leftrightarrow\left(b_{i}+\sum_{\substack{j=1 \\ j \neq i}}^{n}[A]_{i j} \cdot\left([y]_{j}^{(k)} \Leftrightarrow c_{j}\right)\right) /[A]_{i i}=(\Leftrightarrow \infty, \infty)
$$

and thus

$$
x_{i}^{*} \in[y]^{(k)}=(\Leftrightarrow \infty, \infty) \cap[y]^{(k)}=\Gamma_{i}\left([y]^{(k)}\right)=[V]_{k+1, i} \cup[y]_{i}^{(k+1)}
$$

Again we have $x^{*} \in[V]_{k+1} \cup[y]^{(k+1)}=N_{S G S}^{\prime(k+1)}\left([y]^{(k)}\right.$.
So Twith $x^{*} \in[z]^{(k)}$ Twe have that $x^{*} \in[z]^{(k+1)}$ for $k=0, \ldots, m \Leftrightarrow 1$.
Combining a) and b) $\Gamma x^{*} \in[x]$ implies that $x^{*} \in[z]^{(m)}=N_{\text {SGS }}^{\prime}([x])$.
2. Assuming $x^{*} \in[x] \Gamma N_{\text {SGS }}^{\prime}([x])=\emptyset$ contradicts Proposition 1 of the theorem.
3. According to the definition of extended interval operations (c.f. [5] or [7] for details) Гwe know that $\partial\left([y]_{i}\right) \cap \Gamma_{i}([y]) \neq \emptyset$. That isTwhenever extended interval division is applied $N_{\text {SGS }}^{\prime}([x]) \cap \partial([x]) \neq \emptyset$. Since $N_{\text {SGS }}^{\prime}([x]) \stackrel{0}{\subset}[x] \Gamma$ we know that no extended interval operation occurred in the SINGSSF and therefore Proposition 3 of Theorem 3.1 completes the proof.

## 7. Numerical Experiences

For our testsTwe used the group of test functions given in [12]. We carried out the numerical tests on an HP 9000/730 equipped with PASCAL-XSC [8] using the basic toolbox modules for automatic differentiation and extended interval arithmetic [5]. Our test suite compared the methods with branching rules АГВГСГand E combined with the usual splitting technique ( $p \leq 2$ ) and with the special splitting technique ( $p \leq n+1 \Gamma^{"} 0$-width-gaps").

In the following $\Gamma$ we list the complete results for 10 test problems. Important columns of the corresponding tables are the runtime (in STUs) the storage space or maximum list length (LL) and the Eeff ${ }_{1}$ and Eeff 2 values. The latter combine the three values for the number of function (FE) 「gradient (GE) Гand Hessian (HE) evaluation to single values approximating the total evaluation effort in terms of objective function evaluations by

$$
\mathrm{Eeff}_{1}=\mathrm{FE}+n \cdot \mathrm{GE}+\frac{n \cdot(n+1)}{2} \cdot \mathrm{HE}
$$

and

$$
\mathrm{Eeff}_{2}=\mathrm{FE}+\min \{4, n\} \cdot \mathrm{GE}+n \cdot \mathrm{HE}
$$

(with respect to forward $\left(\right.$ Eeff $\left._{1}\right)$ and backward (Eeff 2 ) mode of automatic differentiationTsee [4] for details).

As an example Twe take the last problem (Ratz4) to demonstrate the behavior of the splitting an the influence of the rules. This problem considers the function

$$
f(x)=\sin \left(x_{1}^{2}+2 x_{2}^{2}\right) \exp \left(\Leftrightarrow x_{1}^{2} \Leftrightarrow x_{2}^{2}\right)
$$

in the starting region $[x]_{i}=[\Leftrightarrow 3,3] \Gamma i=1, \ldots, 2$. The following pictures are snapshots of the boxes in the working list $L$ after 125 iterations of the main algorithm. The first four pictures in Figure 3 correspond to the method with the usual splitting technique and the different sorting rules T the pictures in Figure 4 correspond to the method with the special splitting technique.

Figure 3. Boxes in the working list after 125 iterations with usual splitting

Figure 4. Boxes in the working list after 125 iterations with special splitting

Finally「we give an overview on the results for the complete test set by listing the necessary resources (execution time ${ }^{\text {evaluation }}$ efforts $\Gamma$ and maximum list length) for the different variants of our method (Table 1). The values given are relative values (in percent) with respect to the method with Rule A and usual splitting (which is used as reference value corresponding to $100 \%$ ). The table gives the best values the worst values $\Gamma$ and the average values (for all test problems) achieved in the whole test set.

Table 1. Results for the complete test set (relative values)

| $p \leq$ | Rule | Values | STUs | Eeff ${ }_{1}$ | Eeff 2 | LL |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  |  | worst | 100.0\% | 100.0\% | 100.0\% | 530.2\% |

## 8. Conclusion

Studying the numerical results for the four branching rules combined with different splitting techniques $\Gamma$ we recognize that there are test problems for which Rule $\mathrm{B} \Gamma$ Rule CTand Rule E are much more efficient than Rule A. On the other handTthere are also some problems where the new rules are worse. On average $\Gamma$ the branching rules alone lead to an improvement of about $10 \%$.
The special splitting technique improves the performance of the global optimization method significantly lby drastically decreasing the evaluation effort. The price to pay for this improvement is an increasing storage space. Further improvement is due to the branching rules BГСГand ETused as sorting rules in the interval Newton Gauss-Seidel step. This holds for the best cases $\Gamma$ the average $\Gamma$ and for the worst cases.

Summarizing the consequences of the numerical tests $\Gamma$ we can conclude that for Rules BГCГand E combined with the special splitting technique we can expect an average improvement of about $25 \%$ in the efficiency of the methodTkeeping in mind that on average there is approximately a doubling in the necessary storage space.
